expression(atop(x + y, 2)))

grid.newpage()
nrowcol <- n2mfrow(length(tests))
pushViewport(viewport(layout=grid.layout(nrowcol[1], nrowcol[2]),
                gp=gpar(cex=5, lwd=.5)))
for (i in 1:length(tests)) {
do <-(i - 1) %/% nrowcol[2] + 1
row <-(i - 1) %/% nrowcol[2] + 1
pushViewport(viewport(layout.pos.row=row, layout.pos.col=col))
test(tests[i])
popViewport()
}

**dataViewport** Create a Viewport with Scales based on Data

**Description**

This is a convenience function for producing a viewport with x- and/or y-scales based on numeric values passed to the function.

**Usage**

```r
dataViewport(xData = NULL, yData = NULL, xscale = NULL,
             yscale = NULL, extension = 0.05, ...)
```

**Arguments**

- `xData` A numeric vector of data.
- `yData` A numeric vector of data.
- `xscale` A numeric vector (length 2).
- `yscale` A numeric vector (length 2).
- `extension` A numeric. If length greater than 1, then first value is used to extend the xscale and second value is used to extend the yscale.
- `...` All other arguments will be passed to a call to the `viewport()` function.

**Details**

If `xscale` is not specified then the values in `x` are used to generate an x-scale based on the range of `x`, extended by the proportion specified in `extension`. Similarly for the y-scale.

**Value**

A grid viewport object.
**Author(s)**

Paul Murrell

**See Also**

`viewport` and `plotViewport`.

---

**depth**

*Determine the number of levels in an object.*

**Description**

Determine the number of levels in a viewport stack or tree, in a viewport path, or in a grob path.

**Usage**

```r
depth(x, ...)  
## S3 method for class 'viewport'
depth(x, ...)  
## S3 method for class 'path'
depth(x, ...)
```

**Arguments**

- `x` Typically a viewport or viewport stack or viewport tree or viewport list, or a viewport path, or a grob path.
- `...` Arguments used by other methods.

**Details**

Depths of paths are pretty straightforward because they contain no branchings. The depth of a viewport stack is the sum of the depths of the components of the stack. The depth of a viewport tree is the depth of the parent plus the depth of the children. The depth of a viewport list is the depth of the last component of the list.

**Value**

An integer value.

**See Also**

`viewport`, `vpPath`, `gPath`.

**Examples**

```r
vp <- viewport()  
depth(vp)  
depth(vpStack(vp, vp))  
depth(vpList(vpStack(vp, vp), vp))  
depth(vpPath("vp"))  
depth(vpPath("vp1", "vp2"))
```
deviceLoc

Convert Viewport Location to Device Location

Description

These functions take a pair of unit objects and convert them to a pair of device locations (or dimensions) in inches (or native device coordinates).

Usage

deviceLoc(x, y, valueOnly = FALSE, device = FALSE)
deviceDim(w, h, valueOnly = FALSE, device = FALSE)

Arguments

x, y, w, h  A unit object.
valueOnly  A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.
device  A logical indicating whether the returned values should be in inches or native device units.

Details

These functions differ from the functions like convertX() because they convert from the coordinate systems within a viewport to inches on the device (i.e., from one viewport to another) and because they only deal with pairs of values (locations or dimensions).

The functions like convertX() convert between different units within the same viewport and convert along a single dimension.

Value

A list with two components, both of which are unit object in inches (unless valueOnly is TRUE in which case both components are numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid.

Furthermore, the returned value only makes sense with respect to the entire device (i.e., within the context of the root viewport).

unit
**Examples**

```r
## A tautology
grid.newpage()
pushViewport(viewport())
deviceLoc(unit(1, "inches"), unit(1, "inches"))

## Something less obvious
grid.newpage()
pushViewport(viewport(width=.5, height=.5))
grid.rect()
x <- unit(1, "in")
y <- unit(1, "in")
grid.circle(x, y, r=unit(2, "mm"))
loc <- deviceLoc(x, y)
loc
upViewport()
grid.circle(loc$x, loc$y, r=unit(1, "mm"), gp=gpar(fill="black"))

## Something even less obvious
grid.newpage()
pushViewport(viewport(width=.5, height=.5, angle=30))
grid.rect()
x <- unit(.2, "npc")
y <- unit(2, "in")
grid.circle(x, y, r=unit(2, "mm"))
loc <- deviceLoc(x, y)
loc
upViewport()
grid.circle(loc$x, loc$y, r=unit(1, "mm"), gp=gpar(fill="black"))
```

---

**drawDetails**  
*Customising grid Drawing*

**Description**

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing of a new class derived from grob (or gTree).

**Usage**

drawDetails(x, recording)
preDrawDetails(x)
postDrawDetails(x)

**Arguments**

- **x**: A grid grob.
- **recording**: A logical value indicating whether a grob is being added to the display list or redrawn from the display list.
**Details**

**NOTE:** these functions have been largely superceded by the `makeContent` and `makeContext` functions, though they are still run and may still be useful in some contexts.

These functions are called by the `grid.draw` methods for grobs and gTrees.

`preDrawDetails` is called first during the drawing of a grob. This is where any additional viewports should be pushed. Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push up any viewports in the `childrenvp` slot so there is typically nothing to do here.

`drawDetails` is called next and is where any additional calculations and graphical output should occur. Note that the default behaviour for gTrees is to draw all grobs in the `children` slot so there is typically nothing to do here.

`postDrawDetails` is called last and should reverse anything done in `preDrawDetails` (i.e., pop or up any viewports that were pushed). Note that the default behaviour for grobs is to pop any viewports that were pushed so there is typically nothing to do here.

Note that `preDrawDetails` and `postDrawDetails` are also called in the calculation of "grobwidth" and "grobheight" units.

**Value**

None of these functions are expected to return a value.

**Author(s)**

Paul Murrell

**edtDetails**

### Customising grid Editing

**Description**

This generic hook function is called whenever a grid grob is edited via `grid.edit` or `editGrob`. This provides an opportunity for customising the editing of a new class derived from grob (or gTree).

**Usage**

`editDetails(x, specs)`

**Arguments**

- `x` A grid grob.
- `specs` A list of named elements. The names indicate the grob slots to modify and the values are the new values for the slots.
Details

This function is called by grid.edit and editGrob. A method should be written for classes derived from grob or gTree if a change in a slot has an effect on other slots in the grob or children of a gTree (e.g., see grid:::editDetails.xaxis).

Note that the slot already has the new value.

Value

The function MUST return the modified grob.

Paul Murrell

See Also

grid.edit

editViewport Modify a Viewport

Description

This is a convenience function for producing a new viewport from a copy of an existing viewport (by default the current viewport), with specified modifications.

Usage

editViewport(vp=current.viewport(), ...)

Arguments

vp A viewport object.

... Modification of the viewport (should all be valid arguments to the viewport() function.

Value

A grid viewport object.

Author(s)

Paul Murrell

See Also

viewport.
**explode**

*Explode a path into its components.*

**Description**

Explode a viewport path or grob path into its components.

**Usage**

```r
explode(x)
```

## S3 method for class 'character'

```r
explode(x)
```

## S3 method for class 'path'

```r
explode(x)
```

**Arguments**

- `x`

  Typically a viewport path or a grob path, but a character vector containing zero or more path separators may also be given.

**Value**

A character vector.

**See Also**

`vpPath`, `gPath`.

**Examples**

```r
eexplode("vp1::vp2")
eexplode(vpPath("vp1", "vp2"))
```

---

**gEdit**

*Create and Apply Edit Objects*

**Description**

The functions `gEdit` and `gEditList` create objects representing an edit operation (essentially a list of arguments to `editGrob`).

The functions `applyEdit` and `applyEdits` apply one or more edit operations to a graphical object. These functions are most useful for developers creating new graphical functions and objects.

**Usage**

```r
gEdit(...)  
gEditList(...)  
applyEdit(x, edit)  
applyEdits(x, edits)
```
getNames

Arguments

... one or more arguments to the editGrob function (for gEdit) or one or more "gEdit" objects (for gEditList).

x a grob (grid graphical object).

edit a "gEdit" object.

edits either a "gEdit" object or a "gEditList" object.

Value

gEdit returns an object of class "gEdit".
gEditList returns an object of class "gEditList".

applyEdit and applyEditList return the modified grob.

Author(s)

Paul Murrell

See Also

grob editGrob

Examples

grid.rect(gp=gpar(col="red"))
# same thing, but more verbose
grid.draw(applyEdit(rectGrob(), gEdit(gp=gpar(col="red"))))

getNames List the names of grobs on the display list

Description

Returns a character vector containing the names of all top-level grobs on the display list.

Usage

getNames()

Value

A character vector.

Author(s)

Paul Murrell

Examples

grid.grill()
getNames()
Description

gpar() should be used to create a set of graphical parameter settings. It returns an object of class "gpar". This is basically a list of name-value pairs.

gpar() can be used to query the current graphical parameter settings.

Usage

gpar(...)  
get.gpar(names = NULL)

Arguments

... Any number of named arguments.

names A character vector of valid graphical parameter names.

Details

All grid viewports and (predefined) graphical objects have a slot called gp, which contains a "gpar" object. When a viewport is pushed onto the viewport stack and when a graphical object is drawn, the settings in the "gpar" object are enforced. In this way, the graphical output is modified by the gp settings until the graphical object has finished drawing, or until the viewport is popped off the viewport stack, or until some other viewport or graphical object is pushed or begins drawing.

The default parameter settings are defined by the ROOT viewport, which takes its settings from the graphics device. These defaults may differ between devices (e.g., the default fill setting is different for a PNG device compared to a PDF device).

Valid parameter names are:

- col Colour for lines and borders.
- fill Colour for filling rectangles, polygons, ...
- alpha Alpha channel for transparency
- lty Line type
- lwd Line width
- lex Multiplier applied to line width
- lineend Line end style (round, butt, square)
- linejoin Line join style (round, mitre, bevel)
- linemitre Line mitre limit (number greater than 1)
- fontsize The size of text (in points)
- cex Multiplier applied to fontsize
- fontfamily The font family
- fontface The font face (bold, italic, ...)
- lineheight The height of a line as a multiple of the size of text
- font Font face (alias for fontface; for backward compatibility)

For more details of many of these, see the help for the corresponding graphical parameter par in base graphics. (This may have a slightly different name, e.g. lend, ljoin, lmitre, family.)
Colours can be specified in one of the forms returned by `rgb`, as a name (see `colors`) or as a non-negative integer index into the current `palette` (with zero being taken as transparent). (Negative integer values are now an error.)

The `alpha` setting is combined with the alpha channel for individual colours by multiplying (with both alpha settings normalised to the range 0 to 1).

The `fill` setting can also be a linear gradient or a radial gradient or a pattern (see `patterns`).

The size of text is `fontsize*cex`. The size of a line is `fontsize*cex*lineheight`.

The `cex` setting is cumulative; if a viewport is pushed with a `cex` of 0.5 then another viewport is pushed with a `cex` of 0.5, the effective `cex` is 0.25.

The `alpha` and `cex` settings are also cumulative.

Changes to the `fontfamily` may be ignored by some devices, but is supported by PostScript, PDF, X11, Windows, and Quartz. The `fontfamily` may be used to specify one of the Hershey Font families (e.g., `HersheySerif`) and this specification will be honoured on all devices.

The specification of `fontface` can be an integer or a string. If an integer, then it follows the R base graphics standard: 1 = plain, 2 = bold, 3 = italic, 4 = bold italic. If a string, then valid values are: "plain", "bold", "italic", "oblique", and "bold.italic". For the special case of the HersheySerif font family, "cyrillic", "cyrillic.oblique", and "EUC" are also available.

All parameter values can be vectors of multiple values. (This will not always make sense – for example, viewports will only take notice of the first parameter value.)

`get.gpar()` returns all current graphical parameter settings.

### Value

An object of class "gpar".

### Author(s)

Paul Murrell

### See Also

`Hershey`.

### Examples

```r
gp <- get.gpar()
utils::str(gp)
## These *do* nothing but produce a "gpar" object:
gpar(col = "red")
gpar(col = "blue", lty = "solid", lwd = 3, fontsize = 16)
get.gpar(c("col", "lty"))
grid.newpage()
vp <- viewport(width = .8, height = .8, gp = gpar(col="blue"))
grid.draw(gTree(children=gList(rectGrob(gp = gpar(col="red")),
        textGrob(paste("The rect is its own colour (red)",
        "but this text is the colour",
        "set by the gTree (green)",
        sep = "\n"))>,
    gp = gpar(col="green"), vp = vp))
grid.text("This text is the colour set by the viewport (blue)",
y = 1, just = c("center", "bottom"),
gp = gpar(fontsize=20), vp = vp)
```
gPath

grid.newpage()
## example with multiple values for a parameter
pushViewport(viewport())
grid.points(1:10/11, 1:10/11, gp = gpar(col=1:10))
popViewport()

---

**Concatenate Grob Names**

**Description**

This function can be used to generate a grob path for use in `grid.edit` and friends.

A grob path is a list of nested grob names.

**Usage**

`gPath(...)`

**Arguments**

`...`  
Character values which are grob names.

**Details**

Grob names must only be unique amongst grobs which share the same parent in a gTree.

This function can be used to generate a specification for a grob that includes the grob’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

**Value**

A `gPath` object.

**See Also**

grob, editGrob, addGrob, removeGrob, getGrob, setGrob

**Examples**

gPath("g1", "g2")
Grid Viewports

**Description**

General information about the grid graphics package.

**Details**

Grid graphics provides an alternative to the standard R graphics. The user is able to define arbitrary rectangular regions (called *viewports*) on the graphics device and define a number of coordinate systems for each region. Drawing can be specified to occur in any viewport using any of the available coordinate systems.

Grid graphics and standard R graphics do not mix! Type `library(help = grid)` to see a list of (public) Grid graphics functions.

**Author(s)**

Paul Murrell

**See Also**

`viewport`, `grid.layout`, and `unit`.

**Examples**

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
                       heights=unit(rep(1, 4),
                       c("lines", "lines", "lines", "null")),
                       widths=unit(c(1, 1), "inches")))
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
                           width=unit(1, "inches"), height=unit(1, "inches")))
## A flash plotting example
grid.multipanel(vp=viewport(0.5, 0.5, 0.8, 0.8))
```

---

Create a Grid Viewport

**Description**

These functions create viewports, which describe rectangular regions on a graphics device and define a number of coordinate systems within those regions.
Grid Viewports

Usage

```r
viewport(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
       width = unit(1, "npc"), height = unit(1, "npc"),
       default.units = "npc", just = "centre",
       gp = gpar(), clip = "inherit", mask = "inherit",
       xscale = c(0, 1), yscale = c(0, 1),
       angle = 0,
       layout = NULL,
       layout.pos.row = NULL, layout.pos.col = NULL,
       name = NULL)
```

```r
vpList(...)
vpStack(...)
vpTree(parent, children)
```

Arguments

- `x` A numeric vector or unit object specifying x-location.
- `y` A numeric vector or unit object specifying y-location.
- `width` A numeric vector or unit object specifying width.
- `height` A numeric vector or unit object specifying height.
- `default.units` A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- `just` A string or numeric vector specifying the justification of the viewport relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- `gp` An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `clip` One of "on", "inherit", or "off", indicating whether to clip to the extent of this viewport, inherit the clipping region from the parent viewport, or turn clipping off altogether. For back-compatibility, a logical value of TRUE corresponds to "on" and FALSE corresponds to "inherit". May also be a grob (or a gTree) that describes a clipping path or the result of a call to `as.path`.
- `mask` One of "none" (or FALSE) or "inherit" (or TRUE) or a grob (or a gTree). This specifies that the viewport should have no mask, or it should inherit the mask of its parent, or it should have its own mask, as described by the grob.
- `xscale` A numeric vector of length two indicating the minimum and maximum on the x-scale. The limits may not be identical.
- `yscale` A numeric vector of length two indicating the minimum and maximum on the y-scale. The limits may not be identical.
- `angle` A numeric value indicating the angle of rotation of the viewport. Positive values indicate the amount of rotation, in degrees, anticlockwise from the positive x-axis.
- `layout` A Grid layout object which splits the viewport into subregions.
- `layout.pos.row` A numeric vector giving the rows occupied by this viewport in its parent’s layout.
Grid Viewports

- **layout.pos.col**: A numeric vector giving the columns occupied by this viewport in its parent’s layout.

- **name**: A character value to uniquely identify the viewport once it has been pushed onto the viewport tree.

- **...**: Any number of grid viewport objects.

- **parent**: A grid viewport object.

- **children**: A vpList object.

**Details**

The location and size of a viewport are relative to the coordinate systems defined by the viewport’s parent (either a graphical device or another viewport). The location and size can be specified in a very flexible way by specifying them with unit objects. When specifying the location of a viewport, specifying both `layout.pos.row` and `layout.pos.col` as `NULL` indicates that the viewport ignores its parent’s layout and specifies its own location and size (via its `locn`). If only one of `layout.pos.row` and `layout.pos.col` is `NULL`, this means occupy ALL of the appropriate row(s)/column(s). For example, `layout.pos.row = 1` and `layout.pos.col = NULL` means occupy all of row 1. Specifying non-NULL values for both `layout.pos.row` and `layout.pos.col` means occupy the intersection of the appropriate rows and columns. If a vector of length two is specified for `layout.pos.row` or `layout.pos.col`, this indicates a range of rows or columns to occupy. For example, `layout.pos.row = c(1, 3)` and `layout.pos.col = c(2, 4)` means occupy cells in the intersection of rows 1, 2, and 3, and columns, 2, 3, and 4.

Clipping obeys only the most recent viewport clip setting. For example, if you clip to viewport1, then clip to viewport2, the clipping region is determined wholly by viewport2, the size and shape of viewport1 is irrelevant (until viewport2 is popped of course).

If a viewport is rotated (because of its own `angle` setting or because it is within another viewport which is rotated) then the `clip` flag is ignored.

If `clip` is a grob, then that grob (which may be more than one shape) defines a clipping path. The function `as.path` may be used to specify a fill rule for the path.

Viewport names need not be unique. When pushed, viewports sharing the same parent must have unique names, which means that if you push a viewport with the same name as an existing viewport, the existing viewport will be replaced in the viewport tree. A viewport name can be any string, but grid uses the reserved name "ROOT" for the top-level viewport. Also, when specifying a viewport name in `downViewport` and `seekViewport`, it is possible to provide a viewport path, which consists of several names concatenated using the separator (currently `::`). Consequently, it is not advisable to use this separator in viewport names.

The viewports in a `vpList` are pushed in parallel. The viewports in a `vpStack` are pushed in series. When a `vpTree` is pushed, the parent is pushed first, then the children are pushed in parallel.

**Value**

An R object of class `viewport`.

  gp=gpar(fontsize=8))}
grid.add

Add a Grid Graphical Object

Description

Add a grob to a gTree or a descendant of a gTree.

Usage

grid.add(gPath, child, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE, redraw = TRUE)

addGrob(gTree, child, gPath = NULL, strict = FALSE, grep = FALSE, global = FALSE, warn = TRUE)

setChildren(x, children)

Arguments

gTree, x A gTree object.
gPath A gPath object. For grid.add this specifies a gTree on the display list. For addGrob this specifies a descendant of the specified gTree.
child A grob object.
children A gList object.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
warn A logical to indicate whether failing to find the specified gPath should trigger an error.
allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw A logical value to indicate whether to redraw the grob.

Details

addGrob copies the specified grob and returns a modified grob.
grid.add destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.
setChildren is a basic function for setting all children of a gTree at once (instead of repeated calls to addGrob).
grid.bezier

Value

addGrob returns a grob object; grid.add returns NULL.

Author(s)

Paul Murrell

See Also

grob, getGrob, addGrob, removeGrob.

draw a Bezier Curve

Description

These functions create and draw Bezier Curves (a curve drawn relative to 4 control points).

Usage

grid.bezier(...)
bezierGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
    id = NULL, id.lengths = NULL,
    default.units = "npc", arrow = NULL,
    name = NULL, gp = gpar(), vp = NULL)

Arguments

x
A numeric vector or unit object specifying x-locations of spline control points.
y
A numeric vector or unit object specifying y-locations of spline control points.
id
A numeric vector used to separate locations in x and y into multiple beziers. All
    locations with the same id belong to the same bezier.
id.lengths
A numeric vector used to separate locations in x and y into multiple bezier.
    Specifies consecutive blocks of locations which make up separate beziers.
default.units
A string indicating the default units to use if x or y are only given as numeric
    vectors.
arrow
A list describing arrow heads to place at either end of the bezier, as produced by
    the arrow function.
name
A character identifier.
gp
An object of class "gpar", typically the output from a call to the function gpar.
    This is basically a list of graphical parameter settings.
vp
A Grid viewport object (or NULL).
... Arguments to be passed to bezierGrob.
Details

Both functions create a beziergrob (a graphical object describing a Bezier curve), but only `grid.bezier` draws the Bezier curve.

A Bezier curve is a line drawn relative to 4 control points.
Missing values are not allowed for x and y (i.e., it is not valid for a control point to be missing).
The curve is currently drawn using an approximation based on X-splines.

Value

A grob object.

See Also

`Grid, viewport, arrow`.
`grid.xspline`.

Examples

```r
x <- c(0.2, 0.2, 0.4, 0.4)
y <- c(0.2, 0.4, 0.4, 0.2)

grid.newpage()
grid.bezier(x, y)
grid.bezier(c(x, x + .4), c(y + .4, y + .4),
           id=rep(1:2, each=4))
grid.segments(.4, .6, .6, .6)
grid.bezier(x, y,
           gp=gpar(lwd=3, fill="black"),
           arrow=arrow(type="closed"),
           vp=viewport(x=.9))
```

---

grid.cap

Capture a raster image

Description

Capture the current contents of a graphics device as a raster (bitmap) image.

Usage

`grid.cap()`

Details

This function is only implemented for on-screen graphics devices.

Value

A matrix of R colour names, or NULL if not available.
grid.circle

Author(s)
Paul Murrell

See Also
grid.raster
dev.capabilities to see if it is supported.

Examples

dev.new(width=0.5, height=0.5)
grid.rect()
grid.text("hi")
cap <- grid.cap()
dev.off()

if(!is.null(cap))
  grid.raster(cap, width=0.5, height=0.5, interpolate=FALSE)

Description
Functions to create and draw a circle.

Usage

grid.circle(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
gp=gpar(), draw=TRUE, vp=NULL)
circleGrob(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
gp=gpar(), vp=NULL)

Arguments

x
A numeric vector or unit object specifying x-locations.
y
A numeric vector or unit object specifying y-locations.
r
A numeric vector or unit object specifying radii.
default.units
A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name
A character identifier.
gp
An object of class "gpar", typically the output from a call to the function gpar.
This is basically a list of graphical parameter settings.
draw
A logical value indicating whether graphics output should be produced.
vp
A Grid viewport object (or NULL).
Both functions create a circle grob (a graphical object describing a circle), but only `grid.circle()` draws the circle (and then only if `draw` is `TRUE`).

The radius may be given in any units; if the units are `relative` (e.g., "npc" or "native") then the radius will be different depending on whether it is interpreted as a width or as a height. In such cases, the smaller of these two values will be the result. To see the effect, type `grid.circle()` and adjust the size of the window.

What happens for very small radii is device-dependent: the circle may become invisible or be shown at a fixed minimum size. Circles of zero radius will not be plotted.

A circle grob. `grid.circle()` returns the value invisibly.

Negative values for the radius are silently converted to their absolute value.

These functions set the clipping region within the current viewport without altering the current coordinate system.

A numeric vector or unit object specifying x-location.

A numeric vector or unit object specifying y-location.

A numeric vector or unit object specifying width.

A numeric vector or unit object specifying height.
**grid.clip**

`just`  
The justification of the clip rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.

`hjust`  
A numeric vector specifying horizontal justification. If specified, overrides the just setting.

`vjust`  
A numeric vector specifying vertical justification. If specified, overrides the just setting.

`default.units`  
A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.

`name`  
A character identifier.

`vp`  
A Grid viewport object (or NULL).

`...`  
Arguments passed to clipGrob.

**Details**

Both functions create a clip rectangle (a graphical object describing a clip rectangle), but only `grid.clip` enforces the clipping.

Pushing or popping a viewport always overrides the clip region set by a clip grob, regardless of whether that viewport explicitly enforces a clipping region.

**Value**

`clipGrob` returns a clip grob.

**Author(s)**

Paul Murrell

**See Also**

`Grid`, `viewport`

**Examples**

```r
# draw across entire viewport, but clipped
grid.clip(x = 0.3, width = 0.1)
grid.lines(gp=gpar(col="green", lwd=5))
# draw across entire viewport, but clipped (in different place)
grid.clip(x = 0.7, width = 0.1)
grid.lines(gp=gpar(col="red", lwd=5))
# Viewport sets new clip region
pushViewport(viewport(width=0.5, height=0.5, clip=TRUE))
grid.lines(gp=gpar(col="grey", lwd=3))
# Return to original viewport; get
# clip region from previous grid.clip()
# (NOT from previous viewport clip region)
popViewport()
grid.lines(gp=gpar(col="black"))
```
Description

These functions take a unit object and convert it to an equivalent unit object in a different coordinate system.

Usage

convertX(x, unitTo, valueOnly = FALSE)
convertY(x, unitTo, valueOnly = FALSE)
convertWidth(x, unitTo, valueOnly = FALSE)
convertHeight(x, unitTo, valueOnly = FALSE)
convertUnit(x, unitTo,
  axisFrom = "x", typeFrom = "location",
  axisTo = axisFrom, typeTo = typeFrom,
  valueOnly = FALSE)

Arguments

x A unit object.
unitTo The coordinate system to convert the unit to. See the unit function for valid coordinate systems.
axisFrom Either "x" or "y" to indicate whether the unit object represents a value in the x- or y-direction.
typeFrom Either "location" or "dimension" to indicate whether the unit object represents a location or a length.
axisTo Same as axisFrom, but applies to the unit object that is to be created.
typeTo Same as typeFrom, but applies to the unit object that is to be created.
valueOnly A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.

Details

The convertUnit function allows for general-purpose conversions. The other four functions are just more convenient front-ends to it for the most common conversions.

The conversions occur within the current viewport.

It is not currently possible to convert to all valid coordinate systems (e.g., "strwidth" or "grob-width"). I’m not sure if all of these are impossible, they just seem implausible at this stage.

In normal usage of grid, these functions should not be necessary. If you want to express a location or dimension in inches rather than user coordinates then you should simply do something like unit(1, "inches") rather than something like unit(0.134, "native").

In some cases, however, it is necessary for the user to perform calculations on a unit value and this function becomes necessary. In such cases, please take note of the warning below.
Value

A unit object in the specified coordinate system (unless valueOnly is TRUE in which case the returned value is a numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid. For example, suppose that I create a unit object as follows: oneinch <- convertUnit(unit(1, "inches"), "native"). Now if I resize the device, the unit object in oneinch no longer corresponds to a physical length of 1 inch.

            axisFrom="x", axisTo="y")
## Convert several values at once
convertX(unit(c(0.5, 2.54), c("npc", "cm")), c("inches", "native"))
popViewport()
## Convert a complex unit
grid.copy

Make a Copy of a Grid Graphical Object

Description

This function is redundant and will disappear in future versions.

Usage

grid.copy(grob)

Arguments

grob

A grob object.

Value

A copy of the grob object.

Author(s)

Paul Murrell

See Also

grid.grob.

grid.curve

Draw a Curve Between Locations

Description

These functions create and draw a curve from one location to another.

Usage

grid.curve(...)  
curveGrob(x1, y1, x2, y2, default.units = "npc",  
  curvature = 1, angle = 90, ncp = 1, shape = 0.5,  
  square = TRUE, squareShape = 1,  
  inflect = FALSE, arrow = NULL, open = TRUE,  
  debug = FALSE,  
  name = NULL, gp = gpar(), vp = NULL)  
arcCurvature(theta)
grid.curve

Arguments

- **x1**: A numeric vector or unit object specifying the x-location of the start point.
- **y1**: A numeric vector or unit object specifying the y-location of the start point.
- **x2**: A numeric vector or unit object specifying the x-location of the end point.
- **y2**: A numeric vector or unit object specifying the y-location of the end point.
- **default.units**: A string indicating the default units to use if **x1**, **y1**, **x2** or **y2** are only given as numeric values.
- **curvature**: A numeric value giving the amount of curvature. Negative values produce left-hand curves, positive values produce right-hand curves, and zero produces a straight line.
- **angle**: A numeric value between 0 and 180, giving an amount to skew the control points of the curve. Values less than 90 skew the curve towards the start point and values greater than 90 skew the curve towards the end point.
- **ncp**: The number of control points used to draw the curve. More control points create a smoother curve.
- **shape**: A numeric vector of values between -1 and 1, which control the shape of the curve relative to its control points. See grid.xspline for more details.
- **square**: A logical value that controls whether control points for the curve are created city-block fashion or obliquely. When **ncp** is 1 and **angle** is 90, this is typically TRUE, otherwise this should probably be set to FALSE (see Examples below).
- **squareShape**: A shape value to control the behaviour of the curve relative to any additional control point that is inserted if **square** is TRUE.
- **inflect**: A logical value specifying whether the curve should be cut in half and inverted (see Examples below).
- **arrow**: A list describing arrow heads to place at either end of the curve, as produced by the arrow function.
- **open**: A logical value indicating whether to close the curve (connect the start and end points).
- **debug**: A logical value indicating whether debugging information should be drawn.
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).
- **...**: Arguments to be passed to curveGrob.
- **theta**: An angle (in degrees).

Details

Both functions create a curve grob (a graphical object describing an curve), but only grid.curve draws the curve. The arcCurvature function can be used to calculate a curvature such that control points are generated on an arc corresponding to angle theta. This is typically used in conjunction with a large ncp to produce a curve corresponding to the desired arc.

Value

A grob object.
grid.delay

Encapsulate calculations and generating a grob

Description

Evaluates an expression that includes both calculations and generating a grob that depends on the calculations so that both the calculations and the grob generation will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.

Usage

delayGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.delay(expr, list, name=NULL, gp=NULL, vp=NULL)
Arguments

expr  object of mode expression or call or an unevaluated expression.

list  a list defining the environment in which expr is to be evaluated.

name  A character identifier.

gp    An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp    A Grid viewport object (or NULL).

Details

A grob is created of special class "delayedgrob" (and drawn, in the case of grid.delay). The makeContent method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

The expr argument should return a grob as its result.

These functions are analogues of the grid.record() and recordGrob() functions; the difference is that these functions are based on the makeContent() hook, while those functions are based on the drawDetails() hook.

Note

This function must be used instead of the function recordGraphics; all of the dire warnings about using recordGraphics responsibly also apply here.

Author(s)

Paul Murrell

See Also

recordGraphics

Examples

grid.delay({
  w <- convertWidth(unit(1, "inches"), "npc")
  rectGrob(width=w)
},
list())
grid.DLapply

Arguments

on

A logical value to indicate whether the display list should be on or off.

Details

All drawing and viewport-setting operations are (by default) recorded in the Grid display list. This allows redrawing to occur following an editing operation.

This display list could get very large so it may be useful to turn it off in some cases; this will of course disable redrawing.

All graphics output is also recorded on the main display list of the R graphics engine (by default). This supports redrawing following a device resize and allows copying between devices.

Turning off this display list means that grid will redraw from its own display list for device resizes and copies. This will be slower than using the graphics engine display list.

Value

None.

WARNING

Turning the display list on causes the display list to be erased!

Turning off both the grid display list and the graphics engine display list will result in no redrawing whatsoever.

Author(s)

Paul Murrell

grid.DLapply

Modify the Grid Display List

Description

Call a function on each element of the current display list.

Usage

grid.DLapply(FUN, ...)

Arguments

FUN

A function; the first argument to this function is passed each element of the display list.

... Further arguments to pass to FUN.
Details

This function is insanely dangerous (for the grid display list).

Two token efforts are made to try to avoid ending up with complete garbage on the display list:

1. The display list is only replaced once all new elements have been generated (so an error during generation does not result in a half-finished display list).
2. All new elements must be either NULL or inherit from the class of the element that they are replacing.

Value

The side effect of these functions is usually to modify the grid display list.

See Also

Grid.

Examples

```r
grid.newpage()
grid.rect(width=.4, height=.4, x=.25, y=.75, gp=gpar(fill="black"), name="r1")
grid.rect(width=.4, height=.4, x=.5, y=.5, gp=gpar(fill="grey"), name="r2")
grid.rect(width=.4, height=.4, x=.75, y=.25, gp=gpar(fill="white"), name="r3")
grid.DLapply(function(x) { if (is.grob(x)) x$gp <- gpar(); x })
grid.refresh()
```

Description

Draw a grid grob

Produces graphical output from a graphical object.

Usage

```r
grid.draw(x, recording=TRUE)
```

Arguments

- `x` An object of class "grob" or NULL.
- `recording` A logical value to indicate whether the drawing operation should be recorded on the Grid display list.

Details

This is a generic function with methods for grob and gTree objects.

The grob and gTree methods automatically push any viewports in a `vp` slot and automatically apply any `gpar` settings in a `gp` slot. In addition, the gTree method pushes and ups any viewports in a `childrenvp` slot and automatically calls `grid.draw` for any grobs in a `children` slot.

The methods for grob and gTree call the generic hook functions `preDrawDetails`, `drawDetails`, and `postDrawDetails` to allow classes derived from grob or gTree to perform additional viewport pushing/popping and produce additional output beyond the default behaviour for grobs and gTrees.
grid.edit

Edit the Description of a Grid Graphical Object

Description

Changes the value of one of the slots of a grob and redraws the grob.

Usage

grid.edit(gPath, ..., strict = FALSE, grep = FALSE,
          global = FALSE, allDevices = FALSE, redraw = TRUE)

grid.gedit(..., grep = TRUE, global = TRUE)

editGrob(grob, gPath = NULL, ..., strict = FALSE, grep = FALSE,
          global = FALSE, warn = TRUE)

Arguments

grob A grob object.

... Zero or more named arguments specifying new slot values.

gPath A gPath object. For grid.edit this specifies a grob on the display list. For
       editGrob this specifies a descendant of the specified grob.

strict A boolean indicating whether the gPath must be matched exactly.

grep A boolean indicating whether the gPath should be treated as a regular expres-
      sion. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE)
      means that every odd element of the gPath will be treated as a regular expres-
      sion).

global A boolean indicating whether the function should affect just the first match of
        the gPath, or whether all matches should be affected.
grid.force

warn A logical to indicate whether failing to find the specified gPath should trigger an error.

allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

redraw A logical value to indicate whether to redraw the grob.

Details
editGrob copies the specified grob and returns a modified grob.

grid.edit destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

Both functions call editDetails to allow a grob to perform custom actions and validDetails to check that the modified grob is still coherent.

grid.gedit (g for global) is just a convenience wrapper for grid.edit with different defaults.

Value
editGrob returns a grob object; grid.edit returns NULL.

Author(s)
Paul Murrell

See Also
grob, getGrob, addGrob, removeGrob.

Examples

grid.newpage()
grid.xaxis(name = "xa", vp = viewport(width=.5, height=.5))
grid.edit("xa", gp = gpar(col="red"))
# won't work because no ticks (at is NULL)
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
grid.edit("xa", at = 1:4/5)
# Now it should work
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
Usage

```r
grid.force(x, ...)  
## Default S3 method:  
grid.force(x, redraw = FALSE, ...)  
## S3 method for class 'gPath'  
grid.force(x, strict = FALSE, grep = FALSE, global = FALSE,  
          redraw = FALSE, ...)  
## S3 method for class 'grob'  
grid.force(x, draw = FALSE, ...)  
forceGrob(x)  
grid.revert(x, ...)  
## S3 method for class 'gPath'  
grid.revert(x, strict = FALSE, grep = FALSE, global = FALSE,  
           redraw = FALSE, ...)  
## S3 method for class 'grob'  
grid.revert(x, draw = FALSE, ...)  
```

Arguments

- `x` For the default method, `x` should not be specified. Otherwise, `x` should be a grob or a gPath. If `x` is character, it is assumed to be a gPath.
- `strict` A boolean indicating whether the path must be matched exactly.
- `grep` Whether the path should be treated as a regular expression.
- `global` A boolean indicating whether the function should affect just the first match of the path, or whether all matches should be affected.
- `draw` logical value indicating whether a grob should be drawn after it is forced.
- `redraw` logical value indicating whether to redraw the `grid` scene after the forcing operation.
- `...` Further arguments for use by methods.

Details

Some grobs wait until drawing time to generate what content will actually be drawn (an axis, as produced by `grid.xaxis()`, with an at or NULL is a good example because it has to see what viewport it is going to be drawn in before it can decide what tick marks to draw).

The content of such grobs (e.g., the tick marks) are not usually visible to `grid.ls()` or accessible to `grid.edit()`.

The `grid.force()` function replaces a grob with its at-drawing-time contents. For example, an axis will be replaced by a vanilla gTree with lines and text representing the axis tick marks that were actually drawn. This makes the tick marks visible to `grid.ls()` and accessible to `grid.edit()`.

The `forceGrob()` function is the internal work horse for `grid.force()`, so will not normally be called directly by the user. It is exported so that methods can be written for custom grob classes if necessary.

The `grid.revert()` function reverses the effect of `grid.force()`, replacing forced content with the original grob.

Warning

Forcing an explicit grob produces a result as if the grob were drawn in the current drawing context. It may not make sense to draw the result in a different drawing context.
Note

These functions only have an effect for grobs that generate their content at drawing time using makeContext() and makeContent() methods (not for grobs that generate their content at drawing time using preDrawDetails() and drawDetails() methods).

Author(s)

Paul Murrell

Examples

grid.newpage()
pushViewport(viewport(width=.5, height=.5))
  # Draw xaxis
  grid.xaxis(name="xax")
grid.ls()
  # Force xaxis
  grid.force()
grid.ls()
  # Revert xaxis
  grid.revert()
grid.ls()
  # Draw and force yaxis
  grid.force(yaxisGrob(), draw=TRUE)
grid.ls()
  # Revert yaxis
  grid.revert()
grid.ls()
  # Force JUST xaxis
  grid.force("xax")
grid.ls()
  # Force ALL
  grid.force()
grid.ls()
  # Revert JUST xaxis
  grid.revert("xax")
grid.ls()

grid.frame

Create a Frame for Packing Objects

Description

These functions, together with grid.pack, grid.place, packGrob, and placeGrob are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with this function then use grid.pack or whatever to pack/place objects into the frame.

Usage

grid.frame(layout=NULL, name=NULL, gp=gpar(), vp=NULL, draw=TRUE)
frameGrob(layout=NULL, name=NULL, gp=gpar(), vp=NULL)
Arguments

- **layout**: A Grid layout, or NULL. This can be used to initialise the frame with a number of rows and columns, with initial widths and heights, etc.
- **name**: A character identifier.
- **vp**: An object of class `viewport`, or NULL.
- **gp**: An object of class "gpar"; typically the output from a call to the function `gpar`.
- **draw**: Should the frame be drawn.

Details

Both functions create a frame grob (a graphical object describing a frame), but only `grid.frame()` draws the frame (and then only if `draw` is `TRUE`). Nothing will actually be drawn, but it will put the frame on the display list, which means that the output will be dynamically updated as objects are packed into the frame. Possibly useful for debugging.

Value

A frame grob. `grid.frame()` returns the value invisibly.

Author(s)

Paul Murrell

See Also

- `grid.pack`

Examples

```r
grid.newpage()
grid.frame(name="gf", draw=TRUE)
grid.pack("gf", rectGrob(gp=gpar(fill="grey")), width=unit(1, "null"))
grid.pack("gf", textGrob("hi there"), side="right")
```

---

**grid.function**  

*Draw a curve representing a function*

Description

Draw a curve representing a function.

Usage

```r
grid.function(...)  
functionGrob(f, n = 101, range = "x", units = "native",  
    name = NULL, gp=gpar(), vp = NULL)
```

```r
grid.abline(intercept, slope, ...)
```
Arguments

- **f**: A function that must take a single argument and return a list with two numeric components named `x` and `y`.
- **n**: The number values that will be generated as input to the function `f`.
- **range**: Either "x", "y", or a numeric vector. See the 'Details' section.
- **units**: A string indicating the units to use for the `x` and `y` values generated by the function.
- **intercept**: Numeric.
- **slope**: Numeric.
- **...**: Arguments passed to `grid.function()`.
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).

Details

`n` values are generated and passed to the function `f` and a series of lines are drawn through the resulting `x` and `y` values.

The generation of the `n` values depends on the value of `range`. In the default case, `dim` is "x", which means that a set of `x` values are generated covering the range of the current viewport scale in the `x`-dimension. If `dim` is "y" then values are generated from the current `y`-scale instead. If `range` is a numeric vector, then values are generated from that range.

`grid.abline()` provides a simple front-end for a straight line parameterized by `intercept` and `slope`.

Value

A function grob.

# physical abline
grid.newpage()
grid.function(function(x) list(x=x, y=0 + 1*x),
  units="in")

grid.get  

Get a Grid Graphical Object

Description
Retrieve a grob or a descendant of a grob.

Usage
grid.get(gPath, strict = FALSE, grep = FALSE, global = FALSE,
  allDevices = FALSE)

grid.gget(..., grep = TRUE, global = TRUE)

g getS(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE)

Arguments

  gTree  A gTree object.
  gPath  A gPath object. For grid.get this specifies a grob on the display list. For
        getGrob this specifies a descendant of the specified gTree.
  strict A boolean indicating whether the gPath must be matched exactly.
  grep   A boolean indicating whether the gPath should be treated as a regular expres-
        sion. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE)
        means that every odd element of the gPath will be treated as a regular expres-

grid.grab

A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.

allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

Details

grid.gget (g for global) is just a convenience wrapper for grid.get with different defaults.

Value

A grob object.

Author(s)

Paul Murrell

See Also

grob, getGrob, addGrob, removeGrob.

Examples

grid.xaxis(name="xa")
grid.get("xa")
grid.get(gPath("xa", "ticks"))

grid.draw(gTree(name="gt", children=gList(xaxisGrob(name="axis"))))
grid.get(gPath("gt", "axis", "ticks"))

Description

Create a gTree object from the current grid display list or from a scene generated by user-specified code.

Usage

grid.grab(warn = 2, wrap = wrap.grobs, wrap.grobs = FALSE, ...)
grid.grabExpr(expr, warn = 2, wrap = wrap.grobs, wrap.grobs = FALSE, width = 7, height = 7, device = offscreen, ...)
Arguments

expr  An expression to be evaluated. Typically, some calls to grid drawing functions.

warn  An integer specifying the amount of warnings to emit. 0 means no warnings,
       1 means warn when it is certain that the grab will not faithfully represent
       the original scene. 2 means warn if there’s any possibility that the grab will not
       faithfully represent the original scene.

wrap  A logical indicating how the output should be captured. If TRUE, each non-grob
       element on the display list is captured by wrapping it in a grob.

wrap.grobs  A logical indicating whether, if we are wrapping elements (wrap=TRUE), we
            should wrap grobs (or just wrap viewports).

width, height  Size of the device used for temporary rendering.

device  A function that opens a graphics device for temporary rendering. By default
         this is an off-screen, in-memory device based on the pdf device, but this default
         device may not be satisfactory when using custom fonts.

...  arguments passed to gTree, for example, a name and/or class for the gTree that
      is created.

Details

There are four ways to capture grid output as a gTree.

There are two functions for capturing output: use grid.grab to capture an existing drawing and
grid.grabExpr to capture the output from an expression (without drawing anything).

For each of these functions, the output can be captured in two ways. One way tries to be clever and
make a gTree with a childrenvp slot containing all viewports on the display list (including those that
are popped) and every grob on the display list as a child of the new gTree; each child has a vpPath
in the vp slot so that it is drawn in the appropriate viewport. In other words, the gTree contains all
elements on the display list, but in a slightly altered form.

The other way, wrap=TRUE, is to create a grob for every element on the display list (and make all of
those grobs children of the gTree). Only viewports are wrapped unless wrap.grobs is also TRUE.

The first approach creates a more compact and elegant gTree, which is more flexible to work with,
but is not guaranteed to faithfully replicate all possible grid output. The second approach is more
brute force, and harder to work with, but is more likely to replicate the original output.

An example of a case that will NOT be replicated by wrapping, with wrap.grobs=TRUE, is a scene
where the placement of one grob is dependent on another grob (e.g., via grobX or grobWidth).

Value

A gTree object.

gTree

Examples

pushViewport(viewport(width=.5, height=.5))
grid.rect()
grid.points(stats::runif(10), stats::runif(10))
popViewport()
grab <- grid.grab()
grid.grep()  
grid.newpage()  
grid.draw(grab)

grid.grep  
Search for Grobs and/or Viewports

Description
Given a path, find all matching grobs and/or viewports on the display list or within a given grob.

Usage
grid.grep(path, x = NULL, grobs = TRUE, viewports = FALSE, 
strict = FALSE, grep = FALSE, global = FALSE, 
no.match = character(), vpPath = viewports)

Arguments
path  a gPath or a vpPath or a character value that could be interpreted as either.
x  a grob or NULL. If NULL, the display list is searched.
grobs  A logical value indicating whether to search for grobs.
viewports  A logical value indicating whether to search for viewports.
strict  A boolean indicating whether the path must be matched exactly.
grep  Whether the path should be treated as a regular expression.
global  A boolean indicating whether the function should affect just the first match of the path, or whether all matches should be affected.
no.match  The value to return if no matches are found.
vpPath  A logical value indicating whether to return the vpPath for each grob as an attribute of the result.

Value
Either a gPath or a vpPath or, if global is TRUE a list of gPaths and/or vpPaths.
If vpPath is TRUE, each gPath result will have an attribute "vpPath".
If there are no matches, no.match is returned.

Examples
# A gTree, called "grandparent", with child gTree,  
# called "parent", with children vp Stack (vp2 within vp1)  
# and child grob, called "child", with vp vpPath (down to vp2)  
sampleGTree <- gTree(name="grandparent",  
children=gList(gTree(name="parent",  
children=gList(grob(name="child", vp="vp1::vp2"))),  
childrenvp=vpStack(viewport(name="vp1"),
grid.grill

Draw a Grill

Description

This function draws a grill within a Grid viewport.

Usage

grid.grill(h = unit(seq(0.25, 0.75, 0.25), "npc"),
           v = unit(seq(0.25, 0.75, 0.25), "npc"),
           default.units = "npc", gp=gpar(col = "grey"), vp = NULL)

Arguments

h A numeric vector or unit object indicating the horizontal location of the vertical grill lines.

v A numeric vector or unit object indicating the vertical location of the horizontal grill lines.

default.units A string indicating the default units to use if h or v are only given as numeric vectors.

gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp A Grid viewport object.

Value

None.

grid.grob  Create Grid Graphical Objects, aka "Grob"s

Description

Creating grid graphical objects, short ("grob"s).
grob() and gTree() are the basic creators, grobTree() and gList() take several grobs to build a new one.

Usage

## Grob Creation:

```r
# Grob Creation:

grob(..., name = NULL, gp = NULL, vp = NULL, cl = NULL)
gTree(..., name = NULL, gp = NULL, vp = NULL, children = NULL,
       childrenvp = NULL, cl = NULL)
grobTree(..., name = NULL, gp = NULL, vp = NULL,
         childrenvp = NULL, cl = NULL)
gList(...)
```

## Grob Properties:

```r
childNames(gTree)
is.grob(x)
```

Arguments

...  For grob and gTree, the named slots describing important features of the graphical object. For gList and grobTree, a series of grob objects.

name  a character identifier for the grob. Used to find the grob on the display list and/or as a child of another grob.

children  a "gList" object.

childrenvp  a viewport object (or NULL).

gp  A "gpar" object, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp  a viewport object (or NULL).

cl  string giving the class attribute for the new class.

gTree  a "gTree" object.

x  An R object.
Draw a Group

These functions define and draw one or more groups, where a group is a grob that is drawn in isolation before being combined with the main image. The concept of groups allows for compositing operators, object reuse, and affine transformations (see the Details section).

Usage

```r
groupGrob(src, op = "over", dst = NULL,
          name = NULL, gp=gpar(), vp=NULL)
grid.group(src, op = "over", dst = NULL,
           name = NULL, gp=gpar(), vp=NULL)
defineGrob(src, op = "over", dst = NULL,
           name = NULL, gp=gpar(), vp=NULL)
```
grid.group

grid.define(src, op = "over", dst = NULL, 
        name = NULL, gp=gpar(), vp=NULL)

useGrob(group, transform=viewportTransform, 
        name=NULL, gp=gpar(), vp=NULL)

grid.use(group, transform=viewportTransform, 
        name=NULL, gp=gpar(), vp=NULL)

Arguments

src    A grob.
op    The name of a compositing operator (see Details).
dst    A grob.
group    A character identified referring to the name of a defined group.
transform    A function that returns an affine transformation matrix; see viewportTransform.
name    A character identifier.
gp    An object of class "gpar", typically the output from a call to the function gpar.
This is basically a list of graphical parameter settings.
vp    A Grid viewport object (or NULL).

Details

In the simplest usage, we can use grid.group() to specify a grob to be drawn in isolation before being combined with the main image. This can be different from normal drawing if, for example, the grob draws more than one shape and there is a mask currently in effect.

Another possible use of grid.group() is to specify both src and dst and combine them using a compositing operator other than the default "over", before combining the result with the main image. For example, if we use the "clear" operator then dst is only drawn where it is NOT overlapped by src.

It is also possible to break the process into two steps by first using grid.define() to define a group and then grid.use() to draw the group. This allows for reuse of a group (define the group once and use it several times).

If a group is defined in one viewport and used in a different viewport, an implicit transformation is applied. This could be a simple transformation (if the viewports are in different locations, but are the same size), or it could be more complex if the viewports are also different sizes or at different orientations.

NOTE: transformations occur on the graphics device so affect all aspects of drawing. For example, text and line widths are transformed as well as locations.

See viewportTransform for more information about transformations and how to customise them.

Not all graphics devices support these functions: for example xfig and pictex do not. For devices that do provide support, that support may only be partial (e.g., the Cairo-based devices support more compositing operators than the pdf() device).

Value

A grob object.

Grid

Examples

## NOTE: on devices without support for groups (or masks or patterns),
## there will only be two overlapping opaque circles

grid.newpage()
pat <- pattern(rasterGrob(matrix(c(0.5, 1, 1, 0.5), nrow=2),
width=unit(1, "cm"),
height=unit(1, "cm"),
interpolate=FALSE),
width=unit(1, "cm"), height=unit(1, "cm"),
extend="repeat")
grid.rect(gp=gpar(col=NA, fill=pat))
mask <- rectGrob(gp=gpar(col=NA, fill=rgb(0,0,0,.5)))
pushViewport(viewport(mask=mask))
pushViewport(viewport(y=.5, height=.5, just="bottom"))
grid.circle(1:2/3, r=.45, gp=gpar(fill=2:3))
popViewport()
pushViewport(viewport(y=0, height=.5, just="bottom"))
grid.group(circleGrob(1:2/3, r=.45, gp=gpar(fill=2:3)))
popViewport()

grid.layout

Create a Grid Layout

Description

This function returns a Grid layout, which describes a subdivision of a rectangular region.

Usage

```r
grid.layout(nrow = 1, ncol = 1,
widths = unit(rep_len(1, ncol), "null"),
heights = unit(rep_len(1, nrow), "null"),
default.units = "null", respect = FALSE,
just="centre")
```

Arguments

- `nrow`: An integer describing the number of rows in the layout.
- `ncol`: An integer describing the number of columns in the layout.
- `widths`: A numeric vector or unit object describing the widths of the columns in the layout.
- `heights`: A numeric vector or unit object describing the heights of the rows in the layout.
- `default.units`: A string indicating the default units to use if `widths` or `heights` are only given as numeric vectors.
respect A logical value or a numeric matrix. If a logical, this indicates whether row heights and column widths should respect each other. If a matrix, non-zero values indicate that the corresponding row and column should be respected (see examples below).

just A string or numeric vector specifying how the layout should be justified if it is not the same size as its parent viewport. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment. NOTE that in this context, "left", for example, means align the left edge of the left-most layout column with the left edge of the parent viewport.

Details

The unit objects given for the widths and heights of a layout may use a special units that only has meaning for layouts. This is the "null" unit, which indicates what relative fraction of the available width/height the column/row occupies. See the reference for a better description of relative widths and heights in layouts.

Value

A Grid layout object.

WARNING

This function must NOT be confused with the base R graphics function layout. In particular, do not use layout in combination with Grid graphics. The documentation for layout may provide some useful information and this function should behave identically in comparable situations. The grid.layout function has added the ability to specify a broader range of units for row heights and column widths, and allows for nested layouts (see viewport).

Examples

## A variety of layouts (some a bit mid-bending ...)
layout.torture()
## Demonstration of layout justification
grid.newpage()
testlay <- function(just="centre") {
  pushViewport(viewport(layout=grid.layout(1, 1, widths=unit(1, "inches"),
                             heights=unit(0.25, "npc"),
                             just=just)))
  ... }
grid.lines

**Draw Lines in a Grid Viewport**

**Description**

These functions create and draw a series of lines.

**Usage**

```r
grid.lines(x = unit(c(0, 1), "npc"),
    y = unit(c(0, 1), "npc"),
    default.units = "npc",
    arrow = NULL, name = NULL,
    gp=gpar(), draw = TRUE, vp = NULL)
linesGrob(x = unit(c(0, 1), "npc"),
    y = unit(c(0, 1), "npc"),
    default.units = "npc",
    arrow = NULL, name = NULL,
    gp=gpar(), vp = NULL)
grid.polyline(...)
polylineGrob(x = unit(c(0, 1), "npc"),
    y = unit(c(0, 1), "npc"),
    id=NULL, id.lengths=NULL,
    default.units = "npc",
    arrow = NULL, name = NULL,
    gp=gpar(), vp = NULL)
```

**Arguments**

- `x` A numeric vector or unit object specifying x-values.
- `y` A numeric vector or unit object specifying y-values.
- `default.units` A string indicating the default units to use if x or y are only given as numeric vectors.
- `arrow` A list describing arrow heads to place at either end of the line, as produced by the arrow function.
grid.lines

name A character identifier.

gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw A logical value indicating whether graphics output should be produced.

vp A Grid viewport object (or NULL).

id A numeric vector used to separate locations in x and y into multiple lines. All locations with the same id belong to the same line.

id.lengths A numeric vector used to separate locations in x and y into multiple lines. Specifies consecutive blocks of locations which make up separate lines.

... Arguments passed to polylineGrob.

Details

The first two functions create a lines grob (a graphical object describing lines), and grid.lines draws the lines (if draw is TRUE).

The second two functions create or draw a polyline grob, which is just like a lines grob, except that there can be multiple distinct lines drawn.

Value

A lines grob or a polyline grob. grid.lines returns a lines grob invisibly.

Author(s)

Paul Murrell

Grid, viewport, arrow

Examples

grid.lines()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polyline(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
    y=c(rep(.5, 5), (10:6)/10, rep(.5, 5), (0:4)/10),
    id=rep(1:5, 4),
    gp=gpar(col=1:5, lwd=3))
# Using id.lengths
grid.newpage()
grid.polyline(x=outer(c(0, .5, 1, .5), 5:1/5),
    y=outer(c(.5, 1, .5, 0), 5:1/5),
    id.lengths=rep(4, 5),
    gp=gpar(col=1:5, lwd=3))
grid.locator

Capture a Mouse Click

Description

Allows the user to click the mouse once within the current graphics device and returns the location of the mouse click within the current viewport, in the specified coordinate system.

Usage

grid.locator(unit = "native")

Arguments

unit The coordinate system in which to return the location of the mouse click. See the unit function for valid coordinate systems.

Details

This function is modal (like the graphics package function locator) so the command line and graphics drawing is blocked until the use has clicked the mouse in the current device.

Value

A unit object representing the location of the mouse click within the current viewport, in the specified coordinate system.

If the user did not click mouse button 1, the function (invisibly) returns NULL.

Author(s)

Paul Murrell

See Also

viewport, unit, locator in package graphics, and for an application see trellis.focus and panel.identify in package lattice.

Examples

if (dev.interactive()) {
  ## Need to write a more sophisticated unit as.character method
  unittrim <- function(unit) {
    sub("^[0-9]+[.][0-9]+$", "\d\d", as.character(unit))
  }
  do.click <- function(unit) {
    click.locn <- grid.locator(unit)
    grid.segments(unit.c(click.locn$x, unit(0, "npc")),
      unit.c(unit(0, "npc"), click.locn$y),
      click.locn$x, click.locn$y,
      gp=gpar(lty="dashed", col="grey"))
    grid.points(click.locn$x, click.locn$y, pch=16, size=unit(1, "mm"))
    clickx <- unittrim(click.locn$x)
    clicky <- unittrim(click.locn$y)
  }
}
grid.ls

grid.text(paste0("(", clickx, ", ", clicky, ")"),
    click.locn$x + unit(2, "mm"), click.locn$y,
    just="left")
}

grid.newpage() # (empty slate)
## device
do.click("inches")
Sys.sleep(1)
pushViewport(viewport(width=0.5, height=0.5,
    xscale=c(0, 100), yscale=c(0, 10)))
grid.rect()
grid.xaxis()
grid.yaxis()
do.click("native")
popViewport()
}

grid.ls

List the names of grobs or viewports

Description

Return a listing of the names of grobs or viewports.

This is a generic function with methods for grobs (including gTrees) and viewports (including vpTrees).

Usage

grid.ls(x=NULL, grobs=TRUE, viewports=FALSE, fullNames=FALSE,
    recursive=TRUE, print=TRUE, flatten=TRUE, ...)

nestedListing(x, gindent=" ", vpindent=gindent)
pathListing(x, gvpSep=" | ", gAlign=TRUE)
grobPathListing(x, ...)

Arguments

x A grob or viewport or NULL. If NULL, the current grid display list is listed.
    For print functions, this should be the result of a call to grid.ls.
grobs A logical value indicating whether to list grobs.
viewports A logical value indicating whether to list viewports.
fullNames A logical value indicating whether to embellish object names with information
    about the object type.
recursive A logical value indicating whether recursive structures should also list their children.
print A logical indicating whether to print the listing or a function that will print the
    listing.
flatten A logical value indicating whether to flatten the listing. Otherwise a more complex
    hierarchical object is produced.
grid.ls

gindent
vpindent
gvpSep
gAlign

... Arguments passed to the print function.

Details

If the argument x is NULL, the current contents of the grid display list are listed (both viewports and grobs). In other words, all objects representing the current scene are listed.

Otherwise, x should be a grob or a viewport.

The default behaviour of this function is to print information about the grobs in the current scene. It is also possible to add information about the viewports in the scene. By default, the listing is recursive, so all children of gTrees and all nested viewports are reported.

The format of the information can be controlled via the print argument, which can be given a function to perform the formatting. The nestedListing function produces a line per grob or viewport, with indenting used to show nesting. The pathListing function produces a line per grob or viewport, with viewport paths and grob paths used to show nesting. The grobPathListing is a simple derivation that only shows lines for grobs. The user can define new functions.

Value

The result of this function is either a "gridFlatListing" object (if flatten is TRUE) or a "gridListing" object.

The former is a simple (flat) list of vectors. This is convenient, for example, for working programmatically with the list of grob and viewport names, or for writing a new display function for the listing.

The latter is a more complex hierarchical object (list of lists), but it does contain more detailed information so may be of use for more advanced customisations.

grob viewport

Examples

# A gTree, called "parent", with children vpTree (vp2 within vp1) and child grob, called "child", with vp vpPath (down to vp2)
sampleGTree <- gTree(name="parent",
  children=gList(grob(name="child", vp="vp1::vp2")),
  childrenvp=vpTree(parent=viewport(name="vp1"),
    children=vpList(viewport(name="vp2"))))

grid.ls(sampleGTree)
# Show viewports too
grid.ls(sampleGTree, viewports=TRUE)
# Only show viewports
grid.ls(sampleGTree, viewports=TRUE, grobs=FALSE)
# Alternate displays
grid.move.to

Move or Draw to a Specified Position

Description

Grid has the notion of a current location. These functions sets that location.

Usage

grid.move.to(x = 0, y = 0, default.units = "npc", name = NULL, draw = TRUE, vp = NULL)
moveToGrob(x = 0, y = 0, default.units = "npc", name = NULL, vp = NULL)
grid.line.to(x = 1, y = 1, default.units = "npc", arrow = NULL, name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
lineToGrob(x = 1, y = 1, default.units = "npc", arrow = NULL, name = NULL, gp = gpar(), vp = NULL)

Arguments

x A numeric value or a unit object specifying an x-value.
y A numeric value or a unit object specifying a y-value.
default.units A string indicating the default units to use if x or y are only given as numeric values.
arrow A list describing arrow heads to place at either end of the line, as produced by the arrow function.
name A character identifier.
draw A logical value indicating whether graphics output should be produced.
gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
Details
Both functions create a move.to/line.to grob (a graphical object describing a move-to/line-to), but only grid.move.to/line.to() draws the move.to/line.to (and then only if draw is TRUE).

Value
A move.to/line.to grob. grid.move.to/line.to() returns the value invisibly.

Author(s)
Paul Murrell

See Also
Grid, viewport, arrow

Examples
grid.newpage()
grid.move.to(0.5, 0.5)
grid.line.to(1, 1)
grid.line.to(0.5, 0)
pushViewport(viewport(x=0, y=0, width=0.25, height=0.25, just=c("left", "bottom")))
grid.rect()
grid.grill()
grid.line.to(0.5, 0.5)
popViewport()

Description
This function erases the current device or moves to a new page.

Usage
grid.newpage(recording = TRUE, clearGroups = TRUE)

Arguments
recording A logical value to indicate whether the new-page operation should be saved onto the Grid display list.
clearGroups A logical value indicating whether any groups that have been defined on the current page should be released (see grid.group).

Details
The new page is painted with the fill colour (gpar("fill")), which is often transparent. For devices with a canvas colour (the on-screen devices X11, windows and quartz), the page is first painted with the canvas colour and then the background colour.

There are two hooks called "before.grid.newpage" and "grid.newpage" (see setHook). The latter is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, get is called on it from within the grid namespace.)
Value

None.

---

**grid.null**

**Null Graphical Object**

**Description**

These functions create a NULL graphical object, which has zero width, zero height, and draw nothing. It can be used as a place-holder or as an invisible reference point for other drawing.

**Usage**

```r
nullGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
         default.units = "npc",
         name = NULL, vp = NULL)
grid.null(...)```

**Arguments**

- `x` A numeric vector or unit object specifying x-location.
- `y` A numeric vector or unit object specifying y-location.
- `default.units` A string indicating the default units to use if `x`, `y`, `width`, or `height` are only given as numeric vectors.
- `name` A character identifier.
- `vp` A Grid viewport object (or NULL).
- `...` Arguments passed to `nullGrob()`.

**Value**

A null grob.

**Author(s)**

Paul Murrell

**See Also**

`Grid`, `viewport`
Examples

grid.newpage()
grid.null(name="ref")
grid.rect(height=grobHeight("ref"))
grid.segments(0, 0, grobX("ref", 0), grobY("ref", 0))

Description

these functions, together with grid.frame and frameGrob are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with grid.frame or frameGrob then use these functions to pack objects into the frame.

Usage

grid.pack(gPath, grob, redraw = TRUE, side = NULL, row = NULL, row.before = NULL, row.after = NULL, col = NULL, col.before = NULL, col.after = NULL, width = NULL, height = NULL, force.width = FALSE, force.height = FALSE, border = NULL, dynamic = FALSE)
packGrob(frame, grob, side = NULL, row = NULL, row.before = NULL, row.after = NULL, col = NULL, col.before = NULL, col.after = NULL, width = NULL, height = NULL, force.width = FALSE, force.height = FALSE, border = NULL, dynamic = FALSE)

Arguments

gPath A gPath object, which specifies a frame on the display list.
frame An object of class frame, typically the output from a call to grid.frame.
grob An object of class grob. The object to be packed.
redraw A boolean indicating whether the output should be updated.
side One of "left", "top", "right", "bottom" to indicate which side to pack the object on.
row Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame + 1, or NULL in which case the object occupies all rows.
row.before Add the object to a new row just before this row.
row.after Add the object to a new row just after this row.
col Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame + 1, or NULL in which case the object occupies all cols.
col.before Add the object to a new col just before this col.
col.after Add the object to a new col just after this col.
width

Specifies the width of the column that the object is added to (rather than allowing the width to be taken from the object).

height

Specifies the height of the row that the object is added to (rather than allowing the height to be taken from the object).

force.width

A logical value indicating whether the width of the column that the grob is being packed into should be EITHER the width specified in the call to grid.pack OR the maximum of that width and the pre-existing width.

force.height

A logical value indicating whether the height of the column that the grob is being packed into should be EITHER the height specified in the call to grid.pack OR the maximum of that height and the pre-existing height.

border

A unit object of length 4 indicating the borders around the object.

dynamic

If the width/height is taken from the grob being packed, this boolean flag indicates whether the grobwidth/height unit refers directly to the grob, or uses a gPath to the grob. In the latter case, changes to the grob will trigger a recalculation of the width/height.

Details

packGrob modifies the given frame grob and returns the modified frame grob.

grid.pack destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

These are (meant to be) very flexible functions. There are many different ways to specify where the new object is to be added relative to the objects already in the frame. The function checks that the specification is not self-contradictory.

NOTE that the width/height of the row/col that the object is added to is taken from the object itself unless the width/height is specified.

Value

packGrob returns a frame grob, but grid.pack returns NULL.

Author(s)

Paul Murrell

See Also

grid.frame, grid.place, grid.edit, and gPath.
Usage

pathGrob(x, y,
    id= NULL, id.lengths= NULL,
    pathId= NULL, pathId.lengths= NULL,
    rule= "winding",
    default.units="npc",
    name= NULL, gp= gpar(), vp= NULL)

grid.path(...) 

Arguments

x   A numeric vector or unit object specifying x-locations.
y   A numeric vector or unit object specifying y-locations.
id  A numeric vector used to separate locations in x and y into sub-paths. All locations with the same id belong to the same sub-path.
id.lengths A numeric vector used to separate locations in x and y into sub-paths. Specifies consecutive blocks of locations which make up separate sub-paths.
pathId A numeric vector used to separate locations in x and y into distinct paths. All locations with the same pathId belong to the same path.
pathId.lengths A numeric vector used to separate locations in x and y into paths. Specifies consecutive blocks of locations which make up separate paths.
rule  A character value specifying the fill rule: either "winding" or "evenodd".
default.units A string indicating the default units to use if x or y are only given as numeric vectors.
name A character identifier.
gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
... Arguments passed to pathGrob().

Details

Both functions create a path grob (a graphical object describing a path), but only grid.path draws the path (and then only if draw is TRUE).

A path is like a polygon except that the former can contain holes, as interpreted by the fill rule; these fill a region if the path border encircles it an odd or non-zero number of times, respectively.

Not all graphics devices support this function: for example xfig and pictex do not.

Value

A grob object.

grid.place Place an Object within a Frame

Description

These functions provide a simpler (and faster) alternative to the grid.pack() and packGrob functions. They can be used to place objects within the existing rows and columns of a frame layout. They do not provide the ability to add new rows and columns nor do they affect the heights and widths of the rows and columns.

Usage

grid.place(gPath, grob, row = 1, col = 1, redraw = TRUE)
placeGrob(frame, grob, row = NULL, col = NULL)

Arguments

gPath A gPath object, which specifies a frame on the display list.
frame An object of class frame, typically the output from a call to grid.frame.
grob An object of class grob. The object to be placed.
row Which row to add the object to. Must be between 1 and the-number-of-rows-
currently-in-the-frame.
col Which col to add the object to. Must be between 1 and the-number-of-cols-
currently-in-the-frame.
redraw A boolean indicating whether the output should be updated.
Details

placeGrob modifies the given frame grob and returns the modified frame grob.

grid.place destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

Value

placeGrob returns a frame grob, but grid.place returns NULL.

Author(s)

Paul Murrell

See Also

grid.frame, grid.pack, grid.edit, and gPath.

Description

This function is just a wrapper for a simple demonstration of how a basic plot and legend can be drawn from scratch using grid.

Usage

grid.plot.and.legend()

Author(s)

Paul Murrell

Examples

grid.plot.and.legend()
grid.points

Description

These functions create and draw data symbols.

Usage

```r
grid.points(x = stats::runif(10),
          y = stats::runif(10),
          pch = 1, size = unit(1, "char"),
          default.units = "native", name = NULL,
          gp = gpar(), draw = TRUE, vp = NULL)
pointsGrob(x = stats::runif(10),
          y = stats::runif(10),
          pch = 1, size = unit(1, "char"),
          default.units = "native", name = NULL,
          gp = gpar(), vp = NULL)
```

Arguments

- `x`: numeric vector or unit object specifying x-values.
- `y`: numeric vector or unit object specifying y-values.
- `pch`: numeric or character vector indicating what sort of plotting symbol to use. See `points` for the interpretation of these values, and note fill below.
- `size`: unit object specifying the size of the plotting symbols.
- `default.units`: string indicating the default units to use if `x` or `y` are only given as numeric vectors.
- `name`: character identifier.
- `gp`: an R object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings; note that fill (and not bg as in package graphics points) is used to “fill”, i.e., color the background of symbols with `pch = 21:25`.
- `draw`: logical indicating whether graphics output should be produced.
- `vp`: A Grid viewport object (or NULL).

Details

Both functions create a points grob (a graphical object describing points), but only `grid.points` draws the points (and then only if `draw` is TRUE).

Value

A points grob. `grid.points` returns the value invisibly.

draw

grid.polygon | Draw a Polygon

Description

These functions create and draw a polygon. The final point will automatically be connected to the initial point.

Usage

grid.polygon(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
  id=NULL, id.lengths=NULL,
  default.units="npc", name=NULL,
  gp=gpar(), draw=TRUE, vp=NULL)
polygonGrob(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
  id=NULL, id.lengths=NULL,
  default.units="npc", name=NULL,
  gp=gpar(), vp=NULL)

Arguments

x A numeric vector or unit object specifying x-locations.
y A numeric vector or unit object specifying y-locations.
id A numeric vector used to separate locations in x and y into multiple polygons. All locations with the same id belong to the same polygon.
id.lengths A numeric vector used to separate locations in x and y into multiple polygons. Specifies consecutive blocks of locations which make up separate polygons.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name A character identifier.
gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw A logical value indicating whether graphics output should be produced.
vp A Grid viewport object (or NULL).

details

Both functions create a polygon grob (a graphical object describing a polygon), but only grid.polygon draws the polygon (and then only if draw is TRUE).

Value

A grob object.

Examples

grid.polygon()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polygon(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)), 
y=c(rep(.5, 5), (10:6/10), rep(.5, 5), (0:4)/10), 
id=rep(1:5, 4), 
gp=gpar(fill=1:5))
# Using id.lengths
grid.newpage()
grid.polygon(x=outer(c(0, .5, 1, .5), 5:1/5), 
y=outer(c(.5, 1, .5, 0), 5:1/5), 
id.lengths=rep(4, 5), 
gp=gpar(fill=1:5))

grid.pretty

Generate a Sensible ("Pretty") Set of Breakpoints

Description

Produces a pretty set of of approximately n breakpoints within the range given.

This is a direct interface to R’s graphical engine GEpretty() function, which also underlies base graphics’ package axis(), axTicks(), etc.

Usage

grid.pretty(range, n = 5)

Arguments

range

a numeric vector of length at least two, as e.g., returned by range().

n

a non-negative integer specifying the approximate number of breakpoints to be produced.

Value

A numeric vector of “pretty” breakpoints.

Author(s)

Paul Murrell
**grid.raster**

Render a raster object

**Description**

Render a raster object (bitmap image) at the given location, size, and orientation.

**Usage**

```r
grid.raster(image, 
    x = unit(0.5, "npc"), y = unit(0.5, "npc"), 
    width = NULL, height = NULL, 
    just = "centre", hjust = NULL, vjust = NULL, 
    interpolate = TRUE, default.units = "npc", 
    name = NULL, gp = gpar(), vp = NULL)
```

```r
rasterGrob(image, 
    x = unit(0.5, "npc"), y = unit(0.5, "npc"), 
    width = NULL, height = NULL, 
    just = "centre", hjust = NULL, vjust = NULL, 
    interpolate = TRUE, default.units = "npc", 
    name = NULL, gp = gpar(), vp = NULL)
```

**Arguments**

- **image** Any R object that can be coerced to a raster object.
- **x** A numeric vector or unit object specifying x-location.
- **y** A numeric vector or unit object specifying y-location.
- **width** A numeric vector or unit object specifying width.
- **height** A numeric vector or unit object specifying height.
- **just** The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- **hjust** A numeric vector specifying horizontal justification. If specified, overrides the just setting.
- **vjust** A numeric vector specifying vertical justification. If specified, overrides the just setting.
- **default.units** A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- **name** A character identifier.
- **gp** An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **vp** A Grid viewport object (or NULL).
- **interpolate** A logical value indicating whether to linearly interpolate the image (the alternative is to use nearest-neighbour interpolation, which gives a more blocky result).
Details

Neither width nor height needs to be specified, in which case, the aspect ratio of the image is preserved. If both width and height are specified, it is likely that the image will be distorted.

Not all graphics devices are capable of rendering raster images and some may not be able to produce rotated images (i.e., if a raster object is rendered within a rotated viewport). See also the comments under rasterImage.

All graphical parameter settings in gp will be ignored, including alpha.

Value

A rastergrob grob.

Author(s)

Paul Murrell

See Also

as.raster.

dev.capabilities to see if it is supported.

Examples

```r
redGradient <- matrix(hcl(0, 80, seq(50, 80, 10)),
                        nrow=4, ncol=5)
# interpolated
grid.newpage()
grid.raster(redGradient)
# blocky
grid.newpage()
grid.raster(redGradient, interpolate=FALSE)
# blocky and stretched
grid.newpage()
grid.raster(redGradient, interpolate=FALSE, height=unit(1, "npc"))
# The same raster drawn several times
grid.newpage()
grid.raster(0, x=1:3/4, y=1:3/4, width=.1, interpolate=FALSE)
```

Description

Evaluates an expression that includes both calculations and drawing that depends on the calculations so that both the calculations and the drawing will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.
Usage

recordGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.record(expr, list, name=NULL, gp=NULL, vp=NULL)

Arguments

- `expr`: object of mode **expression** or **call** or an unevaluated expression.
- `list`: a list defining the environment in which `expr` is to be evaluated.
- `name`: A character identifier.
- `gp`: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp`: A Grid viewport object (or NULL).

Details

A grob is created of special class "recordedGrob" (and drawn, in the case of `grid.record`). The `drawDetails` method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

Note

This function **must** be used instead of the function `recordGraphics`; all of the dire warnings about using `recordGraphics` responsibly also apply here.

Author(s)

Paul Murrell

See Also

- `recordGraphics`

Examples

```r
grid.record({
  w <- convertWidth(unit(1, "inches"), "npc")
  grid.rect(width=w)
}, list())
```

---

**grid.rect**

*Draw rectangles*

Description

These functions create and draw rectangles.
Usage
grid.rect(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
       width = unit(1, "npc"), height = unit(1, "npc"),
       just = "centre", hjust = NULL, vjust = NULL,
       default.units = "npc", name = NULL,
       gp = gpar(), draw = TRUE, vp = NULL)
rectGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
       width = unit(1, "npc"), height = unit(1, "npc"),
       just = "centre", hjust = NULL, vjust = NULL,
       default.units = "npc", name = NULL,
       gp = gpar(), vp = NULL)

Arguments
x       A numeric vector or unit object specifying x-location.
y       A numeric vector or unit object specifying y-location.
width       A numeric vector or unit object specifying width.
height       A numeric vector or unit object specifying height.
just       The justification of the rectangle relative to its (x, y) location. If there are two
            values, the first value specifies horizontal justification and the second value
            specifies vertical justification. Possible string values are: "left", "right",
            "centre", "center", "bottom", and "top". For numeric values, 0 means left
            alignment and 1 means right alignment.
hjust       A numeric vector specifying horizontal justification. If specified, overrides the
            just setting.
vjust       A numeric vector specifying vertical justification. If specified, overrides the
            just setting.
default.units       A string indicating the default units to use if x, y, width, or height are only
            given as numeric vectors.
name       A character identifier.
gp       An object of class "gpar", typically the output from a call to the function gpar.
            This is basically a list of graphical parameter settings.
draw       A logical value indicating whether graphics output should be produced.
vp       A Grid viewport object (or NULL).

Details
Both functions create a rect grob (a graphical object describing rectangles), but only grid.rect
draws the rectangles (and then only if draw is TRUE).

Value
A rect grob. grid.rect returns the value invisibly.

Refresh the current grid scene

Description
Replays the current grid display list.

Usage
grid.refresh()

Author(s)
Paul Murrell

grid.remove
Remove a Grid Graphical Object

Description
Remove a grob from a gTree or a descendant of a gTree.

Usage
grid.remove(gPath, warn = TRUE, strict = FALSE, grep = FALSE,
            global = FALSE, allDevices = FALSE, redraw = TRUE)

grid.gremove(..., grep = TRUE, global = TRUE)

removeGrob(gTree, gPath, strict = FALSE, grep = FALSE,
            global = FALSE, warn = TRUE)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gTree</td>
<td>A gTree object.</td>
</tr>
<tr>
<td>gPath</td>
<td>A gPath object. For grid.remove this specifies a gTree on the display list. For removeGrob this specifies a descendant of the specified gTree.</td>
</tr>
<tr>
<td>strict</td>
<td>A logical indicating whether the gPath must be matched exactly.</td>
</tr>
<tr>
<td>grep</td>
<td>A logical indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).</td>
</tr>
<tr>
<td>global</td>
<td>A logical indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.</td>
</tr>
<tr>
<td>allDevices</td>
<td>A logical indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.</td>
</tr>
<tr>
<td>warn</td>
<td>A logical to indicate whether failing to find the specified grob should trigger an error.</td>
</tr>
<tr>
<td>redraw</td>
<td>A logical value to indicate whether to redraw the grob.</td>
</tr>
<tr>
<td>...</td>
<td>Arguments passed to grid.get.</td>
</tr>
</tbody>
</table>
### grid.reorder

**Description**

Change the order in which the children of a gTree get drawn.

**Usage**

```r
grid.reorder(gPath, order, back=TRUE, grep=FALSE, redraw=TRUE)
reorderGrob(x, order, back=TRUE)
```

**Arguments**

- `gPath` A gPath object specifying a gTree within the current scene.
- `x` A gTree object to be modified.
- `order` A character vector or a numeric vector that specifies the new drawing order for the children of the gTree. May not refer to all children of the gTree (see Details).
- `back` Controls what happens when the order does not specify all children of the gTree (see Details).
- `grep` Should the gPath be treated as a regular expression?
- `redraw` Should the modified scene be redrawn?

---

### Details

`removeGrob` copies the specified grob and returns a modified grob.

`grid.remove` destructively modifies a grob on the display list. If `redraw` is TRUE it then redraws everything to reflect the change.

`grid.gremove` (g for global) is just a convenience wrapper for `grid.remove` with different defaults.

**Value**

`removeGrob` returns a grob object; `grid.remove` returns NULL.

**Author(s)**

Paul Murrell

**See Also**

`grob`, `getGrob`.

---

<table>
<thead>
<tr>
<th>grid.reorder</th>
<th>Reorder the children of a gTree</th>
</tr>
</thead>
</table>

---

**Description**

Change the order in which the children of a gTree get drawn.
grid.reorder

Details

In the simplest case, `order` specifies a new ordering for all of the children of the gTree. The children may be specified either by name or by existing numerical order.

If the `order` does not specify all children of the gTree then, by default, the children specified by `order` are drawn first and then all remaining children are drawn. If `back=FALSE` then the children not specified in `order` are drawn first, followed by the specified children. This makes it easy to specify a send-to-back or bring-to-front reordering. The `order` argument is always in back-to-front order.

It is not possible to reorder the grid display list (the top-level grobs in the current scene) because the display list is a mixture of grobs and viewports (so it is not clear what reordering even means and it would be too easy to end up with a scene that would not draw). If you want to reorder the grid display list, try `grid.grab()` to create a gTree and then reorder (and redraw) that gTree.

Value

`grid.reorder()` is called for its side-effect of modifying the current scene. `reorderGrob()` returns the modified gTree.

Warning

This function may return a gTree that will not draw. For example, a gTree has two children, A and B (in that order), and the width of child B depends on the width of child A (e.g., a box around a piece of text). Switching the order so that B is drawn before A will not allow B to be drawn. If this happens with `grid.reorder()`, the modification will not be performed. If this happens with `reorderGrob()` it should be possible simply to restore the original order.

Author(s)

Paul Murrell

Examples

```r
# gTree with two children, "red-rect" and "blue-rect" (in that order)
gt <- gTree(children=gList(
  rectGrob(gp=gpar(col=NA, fill="red"),
    width=.8, height=.2, name="red-rect"),
  rectGrob(gp=gpar(col=NA, fill="blue"),
    width=.2, height=.8, name="blue-rect")),
  name="gt")
grid.newpage()
grid.draw(gt)
# Spec entire order as numeric (blue-rect, red-rect)
gt <- grid.reorder(gt, 2:1)
grid.newpage()
grid.draw(gt)
# Spec entire order as character
gt <- grid.reorder(gt, c("red-rect", "blue-rect"))
grid.newpage()
grid.draw(gt)
# Only spec the one I want behind as character
gt <- grid.reorder(gt, "blue-rect")
grid.newpage()
grid.draw(gt)
# Only spec the one I want in front as character
gt <- grid.reorder(gt, "blue-rect", back=FALSE)
```
grid.segments

Draw Line Segments

Description

These functions create and draw line segments.

Usage

```r
grid.segments(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
             x1 = unit(1, "npc"), y1 = unit(1, "npc"),
             default.units = "npc",
             arrow = NULL,
             name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
segmentsGrob(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
             x1 = unit(1, "npc"), y1 = unit(1, "npc"),
             default.units = "npc",
             arrow = NULL, name = NULL, gp = gpar(), vp = NULL)
```

Arguments

- `x0`: Numeric indicating the starting x-values of the line segments.
- `y0`: Numeric indicating the starting y-values of the line segments.
- `x1`: Numeric indicating the stopping x-values of the line segments.
- `y1`: Numeric indicating the stopping y-values of the line segments.
- `default.units`: A string.
- `arrow`: A list describing arrow heads to place at either end of the line segments, as produced by the `arrow` function.
- `name`: A character identifier.
- `gp`: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `draw`: A logical value indicating whether graphics output should be produced.
- `vp`: A Grid viewport object (or NULL).

Details

Both functions create a segments grob (a graphical object describing segments), but only `grid.segments` draws the segments (and then only if `draw` is `TRUE`).

Value

A segments grob. `grid.segments` returns the value invisibly.

grid.set

Set a Grid Graphical Object

Description

Replace a grob or a descendant of a grob.

Usage

grid.set(gPath, newGrob, strict = FALSE, grep = FALSE, redraw = TRUE)

setGrob(gTree, gPath, newGrob, strict = FALSE, grep = FALSE)

Arguments

gTree
   A gTree object.
gPath
   A gPath object. For grid.set this specifies a grob on the display list. For setGrob this specifies a descendant of the specified gTree.
newGrob
   A grob object.
strict
   A boolean indicating whether the gPath must be matched exactly.
grep
   A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
redraw
   A logical value to indicate whether to redraw the grob.

Details

setGrob copies the specified grob and returns a modified grob.

grid.set destructively replaces a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

These functions should not normally be called by the user.

Value

setGrob returns a grob object; grid.set returns NULL.

grid.grob.
grid.show.layout  Draw a Diagram of a Grid Layout

Description
This function uses Grid graphics to draw a diagram of a Grid layout.

Usage
grid.show.layout(l, newpage=TRUE, vp.ex = 0.8, bg = "light grey",
cell.border = "blue", cell.fill = "light blue",
cell.label = TRUE, label.col = "blue",
unit.col = "red", vp = NULL, ...)

Arguments
l                A Grid layout object.
newpage          A logical value indicating whether to move on to a new page before drawing the
diagram.
vp.ex            positive number, typically in (0, 1], specifying the scaling of the layout.
bg               The colour used for the background.
cell.border     The colour used to draw the borders of the cells in the layout.
cell.fill       The colour used to fill the cells in the layout.
cell.label      A logical indicating whether the layout cells should be labelled.
label.col       The colour used for layout cell labels.
unit.col        The colour used for labelling the widths/heights of columns/rows.
vp               A Grid viewport object (or NULL).
...              Arguments passed to format for formatting the layout width and height annota-
tions.

Details
A viewport is created within vp to provide a margin for annotation, and the layout is drawn within
that new viewport. The margin is filled with light grey, the new viewport is filled with white and
framed with a black border, and the layout regions are filled with light blue and framed with a blue
border. The diagram is annotated with the widths and heights (including units) of the columns and
rows of the layout using red text. (All colours are defaults and may be customised via function
arguments.)

Value
None.

Paul Murrell
grid.show.viewport

**See Also**

Grid, viewport, grid.layout

**Examples**

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
   heights=unit(rep(1, 4),
   c("lines", "lines", "lines", "null")),
   widths=unit(c(1, 1), "inches")))
```

**Description**

This function uses Grid graphics to draw a diagram of a Grid viewport.

**Usage**

```r
grid.show.viewport(v, parent.layout = NULL, newpage = TRUE,
   vp.ex = 0.8, border.fill="light grey",
   vp.col="blue", vp.fill="light blue",
   scale.col="red",
   vp = NULL)
```

**Arguments**

- `v` A Grid viewport object.
- `parent.layout` A grid layout object. If this is not NULL and the viewport given in `v` has its location specified relative to the layout, then the diagram shows the layout and which cells `v` occupies within the layout.
- `newpage` A logical value to indicate whether to move to a new page before drawing the diagram.
- `vp.ex` positive number, typically in (0, 1], specifying the scaling of the layout.
- `border.fill` Colour to fill the border margin.
- `vp.col` Colour for the border of the viewport region.
- `vp.fill` Colour to fill the viewport region.
- `scale.col` Colour to draw the viewport axes.
- `vp` A Grid viewport object (or NULL).

**Details**

A viewport is created within `vp` to provide a margin for annotation, and the diagram is drawn within that new viewport. By default, the margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the viewport region is filled with light blue and framed with a blue border. The diagram is annotated with the width and height (including units) of the viewport, the (x, y) location of the viewport, and the x- and y-scales of the viewport, using red lines and text.
Value
None.

                   grid.layout(3, 4))

```
grid.stroke
```

**Stroke or Fill a Path**

Description
These functions stroke (draw a line along the border) or fill (or both) a path, where the path is defined by a grob.

Usage
```
strokeGrob(x, ...)  # S3 method for class 'grob'
strokeGrob(x, name=NULL, gp=gpar(), vp=NULL, ...)
# S3 method for class 'GridPath'
strokeGrob(x, name=NULL, vp=NULL, ...)
grid.stroke(...)
fillGrob(x, ...)  # S3 method for class 'grob'
fillGrob(x, rule=c("winding", "evenodd"),
         name=NULL, gp=gpar(), vp=NULL, ...)
# S3 method for class 'GridPath'
fillGrob(x, name=NULL, vp=NULL, ...)
grid.fill(...)
fillStrokeGrob(x, ...)  # S3 method for class 'grob'
fillStrokeGrob(x, rule=c("winding", "evenodd"),
               name=NULL, gp=gpar(), vp=NULL, ...)
# S3 method for class 'GridPath'
fillStrokeGrob(x, name=NULL, vp=NULL, ...)
grid.fillStroke(...)
as.path(x, gp=gpar(), rule=c("winding", "evenodd"))
```
Arguments

x          A grob or the result of a call to `as.path()`.
rule       A fill rule.
name       A character identifier.
gp         An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
vp          A Grid viewport object (or NULL).
...        Arguments to `grid.*()` passed on to *Grob(), or additional arguments passed on to methods.

Details

A path is defined by the shapes that the grob given in `x` would draw. The grob only contributes to the outline of the path; graphical parameter settings such as line colour and fill are ignored.

`grid.stroke()` will only ever draw the border (even when a fill is specified).

`grid.fill()` will only ever fill the path (even when a line colour is specified).

A stroke will only ever happen if a non-transparent line colour is specified and a fill will only ever happen if a non-transparent fill is specified.

`as.path()` allows graphical parameter settings and a fill rule to be associated with a grob. This can be useful when specifying a clipping path for a viewport (see `viewport`). Not all graphics devices support these functions: for example `xfig` and `pictex` do not.

Value

A grob object.

`Grid`

Examples

## NOTE: on devices without support for stroking and filling
## nothing will be drawn
grid.newpage()
grid.stroke(textGrob("hello", gp=gpar(cex=10)))
grid.fill(circleGrob(1:2/3, r=.3), gp=gpar(fill=rgb(1,0,0,.5)))
grid.text

**Draw Text**

**Description**

These functions create and draw text and plotmath expressions.

**Usage**

```r
grid.text(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
      just = "centre", hjust = NULL, vjust = NULL, rot = 0,
      check.overlap = FALSE, default.units = "npc",
      name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
textGrob(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
      just = "centre", hjust = NULL, vjust = NULL, rot = 0,
      check.overlap = FALSE, default.units = "npc",
      name = NULL, gp = gpar(), vp = NULL)
```

**Arguments**

- **label**: A character or expression vector. Other objects are coerced by `as.graphicsAnnot`.
- **x**: A numeric vector or unit object specifying x-values.
- **y**: A numeric vector or unit object specifying y-values.
- **just**: The justification of the text relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left (bottom) alignment and 1 means right (top) alignment.
- **hjust**: A numeric vector specifying horizontal justification. If specified, overrides the `just` setting.
- **vjust**: A numeric vector specifying vertical justification. If specified, overrides the `just` setting.
- **rot**: The angle to rotate the text.
- **check.overlap**: A logical value to indicate whether to check for and omit overlapping text.
- **default.units**: A string indicating the default units to use if x or y are only given as numeric vectors.
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **draw**: A logical value indicating whether graphics output should be produced.
- **vp**: A Grid viewport object (or NULL).
Details

Both functions create a text grob (a graphical object describing text), but only `grid.text` draws the text (and then only if `draw` is `TRUE`).

If the `label` argument is an expression, the output is formatted as a mathematical annotation, as for base graphics text.

Value

A text grob. `grid.text()` returns the value invisibly.

grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
  gp=gpar(fontsize=20, col="grey"))
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
  gp=gpar(fontsize=20), check.overlap=TRUE)
grid.newpage()
draw.text <- function(just, i, j) {
  grid.text("ABCD", x=x[j], y=y[i], just=just)
  grid.text(deparse(substitute(just)), x=x[j], y=y[i] + unit(2, "lines"),
    gp=gpar(col="grey", fontsize=8))
}
x <- unit(1:4/5, "npc")
y <- unit(1:4/5, "npc")
grid.grill(h=y, v=x, gp=gpar(col="grey"))
draw.text(c("bottom"), 1, 1)
draw.text(c("left", "bottom"), 2, 1)
draw.text(c("right", "bottom"), 3, 1)
draw.text(c("centre", "bottom"), 4, 1)
draw.text(c("centre"), 1, 2)
draw.text(c("left", "centre"), 2, 2)
draw.text(c("right", "centre"), 3, 2)
draw.text(c("centre", "centre"), 4, 2)
draw.text(c("top"), 1, 3)
draw.text(c("left", "top"), 2, 3)
draw.text(c("right", "top"), 3, 3)
draw.text(c("centre", "top"), 4, 3)
draw.text(c(), 1, 4)
draw.text(c("left"), 2, 4)
draw.text(c("right"), 3, 4)
draw.text(c("centre"), 4, 4)
```
grid.xaxis

**Draw an X-Axis**

**Description**

These functions create and draw an x-axis.

**Usage**

```r
grid.xaxis(at = NULL, label = TRUE, main = TRUE,
            edits = NULL, name = NULL,
            gp = gpar(), draw = TRUE, vp = NULL)
```

```r
xaxisGrob(at = NULL, label = TRUE, main = TRUE,
          edits = NULL, name = NULL,
          gp = gpar(), vp = NULL)
```

**Arguments**

- **at**: A numeric vector of x-value locations for the tick marks.
- **label**: A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.
- **main**: A logical value indicating whether to draw the axis at the bottom (TRUE) or at the top (FALSE) of the viewport.
- **edits**: A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **draw**: A logical value indicating whether graphics output should be produced.
- **vp**: A Grid viewport object (or NULL).

**Details**

Both functions create an xaxis grob (a graphical object describing an xaxis), but only `grid.xaxis` draws the xaxis (and then only if `draw` is TRUE).

**Value**

An xaxis grob. `grid.xaxis` returns the value invisibly.

**Children**

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

- **major**: representing the line at the base of the tick marks.
- **ticks**: representing the tick marks.
- **labels**: representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grid.xspline Draw an Xspline

Description
These functions create and draw an xspline, a curve drawn relative to control points.

Usage
grid.xspline(...)  
xsplineGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
            id = NULL, id.lengths = NULL,
            default.units = "npc",
            shape = 0, open = TRUE, arrow = NULL, repEnds = TRUE,
            name = NULL, gp = gpar(), vp = NULL)

Arguments

x A numeric vector or unit object specifying x-locations of spline control points.
y A numeric vector or unit object specifying y-locations of spline control points.
id A numeric vector used to separate locations in x and y into multiple xsplines.  
    All locations with the same id belong to the same xspline.
id.lengths A numeric vector used to separate locations in x and y into multiple xsplines.  
    Specifies consecutive blocks of locations which make up separate xsplines.
default.units A string indicating the default units to use if x or y are only given as numeric  
    vectors.
shape A numeric vector of values between -1 and 1, which control the shape of the  
    spline relative to the control points.
open A logical value indicating whether the spline is a line or a closed shape.
arrow A list describing arrow heads to place at either end of the xspline, as produced  
    by the arrow function.
repEnds A logical value indicating whether the first and last control points should be  
    replicated for drawing the curve (see Details below).
name A character identifier.
gp An object of class "gpar", typically the output from a call to the function gpar.  
    This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
... Arguments to be passed to xsplineGrob.
Details

Both functions create an xspline grob (a graphical object describing an xspline), but only `grid.xspline` draws the xspline.

An xspline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open xsplines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero without warning).

For open xsplines, by default the start and end control points are actually replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the `repEnds` argument, in which case the curve that is drawn starts (approximately) at the second control point and ends (approximately) at the first and second-to-last control point.

The `repEnds` argument is ignored for closed xsplines.

Missing values are not allowed for `x` and `y` (i.e., it is not valid for a control point to be missing).

For closed xsplines, a curve is automatically drawn between the final control point and the initial control point.

Value

A grob object.

**grid.yaxis**

**Draw a Y-Axis**

### Description

These functions create and draw a y-axis.

### Usage

```r
grid.yaxis(at = NULL, label = TRUE, main = TRUE,
edits = NULL, name = NULL,
gp = gpar(), draw = TRUE, vp = NULL)
yaxisGrob(at = NULL, label = TRUE, main = TRUE,
edits = NULL, name = NULL,
gp = gpar(), vp = NULL)
```
Arguments

at  A numeric vector of y-value locations for the tick marks.
label  A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.
main  A logical value indicating whether to draw the axis at the left (TRUE) or at the right (FALSE) of the viewport.
edits  A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.
name  A character identifier.
gp  An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL).

Details

Both functions create a yaxis grob (a graphical object describing a yaxis), but only grid.yaxis draws the yaxis (and then only if draw is TRUE).

Value

A yaxis grob. grid.yaxis returns the value invisibly.

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

major  representing the line at the base of the tick marks.
ticks  representing the tick marks.
labels  representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grobCoords

Calculate Points on the Perimeter of a Grob

Description

These functions calculate points along the perimeter (or length) of a grob.

Usage

grobCoords(x, closed, ...)  
grobPoints(x, closed, ...)  
emptyCoords  
isEmptyCoords(coords)

Arguments

x                    A grob object.  
closed               Whether we are asking for points along the perimeter of a closed object or points along the length of an open object. Some grobs (e.g., X-splines) can do both.  
...                  Arguments to be used by methods.  
coords               A set of grob coordinates (as generated by grobCoords).

Details

The difference between grobCoords and grobPoints is that grobCoords performs all pre- and post-drawing operations on the grob that would normally occur if the grob was being drawn, then calls grobPoints. So the former takes into account any vp and gp settings on the grob. This means that users should usually only want to call grobCoords; only (expert) developers may have a need to call grobPoints.

Custom grobs can write their own methods for grobPoints.

The emptyCoords object can be used to return a "null" result (e.g., when asking for closed coordinates on an open line) and the isEmptyCoords function can be used to check for "null" results.

Value

A list of lists with components x and y. All locations are in inches relative to the current grid viewport.

Author(s)

Paul Murrell
grobName

*Generate a Name for a Grob*

**Description**

This function generates a unique (within-session) name for a grob, based on the grob’s class.

**Usage**

```r
grobName(grob = NULL, prefix = "GRID")
```

**Arguments**

- `grob`: A grob object or `NULL`.
- `prefix`: The prefix part of the name.

**Value**

A character string of the form `prefix.class(grob).index`.

**Author(s)**

Paul Murrell

---

grobWidth

*Create a Unit Describing the Width of a Grob*

**Description**

These functions create a unit object describing the width or height of a grob. They are generic.

**Usage**

```r
grobWidth(x)
grobHeight(x)
grobAscent(x)
grobDescent(x)
```

**Arguments**

- `x`: A grob object.

**Value**

A unit object.

**Author(s)**

Paul Murrell

unit and stringWidth

---

**grobX**

Create a Unit Describing a Grob Boundary Location

**Description**

These functions create a unit object describing a location somewhere on the boundary of a grob. They are generic.

**Usage**

\[
grobX(x, \theta) \\
grobY(x, \theta)
\]

**Arguments**

- **x**
  - A grob, or gList, or gTree, or gPath.
- **theta**
  - An angle indicating where the location is on the grob boundary. Can be one of "east", "north", "west", or "south", which correspond to angles 0, 90, 180, and 270, respectively.

**Details**

The angle is anti-clockwise with zero corresponding to a line with an origin centred between the extreme points of the shape, and pointing at 3 o’clock.

If the grob describes a single shape, the boundary value should correspond to the exact edge of the shape.

If the grob describes multiple shapes, the boundary value will either correspond to the edge of a bounding box around all of the shapes described by the grob (for multiple rectangles, circles, xsplines, or text), or to a convex hull around all vertices of all shapes described by the grob (for multiple polygons, points, lines, polylines, and segments).

Points grobs are currently a special case because the convex hull is based on the data symbol locations and does not take into account the extent of the data symbols themselves.

The extents of any arrow heads are currently not taken into account.

**Value**

A unit object.

**Author(s)**

Paul Murrell

unit and grobWidth
Constructing a Legend Grob

Description

Constructing a legend grob (in progress)

Usage

```r
legendGrob(labels, nrow, ncol, byrow = FALSE,
  do.lines = has.lty || has.lwd, lines.first = TRUE,
  hgap = unit(1, "lines"), vgap = unit(1, "lines"),
  default.units = "lines", pch, gp = gpar(), vp = NULL)
grid.legend(..., draw=TRUE)
```

Arguments

- **labels**: legend labels (expressions)
- **nrow, ncol**: integer; the number of rows or columns, respectively of the legend “layout”. `nrow` is optional and typically computed from the number of labels and `ncol`.
- **byrow**: logical indicating whether rows of the legend are filled first.
- **do.lines**: logical indicating whether legend lines are drawn.
- **lines.first**: logical indicating whether legend lines are drawn first and hence in a plain “below” legend symbols.
- **hgap**: horizontal space between the legend entries
- **vgap**: vertical space between the legend entries
- **default.units**: default units, see `unit`.
- **pch**: legend symbol, numeric or character, passed to `pointsGrob()`; see also `points` for interpretation of the numeric codes.
- **gp**: an R object of class "gpar", typically the output from a call to the function `gpar`, is basically a list of graphical parameter settings.
- **vp**: a Grid `viewport` object (or `NULL`).
- **...**: for `grid.legend()`: all the arguments above are passed to `legendGrob()`.
- **draw**: logical indicating whether graphics output should be produced.

Value

Both functions create a legend `grob` (a graphical object describing a plot legend), but only `grid.legend` draws it (only if `draw` is TRUE).

See Also

`Grid`, `viewport`; `pointsGrob`, `linesGrob`.
`grid.plot.and.legend` contains a simple example.
Examples

```r
## Data:
n <- 10
x <- stats::runif(n); y1 <- stats::runif(n); y2 <- stats::runif(n)
## Construct the grobs:
plot <- gTree(children=gList(rectGrob(),
    pointsGrob(x, y1, pch=21, gp=gpar(col=2, fill="gray")),
    pointsGrob(x, y2, pch=22, gp=gpar(col=3, fill="gray"),
    xaxisGrob(),
    yaxisGrob()))
legd <- legendGrob(c("Girls", "Boys", "Other"), pch=21:23,
    gp=gpar(col = 2:4, fill = "gray"))
## Now draw it on a new device page:
gg <- packGrob(packGrob(frameGrob(), plot),
    legd, height=unit(1,"null"), side="right")
```

makeContent

Customised grid Grobs

Description

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing context and drawing content of a new class derived from grob (or gTree).

Usage

```r
makeContext(x)
makeContent(x)
```

Arguments

- `x` A grid grob.

Details

These functions are called by the `grid.draw` methods for grobs and gTrees.

`makeContext` is called first during the drawing of a grob. This function should be used to modify the `vp` slot of `x` (and/or the `childrenvp` slot if `x` is a gTree). The function must return the modified `x`. Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push and up any viewports in the `childrenvp` slot, so this function is used to customise the drawing context for a grob or gTree.

`makeContent` is called next and is where any additional calculations should occur and graphical content should be generated (see, for example, `grid:::makeContent.xaxis`). This function should be used to modify the children of a gTree. The function must return the modified `x`. Note that the default behaviour for gTrees is to draw all grobs in the `children` slot, so this function is used to customise the drawing content for a gTree. It is also possible to customise the drawing content for
a simple grob, but more care needs to be taken; for example, the function should return a standard
grid primitive with a `drawDetails()` method in this case.

Note that these functions should be *cumulative* in their effects, so that the x returned by
`makeContent()` *includes* any changes made by `makeContext()`.

Note that `makeContext` is also called in the calculation of "grobwidth" and "grobheight" units.

Value
Both functions are expected to return a grob or gTree (a modified version of x).

**Define Gradient and Pattern Fills**

Description
Functions to define gradient fills and pattern fills.

Usage

```r
linearGradient(colours = c("black", "white"),
               stops = seq(0, 1, length.out = length(colours)),
               x1 = unit(0, "npc"), y1 = unit(0, "npc"),
               x2 = unit(1, "npc"), y2 = unit(1, "npc"),
               default.units = "npc",
               extend = c("pad", "repeat", "reflect", "none"))

radialGradient(colours = c("black", "white"),
               stops = seq(0, 1, length.out = length(colours)),
               cx1 = unit(.5, "npc"), cy1 = unit(.5, "npc"),
               r1 = unit(0, "npc"),
               cx2 = unit(.5, "npc"), cy2 = unit(.5, "npc"),
               r2 = unit(.5, "npc"),
               default.units = "npc",
               extend = c("pad", "repeat", "reflect", "none"))

pattern(grob,
        x = 0.5, y = 0.5, width = 1, height = 1,
        default.units = "npc",
        just="centre", hjust=NULL, vjust=NULL,
        extend = c("pad", "repeat", "reflect", "none"),
        gp = gpar(fill="transparent"))
```
Arguments

- **colours**: Two or more colours for the gradient to transition between.
- **stops**: Locations of the gradient colours between the start and end points of the gradient (as a proportion of the distance from the start point to the end point).
- **x1, y1, x2, y2**: The start and end points for a linear gradient.
- **default.units**: The coordinate system to use if any location or dimension is specified as just a numeric value.
- **extend**: What happens outside the start and end of the gradient (see Details).
- **cx1, cy1, r1, cx2, cy2, r2**: The centre and radius of the start and end circles for a radial gradient.
- **grob**: A grob (or a gTree) that will be drawn as the tile in a pattern fill.
- **x, y, width, height**: The size of the tile for a pattern fill.
- **just, hjust, vjust**: The justification of the tile relative to its location.
- **gp**: Default graphical parameter settings for the tile.

Details

Use these functions to define a gradient fill or pattern fill and then use the resulting object as the value for fill in a call to the gpar() function.

The possible values of extend, and their meanings, are:

- `[pad:]` propagate the value of the gradient at its boundary.
- `[none:]` produce no fill beyond the limits of the gradient.
- `[repeat:]` repeat the fill.
- `[reflect:]` repeat the fill in reverse.

To create a tiling pattern, provide a simple grob (like a circle), specify the location and size of the pattern to include the simple grob, and specify extend="repeat".

Value

A linear gradient or radial gradient or pattern object.

Warning

Gradient fills and pattern fills are not supported on all graphics devices. Where they are not supported, closed shapes will be rendered with a transparent fill. Where they are supported, not all values of extend are supported.

gpar
plotViewport

Create a Viewport with a Standard Plot Layout

Description
This is a convenience function for producing a viewport with the common S-style plot layout – i.e., a central plot region surrounded by margins given in terms of a number of lines of text.

Usage
plotViewport(margins=c(5.1, 4.1, 4.1, 2.1), ...)

Arguments
margins A numeric vector interpreted in the same way as par(mar) in base graphics.
... All other arguments will be passed to a call to the viewport() function.

Value
A grid viewport object.

Author(s)
Paul Murrell

See Also
viewport and dataViewport.

Querying the Viewport Tree

Get the Current Grid Viewport (Tree)

Description

current.viewport() returns the viewport that Grid is going to draw into.
current.parent returns the parent of the current viewport.
current.vpTree returns the entire Grid viewport tree.
current.vpPath returns the viewport path to the current viewport.
current.transform returns the transformation matrix for the current viewport.
current.rotation returns the (total) rotation for the current viewport.

Usage

current.viewport()
current.parent(n=1)
current.vpTree(all=TRUE)
current.vpPath()
current.transform()
Querying the Viewport Tree

Arguments

- **n**: The number of generations to go up.
- **all**: A logical value indicating whether the entire viewport tree should be returned.

Details

It is possible to get the grandparent of the current viewport (or higher) using the `n` argument to `current.parent()`.

The parent of the ROOT viewport is `NULL`. It is an error to request the grandparent of the ROOT viewport.

If `all` is `FALSE` then `current.vpTree` only returns the subtree below the current viewport.

Value

A Grid viewport object from `current.viewport` or `current.vpTree`.

`current.transform` returns a 4x4 transformation matrix.

The viewport path returned by `current.vpPath` is `NULL` if the current viewport is the ROOT viewport.

Author(s)

- Paul Murrell

- `viewport`

Examples

```r
grid.newpage()
pushViewport(viewport(width=0.8, height=0.8, name="A"))
pushViewport(viewport(x=0.1, width=0.3, height=0.6, just="left", name="B"))
upViewport(1)
pushViewport(viewport(x=0.5, width=0.4, height=0.8, just="left", name="C"))
pushViewport(viewport(width=0.8, height=0.8, name="D"))
current.vpPath()
upViewport(1)
current.vpPath()
current.vpTree()
current.viewport()
current.vpTree(all=FALSE)
popViewport(0)
```
resolveRasterSize

Utility function to resolve the size of a raster grob

Description

Determine the width and height of a raster grob when one or both are not given explicitly.

The result depends on both the aspect ratio of the raster image and the aspect ratio of the physical drawing context, so the result is only valid for the drawing context in which this function is called.

Usage

```r
classRasterSize(x)
```

Arguments

- `x` A raster grob

Details

A raster grob can be specified with width and/or height of `NULL`, which means that the size at which the raster is drawn will be decided at drawing time.

Value

A raster grob, with explicit width and height.

See Also

- `grid.raster`

Examples

```r
# Square raster
rg <- rasterGrob(matrix(0))
# Fill the complete page (if page is square)
grid.newpage()
resolveRasterSize(rg)$height
grid.draw(rg)
# Forced to fit tall thin region
grid.newpage()
pushViewport(viewport(width=.1))
resolveRasterSize(rg)$height
grid.draw(rg)
```
**roundrect**

*Draw a rectangle with rounded corners*

**Description**

Draw a single rectangle with rounded corners.

**Usage**

```r
circleGrob(x=0.5, y=0.5, width=1, height=1, 
default.units="npc", 
r=unit(0.1,"snpc"), 
just="centre", 
name=NULL, gp=NULL, vp=NULL)
grid.circle(...)
```

**Arguments**

- `x, y, width, height`
  The location and size of the rectangle.
- `default.units`
  A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- `r`
  The radius of the rounded corners.
- `just`
  The justification of the rectangle relative to its location.
- `name`
  A name to identify the grob.
- `gp`
  Graphical parameters to apply to the grob.
- `vp`
  A viewport object or NULL.
- `...`
  Arguments to be passed to `circleGrob()`.

**Details**

At present, this function can only be used to draw one rounded rectangle.

**Examples**

```r
grid.circle(x=grobX("rr", theta[i]), 
y=grobY("rr", theta[i]), 
r=unit(1,"mm"), 
gp=gpar(fill="black"))
```
showGrob  
Label grid grobs.

Description

Produces a graphical display of (by default) the current grid scene, with labels showing the names of each grob in the scene. It is also possible to label only specific grobs in the scene.

Usage

showGrob(x = NULL,
gPath = NULL, strict = FALSE, grep = FALSE,
recurse = TRUE, depth = NULL,
labelfun = grobLabel, ...)

Arguments

x
If NULL, the current grid scene is labelled. Otherwise, a grob (or gTree) to draw and then label.

gPath
A path identifying a subset of the current scene or grob to be labelled.

strict
Logical indicating whether the gPath is strict.

grep
Logical indicating whether the gPath is a regular expression.

recurse
Should the children of gTrees also be labelled?

depth
Only display grobs at the specified depth (may be a vector of depths).

labelfun
Function used to generate a label from each grob.

...
Arguments passed to labelfun to control fine details of the generated label.

Details

None of the labelling is recorded on the grid display list so the original scene can be reproduced by calling grid.refresh.

grob and gTree

Examples

grid.newpage()
gt <- gTree(children=vpStack(
  viewport(x=0, width=.5, just="left", name="vp"),
  viewport(y=.5, height=.5, just="bottom", name="vp2"),
  children=gList(rectGrob(vp="vp::vp2", name="child")))

grid.draw(gt)

showGrob()

showGrob(gPath="child")

showGrob(recurse=FALSE)

showGrob(depth=1)

showGrob(depth=2)
showViewport

Display grid viewports.

showViewport

Description

Produces a graphical display of (by default) the current grid viewport tree. It is also possible to display only specific viewports. Each viewport is drawn as a rectangle and the leaf viewports are labelled with the viewport name.

Usage

showViewport(vp = NULL, recurse = TRUE, depth = NULL, newpage = FALSE, leaves = FALSE, col = rgb(0, 0, 1, 0.2), fill = rgb(0, 0, 1, 0.1), label = TRUE, nrow = 3, ncol = nrow)
Arguments

- **vp** If NULL, the current viewport tree is displayed. Otherwise, a viewport (or vpList, or vpStack, or vpTree) or a vpPath that specifies which viewport to display.
- **recurse** Should the children of the specified viewport also be displayed?
- **depth** Only display viewports at the specified depth (may be a vector of depths).
- **newpage** Start a new page for the display? Otherwise, the viewports are displayed on top of the current plot.
- **leaves** Produce a matrix of smaller displays, with each leaf viewport in its own display.
- **col** The colour used to draw the border of the rectangle for each viewport and to draw the label for each viewport. If a vector, then the first colour is used for the top-level viewport, the second colour is used for its children, the third colour for their children, and so on.
- **fill** The colour used to fill each viewport. May be a vector as per col.
- **label** Should the viewports be labelled (with the viewport name)?
- **nrow, ncol** The number of rows and columns when leaves is TRUE. Otherwise ignored.

See Also

- `viewport` and `grid.show.viewport`

Examples

```r
showViewport(viewport(width=.5, height=.5, name="vp"))
grid.newpage()
pushViewport(viewport(width=.5, height=.5, name="vp"))
upViewport()
showViewport(vpPath("vp"))
showViewport(vpStack(viewport(width=.5, height=.5, name="vp1"),
                      viewport(width=.5, height=.5, name="vp2"),
                      newpage=TRUE))
showViewport(vpStack(viewport(width=.5, height=.5, name="vp1"),
                      viewport(width=.5, height=.5, name="vp2"),
                      fill=rgb(1:0, 0:1, 0, .1),
                      newpage=TRUE))
```

---

**stringWidth**

*Create a Unit Describing the Width and Height of a String or Math Expression*

Description

These functions create a unit object describing the width or height of a string.

Usage

```r
stringWidth(string)
stringHeight(string)
stringAscent(string)
stringDescent(string)
```
unit

Function to Create a Unit Object

Description
This function creates a unit object — a vector of unit values. A unit value is typically just a single numeric value with an associated unit.

Usage
unit(x, units, data=NULL)

Arguments
x A numeric vector.
units A character vector specifying the units for the corresponding numeric values.
data This argument is used to supply extra information for special unit types.

Details
Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the units specifies what coordinate system to use within that viewport. Possible units (coordinate systems) are:

"npc" Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.
"cm" Centimetres.
"inches" Inches. 1 in = 2.54 cm.
"mm" Millimetres. 10 mm = 1 cm.
"points" Points. 72.27 pt = 1 in.
"picas" Picas. 1 pc = 12 pt.
"bigpts" Big Points. 72 bp = 1 in.
"dida" Dida. 1157 dd = 1238 pt.
"cicero" Cicero. 1 cc = 12 dd.
"scaledpts" Scaled Points. 65536 sp = 1 pt.

"lines" Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport's fontsize and lineheight).
"char" Multiples of nominal font height of the viewport (as specified by the viewport's fontsize).
"native" Locations and dimensions are relative to the viewport's xscale and yscale.
"snpc" Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the lesser of npc-width and npc-height. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).

"strwidth" Multiples of the width of the string specified in the data argument. The font size is determined by the fontsize of the viewport.
"strheight" Multiples of the height of the string specified in the data argument. The font size is determined by the fontsize of the viewport.

"grobwidth" Multiples of the width of the grob specified in the data argument.
"grobheight" Multiples of the height of the grob specified in the data argument.

A number of variations are also allowed for the most common units. For example, it is possible to use "in" or "inch" instead of "inches" and "centimetre" or "centimeter" instead of "cm".

A special units value of "null" is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see grid.layout).

The data argument must be a list when the unit.length() is greater than 1. For example,

```
unit(rep(1, 3), c("npc", "strwidth", "inches"),
    data = list(NULL, "my string", NULL))
```

It is possible to subset unit objects in the normal way and to perform subassignment (see the examples), but a special function unit.c is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., unit(1, "npc") - unit(1, "inches")), and to specify the minimum or maximum of a list of unit objects (e.g., min(unit(0.5, "npc"), unit(1, "inches"))).

There is a format method for units, which should respond to the arguments for the default format method, e.g., digits to control the number of significant digits printed for numeric values.

**Value**

An object of class "unit".

**WARNING**

There is a special function unit.c for concatenating several unit objects.

The c function will not give the right answer.

There used to be "mylines", "mychar", "mystrwidth", "mystrheight" units. These will still be accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".
unit.c

Author(s)
Paul Murrell

See Also
unit.c

Examples

unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
unit(1, "strwidth", "hi there"))
x <- unit(1:5, "npc")
x[2:4]
x[2:4] <- unit(1, "mm")
x

unit.c Combine Unit Objects

Description
This function produces a new unit object by combining the unit objects specified as arguments.

Usage
unit.c(..., check = TRUE)

Arguments
...
An arbitrary number of unit objects.
check
Should input be checked? If you are certain all arguments are unit objects this can be set to FALSE

Value
An object of class unit.

Author(s)
Paul Murrell

See Also
unit.
### unit.length

**Length of a Unit Object**

**Description**

The length of a unit object is defined as the number of unit values in the unit object.

This function has been deprecated in favour of a unit method for the generic `length` function.

**Usage**

```r
unit.length(unit)
```

**Arguments**

- `unit` A unit object.

**Value**

An integer value.

**Author(s)**

Paul Murrell

**See Also**

- `unit`

**Examples**

```r
length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4))
length(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)
```

---

### unit.pmin

**Parallel Unit Minima and Maxima**

**Description**

Returns a unit object whose i’th value is the minimum (or maximum) of the i’th values of the arguments.

**Usage**

```r
unit.pmin(...)  
unit.pmax(...)  
unit.psum(...) 
```
Arguments

... One or more unit objects.

Details

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

Value

A unit object.

Author(s)

Paul Murrell

Examples

max(unit(1:3, "cm"), unit(0.5, "npc"))
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))

Description

Replicates the units according to the values given in times and length.out.
This function has been deprecated in favour of a unit method for the generic rep function.

Usage

unit.rep(x, ...)

Arguments

x An object of class "unit".
...
arguments to be passed to rep such as times and length.out.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

rep
Examples

- `rep(unit(1:3, "npc"), 3)`
- `rep(unit(1:3, "npc"), 1:3)`
- `rep(unit(1:3, "npc") + unit(1, "inches"), 3)`
- `rep(max(unit(1:3, "npc") + unit(1, "inches")), 3)`
- `rep(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)`
- `rep(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)`

Description

This function returns the units of a unit object.

Usage

`unitType(x, recurse = FALSE)`

Arguments

- `x` A unit object.
- `recurse` Whether to recurse into complex units.

Value

For simple units, this will be just a vector of coordinate systems, like "inches" or "npc".

More complex units that involve an operation on units return an operator, like "sum", "min", or "max".

When `recurse = TRUE`, the result is always a list and more complex units generate sublists (see the Examples below).

Author(s)

Thomas Lin Pedersen and Paul Murrell

See Also

`unit`

Examples

```r
u <- unit(1:5, c("cm", "mm", "in", "pt", "null"))

unitType(u)
unitType(unit(1, "npc"))
unitType(unit(1:3/4, "npc"))
unitType(unit(1:3/4, "npc") + unit(1, "inches"))
unitType(min(unit(0.5, "npc"), unit(1, "inches")))
unitType(unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
               unit(1, "strwidth", "hi there")))
unitType(min(unit(1, "in"), unit(1, "npc") + unit(1, "mm")))
```
valid.just

Validate a Justification

Description

Utility functions for determining whether a justification specification is valid and for resolving a single justification value from a combination of character and numeric values.

Usage

valid.just(just)
resolveHJust(just, hjust)
resolveVJust(just, vjust)

Arguments

just A justification either as a character value, e.g., "left", or as a numeric value, e.g., 0.
hjust A numeric horizontal justification
vjust A numeric vertical justification

Details

These functions may be useful within a validDetails method when writing a new grob class.

Value

A numeric representation of the justification (e.g., "left" becomes 0, "right" becomes 1, etc, ...).
An error is given if the justification is not valid.

Author(s)

Paul Murrell
validDetails  
*Customising grid grob Validation*

**Description**

This generic hook function is called whenever a grid grob is created or edited via `grob`, `gRoot`, `grid.edit` or `editGrob`. This provides an opportunity for customising the validation of a new class derived from grob (or gTree).

**Usage**

```r
validDetails(x)
```

**Arguments**

- `x`  
  A grid grob.

**Details**

This function is called by `grob`, `gTree`, `grid.edit` and `editGrob`. A method should be written for classes derived from grob or gTree to validate the values of slots specific to the new class. (e.g., see `grid:::validDetails.axis`).

Note that the standard slots for grobs and gTrees are automatically validated (e.g., `vp`, `gp` slots for grobs and, in addition, `children` and `childrenvp` slots for gTrees) so only slots specific to a new class need to be addressed.

**Value**

The function MUST return the validated grob.

**Author(s)**

Paul Murrell

**See Also**

- `grid.edit`

---

**viewportTransform**  
*Define a Group Transformation*

**Description**

These functions define the transformation that will be applied when a `grid.define()`d group is `grid.use()`d.
viewportTransform

Usage

viewportTransform(group, shear=groupShear(), flip=groupFlip(), ...)
viewportTranslate(group, ...)
viewportScale(group, ...)
viewportRotate(group, ...)
defnTranslate(group, inverse=FALSE, ...)
defnScale(group, inverse=FALSE, ...)
defnRotate(group, inverse=FALSE, ...)
useTranslate(group, inverse=FALSE, ...)
useScale(group, inverse=FALSE, ...)
useRotate(group, inverse=FALSE, ...)
groupTranslate(dx=0, dy=0)
groupRotate(r=0)
groupScale(sx=1, sy=1)
groupShear(sx=0, sy=0)
groupFlip(flipX=FALSE, flipY=FALSE)

Arguments

group The group that is being transformed.
inverse A logical indicating whether we want the forward or backward transformation.
shear An affine transformation matrix that describes a shear transformation.
flip An affine transformation matrix that describes a scaling inversion.
dx, dy The translation to apply.
r The rotation to apply.
sx, sy The scaling (or shear) to apply.
flipX, flipY Whether to negate the x-scaling or y-scaling (logical).
... Arguments passed on to lower-level transformation functions.

Details

The viewport*() functions are not called directly. They are passed as the transform argument to grid.use.

The defn*() and use*() functions are also not called directly, but can be useful to create custom transformation functions. For example, see the source code for viewportTransform.

The group*() functions generate basic affine transformation matrices and may also be useful to create custom transformation functions. For example, the groupShear() function can be used to specify a shear transform to viewportTransform().

It is also possible to define any function that returns a 4x4 matrix and use it as the transform argument to grid.use, but the results will probably be device-dependent may be very difficult to predict.

Value

An affine transformation matrix.

Grid

Examples

## NOTE: on devices without support for groups nothing will be drawn
grid.newpage()
## Define and use group in same viewport
pushViewport(viewport(width=.2, height=.2))
grid.define(circleGrob(gp=gpar(lwd=5)), name="circle")
grid.use("circle")
popViewport()
## Use group in viewport that is translated and scaled
pushViewport(viewport(x=.2, y=.2, width=.1, height=.1))
grid.use("circle")
popViewport()
## Use group in viewport that is translated and scaled
## BUT only make use of the translation
pushViewport(viewport(x=.2, y=.8, width=.1, height=.1))
grid.use("circle", transform=viewportTranslate)
popViewport()
## Use group in viewport that is translated and scaled
## unevenly (distorted)
pushViewport(viewport(x=.8, y=.7, width=.2, height=.4))
grid.use("circle")
popViewport()

vpPath

Concatenate Viewport Names

Description

This function can be used to generate a viewport path for use in downViewport or seekViewport.
A viewport path is a list of nested viewport names.

Usage

vpPath(...)

Arguments

... Character values which are viewport names.

Details

Viewport names must only be unique amongst viewports which share the same parent in the view-
port tree.
This function can be used to generate a specification for a viewport that includes the viewport’s
parent’s name (and the name of its parent and so on).
For interactive use, it is possible to directly specify a path, but it is strongly recommended that this
function is used otherwise in case the path separator is changed in future versions of grid.
Value

A vpPath object.

See Also

viewport, pushViewport, popViewport, downViewport, seekViewport, upViewport

Examples

vpPath("vp1", "vp2")

Description

These generic functions are used to determine the size of grid grobs.

Usage

widthDetails(x)
heightDetails(x)
ascentDetails(x)
descentDetails(x)

Arguments

x A grid grob.

Details

These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example grid:::widthDetails.frame).

The ascent of a grob is the height of the grob by default and the descent of a grob is zero by default, except for text grobs where the label is a single character value or expression.

Value

A unit object.

Author(s)

Paul Murrell

See Also

absolute.size
Description

Grid maintains a tree of viewports — nested drawing contexts.

These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage

pushViewport(..., recording=TRUE)
popViewport(n = 1, recording=TRUE)
downViewport(name, strict=FALSE, recording=TRUE)
seekViewport(name, recording=TRUE)
upViewport(n = 1, recording=TRUE)

Arguments

... One or more objects of class "viewport".

n An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.

name A character value to identify a viewport in the tree.

strict A boolean indicating whether the vpPath must be matched exactly.

recording A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details

Objects created by the viewport() function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.

The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using pushViewport() and removed from the tree using popViewport().

There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current viewport. Use upViewport to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use downViewport to navigate to a viewport further down the viewport tree and seekViewport to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same name as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.

Value

downViewport returns the number of viewports it went down.

This can be useful for returning to your starting point by doing something like depth <- downViewport() then upViewport(depth).

seekViewport(vpPath("B", "A"))
grid.text("11. Seek from\nA (in ROOT)\nto A (in B)"
  )
popViewport(0)

xDetails  Boundary of a grid grob

Description
These generic functions are used to determine a location on the boundary of a grid grob.

Usage
xDetails(x, theta)
yDetails(x, theta)

Arguments
x
  A grid grob.

theta
  A numeric angle, in degrees, measured anti-clockwise from the 3 o’clock or one of the following character strings: "north", "east", "west", "south".

Details
The location on the grob boundary is determined by taking a line from the centre of the grob at the angle theta and intersecting it with the convex hull of the grob (for the basic grob primitives, the centre is determined as half way between the minimum and maximum values in x and y directions).
These functions are called in the calculation of "grobx" and "groby" units as produced by the grobx and groby functions. Methods should be written for classes derived from grob or gTree where the boundary of the grob can be determined.

Value
A unit object.
xsplinePoints

Author(s)
Paul Murrell

See Also
~grobx, grobY.

xsplinePoints Return the points that would be used to draw an Xspline (or a Bezier curve).

Description
Rather than drawing an Xspline (or Bezier curve), this function returns the points that would be used to draw the series of line segments for the Xspline. This may be useful to post-process the Xspline curve, for example, to clip the curve.

Usage
xsplinePoints(x)
bezierPoints(x)

Arguments
x An Xspline grob, as produced by the xsplineGrob() function (or a beziergrob, as produced by the bezierGrob() function).

Details
The points returned by this function will only be relevant for the drawing context in force when this function was called.

Value
Depends on how many Xsplines would be drawn. If only one, then a list with two components, named x and y, both of which are unit objects (in inches). If several Xsplines would be drawn then the result of this function is a list of lists.

grid.newpage()
xsg <- xsplineGrob(c(.1, .1, .9, .9), c(.1, .9, .9, .1), shape=1)
grid.draw(xsg)
trace <- xsplinePoints(xsg)
grid.circle(trace$x, trace$y, default.units="inches", r=unit(.5, "mm"))

grid.newpage()
vp <- viewport(width=.5)
xg <- xsplineGrob(x=c(0, .2, .4, .2, .5, .7, .9, .7),
                   y=c(.5, 1, .5, 0, .5, 1, .5, 0),
                   id=rep(1:2, each=4),
                   shape=1,
                   vp=vp)
grid.draw(xg)
trace <- xsplinePoints(xg)
pushViewport(vp)
invisible(lapply(trace, function(t) grid.lines(t$x, t$y, gp=gpar(col="red")))))
popViewport()

grid.newpage()
bg <- bezierGrob(c(.2, .2, .8, .8), c(.2, .8, .8, .2))
grid.draw(bg)
trace <- bezierPoints(bg)
g```
Chapter 7

The methods package

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the “S4” or “S version 4” approach to methods and classes in a functional language.

For basic use of the techniques, start with Introduction and follow the links there to the key functions for programming, notably setClass and setMethod.

Some specific topics:

Classes: Creating one, see setClass; examining definitions, see getClassDef and classRepresentation; inheritance and coercing, see is and as

Generic functions: Basic programming, see setGeneric; the class of objects, see genericFunction; other functions to examine or manipulate them, see GenericFunctions.

S3: Using classes, see setOldClass; methods, see Methods_for_S3.

Reference classes: See ReferenceClasses.

Class unions; virtual classes See setClassUnion.

These pages will have additional links to related topics.

For a complete list of functions and classes, use library(help="methods").

**.BasicFunsList**  
*List of Built-in and Special Functions*

Description

A named list providing instructions for turning built-in and special functions into generic functions. Functions in R that are defined as `.Primitive(<name>)` are not suitable for formal methods, because they lack the basic reflectance property. You can’t find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same, the list flags those specials for which methods are meaningless (e.g., `for`) or just a very bad idea (e.g., `.Primitive`). A generic function created via `setMethod`, for example, for one of these special functions will have the argument list from `.BasicFunsList`. If no entry exists, the argument list `(x, ...)` is assumed.

---

**as**  
*Force an Object to Belong to a Class*

Description

Coerce an object to a given class.

Usage

```r
as(object, Class, strict=TRUE, ext)
```

```r
as(object, Class) <- value
```
Arguments

object: any R object.
Class: the name of the class to which object should be coerced.
strict: logical flag. If TRUE, the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class, in particular the original object, if that class extends the virtual class directly).
If strict = FALSE, any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.
value: The value to use to modify object (see the discussion below). You should supply an object with class Class; some coercion is done, but you’re unwise to rely on it.

Description

as(object) returns the version of this object coerced to be the given Class. When used in the replacement form on the left of an assignment, the portion of the object corresponding to Class is replaced by value.

The operation of as() in either form depends on the definition of coerce methods. Methods are defined automatically when the two classes are related by inheritance; that is, when one of the classes is a subclass of the other.
Coerce methods are also predefined for basic classes (including all the types of vectors, functions and a few others).
Beyond these two sources of methods, further methods are defined by calls to the setAs function. See that documentation also for details of how coerce methods work. Use showMethods(coerce) for a list of all currently defined methods, as in the example below.

Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, as(x, "numeric") uses the existing as.numeric function. These and all other existing methods can be listed as shown in the example.

References

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also

If you think of using try(as(x, cl)), consider canCoerce(x, cl) instead.

Examples

### Show all the existing methods for as()
showMethods("coerce")
**Description**

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

**Usage**

### The following are all basic vector classes.
### They can appear as class names in method signatures, 
### in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### the class
"S4"
### is an object type for S4 objects that do not extend 
### any of the basic vector classes. It is a virtual class.

### The following are additional basic classes
"NULL"  # NULL objects
"Function"  # function objects, including primitives
"externalptr"  # raw external pointers for use in C code

"ANY"  # virtual classes used by the methods package itself
"VIRTUAL"
"missing"

"namedList"  # the alternative to "list" that preserves
  # the names attribute

**Objects from the Classes**

If a class is not virtual (see section in Classes_Details), objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.
The class "expression" is slightly odd, in that the ... arguments will not be evaluated; therefore, don't enclose them in a call to `quote()`.

Note that class "list" is a pure vector. Although lists with names go back to the earliest versions of S, they are an extension of the vector concept in that they have an attribute (which can now be a slot) and which is either NULL or a character vector of the same length as the vector. If you want to guarantee that list names are preserved, use class "namedList", rather than "list". Objects from this class must have a names attribute, corresponding to slot "names", of type "character". Internally, R treats names for lists specially, which makes it impractical to have the corresponding slot in class "namedList" be a union of character names and NULL.

**Classes and Types**

The basic classes include classes for the basic R types. Note that objects of these types will not usually be S4 objects (`isS4` will return `FALSE`), although objects from classes that contain the basic class will be S4 objects, still with the same type. The type as returned by `typeof` will sometimes differ from the class, either just from a choice of terminology (type "symbol" and class "name", for example) or because there is not a one-to-one correspondence between class and type (most of the classes that inherit from class "language" have type "language", for example).

**Extends**

The vector classes extend "vector", directly.

**Methods**

`coerce`  Methods are defined to coerce arbitrary objects to the vector classes, by calling the corresponding basic function, for example, `as(x, "numeric")` calls `as.numeric(x)`.

---

**callGeneric**

*Call the Current Generic Function from a Method*

**Description**

A call to `callGeneric` can only appear inside a method definition. It then results in a call to the current generic function. The value of that call is the value of `callGeneric`. While it can be called from any method, it is useful and typically used in methods for group generic functions.

**Usage**

`callGeneric(...)`

**Arguments**

*...*  Optionally, the arguments to the function in its next call.

If no arguments are included in the call to `callGeneric`, the effect is to call the function with the current arguments. See the detailed description for what this really means.
callGeneric

Details

The name and package of the current generic function is stored in the environment of the method definition object. This name is looked up and the corresponding function called.

The statement that passing no arguments to callGeneric causes the generic function to be called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say \( x \), that appears in the original call, there is a corresponding argument in the generated call equivalent to \( x = x \). In effect, this means that the generic function sees the same actual arguments, but arguments are evaluated only once.

Using callGeneric with no arguments is prone to creating infinite recursion, unless one of the arguments in the signature has been modified in the current method so that a different method is selected.

Value

The value returned by the new call.

GroupGenericFunctions for other information about group generic functions; Methods_Details for the general behavior of method dispatch

Examples

```r
## the method for group generic function Ops
## for signature( e1="structure", e2="vector")
function (e1, e2)
{
  value <- callGeneric(e1@.Data, e2)
  if (length(value) == length(e1)) {
    e1@.Data <- value
    e1
  } else value
}

## For more examples
## Not run:
showMethods("Ops", includeDefs = TRUE)

## End(Not run)
```
**Description**

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

**Usage**

`callNextMethod(...)`

**Arguments**

...  

Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

**Details**

The ‘next’ method (i.e., the first inherited method) is defined to be that method which *would* have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the defined slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in the method object where the call occurred, so the search typically happens only once per session per combination of argument classes).

The next method is defined from the *signature* of the current method, not from the actual classes of the arguments. In particular, modifying any of the arguments has no effect on the selection. As a result, the selected next method can be called with invalid arguments if the calling function assigns objects of a different class before the `callNextMethod()` call. Be careful of any assignments to such arguments.

It is possible for the selection of the next method to be ambiguous, even though the original set of methods was consistent. See the section “Ambiguous Selection”.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the next method call equivalent to `x = x`. In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

**Value**

The value returned by the selected method.
Ambiguous Selection

There are two fairly common situations in which the choice of a next method is ambiguous, even when the original set of methods uniquely defines all method selection unambiguously. In these situations, `callNextMethod()` should be replaced, either by a call to a specific function or by recalling the generic with different arguments.

The most likely situation arises with methods for binary operators, typically through one of the group generic functions. See the example for class "rnum" below. Examples of this sort usually require three methods: two for the case that the first or the second argument comes from the class, and a third for the case that both arguments come from the class. If that last method uses `callNextMethod`, the other two methods are equally valid. The ambiguity is exactly the same that required defining the two-argument method in the first place.

In fact, the two possibilities are equally valid conceptually as well as formally. As in the example below, the logic of the application usually requires selecting a computation explicitly or else calling the generic function with modified arguments to select an appropriate method.

The other likely source of ambiguity arises from a class that inherits directly from more than one other class (a “mixin” in standard terminology). If the generic has methods corresponding to both superclasses, a method for the current class is again needed to resolve ambiguity. Using `callNextMethod` will again reimpose the ambiguity. Again, some explicit choice has to be made in the calling method instead.

These ambiguities are not the result of bad design, but they do require workarounds. Other ambiguities usually reflect inconsistencies in the tree of inheritances, such as a class appearing in more than one place among the superclasses. Such cases should be rare, but with the independent definition of classes in multiple packages, they can’t be ruled out.

`callGeneric` to call the generic function with the current dispatch rules (typically for a group generic function); `Methods_Details` for the general behavior of method dispatch.

Examples

```r
## callNextMethod() used for the Math, Math2 group generic functions
## A class to automatically round numeric results to "d" digits
rnum <- setClass("rnum", slots = c(d = "integer"), contains = "numeric")
## Math functions operate on the rounded numbers, return a plain vector. The next method will always be the default, usually a primitive.
setMethod("Math", "rnum",
  function(x)
    callNextMethod(round(as.numeric(x), x@d)))
setMethod("Math2", "rnum",
  function(x, digits)
    callNextMethod(round(as.numeric(x), x@d), digits))
## Examples of callNextMethod with two arguments in the signature.
## For arithmetic and one rnum with anything, callNextMethod with no arguments
```
callNextMethod

## round the full accuracy result, and return as plain vector
setMethod("Arith", c(e1 = "rnum"),
  function(e1, e2)
  as.numeric(round(callNextMethod(), e1@d)))
setMethod("Arith", c(e2 = "rnum"),
  function(e1, e2)
  as.numeric(round(callNextMethod(), e2@d)))

## A method for BOTH arguments from "rnum" would be ambiguous
## for callNextMethod(): the two methods above are equally valid.
## The method chooses the smaller number of digits,
## and then calls the generic function, postponing the method selection
## until it's not ambiguous.
setMethod("Arith", c(e1 = "rnum", e2 = "rnum"),
  function(e1, e2) {
    if(e1@d <= e2@d)
      callGeneric(e1, as.numeric(e2))
    else
      callGeneric(as.numeric(e1), e2)
  })

## For comparisons, callNextMethod with the rounded arguments
setMethod("Compare", c(e1 = "rnum"),
  function(e1, e2)
  callNextMethod(round(e1, e1@d), round(e2, e1@d)))
setMethod("Compare", c(e2 = "rnum"),
  function(e1, e2)
  callNextMethod(round(e1, e2@d), round(e2, e2@d)))

## similarly to the Arith case, the method for two "rnum" objects
## can not unambiguously use callNextMethod(). Instead, we rely on
## The rnum() method inherited from Math2 to return plain vectors.
setMethod("Compare", c(e1 = "rnum", e2 = "rnum"),
  function(e1, e2) {
    d <- min(e1@d, e2@d)
    callGeneric(round(e1, d), round(e2, d))
  })

set.seed(867)
x1 <- rnum(10*runif(5), d=1L)
x2 <- rnum(10*runif(5), d=2L)
x1+1
x2*2
x1-x2

## Simple examples to illustrate callNextMethod with and without arguments
B0 <- setClass("B0", slots = c(s0 = "numeric"))

## and a function to illustrate callNextMethod
f <- function(x, text = "default") {
  str(x) # print a summary
paste(text, ":", class(x))
)

setGeneric("f")
setMethod("f", "B0", function(x, text = "B0") {
    cat("B0 method called with s0 =", x@s0, "\n")
callNextMethod()
})

b0 <- B0(s0 = 1)

## call f() with 2 arguments: callNextMethod passes both to the default method
f(b0, "first test")

## call f() with 1 argument: the default "B0" is not passed by callNextMethod
f(b0)

## Now, a class that extends B0, with no methods for f()
B1 <- setClass("B1", slots = c(s1 = "character"), contains = "B0")
b1 <- B1(s0 = 2, s1 = "Testing B1")

## the two cases work as before, by inheriting the "B0" method
f(b1, b1@s1)

f(b1)

B2 <- setClass("B2", contains = "B1")

## And, a method for "B2" that calls with explicit arguments.
## Note that the method selection in callNextMethod
## uses the class of the argument to consistently select the "B0" method
setMethod("f", "B2", function(x, text = "B1 method") {
    y <- B1(s0 = -x@s0, s1 = "Modified x")
callNextMethod(y, text)
})

b2 <- B2(s1 = "Testing B2", s0 = 10)

f(b2, b2@s1)

f(b2)

## Be careful: the argument passed must be legal for the method selected
## Although the argument here is numeric, it's still the "B0" method that's called
setMethod("f", "B2", function(x, text = "B1 method") {
callNextMethod(x@s0, text)
})

## Now the call will cause an error:
tryCatch(f(b2), error = function(e) cat(e$message,"\n"))
canCoerce

Can an Object be Coerced to a Certain S4 Class?

Description
Test if an object can be coerced to a given S4 class. Maybe useful inside if() to ensure that calling as(object, Class) will find a method.

Usage
canCoerce(object, Class)

Arguments
- object: any R object, typically of a formal S4 class.
- Class: an S4 class (see isClass).

Value
a scalar logical, TRUE if there is a coerce method (as defined by e.g. setAs) for the signature (from = class(object), to = Class).

See Also
as, setAs, selectMethod, setClass,

Examples
m <- matrix(pi, 2,3)
canCoerce(m, "numeric") # TRUE
canCoerce(m, "array") # TRUE

cbind2

Combine two Objects by Columns or Rows

Description
Combine two matrix-like R objects by columns (cbind2) or rows (rbind2). These are (S4) generic functions with default methods.

Usage
cbind2(x, y, ...)
rbind2(x, y, ...)
**Arguments**

- **x**: any R object, typically matrix-like.
- **y**: any R object, typically similar to `x`, or missing completely.
- ... optional arguments for methods.

**Details**

The main use of `cbind2` (rbind2) is to be called recursively by `cbind()` (rbind()) when both of these requirements are met:

- There is at least one argument that is an S4 object, and
- S3 dispatch fails (see the Dispatch section under `cbind`).

The methods on `cbind2` and `rbind2` effectively define the type promotion policy when combining a heterogeneous set of arguments. The homogeneous case, where all objects derive from some S4 class, can be handled via S4 dispatch on the ... argument via an externally defined S4 `cbind` (rbind) generic.

Since (for legacy reasons) S3 dispatch is attempted first, it is generally a good idea to additionally define an S3 method on `cbind` (rbind) for the S4 class. The S3 method will be invoked when the arguments include objects of the S4 class, along with arguments of classes for which no S3 method exists. Also, in case there is an argument that selects a different S3 method (like the one for `data.frame`), this S3 method serves to introduce an ambiguity in dispatch that triggers the recursive fallback to `cbind2` (rbind2). Otherwise, the other S3 method would be called, which may not be appropriate.

**Value**

A matrix (or matrix like object) combining the columns (or rows) of `x` and `y`. Note that methods must construct `colnames` and `rownames` from the corresponding column and row names of `x` and `y` (but not from deparsing argument names such as in `cbind(..., deparse.level = d)` for `d ≥ 1`).

**Methods**

- `signature(x = "ANY", y = "ANY")`: the default method using R’s internal code.
- `signature(x = "ANY", y = "missing")`: the default method for one argument using R’s internal code.

**See Also**

`cbind`, `rbind`; further, `cBind`, `rBind` in the `Matrix` package.

**Examples**

```r
cbind2(1:3, 4)
m <- matrix(3:8, 2,3, dimnames=list(c("a","b"), LETTERS[1:3]))
cbind2(1:2, m) # keeps dimnames from m
```

```r
## rbind() and cbind() now make use of rbind2()/cbind2() methods
setClass("Num", contains="numeric")
setMethod("cbind2", c("Num", "missing"),
  function(x,y, ...) { cat("Num-miss--meth\n"); as.matrix(x)})
setMethod("cbind2", c("Num","ANY"), function(x,y, ...) {
  cat("Num-A.--method\n") ; cbind(getDataPart(x), y, ... ) })
```
`setMethod("cbind2", c("ANY","Num"), function(x,y, ...) {
    cat("A.-Num--method\n") ; cbind(x, getDataPart(y), ... ) })

a <- new("Num", 1:3)
trace("cbind2")
cbind(a)
cbind(a, four=4, 7:9)# calling cbind2() twice

cbind(m,a, ch=c("D","E"), a*3)
cbind(t,a, m) # ok with a warning
untrace("cbind2")

---

### Description

You have navigated to an old link to documentation of S4 classes.

**Compute an Adjacency Matrix for Superclasses of Class Definitions**

**Description**

Given a vector of class names or a list of class definitions, the function returns an adjacency matrix of the superclasses of these classes; that is, a matrix with class names as the row and column names and with element [i, j] being 1 if the class in column j is a direct superclass of the class in row i, and 0 otherwise.

The matrix has the information implied by the contains slot of the class definitions, but in a form that is often more convenient for further analysis; for example, an adjacency matrix is used in packages and other software to construct graph representations of relationships.

**Usage**

`classesToAM(classes, includeSubclasses = FALSE, abbreviate = 2)`
Arguments

classes Either a character vector of class names or a list, whose elements can be either class names or class definitions. The list is convenient, for example, to include the package slot for the class name. See the examples.

includeSubclasses A logical flag: if TRUE, then the matrix will include all the known subclasses of the specified classes as well as the superclasses. The argument can also be a logical vector of the same length as classes, to include subclasses for some but not all the classes.

abbreviate Control of the abbreviation of the row and/or column labels of the matrix returned: values 0, 1, 2, or 3 abbreviate neither, rows, columns or both. The default, 2, is useful for printing the matrix, since class names tend to be more than one character long, making for spread-out printing. Values of 0 or 3 would be appropriate for making a graph (3 avoids the tendency of some graph plotting software to produce labels in minuscule font size).

Details

For each of the classes, the calculation gets all the superclass names from the class definition, and finds the edges in those classes’ definitions; that is, all the superclasses at distance 1. The corresponding elements of the adjacency matrix are set to 1.

The adjacency matrices for the individual class definitions are merged. Note two possible kinds of inconsistency, neither of which should cause problems except possibly with identically named classes from different packages. Edges are computed from each superclass definition, so that information overrides a possible inference from extension elements with distance > 1 (and it should). When matrices from successive classes in the argument are merged, the computations do not currently check for inconsistencies—this is the area where possible multiple classes with the same name could cause confusion. A later revision may include consistency checks.

Value

As described, a matrix with entries 0 or 1, non-zero values indicating that the class corresponding to the column is a direct superclass of the class corresponding to the row. The row and column names are the class names (without package slot).

See Also

extends and classRepresentation for the underlying information from the class definition.

Examples

```r
## the super- and subclasses of "standardGeneric" and "derivedDefaultMethod"
am <- classesToAM(list(class(show), class(getMethod(show))), TRUE)

## Not run:
## the following function depends on the Bioconductor package Rgraphviz
plotInheritance <- function(classes, subclasses = FALSE, ...) {
  if(!require("Rgraphviz", quietly=TRUE))
    stop("Only implemented if Rgraphviz is available")
  mm <- classesToAM(classes, subclasses)
  classes <- rownames(mm); rownames(mm) <- colnames(mm)
```
graph <- new("graphAM", mm, "directed", ...)  
plot(graph)  
cat("Key:\n", paste(abbreviate(classes), " = ", classes, "",  
     sep = "\"", sep = "\", fill = TRUE)  
invisible(graph)  
}  
## The plot of the class inheritance of the package "graph"  
require(graph)  
plotInheritance(getClasses("package:graph"))  
## End(Not run)  

Classes_Details

Class Definitions

Description

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects, see help for the class classRepresentation.

Metadata Information

When a class is defined, an object is stored that contains the information about that class. The object, known as the metadata defining the class, is not stored under the name of the class (to allow programmers to write generating functions of that name), but under a specially constructed name. To examine the class definition, call getClass. The information in the metadata object includes:

- **Slots**: The data contained in an object from an S4 class is defined by the slots in the class definition. Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function slot() or more often the operator "@". However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements. All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always is an object of the class specified for this slot in the definition of the current class. The word "is" corresponds to the R function of the same name (is), meaning that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition (a subclass). A special slot name, .Data, stands for the ‘data part’ of the object. An object from a class with a data part is defined by specifying that the class contains one of the R object types or one of the special pseudo-classes, matrix or array, usually because the definition of the class, or of one of its superclasses, has included the type or pseudo-class in its contains argument. A second special slot name, .xData, is used to enable inheritance from abnormal types such as "environment". See the section on inheriting from non-S4 classes for details on the representation and for the behavior of S3 methods with objects from these classes. Some slot names correspond to attributes used in old-style S3 objects and in R objects without an explicit class, for example, the names attribute. If you define a class for which that attribute
Classes_Details

will be set, such as a subclass of named vectors, you should include "names" as a slot. See the
definition of class "namedList" for an example. Using the names() assignment to set such
names will generate a warning if there is no names slot and an error if the object in question
is not a vector type. A slot called "names" can be used anywhere, but only if it is assigned as
a slot, not via the default names() assignment.

Superclasses: The definition of a class includes the superclasses — the classes that this class ex-
tends. A class Fancy, say, extends a class Simple if an object from the Fancy class has all
the capabilities of the Simple class (and probably some more as well). In particular, and very
usefully, any method defined to work for a Simple object can be applied to a Fancy object as
well.

This relationship is expressed equivalently by saying that Simple is a superclass of Fancy, or
that Fancy is a subclass of Simple.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses
can be defined in three ways. Most commonly, the superclasses are listed in the contains=
argument in the call to setClass that creates the subclass. In this case the subclass will
contain all the slots of the superclass, and the relation between the class is called simple, as
it in fact is. Superclasses can also be defined explicitly by a call to setIs; in this case, the
relation requires methods to be specified to go from subclass to superclass. Thirdly, a class
union is a superclass of all the members of the union. In this case too the relation is simple,
but notice that the relation is defined when the superclass is created, not when the subclass is
created as with the contains= mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These
are considered (and shown) as superclasses at distance 2 from the original class; their direct
superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes
such as method selection.

When superclasses are defined by including the names of superclasses in the contains= arg-
ument to setClass, an object from the class will have all the slots defined for its own class
and all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an
object of class SClassExtension. A list of such objects for the superclasses (and sometimes
for the subclasses) is included in the metadata object defining the class. If you need to compute
with these objects (for example, to compare the distances), call the function extends with
argument fullInfo=TRUE.

Prototype: The objects from a class created by a call to new are defined by the prototype object for
the class and by additional arguments in the call to new, which are passed to a method for that
class for the function initialize.

Each class representation object contains a prototype object for the class (although for a virtual
class the prototype may be NULL). The prototype object must have values for all the slots of
the class. By default, these are the prototypes of the corresponding slot classes. However, the
definition of the class can specify any valid object for any of the slots.

Basic classes

There are a number of 'basic' classes, corresponding to the ordinary kinds of data occurring in
R. For example, "numeric" is a class corresponding to numeric vectors. The other vector basic
classes are "logical", "integer", "complex", "character", "raw", "list" and "expression".
The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that
basic classes are unusual in that the prototype object is from the class itself.

In addition to the vector classes there are also basic classes corresponding to objects in the language,
such as "function" and "call". These classes are subclasses of the virtual class "language".
Finally, there are object types and corresponding basic classes for "abnormal" objects, such as
"environment" and "externalptr". These objects do not follow the functional behavior of the language; in particular, they are not copied and so cannot have attributes or slots defined locally.

All these classes can be used as slots or as superclasses for any other class definitions, although they do not themselves come with an explicit class. For the abnormal object types, a special mechanism is used to enable inheritance as described below.

**Inheriting from non-S4 Classes**

A class definition can extend classes other than regular S4 classes, usually by specifying them in the `contains=` argument to `setClass`. Three groups of such classes behave distinctly:

1. S3 classes, which must have been registered by a previous call to `setOldClass` (you can check that this has been done by calling `getClass`, which should return a class that extends `oldClass`);
2. One of the R object types, typically a vector type, which then defines the type of the S4 objects, but also a type such as `environment` that can not be used directly as a type for an S4 object. See below.
3. One of the pseudo-classes `matrix` and `array`, implying objects with arbitrary vector types plus the `dim` and `dimnames` attributes.

This section describes the approach to combining S4 computations with older S3 computations by using such classes as superclasses. The design goal is to allow the S4 class to inherit S3 methods and default computations in as consistent a form as possible.

As part of a general effort to make the S4 and S3 code in R more consistent, when objects from an S4 class are used as the first argument to a non-default S3 method, either for an S3 generic function (one that calls `UseMethod`) or for one of the primitive functions that dispatches S3 methods, an effort is made to provide a valid object for that method. In particular, if the S4 class extends an S3 class or `matrix` or `array`, and there is an S3 method matching one of these classes, the S4 object will be coerced to a valid S3 object, to the extent that is possible given that there is no formal definition of an S3 class.

For example, suppose "myFrame" is an S4 class that includes the S3 class "data.frame" in the `contains=` argument to `setClass`. If an object from this S4 class is passed to a function, say `as.matrix`, that has an S3 method for "data.frame", the internal code for `UseMethod` will convert the object to a data frame; in particular, to an S3 object whose class attribute will be the vector corresponding to the S3 class (possibly containing multiple class names). Similarly for an S4 object inheriting from "matrix" or "array", the S4 object will be converted to a valid S3 matrix or array.

Note that the conversion is not applied when an S4 object is passed to the default S3 method. Some S3 generics attempt to deal with general objects, including S4 objects. Also, no transformation is applied to S4 objects that do not correspond to a selected S3 method; in particular, to objects from a class that does not contain either an S3 class or one of the basic types. See `asS4` for the transformation details.

In addition to explicit S3 generic functions, S3 methods are defined for a variety of operators and functions implemented as primitives. These methods are dispatched by some internal C code that operates partly through the same code as real S3 generic functions and partly via special considerations (for example, both arguments to a binary operator are examined when looking for methods). The same mechanism for adapting S4 objects to S3 methods has been applied to these computations as well, with a few exceptions such as generating an error if an S4 object that does not extend an appropriate S3 class or type is passed to a binary operator.

The remainder of this section discusses the mechanisms for inheriting from basic object types. See `matrix` or `array` for inheriting from the matrix and array pseudo-classes, or from time-series. For the corresponding details for inheritance from S3 classes, see `setOldClass`. 
An object from a class that directly and simply contains one of the basic object types in \( R \), has implicitly a corresponding .Data slot of that type, allowing computations to extract or replace the data part while leaving other slots unchanged. If the type is one that can accept attributes and is duplicated normally, the inheritance also determines the type of the object; if the class definition has a .Data slot corresponding to a normal type, the class of the slot determines the type of the object (that is, the value of \texttt{typeof(x)}). For such classes, .Data is a pseudo-slot; that is, extracting or setting it modifies the non-slot data in the object. The functions \texttt{getDataPart} and \texttt{setDataPart} are a cleaner, but essentially equivalent way to deal with the data part.

Extending a basic type this way allows objects to use old-style code for the corresponding type as well as S4 methods. Any basic type can be used for .Data, but a few types are treated differently because they do not behave like ordinary objects; for example, "NULL", environments, and external pointers. Classes extend these types by having a slot, .xData, itself inherited from an internally defined S4 class. This slot actually contains an object of the inherited type, to protect computations from the reference semantics of the type. Coercing to the nonstandard object type then requires an actual computation, rather than the "simple" inclusion for other types and classes. The intent is that programmers will not need to take account of the mechanism, but one implication is that you should not explicitly use the type of an S4 object to detect inheritance from an arbitrary object type. Use \texttt{is} and similar functions instead.

### className

\begin{itemize}
  \item \texttt{className()} generates a valid references to a class, including the name of the package containing the class definition. The object returned, from class "className", is the unambiguous way to refer to a class, for example when calling \texttt{setMethod}, just in case multiple definitions of the class exist.
  \item Function "multipleClasses" returns information about multiple definitions of classes with the same name from different packages.
\end{itemize}

#### Usage

\texttt{className(class, package)}

\texttt{multipleClasses(details = FALSE)}
Arguments

class, package The character string name of a class and, optionally, of the package to which it belongs. If argument package is missing and the class argument has a package slot, that is used (in particular, passing in an object from class "className" returns itself in this case, but changes the package slot if the second argument is supplied).

If there is no package argument or slot, a definition for the class must exist and will be used to define the package. If there are multiple definitions, one will be chosen and a warning printed giving the other possibilities.

details If FALSE, the default, multipleClasses() returns a character vector of those classes currently known with multiple definitions.
If TRUE, a named list of those class definitions is returned. Each element of the list is itself a list of the corresponding class definitions, with the package names as the names of the list. Note that identical class definitions will not be considered “multiple” definitions (see the discussion of the details below).

Details

The table of class definitions used internally can maintain multiple definitions for classes with the same name but coming from different packages. If identical class definitions are encountered, only one class definition is kept; this occurs most often with S3 classes that have been specified in calls to setOldClass. For true classes, multiple class definitions are unavoidable in general if two packages happen to have used the same name, independently.

Overriding a class definition in another package with the same name deliberately is usually a bad idea. Although R attempts to keep and use the two definitions (as of version 2.14.0), ambiguities are always possible. It is more sensible to define a new class that extends an existing class but has a different name.

Value

A call to className() returns an object from class "className".

A call to multipleClasses() returns either a character vector or a named list of class definitions. In either case, testing the length of the returned value for being greater than 0 is a check for the existence of multiply defined classes.

Objects from the Class

The class "className" extends "character" and has a slot "package", also of class "character".

Examples

## Not run:
className("vector") # will be found, from package "methods"
className("vector", "magic") # OK, even though the class doesn't exist

className("An unknown class") # Will cause an error

## End(Not run)
Description

These are the objects that hold the definition of classes of objects. They are constructed and stored as meta-data by calls to the function `setClass`. Don’t manipulate them directly, except perhaps to look at individual slots.

Details

Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to `setIs`). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class "classRepresentation", cached for the session or until something happens to change the information. A call to `getClass` returns the completed definition of a class; a call to `getClassDef` returns the stored definition (uncompleted).

In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots `contains` and `subclasses` respectively. It’s in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

Slots

`slots`: A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.

`contains`: A named list of the classes this class ‘contains’; the elements of the list are objects of `SClassExtension`. The list may be only the direct extensions or all the currently known extensions (see the details).

`virtual`: Logical flag, set to `TRUE` if this is a virtual class.

`prototype`: The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to `new` for this class with no special arguments. Don’t mess with the prototype object directly.

`validity`: Optionally, a function to be used to test the validity of objects from this class. See `validObject`.

`access`: Access control information. Not currently used.

`className`: The character string name of the class.

`package`: The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.

`subclasses`: A named list of the classes known to extend this class; the elements of the list are objects of class `SClassExtension`. The list is currently only filled in when completing the class definition (see the details).

`versionKey`: Object of class “externalptr”; eventually will perhaps hold some versioning information, but not currently used.

`sealed`: Object of class “logical”; is this class sealed? If so, no modifications are allowed.

See function `setClass` to supply the information in the class definition. See `Classes_Details` for a more basic discussion of class information.

Documentation

Using and Creating On-line Documentation for Classes and Methods

Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the methods package. Techniques to access this documentation and to create it in R help files are described here.

Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the `?` operator (see `help` for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there is any documentation on the corresponding topics.

Documentation on a class uses the argument `class` on the left of the `?`, and the name of the class on the right; for example,

class ? genericFunction

to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the `?` operator with `methods` as the left-side argument and the name of the function as the right-side argument. For example,

methods ? initialize

asks for documentation on the methods for the `initialize` function.

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the "?" operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.

If you planned to evaluate a function call, say `myFun(x, sqrt(wt))` and wanted to find out something about the method that would be used for this call, put the call on the right of the "?" operator:

?myFun(x, sqrt(wt))

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If `myFun` is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class "maybeNumber" and the second "logical", call the "?" operator, this time with a left-side argument method, and with a function call on the right using the class names as arguments:

method ? myFun("maybeNumber", "logical")
Once again, a method will be selected, this time corresponding to the specified classes, and method documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn’t require you to figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments may take some time, depending on the example. The version with class names does require you to pick classes, but it’s otherwise unambiguous. It has a subtler advantage, in that the classes supplied may be virtual classes, in which case no actual argument will have specifically this class. The class "maybeNumber", for example, might be a class union (see the example for setClassUnion).

In either form, methods will be selected as they would be in actual computation, including use of inheritance and group generic functions. See selectMethod for the details, since it is the function used to find the appropriate method.

Writing Documentation for Methods

The on-line documentation for methods and classes uses some extensions to the R documentation format to implement the requests for class and method documentation described above. See the document Writing R Extensions for the available markup commands (you should have consulted this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file with a skeleton of documentation for the methods defined for a particular generic function:

promptMethods("myFun")

will create a file, ‘myFun-methods.Rd’ with a skeleton of documentation for the methods defined for function myFun. The output from promptMethods is suitable if you want to describe all or most of the methods for the function in one file, separate from the documentation of the generic function itself. Once the file has been filled in and moved to the ‘man’ subdirectory of your source package, requests for methods documentation will use that file, both for specific methods documentation as described above, and for overall documentation requested by

methods ? myFun

You are not required to use promptMethods, and if you do, you may not want to use the entire file created:

- If you want to document the methods in the file containing the documentation for the generic function itself, you can cut-and-paste to move the \alias lines and the Methods section from the file created by promptMethods to the existing file.
- On the other hand, if these are auxiliary methods, and you only want to document the added or modified software, you should strip out all but the relevant \alias lines for the methods of interest, and remove all but the corresponding \item entries in the Methods section. Note that in this case you will usually remove the first \alias line as well, since that is the marker for general methods documentation on this function (in the example, \alias{myfun-methods}).

If you simply want to direct documentation for one or more methods to a particular R documentation file, insert the appropriate alias.
**Description**

The “...” argument in R functions is treated specially, in that it matches zero, one or more actual arguments (and so, objects). A mechanism has been added to R to allow “...” as the signature of a generic function. Methods defined for such functions will be selected and called when all the arguments matching “...” are from the specified class or from some subclass of that class.

**Using "..." in a Signature**

Beginning with version 2.8.0 of R, S4 methods can be dispatched (selected and called) corresponding to the special argument “...”. Currently, “...” cannot be mixed with other formal arguments: either the signature of the generic function is “...” only, or it does not contain “...”. (This restriction may be lifted in a future version.)

Given a suitable generic function, methods are specified in the usual way by a call to `setMethod`. The method definition must be written expecting all the arguments corresponding to “...” to be from the class specified in the method’s signature, or from a class that extends that class (i.e., a subclass of that class).

Typically the methods will pass “...” down to another function or will create a list of the arguments and iterate over that. See the examples below.

When you have a computation that is suitable for more than one existing class, a convenient approach may be to define a union of these classes by a call to `setClassUnion`. See the example below.

**Method Selection and Dispatch for "..."**

See Methods_Details for a general discussion. The following assumes you have read the “Method Selection and Dispatch” section of that documentation.

A method selecting on “...” is specified by a single class in the call to `setMethod`. If all the actual arguments corresponding to “...” have this class, the corresponding method is selected directly.

Otherwise, the class of each argument and that class’ superclasses are computed, beginning with the first “...” argument. For the first argument, eligible methods are those for any of the classes. For each succeeding argument that introduces a class not considered previously, the eligible methods are further restricted to those matching the argument’s class or superclasses. If no further eligible classes exist, the iteration breaks out and the default method, if any, is selected.

At the end of the iteration, one or more methods may be eligible. If more than one, the selection looks for the method with the least distance to the actual arguments. For each argument, any inherited method corresponds to a distance, available from the `contains` slot of the class definition. Since the same class can arise for more than one argument, there may be several distances associated with it. Combining them is inevitably arbitrary: the current computation uses the minimum distance. Thus, for example, if a method matched one argument directly, one as first generation superclass and another as a second generation superclass, the distances are 0, 1 and 2. The current selection computation would use distance 0 for this method. In particular, this selection criterion tends to use a method that matches exactly one or more of the arguments’ class.

As with ordinary method selection, there may be multiple methods with the same distance. A warning message is issued and one of the methods is chosen (the first encountered, which in this case is rather arbitrary).

Notice that, while the computation examines all arguments, the essential cost of dispatch goes up with the number of distinct classes among the arguments, likely to be much smaller than the number of arguments when the latter is large.
Implementation Details

Methods dispatching on “…” were introduced in version 2.8.0 of R. The initial implementation of the corresponding selection and dispatch is in an R function, for flexibility while the new mechanism is being studied. In this implementation, a local version of \texttt{standardGeneric} is inserted in the generic function’s environment. The local version selects a method according to the criteria above and calls that method, from the environment of the generic function. This is slightly different from the action taken by the C implementation when “…” is not involved. Aside from the extra computing time required, the method is evaluated in a true function call, as opposed to the special context constructed by the C version (which cannot be exactly replicated in R code.) However, situations in which different computational results would be obtained have not been encountered so far, and seem very unlikely.

Methods dispatching on arguments other than “…” are \textit{cached} by storing the inherited method in the table of all methods, where it will be found on the next selection with the same combination of classes in the actual arguments (but not used for inheritance searches). Methods based on “…” are also cached, but not found quite as immediately. As noted, the selected method depends only on the set of classes that occur in the “…” arguments. Each of these classes can appear one or more times, so many combinations of actual argument classes will give rise to the same effective signature. The selection computation first computes and sorts the distinct classes encountered. This gives a label that will be cached in the table of all methods, avoiding any further search for inherited classes after the first occurrence. A call to \texttt{showMethods} will expose such inherited methods.

The intention is that the “…” features will be added to the standard C code when enough experience with them has been obtained. It is possible that at the same time, combinations of “…” with other arguments in signatures may be supported.

Examples

```r
cc <- function(...)c(...)
setGeneric("cc")
setMethod("cc", "character", function(...)paste(...))
setClassUnion("Number", c("numeric", "complex"))
setMethod("cc", "Number", function(...) sum(...))
setClass("cdate", contains = "character", slots = c(date = "Date"))
setClass("vdate", contains = "vector", slots = c(date = "Date"))

cd1 <- new("cdate", "abcdef", date = Sys.Date())
cd2 <- new("vdate", "abcdef", date = Sys.Date())
```
environment-class

A formal class for R environments.

Objects from the Class

Objects can be created by calls of the form `new("environment", ...). The arguments in ..., if any, should be named and will be assigned to the newly created environment.

Methods

- **coerce** signature(from = "ANY", to = "environment"): calls `as.environment`
- **initialize** signature(object = "environment"): Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is always created, since environments are not protected by copying.

envRefClass-class  Class "envRefClass"

Description

Support Class to Implement R Objects using Reference Semantics

NOTE:

The software described here is an initial version. The eventual goal is to support reference-style classes with software in R itself or using inter-system interfaces. The current implementation (R version 2.12.0) is preliminary and subject to change, and currently includes only the R-only implementation. Developers are encouraged to experiment with the software, but the description here is more than usually subject to change.

Purpose of the Class

This class implements basic reference-style semantics for R objects. Objects normally do not come directly from this class, but from subclasses defined by a call to setRefClass. The documentation below is technical background describing the implementation, but applications should use the interface documented under setRefClass, in particular the $ operator and field accessor functions as described there.

A Basic Reference Class

The design of reference classes for R divides those classes up according to the mechanism used for implementing references, fields, and class methods. Each version of this mechanism is defined by a basic reference class, which must implement a set of methods and provide some further information used by setRefClass.

The required methods are for operators $ and $<- to get and set a field in an object, and for initialize to initialize objects.

To support these methods, the basic reference class needs to have some implementation mechanism to store and retrieve data from fields in the object. The mechanism needs to be consistent with reference semantics; that is, changes made to the contents of an object are global, seen by any code accessing that object, rather than only local to the function call where the change takes place. As described below, class envRefClass implements reference semantics through specialized use of environment objects. Other basic reference classes may use an interface to a language such as Java or C++ using reference semantics for classes.

Usually, the R user will be able to invoke class methods on the class, using the $ operator. The basic reference class method for $ needs to make this possible. Essentially, the operator must return an R function corresponding to the object and the class method name.

Class methods may include an implementation of data abstraction, in the sense that fields are accessed by “get” and “set” methods. The basic reference class provides this facility by setting the "fieldAccessorGenerator" slot in its definition to a function of one variable. This function will be called by setRefClass with the vector of field names as arguments. The generator function must return a list of defined accessor functions. An element corresponding to a get operation is invoked with no arguments and should extract the corresponding field; an element for a set operation will
evalSource

1139

be invoked with a single argument, the value to be assigned to the field. The implementation needs
to supply the object, since that is not an argument in the method invocation. The mechanism used
currently by envRefClass is described below.
Support Classes
Two virtual classes are supplied to test for reference objects: is(x, "refClass") tests whether
x comes from a class defined using the reference class mechanism described here; is(x,
"refObject") tests whether the object has reference semantics generally, including the previous classes and also classes inheriting from the R types with reference semantics, such as
"environment".
Installed class methods are "classMethodDefinition" objects, with slots that identify the name
of the function as a class method and the other class methods called from this method. The latter
information is determined heuristically when the class is defined by using the codetools recommended package. This package must be installed when reference classes are defined, but is not
needed in order to use existing reference classes.

evalSource

Use Function Definitions from a Source File without Reinstalling a
Package

Description
Definitions of functions and/or methods from a source file are inserted into a package, using the
trace mechanism. Typically, this allows testing or debugging modified versions of a few functions
without reinstalling a large package.
Usage
evalSource(source, package = "", lock = TRUE, cache = FALSE)
insertSource(source, package = "", functions = , methods = ,
force = )

Arguments
source

A file to be parsed and evaluated by evalSource to find the new function and
method definitions.
The argument to insertSource can be an object of class
"sourceEnvironment" returned from a previous call to evalSource If a
file name is passed to insertSource it calls evalSource to obtain the
corresponding object. See the section on the class for details.

package

Optionally, the name of the package to which the new code corresponds and into
which it will be inserted. Although the computations will attempt to infer the
package if it is omitted, the safe approach is to supply it. In the case of a package
that is not attached to the search list, the package name must be supplied.


functions, methods

Optionally, the character-string names of the functions to be used in the insertion. Names supplied in the functions argument are expected to be defined as functions in the source. For names supplied in the methods argument, a table of methods is expected (as generated by calls to `setMethod`, see the details section); methods from this table will be inserted by `insertSource`. In both cases, the revised function or method is inserted only if it differs from the version in the corresponding package as loaded.

If what is omitted, the results of evaluating the source file will be compared to the contents of the package (see the details section).

lock, cache

Optional arguments to control the actions taken by `evalSource`. If `lock` is `TRUE`, the environment in the object returned will be locked, and so will all its bindings. If `cache` is `FALSE`, the normal caching of method and class definitions will be suppressed during evaluation of the source file.

The default settings are generally recommended, the lock to support the credibility of the object returned as a snapshot of the source file, and the second so that method definitions can be inserted later by `insertSource` using the trace mechanism.

force

If `FALSE`, only functions currently in the environment will be redefined, using `trace`. If `TRUE`, other objects/functions will be simply assigned. By default, `TRUE` if neither the `functions` nor the `methods` argument is supplied.

Details

The source file is parsed and evaluated, suppressing by default the actual caching of method and class definitions contained in it, so that functions and methods can be tested out in a reversible way. The result, if all goes well, is an environment containing the assigned objects and metadata corresponding to method and class definitions in the source file.

From this environment, the objects are inserted into the package, into its namespace if it has one, for use during the current session or until reverting to the original version by a call to `untrace`. The insertion is done by calls to the internal version of `trace`, to make reversion possible.

Because the trace mechanism is used, only function-type objects will be inserted, functions themselves or S4 methods.

When the `functions` and `methods` arguments are both omitted, `insertSource` selects all suitable objects from the result of evaluating the source file.

In all cases, only objects in the source file that differ from the corresponding objects in the package are inserted. The definition of “differ” is that either the argument list (including default expressions) or the body of the function is not identical. Note that in the case of a method, there need be no specific method for the corresponding signature in the package: the comparison is made to the method that would be selected for that signature.

Nothing in the computation requires that the source file supplied be the same file as in the original package source, although that case is both likely and sensible if one is revising the package. Nothing in the computations compares source files: the objects generated by evaluating `source` are compared as objects to the content of the package.

Value

An object from class “sourceEnvironment”, a subclass of “environment” (see the section on the class) The environment contains the versions of all object resulting from evaluation of the source file. The class also has slots for the time of creation, the source file and the package name. Future extensions may use these objects for versioning or other code tools.
The object returned can be used in debugging (see the section on that topic) or as the source argument in a future call to insertSource. If only some of the revised functions were inserted in the first call, others can be inserted in a later call without re-evaluating the source file, by supplying the environment and optionally suitable functions and/or methods argument.

Debugging

Once a function or method has been inserted into a package by insertSource, it can be studied by the standard debugging tools; for example, debug or the various versions of trace. Calls to trace should take the extra argument edit = env, where env is the value returned by the call to evalSource. The trace mechanism has been used to install the revised version from the source file, and supplying the argument ensures that it is this version, not the original, that will be traced. See the example below.

To turn tracing off, but retain the source version, use trace(x, edit = env) as in the example. To return to the original version from the package, use untrace(x).

Class "sourceEnvironment"

Objects from this class can be treated as environments, to extract the version of functions and methods generated by evalSource. The objects also have the following slots:

packageName: The character-string name of the package to which the source code corresponds.
dateCreated: The date and time that the source file was evaluated (usually from a call to Sys.time).
sourceFile: The character-string name of the source file used.

Note that using the environment does not change the dateCreated.

See Also

trace for the underlying mechanism, and also for the edit= argument that can be used for somewhat similar purposes; that function and also debug and setBreakpoint, for techniques more oriented to traditional debugging styles. The present function is directly intended for the case that one is modifying some of the source for an existing package, although it can be used as well by inserting debugging code in the source (more useful if the debugging involved is non-trivial). As noted in the details section, the source file need not be the same one in the original package source.

Examples

## Not run:
## Suppose package P0 has a source file "all.R"
## First, evaluate the source, and from it
## insert the revised version of methods for summary()
env <- insertSource("./P0/R/all.R", package = "P0",
  methods = "summary")
## now test one of the methods, tracing the version from the source
trace("summary", signature = "myMat", browser, edit = env)
## After testing, remove the browser() call but keep the source
trace("summary", signature = "myMat", edit = env)
## Now insert all the (other) revised functions and methods
## without re-evaluating the source file.
## The package name is included in the object env.
insertSource(env)

## End(Not run)
findClass  

Find Class Definitions

Description

Functions to find classes: isClass tests for a class; findClass returns the name(s) of packages containing the class; getClasses returns the names of all the classes in an environment, typically a namespace. To examine the definition of a class, use getClass.

Usage

isClass(Class, formal=TRUE, where)

getClasses(where, inherits = missing(where))

findClass(Class, where, unique = "")

## The remaining functions are retained for compatibility
## but not generally recommended

removeClass(Class, where)

resetClass(Class, classDef, where)

sealClass(Class, where)

Arguments

Class  

character string name for the class. The functions will usually take a class definition instead of the string. To restrict the class to those defined in a particular package, set the packageSlot of the character string.

where  

the environment in which to search for the class definition. Defaults to the top-level environment of the calling function. When called from the command line, this has the effect of using all the package environments in the search list.

To restrict the search to classes in a particular package, use where = asNamespace(pkg) with pkg the package name; to restrict it to the exported classes, use where = "package:pkg" after the package is attached to the search list.

formal  

logical is a formal definition required? For S compatibility, and always treated as TRUE.

unique  

if findClass expects a unique location for the class, unique is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.

inherits  

in a call to getClasses, should the value returned include all parent environments of where, or that environment only? Defaults to TRUE if where is omitted, and to FALSE otherwise.

classDef  

For resetClass, the optional class definition.
findMethods

Functions

isClass: Is this the name of a formally defined class?

getClasses: The names of all the classes formally defined on where. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The where argument is used to search only in a particular package.

findClass: The list of environments in which a class definition of Class is found. If where is supplied, a list is still returned, either empty or containing the environment corresponding to where. By default when called from the R session, the global environment and all the currently attached packages are searched.

If unique is supplied as a character string, findClass will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

The remaining functions are retained for back-compatibility and internal use, but not generally recommended.

removeClass: Remove the definition of this class. This can’t be used if the class is in another package, and would rarely be needed in source code defining classes in a package.

resetClass: Reset the internal definition of a class. Not legitimate for a class definition not in this package and rarely needed otherwise.

sealClass: Seal the current definition of the specified class, to prevent further changes, by setting the corresponding slot in the class definition. This is rarely used, since classes in loaded packages are sealed by locking their namespace.

findMethods

Description of the Methods Defined for a Generic Function

Description

The function findMethods converts the methods defined in a table for a generic function (as used for selection of methods) into a list, for study or display. The list is actually from the class listOfMethods (see the section describing the class, below).

The list will be limited to the methods defined in environment where if that argument is supplied and limited to those including one or more of the specified classes in the method signature if that argument is supplied.

To see the actual table (an environment) used for methods dispatch, call getMethodsForDispatch. The names of the list returned by findMethods are the names of the objects in the table.
The function `findMethodSignatures` returns a character matrix whose rows are the class names from the signature of the corresponding methods; it operates either from a list returned by `findMethods`, or by computing such a list itself, given the same arguments as `findMethods`.

The function `hasMethods` returns TRUE or FALSE according to whether there is a non-empty table of methods for function f in the environment or search position where (or for the generic function generally if `where` is missing).

The defunct function `getMethods` is an older alternative to `findMethods`, returning information in the form of an object of class `MethodsList`, previously used for method dispatch. This class of objects is deprecated generally and will disappear in a future version of R.

**Usage**

```r
findMethods(f, where, classes = character(), inherited = FALSE, package = "")
findMethodSignatures(..., target = TRUE, methods = )
hasMethods(f, where, package)
```

## Deprecated in 2010 and defunct in 2015 for 'table = FALSE':
`getMethods(f, where, table = FALSE)`

**Arguments**

- **f**  A generic function or the character-string name of one.

- **where**  Optionally, an environment or position on the search list to look for methods metadata. If `where` is missing, `findMethods` uses the current table of methods in the generic function itself, and `hasMethods` looks for metadata anywhere in the search list.

- **table**  If TRUE in a call to `getMethods` the returned value is the table used for dispatch, including inherited methods discovered to date. Used internally, but since the default result is the now unused `mList` object, the default will likely be changed at some point.

- **classes**  If supplied, only methods whose signatures contain at least one of the supplied classes will be included in the value returned.

- **inherited**  Logical flag; if TRUE, the table of all methods, inherited or defined directly, will be used; otherwise, only the methods explicitly defined. Option TRUE is meaningful only if `where` is missing.

- **...**  In the call to `findMethodSignatures`, any arguments that might be given to `findMethods`.

- **target**  Optional flag to `findMethodSignatures`; if TRUE, the signatures used are the target signatures (the classes for which the method will be selected); if FALSE, they will be the signatures are defined. The difference is only meaningful if `inherited` is TRUE.

- **methods**  In the call to `findMethodSignatures`, an optional list of methods, presumably returned by a previous call to `findMethods`. If missing, that function will be call with the ...arguments.
findMethods

package In a call to hasMethods, the package name for the generic function (e.g., "base" for primitives). If missing this will be inferred either from the "package" attribute of the function name, if any, or from the package slot of the generic function. See 'Details'.

Details

The functions obtain a table of the defined methods, either from the generic function or from the stored metadata object in the environment specified by where. In a call to getMethods, the information in the table is converted as described above to produce the returned value, except with the table argument.

Note that hasMethods, but not the other functions, can be used even if no generic function of this name is currently found. In this case package must either be supplied as an argument or included as an attribute of f, since the package name is part of the identification of the methods tables.

The Class for lists of methods

The class "listOfMethods" returns the methods as a named list of method definitions (or a primitive function, see the slot documentation below). The names are the strings used to store the corresponding objects in the environment from which method dispatch is computed. The current implementation uses the names of the corresponding classes in the method signature, separated by "#" if more than one argument is involved in the signature.

Slots

.Data: Object of class "list" The method definitions.

Note that these may include the primitive function itself as default method, when the generic corresponds to a primitive. (Basically, because primitive functions are abnormal R objects, which cannot currently be extended as method definitions.) Computations that use the returned list to derive other information need to take account of this possibility. See the implementation of findMethodSignatures for an example.

arguments: Object of class "character". The names of the formal arguments in the signature of the generic function.

signatures: Object of class "list". A list of the signatures of the individual methods. This is currently the result of splitting the names according to the "#" separator.

If the object has been constructed from a table, as when returned by findMethods, the signatures will all have the same length. However, a list rather than a character matrix is used for generality. Calling findMethodSignatures as in the example below will always convert to the matrix form.

generic: Object of class "genericFunction". The generic function corresponding to these methods. There are plans to generalize this slot to allow reference to the function.

names: Object of class "character". The names as noted are the class names separated by "#".

Extends

Class "namedList", directly.
Class "list", by class "namedList", distance 2.
Class "vector", by class "namedList", distance 3.

mm <- findMethods("Ops")
findMethodSignatures(methods = mm)
```

---

**fixPre1.8**  
*Fix Objects Saved from R Versions Previous to 1.8*

**Description**

Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function `fixPre1.8` fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

**Usage**

```r
fixPre1.8(names, where)
```

**Arguments**

- `names`: Character vector of the names of all the objects to be fixed and re-assigned.
- `where`: The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to `fixPre1.8`, the global environment if the function is used interactively.

**Details**

The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:

1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that `fixPre1.8` currently fixes only the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

**Value**

The names of all the objects that were in fact re-assigned.
Description

Generic functions (objects from or extending class genericFunction) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

Objects from the Class

Generic functions are created and assigned by setGeneric or setGroupGeneric and, indirectly, by setMethod.

As you might expect setGeneric and setGroupGeneric create objects of class "genericFunction" and "groupGenericFunction" respectively.

Slots

.Data: Object of class "function", the function definition of the generic, usually created automatically as a call to standardGeneric.

generic: Object of class "character", the name of the generic function.

package: Object of class "character", the name of the package to which the function definition belongs (and not necessarily where the generic function is stored). If the package is not specified explicitly in the call to setGeneric, it is usually the package on which the corresponding non-generic function exists.

group: Object of class "list", the group or groups to which this generic function belongs. Empty by default.

valueClass: Object of class "character"; if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).

signature: Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for .... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.

default: Object of class "optionalMethod" (a union of classes "function" and "NULL"), containing the default method for this function if any. Generated automatically and used to initialize method dispatch.

skeleton: Object of class "call", a slot used internally in method dispatch. Don't expect to use it directly.

Extends

Class "function", from data part.
Class "OptionalMethods", by class "function".
Class "PossibleMethod", by class "function".
Methods

Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

Description

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

Usage

```r
isGeneric(f, where, fdef, getName = FALSE)
isGroup(f, where, fdef)
removeGeneric(f, where)

dumpMethod(f, signature, file, where, def)
findFunction(f, generic = TRUE, where = topenv(parent.frame()))
dumpMethods(f, file, signature, methods, where)
signature(...)

removeMethods(f, where = topenv(parent.frame()), all = missing(where))

setReplaceMethod(f, ..., where = topenv(parent.frame()))

getGenerics(where, searchForm = FALSE)
```

Arguments

- `f` The character string naming the function.
- `where` The environment, namespace, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the namespace of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package namespaces, the default is likely to be wrong in such calls.
- `signature` The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. Signatures are matched to the arguments specified in the signature slot of the generic function (see the Details section of the `setMethod` documentation). The signature argument to `dumpMethods` is ignored (it was used internally in previous implementations).
- `file` The file or connection on which to dump method definitions.
- `def` The function object defining the method; if omitted, the current method definition corresponding to the signature.
GenericFunctions

... Named or unnamed arguments to form a signature.

generic In testing or finding functions, should generic functions be included. Supply as FALSE to get only non-generic functions.

fdef Optional, the generic function definition. Usually omitted in calls to isGeneric

getName If TRUE, isGeneric returns the name of the generic. By default, it returns TRUE.

methods The methods object containing the methods to be dumped. By default, the methods defined for this generic (optionally on the specified where location).

all in removeMethods, logical indicating if all (default) or only the first method found should be removed.

searchForm In getGenerics, if TRUE, the package slot of the returned result is in the form used by search(), otherwise as the simple package name (e.g. "package:base" vs "base").

Summary of Functions

isGeneric: Is there a function named f, and if so, is it a generic?

The getName argument allows a function to find the name from a function definition. If it is TRUE then the name of the generic is returned, or FALSE if this is not a generic function definition.

The behavior of isGeneric and getGeneric for primitive functions is slightly different. These functions don’t exist as formal function objects (for efficiency and historical reasons), regardless of whether methods have been defined for them. A call to isGeneric tells you whether methods have been defined for this primitive function, anywhere in the current search list, or in the specified position where. In contrast, a call to getGeneric will return what the generic for that function would be, even if no methods have been currently defined for it.

removeGeneric, removeMethods: Remove all the methods for the generic function of this name.

In addition, removeGeneric removes the function itself; removeMethods restores the non-generic function which was the default method. If there was no default method, removeMethods leaves a generic function with no methods.

standardGeneric: Dispatches a method from the current function call for the generic function f. It is an error to call standardGeneric anywhere except in the body of the corresponding generic function.

Note that standardGeneric is a primitive function in the base package for efficiency reasons, but rather documented here where it belongs naturally.

dumpMethod: Dump the method for this generic function and signature.

findFirst: return a list of either the positions on the search list, or the current top-level environment, on which a function object for name exists. The returned value is always a list, use the first element to access the first visible version of the function. See the example.

NOTE: Use this rather than find with mode="function", which is not as meaningful, and has a few subtle bugs from its use of regular expressions. Also, findFunction works correctly in the code for a package when attaching the package via a call to library.

dumpMethods: Dump all the methods for this generic.

signature: Returns a named list of classes to be matched to arguments of a generic function.

getGenerics: returns the names of the generic functions that have methods defined on where; this argument can be an environment or an index into the search list. By default, the whole search list is used.
The methods definitions are stored with package qualifiers; for example, methods for function "initialize" might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot package of the returned object. The form of the returned name can be plain (e.g., "base"), or in the form used in the search list ("package:base") according to the value of searchForm.

Details

isGeneric: If the fdef argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with f as the name of the generic. (This argument is not available in S-Plus.)

removeGeneric: If where supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.

standardGeneric: Generic functions should usually have a call to standardGeneric as their entire body. They can, however, do any other computations as well.

The usual setGeneric (directly or through calling setMethod) creates a function with a call to standardGeneric.

dumpMethod: The resulting source file will recreate the method.

findFirst: If generic is FALSE, ignore generic functions.

dumpMethods: If signature is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don’t use it if you want compatibility.)

signature: The advantage of using signature is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, signature checks that each of the elements is a single character string.

removeMethods: Returns TRUE if f was a generic function, FALSE (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to setMethod will consistently re-establish the same generic function as before.

require(stats) # for lm

## get the function "myFun" -- throw an error if 0 or > 1 versions visible:
findFirstStrict <- function(fName) {
  allF <- findFunction(fName)
  if(length(allF) == 0)
    stop("No versions of ",fName," visible")
  else if(length(allF) > 1)
    stop(fName," is ambiguous: ", length(allF), " versions")
  else
    get(fName, allF[[1]])
}
try(findFuncStrict("myFun")) # Error: no version
lm <- function(x) x+1
try(findFuncStrict("lm")) # Error: 2 versions
findFuncStrict("findFuncStrict") # just 1 version
rm(lm)

## method dumping -----------------------------------
setClass("A", slots = c(a="numeric"))
setMethod("plot", "A", function(x,y,...){ cat("A meth\n") })
dumpMethod("plot","A", file="")
## Not run:
setMethod("plot", "A",
function (x, y, ...)
{
    cat("AAAAA\n")
})
## End(Not run)
tmp <- tempfile()
dumpMethod("plot","A", file=tmp)
## now remove, and see if we can parse the dump
stopifnot(removeMethod("plot", "A"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"))

## same with dumpMethods():
setClass("B", contains="A")
setMethod("plot", "B", function(x,y,...){ cat("B ...
") })
dumpMethods("plot", file=tmp)
stopifnot(removeMethod("plot", "A"),
    removeMethod("plot", "B"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"),
    is(getMethod("plot", "B"), "MethodDefinition"))

---

getch

Get Class Definition

Description

Get the definition of a class.

Usage

getch (Class, .Force = FALSE, where)
getchDef(Class, where, package, inherits = TRUE)
**Arguments**

- **Class**: the character-string name of the class, often with a "package" attribute as noted below under package.
- **.Force**: if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.
- **where**: environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.
- **package**: the name or environment of the package asserted to hold the definition. If it is a non-empty string it is used instead of where, as the first place to look for the class. Note that the package must be loaded but need not be attached. By default, the package attribute of the Class argument is used, if any. There will usually be a package attribute if Class comes from `class(x)` for some object.
- **inherits**: logical; should the class definition be retrieved from any enclosing environment and also from the cache? If FALSE only a definition in the environment where will be returned.

**Details**

Class definitions are stored in metadata objects in a package namespace or other environment where they are defined. When packages are loaded, the class definitions in the package are cached in an internal table. Therefore, most calls to `getClassDef` will find the class in the cache or fail to find it at all, unless inherits is FALSE, in which case only the environment(s) defined by package or where are searched.

The class cache allows for multiple definitions of the same class name in separate environments, with of course the limitation that the package attribute or package name must be provided in the call to

**Value**

The object defining the class. If the class definition is not found, `getClassDef` returns `NULL`, while `getClass`, which calls `getClassDef`, either generates an error or, if .Force is TRUE, returns a simple definition for the class. The latter case is used internally, but is not typically sensible in user code.

The non-null returned value is an object of class `classRepresentation`. Use functions such as `setClass` and `setClassUnion` to create class definitions.

**References**

**See Also**

`classRepresentation`, `setClass`, `isClass`.

**Examples**

```r
getclass("numeric") ## a built in class
cld <- getClass("thisIsAnUndefinedClass", .Force = TRUE)
cld ## a NULL prototype
## If you are really curious:
```
utils::str(clb)
## Whereas these generate errors:
try(getClass("thisIsAnUndefinedClass"))
try(getClassDef("thisIsAnUndefinedClass"))

---

**getMethod**

Get or Test for the Definition of a Method

### Description

The function `selectMethod()` returns the method that would be selected for a call to function \( f \) if the arguments had classes as specified by `signature`. Failing to find a method is an error, unless `argument optional = TRUE`, in which case `NULL` is returned.

The function `findMethod()` returns a list of environments that contain a method for the specified function and `signature`; by default, these are a subset of the packages in the current search list. See section “Using `findMethod()`” for details.

The function `getMethod()` returns the method corresponding to the function and `signature` supplied similarly to `selectMethod`, but without using inheritance or group generics.

The functions `hasMethod()` and `existsMethod()` test whether `selectMethod()` or `getMethod()`, respectively, finds a matching method.

### Usage

```r
selectMethod(f, signature, optional = FALSE, useInherited = ,
        mlist = , fdef = , verbose = , doCache = )
```

```r
findMethod(f, signature, where)
```

```r
getMethod(f, signature = character(), where, optional = FALSE,
        mlist, fdef)
```

```r
existsMethod(f, signature = character(), where)
```

```r
hasMethod(f, signature = character(), where)
```

### Arguments

- `f`  
  a generic function or the character-string name of one.

- `signature`  
  the signature of classes to match to the arguments of \( f \). See the details below.

- `where`  
  the environment in which to look for the method(s). By default, if the call comes from the command line, the table of methods defined in the generic function itself is used, except for `findMethod` (see the section below).

- `optional`  
  if the selection in `selectMethod` does not find a valid method an error is generated, unless `optional` is `TRUE`, in which case the value returned is `NULL`.

- `mlist, fdef, useInherited, verbose, doCache`
  optional arguments to `getMethod` and `selectMethod` for internal use. Avoid these: some will work as expected and others will not, and none of them is required for normal use of the functions. But see the section “Methods for `as()`” for nonstandard inheritance.
Details

The signature argument specifies classes, corresponding to formal arguments of the generic function; to be precise, to the signature slot of the generic function object. The argument may be a vector of strings identifying classes, and may be named or not. Names, if supplied, match the names of those formal arguments included in the signature of the generic. That signature is normally all the arguments except .... However, generic functions can be specified with only a subset of the arguments permitted, or with the signature taking the arguments in a different order.

It's a good idea to name the arguments in the signature to avoid confusion, if you're dealing with a generic that does something special with its signature. In any case, the elements of the signature are matched to the formal signature by the same rules used in matching arguments in function calls (see \texttt{match.call}).

The strings in the signature may be class names, "missing" or "ANY". See \texttt{Methods_Details} for the meaning of these in method selection. Arguments not supplied in the signature implicitly correspond to class "ANY"; in particular, giving an empty signature means to look for the default method.

A call to \texttt{getMethod} returns the method for a particular function and signature. The search for the method makes no use of inheritance.

The function \texttt{selectMethod} also looks for a method given the function and signature, but makes full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into account just as they would be in dispatching a method for the corresponding signature, with the one exception that conditional inheritance is not used. Like \texttt{getMethod}, \texttt{selectMethod} returns \texttt{NULL} or generates an error if the method is not found, depending on the argument optional.

Both \texttt{selectMethod} and \texttt{getMethod} will normally use the current version of the generic function in the R session, which has a table of the methods obtained from all the packages loaded in the session. Optional arguments can cause a search for the generic function from a specified environment, but this is rarely a useful idea. In contrast, \texttt{findMethod} has a different default and the optional \texttt{where=} argument may be needed. See the section “Using \texttt{findMethod}()”.

The functions \texttt{existsMethod} and \texttt{hasMethod} return TRUE or FALSE according to whether a method is found, the first corresponding to \texttt{getMethod} (no inheritance) and the second to \texttt{selectMethod}.

Value

The call to \texttt{selectMethod} or \texttt{getMethod} returns the selected method, if one is found. (This class extends function, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if optional is FALSE and \texttt{NULL} is returned if optional is TRUE.

The returned method object is a \texttt{MethodDefinition} object, except that the default method for a primitive function is required to be the primitive itself. Note therefore that the only reliable test that the search failed is \texttt{is.null()).

The returned value of \texttt{findMethod} is a list of environments in which a corresponding method was found; that is, a table of methods including the one specified.

Using \texttt{findMethod}()

As its name suggests, this function is intended to behave like \texttt{find}, which produces a list of the packages on the current search list which have, and have exported, the object named. That’s what \texttt{findMethod} does also, by default. The “exported” part in this case means that the package’s namespace has an \texttt{exportMethods} directive for this generic function.

An important distinction is that the absence of such a directive does not prevent methods from the package from being called once the package is loaded. Otherwise, the code in the package could not use un-exported methods.
So, if your question is whether loading package thisPkg will define a method for this function and signature, you need to ask that question about the namespace of the package:

```r
findMethod(f, signature, where = asNamespace("thisPkg"))
```

If the package did not export the method, attaching it and calling findMethod with no where argument will not find the method.

Notice also that the length of the signature must be what the corresponding package used. If thisPkg had only methods for one argument, only length-1 signatures will match (no trailing "ANY"), even if another currently loaded package had signatures with more arguments.

**Methods for `as()`**

The function `setAs` allows packages to define methods for coercing one class of objects to another class. This works internally by defining methods for the generic function `coerce(from, to)`, which can not be called directly.

The R evaluator selects methods for this purpose using a different form of inheritance. While methods can be inherited for the object being coerced, they cannot inherit for the target class, since the result would not be a valid object from that class. If you want to examine the selection procedure, you must supply the optional argument `useInherited = c(TRUE, FALSE)` to `selectMethod`.

**References**

**See Also**

`Methods_Details` for the details of method selection; `GenericFunctions` for other functions manipulating methods and generic function objects; `MethodDefinition` for the class that represents method definitions.

**Examples**

```r
testFun <- function(x)x
setGeneric("testFun")
setMethod("testFun", "numeric", function(x)x+1)

hasMethod("testFun", "numeric") # TRUE

hasMethod("testFun", "integer") # TRUE, inherited

existsMethod("testFun", "integer") # FALSE

hasMethod("testFun") # TRUE, default method

hasMethod("testFun", "ANY")
```
**getPackageName**

*The Name associated with a Given Package*

**Description**

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

**Usage**

```r
getPackageName(where, create = TRUE)
setPackageName(pkg, env)

packageSlot(object)
packageSlot(object) <- value
```

**Arguments**

- `where`: the environment or position on the search list associated with the desired package.
- `object`: object providing a character string name, plus the package in which this object is to be found.
- `value`: the name of the package.
- `create`: flag, should a package name be created if none can be inferred? If `TRUE` and no non-empty package name is found, the current date and time are used as a package name, and a warning is issued. The created name is stored in the environment if that environment is not locked.
- `pkg, env`: make the string in `pkg` the internal package name for all computations that set class and method definitions in environment `env`.

**Details**

Package names are normally installed during loading of the package, by the `INSTALL` script or by the `library` function. (Currently, the name is stored as the object `.packageName` but don’t trust this for the future.)

**Value**

- `getPackageName` returns the character-string name of the package (without the extraneous "package:" found in the search list).
- `packageSlot` returns or sets the package name slot (currently an attribute, not a formal slot, but this may change someday).
- `setPackageName` can be used to establish a package name in an environment that would otherwise not have one. This allows you to create classes and/or methods in an arbitrary environment, but it is usually preferable to create packages by the standard R programming tools (`package.skeleton`, etc.)
hasArg

Description
Returns TRUE if name corresponds to an argument in the call, either a formal argument to the function, or a component of . . . , and FALSE otherwise.

Usage
hasArg(name)

Arguments
name The name of a potential argument, as an unquoted name or character string.

Details
The expression hasArg(x), for example, is similar to !missing(x), with two exceptions. First, hasArg will look for an argument named x in the call if x is not a formal argument to the calling function, but . . . is. Second, hasArg never generates an error if given a name as an argument, whereas missing(x) generates an error if x is not a formal argument.

Value
Always TRUE or FALSE as described above.

See Also
missing

Examples
ftest <- function(x1, ...) c(hasArg(x1), hasArg("y2"))

ftest(1) ## c(TRUE, FALSE)
ftest(1, 2) ## c(TRUE, FALSE)
ftest(y2 = 2) ## c(FALSE, TRUE)
ftest(y = 2) ## c(FALSE, FALSE) (no partial matching)
ftest(y2 = 2, x = 1) ## c(TRUE, TRUE) partial match x1
Description

The implicit generic mechanism stores generic versions of functions in a table in a package. The package does not want the current version of the function to be a generic, however, and retains the non-generic version.

When a call to `setMethod` or `setGeneric` creates a generic version for one of these functions, the object in the table is used. This mechanism is only needed if special arguments were used to create the generic; e.g., the `signature` or the `valueClass` options.

Function `implicitGeneric()` returns the implicit generic version, `setGenericImplicit()` turns a generic implicit, `prohibitGeneric()` prevents your function from being made generic, and `registerImplicitGenerics()` saves a set of implicit generic definitions in the cached table of the current session.

Usage

```r
implicitGeneric(name, where, generic)
setGenericImplicit(name, where, restore = TRUE)
prohibitGeneric(name, where)
registerImplicitGenerics(what, where)
```

Arguments

- `name`: Character string name of the function.
- `where`: Package or environment in which to register the implicit generics. When using the functions from the top level of your own package source, this argument should be omitted.
- `generic`: Obsolete, and likely to be deprecated.
- `restore`: Should the non-generic version of the function be restored?.
- `what`: Optional table of the implicit generics to register, but nearly always omitted, when it defaults to a standard metadata name.

Details

Multiple packages may define methods for the same function, to apply to classes defined in that package. Arithmetic and other operators, `plot()` and many other basic computations are typical examples. It’s essential that all such packages write methods for the *same* definition of the generic function. So long as that generic uses the default choice for signature and other parameters, nothing needs to be done.

If the generic has special properties, these need to be ensured for all packages creating methods for it. The simplest solution is just to make the function generic in the package that originally owned it. If for some reason the owner(s) of that package are unwilling to do this, the alternative is to define the correct generic, save it in a special table and restore the non-generic version by calling `setGenericImplicit`.

Note that the package containing the function can define methods for the implicit generic as well; when the implicit generic is made a real generic, those methods will be included.
The usual reason for having a non-default implicit generic is to provide a non-default signature, and the usual reason for that is to allow lazy evaluation of some arguments. All arguments in the signature of a generic function must be evaluated at the time the function needs to select a method. In the base function `with()` in the example below, evaluation of the argument `expr` must be delayed; therefore, it is excluded from the signature.

If you want to completely prohibit anyone from turning your function into a generic, call `prohibitGeneric()`.

Function `implicitGeneric()` returns the implicit generic version of the named function. If there is no table of these or if this function is not in the table, the result of a simple call `setGeneric(name)` is returned.

**Value**

`Function implicitGeneric()` returns the implicit generic definition (and caches that definition the first time if it has to construct it).

The other functions exist for their side effect and return nothing useful.

**Implicit Generics for Base Functions**

Implicit generic versions exist for some functions in the packages supplied in the distribution of R itself. These are stored in the ‘methods’ package itself and will always be available.

As emphasized repeatedly in the documentation, `setGeneric()` calls for a function in another package should never have non-default settings for arguments such as `signature`. The reasoning applies specially to functions in supplied packages, since methods for these are likely to exist in multiple packages. A call to `implicitGeneric()` will show the generic version.

**See Also**

`setGeneric`

**Examples**

### How we would make the function with() into a generic:

```r
## Since the second argument, 'expr' is used literally, we want
## with() to only have "data" in the signature.

## Not run:
setGeneric("with", signature = "data")
## Now we could predefine methods for "with" if we wanted to.

## When ready, we store the generic as implicit, and restore the original
setGenericImplicit("with")

## End(Not run)

implicitGeneric("with")
```

# (This implicit generic is stored in the 'methods' package.)
inheritedSlotNames  

*Names of Slots Inherited From a Super Class*

**Description**

For a class (or class definition, see `getClass` and the description of class `classRepresentation`), give the names which are inherited from “above”, i.e., super classes, rather than by this class’ definition itself.

**Usage**

```
inheritedSlotNames(Class, where = topoenv(parent.frame()))
```

**Arguments**

- **Class**: character string or `classRepresentation`, i.e., resulting from `getClass`.
- **where**: environment, to be passed further to `isClass` and `getClass`.

**Value**

character vector of slot names, or `NULL`.

**See Also**

`slotNames`, `slot`, `setClass`, etc.

**Examples**

```
.srch <- search()
library(stats4)
inheritedSlotNames("mle")

if(require("Matrix", quietly = TRUE)) withAutoprint({
inheritedSlotNames("Matrix")  # NULL
  ## whereas
  inheritedSlotNames("sparseMatrix")  # --> Dim & Dimnames
  ## i.e. inherited from "Matrix" class
  cl <- getClass("dgCMatrix")    # six slots, etc
  inheritedSlotNames(cl) # *all* six slots are inherited
})

## Not run:
## detach package we've attached above:
for(n in rev(which(is.na(match(search(), .srch))))
  try( detach(pos = n) )

## End(Not run)
```
Description

The arguments to function `new` to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function `initialize` for the class. This documentation describes some existing methods, and also outlines how to write new ones.

Methods

`signature(.Object = "ANY")` The default method for `initialize` takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, `as(object, Class, strict = FALSE)`).

Unnamed arguments must be objects of this class, of one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object. If the object is from a subclass, the new object is that argument, coerced to the current class.

Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

`signature(.Object = "traceable")` Objects of a class that extends `traceable` are used to implement debug tracing (see class `traceable` and `trace`).

The `initialize` method for these classes takes special arguments `def`, `tracer`, `exit`, `at`, `print`. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to `trace`.

`signature(.Object = "environment"), signature(.Object = ".environment")` The `initialize` method for environments takes a named list of objects to be used to initialize the environment. Subclasses of "environment" inherit an initialize method through ".environment", which has the additional effect of allocating a new environment. If you define your own method for such a subclass, be sure either to call the existing method via `callNextMethod` or allocate an environment in your method, since environments are references and are not duplicated automatically.

`signature(.Object = "signature")` This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a `signature` slot to define the argument names. See `Methods_Details` for details.

Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and `...`. Nearly always, `initialize` is called from `new`, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`. 
You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to .Object (always) and ...(optionally). For example, the method for class "traceable" documented above would be created by a call to setMethod of the form:

```
setMethod("initialize", "traceable",
  function(.Object, def, tracer, exit, at, print) { .... }
)
```

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the initialize method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument \texttt{x}, but you also want users to be able to set slots specifically. If you want \texttt{x} to override the slot information, the beginning of your method definition might look something like this:

```
function(.Object, x, ...) {
  Object <- callNextMethod(.Object, ...)
  if(!missing(x)) { # do something with \texttt{x}
```

You could also choose to have the inherited method override, by first interpreting \texttt{x}, and then calling the next method.

---

### Description

The majority of applications using methods and classes will be in \texttt{R} packages implementing new computations for an application, using new classes of objects that represent the data and results. Computations will be implemented using methods that implement functional computations when one or more of the arguments is an object from these classes.

Calls to the functions \texttt{setClass()} define the new classes; calls to \texttt{setMethod} define the methods. These, along with ordinary \texttt{R} computations, are sufficient to get started for most applications.

Classes are defined in terms of the data in them and what other classes of data they inherit from. Section ‘Defining Classes’ outlines the basic design of new classes.

Methods are \texttt{R} functions, often implementing basic computations as they apply to the new classes of objects. Section ‘Defining Methods’ discusses basic requirements and special tools for defining methods.

The classes discussed here are the original functional classes. \texttt{R} also supports formal classes and methods similar to those in other languages such as Python, in which methods are part of class definitions and invoked on an object. These are more appropriate when computations expect references to objects that are persistent, making changes to the object over time. See ReferenceClasses and Chapter 9 of the reference for the choice between these and S4 classes.
Defining Classes

All objects in R belong to a class; ordinary vectors and other basic objects are built-in (builtin-class). A new class is defined in terms of the named slots that it has and/or in terms of existing classes that it inherits from, or contains (discussed in ‘Class Inheritance’ below). A call to setClass() names a new class and uses the corresponding arguments to define it.

For example, suppose we want a class of objects to represent a collection of positions, perhaps from GPS readings. A natural way to think of these in R would have vectors of numeric values for latitude, longitude and altitude. A class with three corresponding slots could be defined by:

```r
Pos <- setClass("Pos", slots = c(latitude = "numeric", longitude = "numeric", altitude = "numeric"))
```

The value returned is a function, typically assigned as here with the name of the class. Calling this function returns an object from the class; its arguments are named with the slot names. If a function in the class had read the corresponding data, perhaps from a CSV file or from a database, it could return an object from the class by:

```r
Pos(latitude = x, longitude = y, altitude = z)
```

The slots are accessed by the `@` operator; for example, if `g` is an object from the class, `g@latitude`.

In addition to returning a generator function the call to setClass() assigns a definition of the class in a special metadata object in the package’s namespace. When the package is loaded into an R session, the class definition is added to a table of known classes.

To make the class and the generating function publicly available, the package should include `POS` in `exportClasses()` and `export()` directives in its `NAMESPACE` file:

```r
exportClasses(Pos); export(Pos)
```

Defining Methods

Defining methods for an R function makes that function generic. Instead of a call to the function always being carried out by the same method, there will be several alternatives. These are selected by matching the classes of the arguments in the call to a table in the generic function, indexed by classes for one or more formal arguments to the function, known as the signatures for the methods.

A method definition then specifies three things: the name of the function, the signature and the method definition itself. The definition must be a function with the same formal arguments as the generic.

For example, a method to make a plot of an object from class "Pos" could be defined by:

```r
setMethod("plot", c("Pos", "missing"), function(x, y, ...) { plotPos(x, y) })
```

This method will match a call to `plot()` if the first argument is from class "Pos" or a subclass of that. The second argument must be missing; only a missing argument matches that class in the signature. Any object will match class "ANY" in the corresponding position of the signature.

Class Inheritance

A class may inherit all the slots and methods of one or more existing classes by specifying the names of the inherited classes in the `contains =` argument to `setClass()`.

To define a class that extends class "Pos" to a class "GPS" with a slot for the observation times:

```r
GPS <- setClass("GPS", slots = c(time = "POSIXt"), contains = "Pos")
```

The inherited classes may be S4 classes, S3 classes or basic data types. S3 classes need to be identified as such by a call to `setOldClass()`: most S3 classes in the base package and many in the other built-in packages are already declared, as is "POSIXt". If it had not been, the application package should contain:
Inheriting from one of the R types is special. Objects from the new class will have the same type. A class \texttt{Currency} that contains numeric data plus a slot "unit" would be created by

\begin{verbatim}
Currency <- setClass("Currency", slots = c(unit = "character"), contains = "numeric")
\end{verbatim}

Objects created from this class will have type "numeric" and inherit all the builtin arithmetic and other computations for that type. Classes can only inherit from at most one such type; if the class does not inherit from a type, objects from the class will have type "S4".

References

Chambers, John M. (2016) \textit{Extending R}, Chapman & Hall. (Chapters 9 and 10.)

\begin{verbatim}
is

\textbf{Is an Object from a Class?}

\textbf{Description}

Functions to test inheritance relationships between an object and a class or between two classes (extends).

\textbf{Usage}

\begin{verbatim}
is(object, class2)
extends(class1, class2, maybe = TRUE, fullInfo = FALSE)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{object} any R object.
  \item \texttt{class1, class2} the names of the classes between which \texttt{is} relations are to be examined defined, or (more efficiently) the class definition objects for the classes.
  \item \texttt{fullInfo} In a call to \texttt{extends}, with \texttt{class2} missing, \texttt{fullInfo} is a flag, which if TRUE causes a list of objects of class \texttt{SClassExtension} to be returned, rather than just the names of the classes. Only the distance slot is likely to be useful in practice; see the ‘Selecting Superclasses’ section;
  \item \texttt{maybe} What to return for conditional inheritance. But such relationships are rarely used and not recommended, so this argument should not be needed.
\end{itemize}

\textbf{Selecting Superclasses}

A call to \texttt{selectSuperClasses(cl)} returns a list of superclasses, similarly to \texttt{extends(cl)}. Additional arguments restrict the class names returned to direct superclasses and/or to non-virtual classes.

Either way, programming with the result, particularly using \texttt{sapply}, can be useful.

To find superclasses with more generally defined properties, one can program with the result returned by \texttt{extends} when called with one class as argument. By default, the call returns a character vector including the name of the class itself and of all its superclasses. Alternatively, if
extends is called with fullInfo = TRUE, the return value is a named list, its names being the previous character vector. The elements of the list corresponding to superclasses are objects of class SClassExtension. Of the information in these objects, one piece can be useful: the number of generations between the classes, given by the "distance" slot.

Programming with the result of the call to extends, particularly using sapply, can select superclasses. The programming technique is to define a test function that returns TRUE for superclasses or relationships obeying some requirement. For example, to find only next-to-direct superclasses, use this function with the list of extension objects:

```r
function(what) is(what, "SClassExtension") && what@distance == 2
```

or, to find only superclasses from "myPkg", use this function with the simple vector of names:

```r
function(what) getClassDef(what)@package == "myPkg"
```

Giving such functions as an argument to sapply called on the output of extends allows you to find superclasses with desired properties. See the examples below.

Note that the function using extension objects must test the class of its argument since, unfortunately for this purpose, the list returned by extends includes class1 itself, as the object TRUE.

References

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also

Although inherits is defined for S3 classes, it has been modified so that the result returned is nearly always equivalent to is, both for S4 and non-S4 objects. Since it is implemented in C, it is somewhat faster. The only non-equivalences arise from use of setIs, which should rarely be encountered.

Examples

```r
## Not run:  
## this example can be run if package XRPython from CRAN is installed.
supers <- extends("PythonInterface")
## find all the superclasses from package XR
fromXR <- sapply(supers,
    function(what) getClassDef(what)@package == "XR")
## print them
supers[fromXR]

## find all the superclasses at distance 2
superRelations <- extends("PythonInterface", fullInfo = TRUE)
dist2 <- sapply(superRelations,
    function(what) is(what, "SClassExtension") && what@distance == 2)
## print them
names(superRelations)[dist2]

## End(Not run)
```
isSealedMethod  

Check for a Sealed Method or Class

Description

These functions check for either a method or a class that has been sealed when it was defined, and which therefore cannot be re-defined.

Usage

isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)

Arguments

f  
The quoted name of the generic function.

signature  
The class names in the method’s signature, as they would be supplied to setMethod.

fdef  
Optional, and usually omitted: the generic function definition for f.

Class  
The quoted name of the class.

where  
where to search for the method or class definition. By default, searches from the top environment of the call to isSealedMethod or isSealedClass, typically the global environment or the namespace of a package containing a call to one of the functions.

Details

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if one of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the sealed argument to setClass or setMethod.

Value

The functions return FALSE if the method or class is not sealed (including the case that it is not defined); TRUE if it is.

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)
language-class

Examples

```r
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track", slots = c(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```

Classes to Represent Unevaluated Language Objects

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as `quote`.

Usage

```r
### each of these classes corresponds to an unevaluated object
### in the S language.
### The class name can appear in method signatures,
### and in a few other contexts (such as some calls to as()).

"(" 
"<-" 
"call" 
"for" 
"if" 
"repeat" 
"while" 
"name" 
"{" 

### Each of the classes above extends the virtual class
"language"
```

Objects from the Class

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to `new(Class, ...)`, where `Class` is the quoted class name, and the `...` arguments are either empty or a `single` object that is from this class (or an extension).
LinearMethodsList-class

Methods

coerce signature(from = "ANY", to = "call"). A method exists for as(object, "call"), calling as.call().

Examples

showClass("language")

is(quote(sin(x))) # "call" "language"

(ff <- new("if")) ; is(ff) # "if" "language"

(ff <- new("for")) ; is(ff) # "for" "language"

LinearMethodsList-class

Class "LinearMethodsList"

Description

A version of methods lists that has been ‘linearized’ for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.

Objects from the Class

The function linearizeMlist converts an ordinary methods list object into the linearized form.

Slots

methods: Object of class "list", the method definitions.

arguments: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.

classes: Object of class "list", the corresponding classes in the signatures.

generic: Object of class "genericFunction"; the generic function to which the methods correspond.

Future Note

The current version of linearizeMlist does not take advantage of the MethodDefinition class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don’t write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function linearizeMlist for the computation, and class MethodsList for the original, recursive form.
Description

Local reference classes are modified ReferenceClasses that isolate the objects to the local frame. Therefore, they do not propagate changes back to the calling environment. At the same time, they use the reference field semantics locally, avoiding the automatic duplication applied to standard R objects.

The current implementation has no special construction. To create a local reference class, call setRefClass() with a contains= argument that includes "localRefClass". See the example below.

Local reference classes operate essentially as do regular, functional classes in R; that is, changes are made by assignment and take place in the local frame. The essential difference is that replacement operations (like the change to the twiddle field in the example) do not cause duplication of the entire object, as would be the case for a formal class or for data with attributes or in a named list. The purpose is to allow large objects in some fields that are not changed along with potentially frequent changes to other fields, but without copying the large fields.

Usage

setRefClass(Class, fields = , contains = c("localRefClass","..."), methods = , where = , ...)

Details

Localization of objects is only partially automated in the current implementation. Replacement expressions using the $<- operator are safe.

However, if reference methods for the class themselves modify fields, using $<-, for example, then one must ensure that the object is local to the relevant frame before any such method is called. Otherwise, standard reference class behavior still prevails.

There are two ways to ensure locality. The direct way is to invoke the special method x$ensureLocal() on the object. The other way is to modify a field explicitly by x$field <- ... It’s only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it’s done, localization must occur before any methods make changes. (Eventually, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

Author(s)

John Chambers

Examples

## class "myIter" has a BigData field for the real (big) data
## and a "twiddle" field for some parameters that it twiddles
## (for some reason)
myIter <- setRefClass("myIter", contains = "localRefClass",
    fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big

twiddler <- function(x, n) {
    x$ensureLocal() # see the Details. Not really needed in this example
    for(i in seq_len(n)) {
        x$twiddle <- x$twiddle + rnorm(length(x$twiddle))
        ## then do something ....
        ## Snooping in gdb, etc will show that x$BigData is not copied
    }
    return(x)
}

x2 <- twiddler(x1, 10)
stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))

makeClassRepresentation

Create a Class Definition

Description

Constructs an object of class classRepresentation to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as setClass would do.

Usage

makeClassRepresentation(name, slots=list(), superClasses=character(),
    prototype=NULL, package, validity, access,
    version, sealed, virtual=NA, where)

Arguments

name character string name for the class
slots named list of slot classes as would be supplied to setClass, but without the unnamed arguments for superClasses if any.
superClasses what classes does this class extend
prototype an object providing the default data for the class, e.g., the result of a call to prototype.
package The character string name for the package in which the class will be stored; see getPackageName.
validity Optional validity method. See validObject, and the discussion of validity methods in the reference.
access Access information. Not currently used.
version Optional version key for version control. Currently generated, but not used.
**method.skeleton**

sealed  Is the class sealed? See `setClass`.

virtual Is this known to be a virtual class?

where  The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under `GenericFunctions`.

**method.skeleton**  
Create a Skeleton File for a New Method

**Description**

This function writes a source file containing a call to `setMethod` to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

**Usage**

```r
method.skeleton(generic, signature, file, external = FALSE, where)
```

**Arguments**

- `generic`: the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to `setMethod`.

- `signature`: the method signature, as it would be given to `setMethod`

- `file`: a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R". To write multiple method skeletons to one file, open the file connection first and then pass it to `method.skeleton()` in multiple calls.

- `external`: flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to `setMethod`. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.

- `where`: The environment in which to look for the function; by default, the top-level environment of the call to `method.skeleton`.

**Value**

The `file` argument, invisibly, but the function is used for its side effect.
See Also

`setMethod`, `package.skeleton`

Examples

```
setClass("track", slots = c(x = "numeric", y = "numeric"))
method.skeleton("show", "track") # writes show_track.R
method.skeleton("Ops", c("track", "track")) # writes "Ops_track_track.R"

# write multiple method skeletons to one file
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
close(con)
```

MethodDefinition-class

*Classes to Represent Method Definitions*

Description

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

Details

Method definition objects are functions with additional information defining how the function is being used as a method. The target slot is the class signature for which the method will be dispatched, and the defined slot the signature for which the method was originally specified (that is, the one that appeared in some call to `setMethod`).

Objects from the Class

The action of setting a method by a call to `setMethod` creates an object of this class. It’s unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to `setMethod` with argument `sealed = TRUE`. It has the same representation as "MethodDefinition".

Slots

- `.Data`: Object of class "function"; the data part of the definition.
- `target`: Object of class "signature"; the signature for which the method was wanted.
- `defined`: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to target.
- `generic`: Object of class "character"; the function for which the method was created.
**Methods**

**Description**

You have navigated to an old link to documentation of S4 methods.

For basic use of classes and methods, see *Introduction*; to create new method definitions, see *setMethod*; for technical details on S4 methods, see *Methods_Details*.

**References**

**MethodsList-class**

Class MethodsList, Defunct Representation of Methods

**Description**

This class of objects was used in the original implementation of the package to control method dispatch. Its use is now defunct, but object appear as the default method slot in generic functions. This and any other remaining uses will be removed in the future.

For the modern alternative, see *listOfMethods*.

The details in this documentation are retained to allow analysis of old-style objects.

**Details**

Suppose a function \( f \) has formal arguments \( x \) and \( y \). The methods list object for that function has the object \( \text{as.name}("x") \) as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to \( x \) is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which \( x \) is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, \( y \).

Each method corresponds conceptually to a *signature*: that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for \( x \), finding that the selection was another methods list and then selecting class "numeric" for \( y \) would produce a method associated with the signature \( x = "\text{track}", y = "\text{numeric}". \)
Methods_Details

Slots

argument: Object of class "name". The name of the argument being used for dispatch at this level.

methods: A named list of the methods (and method lists) defined explicitly for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.

allMethods: A named list, contains all the directly defined methods from the methods slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see Methods_Details).

Extends

Class "OptionalMethods", directly.

Methods_Details  General Information on Methods

Description

This documentation covers some general topics on how methods work and how the methods package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn’t work as expected.

For additional information see documentation for the important steps: (setMethod(), setClass() and setGeneric()). Also Methods_for_Nongenerics on defining formal methods for functions(2,5),(993,992) that are not currently generic functions; Methods_for_S3 for the relation to S3 classes and methods; Classes_Details for class definitions and Chapters 9 and 10 of the reference.

How Methods Work

A call to a generic function selects a method matching the actual arguments in the call. The body of the method is evaluated in the frame of the call to the generic function. A generic function is identified by its name and by the package to which it correspond. Unlike ordinary functions, the generic has a slot that specifies its package.

In an R session, there is one version of each such generic, regardless of where the call to that generic originated, and the generic function has a table of all the methods currently available for it; that is, all the methods in packages currently loaded into the session.

Methods are frequently defined for functions that are non-generic in their original package, for example, for function plot() in package graphics. An identical version of the corresponding generic function may exist in several packages. All methods will be dispatched consistently from the R session.

Each R package with a call to setMethod in its source code will include a methods metadata object for that generic. When the package is loaded into an R session, the methods for each generic function are cached, that is, added to the environment of the generic function. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see GroupGenericFunctions) to find an applicable method. See the “Method Selection and Dispatch” section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection.
In contrast, it is possible for the same function name to refer to more than one generic function, when these have different package slots. In the latter case, R considers the functions unrelated: A generic function is defined by the combination of name and package. See the “Generic Functions” section below.

The methods for a generic are stored according to the corresponding signature in the call to `setMethod` that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the "signature" slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except . . . , in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be inactive if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using lazy evaluation. Therefore, it’s important to exclude from the signature any arguments that need to be dealt with symbolically (such as the `expr` argument to function `with`). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.

### Method Selection: Details

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of `class(x)` for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes. A method found by this search is cached in the generic function so that future calls with the same argument classes will not require repeating the search. In any likely application, the search for inherited methods will be a negligible overhead.

Each class definition may include a list of one or more direct superclasses of the new class. The simplest and most common specification is by the `contains=` argument in the call to `setClass`. Each class named in this argument is a superclass of the new class. A class will also have as a direct superclass any class union to which it is a member. Class unions are created by a call to `setClassUnion`. Additional members can be added to the union by a simple call to `setIs`. Superclasses specified by either mechanism are the direct superclasses.

Inheritance specified in either of these forms is simple in the sense that all the information needed for the superclass is asserted to be directly available from the object. R inherited from S a more general form of inheritance in which inheritance may require some transformation or be conditional on a test. This more general form has not proved to be useful in general practical situations. Since it also adds some computational costs non-simple inheritance is not recommended. See `setIs` for the general version.

The direct superclasses themselves may have direct superclasses and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. The distance between the two classes is defined to be the number of generations: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. To see all the superclasses, with their distance, print the class definition by calling
**Methods_Details**

**getClass.** In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

When a method is to be selected by inheritance, a search is made in the table for all methods corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the recommended package Matrix). This class has (currently) three direct superclasses and through these additional superclasses at distances 2 through 4. A method that had been defined for any of these classes or for class "ANY" (the default method) would be eligible. Methods for the shortest difference are preferred. If there is only one best method in this sense, method selection is unambiguous.

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function outer generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the distance to the superclass defines which method(s) are preferred for that argument. A method is considered best for selection if it is among the best (i.e., has the least distance) for each argument.

The end result is that zero, one or more methods may be “best”. If one, this method is selected and cached in the table of methods. If there is more than one best match, the selection is ambiguous and a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling testInheritedMethods.

Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call resetGeneric. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function selectMethod. Note that some computations may use this function directly, with optional arguments. The prime example is the use of coerce() methods by function as().

There has been some confusion from comparing coerce methods to a call to selectMethod with other options.

**Method Evaluation: Details**

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will not have been evaluated, since method dispatch always uses class missing for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent ("enclosing") environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the references in the sections indicated.
Generic Functions

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class `genericFunction`. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in R by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, R will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of R.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

R distinguishes standard and nonstandard generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, implicit generic functions and the special computations required to deal with R's primitive functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See `implicitGeneric` for how this is done.) The mechanism is mainly used for functions in the older packages in R, which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except . . . .

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must not be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument `expr` to the function `with` is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the methods package to be available.
Methods for Non-Generic Functions in Other Packages

Description

In writing methods for an R package, it's common for these methods to apply to a function (in another package) that is not generic in that package; that is, there are no formal methods for the function in its own package, although it may have S3 methods. The programming in this case involves one extra step, to call `setGeneric()` to declare that the function is generic in your package. Calls to the function in your package will then use all methods defined there or in any other loaded package that creates the same generic function. Similarly, calls to the function in those packages will use your methods.
The original version, however, remains non-generic. Calls in that package or in other packages that use that version will not dispatch your methods except for special circumstances:

1. If the function is one of the primitive functions that accept methods, the internal C implementation will dispatch methods if one of the arguments is an S4 object, as should be the case.
2. If the other version of the function dispatches S3 methods and your methods are also registered as S3 methods, the method will usually be dispatched as that S3 method.
3. Otherwise, you will need to ensure that all calls to the function come from a package in which the function is generic, perhaps by copying code to your package.

Details and the underlying reasons are discussed in the following sections.

Generic and Non-Generic Calls

Creating methods for a function (any function) in a package means that calls to the function in that package will select methods according to the actual arguments. However, if the function was originally a non-generic in another package, calls to the function from that package will not dispatch methods. In addition, calls from any third package that imports the non-generic version will also not dispatch methods. This section considers the reason and how one might deal with the consequences.

The reason is simply the R namespace mechanism and its role in evaluating function calls. When a name (such as the name of a function) needs to be evaluated in a call to a function from some package, the evaluator looks first in the frame of the call, then in the namespace of the package and then in the imports to that package.

Defining methods for a function in a package ensures that calls to the function in that package will select the methods, because a generic version of the function is created in the namespace. Similarly, calls from another package that has or imports the generic version will select methods. Because the generic versions are identical, all methods will be available in all these packages.

However, calls from any package that imports the old version or just selects it from the search list will usually not select methods.

A an example, consider the function `data.frame()` in the base package. This function takes any number of objects as arguments and attempts to combine them as variables into a data frame object. It does this by calling `as.data.frame()`, also in the base package, for each of the objects.

A reasonable goal would be to extend the classes of objects that can be included in a data frame by defining methods for `as.data.frame()`. But calls to `data.frame()`, will still use the version of that function in the base package, which continues to call the non-generic `as.data.frame()` in that package.

The details of what happens and options for dealing with it depend on the form of the function: a primitive function; a function that dispatches S3 methods; or an ordinary R function.

Primitive functions are not actual R function objects. They go directly to internal C code. Some of them, however, have been implemented to recognize methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method.

So defining methods for these functions works as long as the relevant classes have been defined, which should always be the case.

A function dispatches S3 methods by calling `UseMethod()`, which does not look for formal methods regardless of whether the first argument is an S4 object or not. This applies to the `as.data.frame()` example above. To have methods called in this situation, your package must also define the method as an S3 method, if possible. See section ‘S3 “Generic” Functions’.
In the third possibility, the function is defined with no expectation of methods. For example, the base package has a number of functions that compute numerical decompositions of matrix arguments. Some, such as `chol()` and `qr()` are implemented to dispatch S3 methods; others, such as `svd()` are implemented directly as a specific computation. A generic version of the latter functions can be written and called directly to define formal methods, but no code in another package that does not import this generic version will dispatch such methods.

In this case, you need to have the generic version used in all the indirect calls to the function supplying arguments that should dispatch methods. This may require supplying new functions that dispatch methods and then call the function they replace. For example, if S3 methods did not work for `as.data.frame()`, one could call a function that applied the generic version to all its arguments and then called `data.frame()` as a replacement for that function. If all else fails, it might be necessary to copy over the relevant functions so that they would find the generic versions.

### S3 “Generic” Functions

S3 method dispatch looks at the class of the first argument. S3 methods are ordinary functions with the same arguments as the generic function. The “signature” of an S3 method is identified by the name to which the method is assigned, composed of the name of the generic function, followed by “.”, followed by the name of the class. For details, see `UseMethod`.

To implement a method for one of these functions corresponding to S4 classes, there are two possibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only possible if the intended signature has the first argument and nothing else. In this case, the recommended approach is to define the S3 method and also supply the identical function as the definition of the S4 method. If the S3 generic function was `f3(x, ...)` and the S4 class for the new method was "myClass":

```r
f3.myClass <- function(x, ...) { ..... }
setMethod("f3", "myClass", f3.myClass)
```

Defining both methods usually ensures that all calls to the original function will dispatch the intended method. The S4 method alone would not be called from other packages using the original version of the function. On the other hand, an S3 method alone will not be called if there is any eligible non-default S4 method.

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as `asS3` and `S3Part` may be useful. If the S3 method fails on the S4 object, `asS3(x)` may be passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for `S3Part` may be useful.

## Methods for Nongenerics

### Examples

```r
## A class that extends a registered S3 class inherits that class' S3 methods.

setClass("myFrame", contains = "data.frame",
  slots = c(timestamps = "POSIXt"))
df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters, 10))
mydf1 <- new("myFrame", df1, timestamps = Sys.time())

## "myFrame" objects inherit "data.frame" S3 methods; e.g., for `[`

mydf1[1:2, ] # a data frame object (with extra attributes)

## a method explicitly for "myFrame" class

setMethod("[",
  signature(x = "myFrame"),
  function (x, i, j, ..., drop = TRUE)
  {
    S3Part(x) <- callNextMethod()
    x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps))
    x
  }
)

mydf1[1:2, ]

## IGNORE_RDIFF_BEGIN
## IGNORE_RDIFF_END

## S3 methods for an S4 object will be selected using S4 inheritance
## Objects mCt and mLt have different S3Class() values, but this is
## not used.

f3 <- function(x)UseMethod("f3") # an S3 generic to illustrate inheritance
f3.POSIXct <- function(x) "The POSIXct result"
f3.POSIXlt <- function(x) "The POSIXlt result"
f3.POSIXt <- function(x) "The POSIXt result"

stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
stopifnot(identical(f3(mLt), f3.POSIXt(mLt)))

## An S4 object selects S3 methods according to its S4 "inheritance"
```

```
Methods for Nongenerics

```r
setClass("classA", contains = "numeric", 
  slots = c(realData = "numeric"))

Math.classA <- function(x) { (getFunction(.Generic))(x@realData) }
setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)
stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")

y <- new("classB", x)
stopifnot(identical(abs(y), abs(x))) # (version 2.9.0 or earlier fails here)

## an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")

f3.default <- function(x, ...) "Default f3"

## S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

## S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"
setMethod("f3", "numeric", f3.numeric)

## The S3 method for classA and the closest inherited S3 method for classB
## are not found.

f3(x); f3(y) # both choose "numeric" method

## to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

## Need to define an S3 as well as S4 method to use on an S3 object
## or if called from a package without the S4 generic

MathFun <- function(x) { # a smarter "data.frame" method for Math group
  for (i in seq_len(ncol(x))[sapply(x, is.numeric)])
    x[, i] <- (getFunction(.Generic))(x[, i])
  x
}
setMethod("Math", "data.frame", MathFun)

## S4 method works for an S4 class containing data.frame,
## but not for data.frame objects (not S4 objects)

try(logIris <- log(iris)) # gets an error from the old method

## Define an S3 method with the same computation
```
Math.data.frame <- MathFun

logIris <- log(iris)

Description

The S3 and S4 software in R are two generations implementing functional object-oriented programming. S3 is the original, simpler for initial programming but less general, less formal and less open to validation. The S4 formal methods and classes provide these features but require more programming.

In modern R, the two versions attempt to work together. This documentation outlines how to write methods for both systems by defining an S4 method for a function that dispatches S3 methods.

The systems can also be combined by using an S3 class with S4 method dispatch or in S4 class definitions. See setOldClass.

S3 Method Dispatch

The R evaluator will ‘dispatch’ a method from a function call either when the body of the function calls the special primitive UseMethod or when the call is to one of the builtin primitives such as the math functions or the binary operators.

S3 method dispatch looks at the class of the first argument or the class of either argument in a call to one of the primitive binary operators. In pure S3 situations, ‘class’ in this context means the class attribute or the implied class for a basic data type such as "numeric". The first S3 method that matches a name in the class is called and the value of that call is the value of the original function call. For details, see S3Methods.

In modern R, a function meth in a package is registered as an S3 method for function fun and class Class by including in the package’s NAMESPACE file the directive

S3method(fun, Class, meth)

By default (and traditionally), the third argument is taken to be the function fun.Class; that is, the name of the generic function, followed by ".", followed by the name of the class.

As with S4 methods, a method that has been registered will be added to a table of methods for this function when the corresponding package is loaded into the session. Older versions of R, copying the mechanism in S, looked for the method in the current search list, but packages should now always register S3 methods rather than requiring the package to be attached.

Methods for S4 Classes

Two possible mechanisms for implementing a method corresponding to an S4 class, there are two possibilities are to register it as an S3 method with the S4 class name or to define and set an S4 method, which will have the side effect of creating an S4 generic version of this function.
Methods_for_S3

For most situations either works, but the recommended approach is to do both: register the S3 method and supply the identical function as the definition of the S4 method. This ensures that the proposed method will be dispatched for any applicable call to the function.

As an example, suppose an S4 class "uncased" is defined, extending "character" and intending to ignore upper- and lower-case. The base function unique dispatches S3 methods. To define the class and a method for this function:

```r
setClass("uncased", contains = "character")
unique.uncased <- function(x, incomparables = FALSE, ...) nextMethod(tolower(x))
setMethod("unique", "uncased", unique.uncased)
```

In addition, the NAMESPACE for the package should contain:

```r
S3method(unique, uncased)
exportMethods(unique)
```

The result is to define identical S3 and S4 methods and ensure that all calls to unique will dispatch that method when appropriate.

**Details**

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. This will be the case, for example, if some function calls unique() from a package that does not make that function an S4 generic.

   However, primitive functions and operators are exceptions: The internal C code will look for S4 methods if and only if the object is an S4 object. S4 method dispatch would be used to dispatch any binary operator calls where either of the operands was an S4 object, for example.

2. An S3 method alone will not be called if there is any eligible non-default S4 method.

   So if a package defined an S3 method for unique for an S4 class but another package defined an S4 method for a superclass of that class, the superclass method would be chosen, probably not what was intended.

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

For the details of S4 and S3 dispatch see `Methods_Details` and `S3Methods`.

MethodWithNext-class

Class MethodWithNext

Description

Class of method definitions set up for callNextMethod.

Objects from the Class

Objects from this class are generated as a side-effect of calls to callNextMethod.

Slots

.Data: Object of class "function"; the actual function definition.

nextMethod: Object of class "PossibleMethod"; the method to use in response to a callNextMethod() call.

excluded: Object of class "list"; one or more signatures excluded in finding the next method.

target: Object of class "signature", from class "MethodDefinition"

defined: Object of class "signature", from class "MethodDefinition"

generic: Object of class "character"; the function for which the method was created.

Extends

Class "MethodDefinition", directly.
Class "function", from data part.
Class "PossibleMethod", by class "MethodDefinition".
Class "OptionalMethods", by class "MethodDefinition".

Methods

findNextMethod signature(method = "MethodWithNext"): used internally by method dispatch.

loadMethod signature(method = "MethodWithNext"): used internally by method dispatch.

show signature(object = "MethodWithNext")

See Also

callNextMethod, and class MethodDefinition.
Generate an Object from a Class

Description

A call to new returns a newly allocated object from the class identified by the first argument. This call in turn calls the method for the generic function initialize corresponding to the specified class, passing the ... arguments to this method. In the default method for initialize(), named arguments provide values for the corresponding slots and unnamed arguments must be objects from superclasses of this class.

A call to a generating function for a class (see setClass) will pass its ... arguments to a corresponding call to new().

Usage

new(Class, ...)

initialize(.Object, ...)

Arguments

Class
either the name of a class, a character string, (the usual case) or the object describing the class (e.g., the value returned by getClass). Note that the character string passed from a generating function includes the package name as an attribute, avoiding ambiguity if two packages have identically named classes.

...
arguments to specify properties of the new object, to be passed to initialize().

.Object
An object: see the “Initialize Methods” section.

Initialize Methods

The generic function initialize is not called directly. A call to new begins by copying the prototype object from the class definition, and then calls initialize() with this object as the first argument, followed by the ... arguments.

The interpretation of the ... arguments in a call to a generator function or to new() can be specialized to particular classes, by defining an appropriate method for "initialize".

In the default method, unnamed arguments in the ... are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Explicitly specified slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The initialize methods do not have to have ... as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, you should include ... as a formal argument, and your method should pass such arguments along via callNextMethod. This helps the definition of future subclasses of your class. If these have additional slots and your method does not have this argument, it will be difficult for these slots to be included in an initializing call.

See initialize-methods for a discussion of some classes with existing methods.
Methods for `initialize` can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use `new` for these classes. The ...arguments are interpreted as objects of this type and are concatenated into the resulting vector.

`Classes_Details` for details of class definitions, and `setOldClass` for the relation to S3 classes.

Examples

```r
## using the definition of class "track" from \link{setClass}

## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)

# a new object including an object from a superclass, plus a slot
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots. In this version, the slots must still be
### supplied by name.
setMethod("initialize", "track",
    function(.Object, ...) {
        .Object <- callNextMethod()
        if(length(.Object@x) != length(.Object@y))
            stop("specified x and y of different lengths")
        .Object
    })

### An alternative version that allows x and y to be supplied
### unnamed. A still more friendly version would make the default x
### a vector of the same length as y, and vice versa.
setMethod("initialize", "track",
    function(.Object, x = numeric(0), y = numeric(0), ...) {
        .Object <- callNextMethod(.Object, ...)
        if(length(x) != length(y))
            stop("specified x and y of different lengths")
        .Object@x <- x
        .Object@y <- y
        .Object
    })
```
## nonStructure-class

A non-structure S4 Class for basic types

### Description

S4 classes that are defined to extend one of the basic vector classes should contain the class `structure` if they behave like structures; that is, if they should retain their class behavior under math functions or operators, so long as their length is unchanged. On the other hand, if their class depends on the values in the object, not just its structure, then they should lose that class under any such transformations. In the latter case, they should be defined to contain `nonStructure`.

If neither of these strategies applies, the class likely needs some methods of its own for `Ops`, `Math`, and/or other generic functions. What is not usually a good idea is to allow such computations to drop down to the default, base code. This is inconsistent with most definitions of such classes.

### Methods

Methods are defined for operators and math functions (groups `Ops`, `Math`, and `Math2`). In all cases the result is an ordinary vector of the appropriate type.

### References

### See Also

structure

### Examples

```r
setClass("NumericNotStructure", contains = c("numeric","nonStructure"))
xx <- new("NumericNotStructure", 1:10)
xx + 1 # vector
log(xx) # vector
sample(xx) # vector
```

## ObjectsWithPackage-class

A Vector of Object Names, with associated Package Names

### Description

This class of objects is used to represent ordinary character string object names, extended with a package slot naming the package associated with each object.

### Objects from the Class

The function `getGenerics` returns an object of this class.
promptClass

Slots

.Data: Object of class "character": the object names.

package: Object of class "character" the package names.

Extends

Class "character", from data part.
Class "vector", by class "character".

See Also

Methods for general background.

Description

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

Usage

promptClass(clName, filename = NULL, type = "class",
keywords = "classes", where = topoenv(parent.frame()),
generatorName = clName)

Arguments

clName a character string naming the class to be documented.
filename usually, a connection or a character string giving the name of the file to which
the documentation shell should be written. The default corresponds to a file
whose name is the topic name for the class documentation, followed by ".Rd".
Can also be NA (see below).
type the documentation type to be declared in the output file.
keywords the keywords to include in the shell of the documentation. The keyword
"classes" should be one of them.
where where to look for the definition of the class and of methods that use it.
generatorName the name for a generator function for this class; only required if a generator
function was created and saved under a name different from the class name.

Details

The class definition is found on the search list. Using that definition, information about classes
extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using
getGenerics). Note that these methods need not be in the same environment as the class defi-
nition; in particular, this part of the output may depend on which packages are currently in the
search list.
As with other prompt-style functions, unless filename is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the meaning of the class. The output of promptClass can only contain information from the metadata about the formal definition and how it is used.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If a generator function is found assigned under the class name or the optional generatorName, skeleton documentation for that function is added to the file.

**Value**

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

**Author(s)**

VJ Carey <stvjc@channing.harvard.edu> and John Chambers

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

`prompt` for documentation of functions, `promptMethods` for documentation of method definitions.

For processing of the edited documentation, either use R CMD Rdconv, or include the edited file in the ‘man’ subdirectory of a package.

**Examples**

```
## Not run: > promptClass("track")
A shell of class documentation has been written to the
file "track-class.Rd".

## End(Not run)
```

promptMethods

**Generate a Shell for Documentation of Formal Methods**

**Description**

Generates a shell of documentation for the methods of a generic function.

**Usage**

`promptMethods(f, filename = NULL, methods)`
Arguments

f a character string naming the generic function whose methods are to be documented.

filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, f followed by "-methods.Rd"). Can also be FALSE or NA (see below).

methods optional "listOfMethods" object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for f, these would be documented). If this argument is supplied, it is likely to be findMethods(f, where), with where some package containing methods for f.

Details

If filename is FALSE, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see prompt).

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Otherwise, the documentation shell is written to the file specified by filename.

Value

If filename is FALSE, the text generated; if filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

ReferenceClasses  Objects With Fields Treated by Reference (OOP-style)

Description

The software described here allows packages to define reference classes that behave in the style of “OOP” languages such as Java and C++. This model for OOP differs from the functional model implemented by S4 (and S3) classes and methods, in which methods are defined for generic functions. Methods for reference classes are “encapsulated” in the class definition.

Computations with objects from reference classes invoke methods on them and extract or set their fields, using the `$` operator in R. The field and method computations potentially modify the
object. All computations referring to the objects see the modifications, in contrast to the usual functional programming model in R.

A call to `setRefClass` in the source code for a package defines the class and returns a generator object. Subsequent calls to the `$methods()` method of the generator will define methods for the class. As with functional classes, if the class is exported from the package, it will be available when the package is loaded.

Methods are R functions. In their usual implementation, they refer to fields and other methods of the class directly by name. See the section on “Writing Reference Methods”.

As with functional classes, reference classes can inherit from other reference classes via a `contains=` argument to `setRefClass`. Fields and methods will be inherited, except where the new class overrides method definitions. See the section on “Inheritance”.

Usage

```r
setRefClass(Class, fields = , contains = , methods =,
            where = , inheritPackage =, ...)  
getRefClass(Class, where =)
```

Arguments

- **Class** character string name for the class.
  In the call to `getRefClass()` this argument can also be any object from the relevant class.

- **fields** either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, each element of the list should usually be the character string name of a class, in which case the object in the field must be from that class or a subclass. An alternative, but not generally recommended, is to supply an accessor function; see the section on “Implementation” for accessor functions and the related internal mechanism.
  Note that fields are distinct from slots. Reference classes should not define class-specific slots. See the note on slots in the “Implementation” section.

- **contains** optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.

- **methods** a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the `$methods()` method on the generator object returned. See the section on “Writing Reference Methods” for details.

- **where** for `setRefClass`, the environment in which to store the class definition. Should be omitted in calls from a package’s source code.
  For `getRefClass`, the environment from which to search for the definition. If the package is not loaded or you need to be specific, use `asNamespace` with the package name.

- **inheritPackage** Should objects from the new class inherit the package environment of a contained superclass? Default `FALSE`. See the Section “Inter-Package Superclasses and External Methods”.

- **...** other arguments to be passed to `setClass`.
setRefClass() returns a generator function suitable for creating objects from the class, invisibly. A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).

The generator function is similar to the S4 generator function returned by setClass. In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

getRefClass() also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the where argument, which is used only to find the class if necessary.

Reference Objects

Normal objects in R are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for R) is suitable for many statistical computations and is implicit, for example, in the basic R software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the R syntax we use "$" for this operation; one invokes a method, m1 say, on an object x by the expression x$m1(...).

Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in R, for example, a generic function in an R session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the R implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class "ANY".

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.

Programming for such classes involves writing new methods for a particular class. In the R implementation, these methods are R functions, with zero or more formal arguments. For standard reference methods, the object itself is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses R environments to make fields and other methods available by name within the method. Specifically, the parent environment of the method is the object itself. See the section on “Writing Reference Methods”. This special use of environments is optional. If a method is defined with an initial formal argument .self, that will be passed in as the whole object, and the method follows the standard rules for any function in a package. See the section on “External Methods”
The goal of the software described here is to provide a uniform programming style in \texttt{R} for software dealing with reference classes, whether implemented directly in \texttt{R} or through an interface to one of the OOP languages.

**Writing Reference Methods**

Reference methods are functions supplied as elements of a named list, either when invoking \texttt{methods()} on a generator object \texttt{g} or as the argument \texttt{methods} in a call to \texttt{setRefClass}. The two mechanisms have the same effect, but the first makes the code more readable.

Methods are written as ordinary \texttt{R} functions but have some special features and restrictions in their usual form. In contrast to some other languages (e.g., Python), the object itself does not need to be an argument in the method definition. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to methods and to fields in the object by name.

Alternatively, a method may be an *external* method. This is signalled by \texttt{.self} being the first formal argument to the method. The body of the method then works like any ordinary function. The methods are called like other methods (without the \texttt{.self} argument, which is supplied internally and always refers to the object itself). Inside the method, fields and other methods are accessed in the form \texttt{.self$x}. External methods exist so that reference classes can inherit the package environment of superclasses in other packages; see the section on “External Methods”.

Fields may be modified in a method by using the non-local assignment operator, \texttt{<<-}, as in the \texttt{$edit} and \texttt{$undo} methods in the example below. Note that non-local assignment is required: a local assignment with the \texttt{<-} operator just creates a local object in the function call, as it would in any \texttt{R} function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple; if they need to do some specialized \texttt{R} computation, that computation should use a separate \texttt{R} function that is called from the reference method. Specifically, methods can not use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Two method names are interpreted specially, \texttt{initialize} and \texttt{finalize}. If an \texttt{initialize} method is defined, it will be invoked when an object is generated from the class. See the discussion of method \texttt{$new(...)} in the section “Initialization Methods”.

If a \texttt{finalize} method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector; finalizers are registered with \texttt{atexit=TRUE}, and so are also run at the end of \texttt{R} sessions. See the matrix viewer example for both \texttt{initialize} and \texttt{finalize} methods.

Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

Two special object names are available. The entire object can be referred to in a method by the reserved name \texttt{.self}. The object \texttt{.refClassDef} contains the definition of the class of the object. These are accessed as fields but are read-only, with one exception. In principal, the \texttt{.self} field can be modified in the \texttt{$initialize} method, because the object is still being created at this stage. This is not recommended, as it can invalidate the object with respect to its class.

The methods available include methods inherited from superclasses, as discussed in the section “Inheritance”.

Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to \texttt{$usingMethods()} with the name of the other method as an argument. Declaring the methods
this way is essential if the other method is used indirectly (e.g., via \texttt{sapply()} or \texttt{do.call()}). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the \texttt{$help} method for the generator object. Methods for classes are not documented in the Rd format used for R functions. Instead, the \texttt{$help} method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.

### Initialization Methods

If the class has a method defined for \texttt{initialize()}, this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function \texttt{initialize()}, because some special initialization is required for reference objects before the initialization of fields. As with S4 classes, methods are written for \texttt{initialize()} and not for \texttt{new()}, both for the previous reason and also because \texttt{new()} is invoked on the generator object and would be a method for that class.

The default method for \texttt{initialize()} is equivalent to invoking the method \texttt{initFields(...)}. Named arguments assign initial values to the corresponding fields. Unnamed arguments must be objects from this class or a reference superclass of this class. Fields will be initialized to the contents of the fields in such objects, but named arguments override the corresponding inherited fields. Note that fields are simply assigned. If the field is itself a reference object, that object is not copied. The new and previous object will share the reference. Also, a field assigned from an unnamed argument counts as an assignment for locked fields. To override an inherited value for a locked field, the new value must be one of the named arguments in the initializing call. A later assignment of the field will result in an error.

Initialization methods need some care in design. The generator for a reference class will be called with no arguments, for example when copying the object. To ensure that these calls do not fail, the method must have defaults for all arguments or check for \texttt{missing()}. The method should include \ldots as an argument and pass this on via \texttt{$callSuper()} (or \texttt{initFields()} if you know that your superclasses have no initialization methods). This allows future class definitions that subclass this class, with additional fields.

### Inheritance

Reference classes inherit from other reference classes by using the standard R inheritance; that is, by including the superclasses in the \texttt{contains=} argument when creating the new class. The names of the reference superclasses are in slot \texttt{refSuperClasses} of the class definition. Reference classes can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call the superclass method by \texttt{callSuper(...)} as described below.
Methods Provided for all Objects

All reference classes inherit from the class "envRefClass". All reference objects can use the following methods.

$\texttt{callSuper}(\ldots)$ Calls the method inherited from a reference superclass. The call is meaningful only from within another method, and will be resolved to call the inherited method of the same name. The arguments to $\texttt{callSuper}$ are passed to the superclass version. See the matrix viewer class in the example.

Note that the intended arguments for the superclass method must be supplied explicitly; there is no convention for supplying the arguments automatically, in contrast to the similar mechanism for functional methods.

$\texttt{copy}(\texttt{shallow} = \texttt{FALSE})$ Creates a copy of the object. With reference classes, unlike ordinary \texttt{R} objects, merely assigning the object with a different name does not create an independent copy. If \texttt{shallow} is \texttt{FALSE}, any field that is itself a reference object will also be copied, and similarly recursively for its fields. Otherwise, while reassigning a field to a new reference object will have no side effect, modifying such a field will still be reflected in both copies of the object. The argument has no effect on non-reference objects in fields. When there are reference objects in some fields but it is asserted that they will not be modified, using \texttt{shallow} = \texttt{TRUE} will save some memory and time.

$\texttt{field}(\texttt{name}, \texttt{value})$ With one argument, returns the field of the object with character string \texttt{name}. With two arguments, the corresponding field is assigned \texttt{value}. Assignment checks that \texttt{name} specifies a valid field, but the single-argument version will attempt to get anything of that name from the object’s environment.

The $\texttt{field}()$ method replaces the direct use of a field name, when the name of the field must be calculated, or for looping over several fields.

$\texttt{export}(\texttt{Class})$ Returns the result of coercing the object to \texttt{Class} (typically one of the superclasses of the object’s class). Calling the method has no side effect on the object itself.

$\texttt{getRefClass}(); \texttt{getClass}()$ These return respectively the generator object and the formal class definition for the reference class of this object, efficiently.

$\texttt{import}(\texttt{value}, \texttt{Class} = \texttt{class}(\texttt{value}))$ Import the object \texttt{value} into the current object, replacing the corresponding fields in the current object. Object \texttt{value} must come from one of the superclasses of the current object’s class. If argument \texttt{Class} is supplied, \texttt{value} is first coerced to that class.

$\texttt{initFields}(\ldots)$ Initialize the fields of the object from the supplied arguments. This method is usually only called from a class with a $\texttt{initialize}()$ method. It corresponds to the default initialization for reference classes. If there are slots and non-reference superclasses, these may be supplied in the \ldots argument as well.

Typically, a specialized $\texttt{initialize}()$ method carries out its own computations, then invokes $\texttt{initFields}()$ to perform standard initialization, as shown in the \texttt{matrixViewer} class in the example below.

$\texttt{show}()$ This method is called when the object is printed automatically, analogously to the \texttt{show} function. A general method is defined for class "envRefClass". User-defined reference classes will often define their own method: see the Example below.

Note two points in the example. As with any \texttt{show}() method, it is a good idea to print the class explicitly to allow for subclasses using the method. Second, to call the \texttt{function} \texttt{show}() from the method, as opposed to the $\texttt{show}()$ method itself, refer to \texttt{methods::show}() explicitly.

$\texttt{trace}(\texttt{what}, \ldots), \texttt{untrace}(\texttt{what})$ Apply the tracing and debugging facilities of the \texttt{trace} function to the reference method \texttt{what}. 
All the arguments of the trace function can be supplied, except for signature, which is not meaningful.

The reference method can be invoked on either an object or the generator for the class. See the section on Debugging below for details.

$usingMethods(...) Reference methods used by this method are named as the arguments either quoted or unquoted. In the code analysis phase of installing the the present method, the declared methods will be included. It is essential to declare any methods used in a nonstandard way (e.g., via an apply function). Methods called directly do not need to be declared, but it is harmless to do so. $usingMethods() does nothing at run time.

Objects also inherit two reserved fields:
.
self a reference to the entire object;
.
refClassDef the class definition.

The defined fields should not override these, and in general it is unwise to define a field whose name begins with ".", since the implementation may use such names for special purposes.

External Methods; Inter-Package Superclasses

The environment of a method in a reference class is the object itself, as an environment. This allows the method to refer directly to fields and other methods, without using the whole object and the "$" operator. The parent of that environment is the namespace of the package in which the reference class is defined. Computations in the method have access to all the objects in the package’s namespace, exported or not.

When defining a class that contains a reference superclass in another package, there is an ambiguity about which package namespace should have that role. The argument inheritPackage to setRefClass() controls whether the environment of new objects should inherit from an inherited class in another package or continue to inherit from the current package’s namespace.

If the superclass is "lean", with few methods, or exists primarily to support a family of subclasses, then it may be better to continue to use the new package’s environment. On the other hand, if the superclass was originally written as a standalone, this choice may invalidate existing superclass methods. For the superclass methods to continue to work, they must use only exported functions in their package and the new package must import these.

Either way, some methods may need to be written that do not assume the standard model for reference class methods, but behave essentially as ordinary functions would in dealing with reference class objects.

The mechanism is to recognize external methods. An external method is written as a function in which the first argument, named .self, stands for the reference class object. This function is supplied as the definition for a reference class method. The method will be called, automatically, with the first argument being the current object and the other arguments, if any, passed along from the actual call.

Since an external method is an ordinary function in the source code for its package, it has access to all the objects in the namespace. Fields and methods in the reference class must be referred to in the form .self$name.

If for some reason you do not want to use .self as the first argument, a function f() can be converted explicitly as externalRefMethod(f), which returns an object of class "externalRefMethod” that can be supplied as a method for the class. The first argument will still correspond to the whole object.

External methods can be supplied for any reference class, but there is no obvious advantage unless they are needed. They are more work to write, harder to read and (slightly) slower to execute.
NOTE: If you are the author of a package whose reference classes are likely to be subclassed in other packages, you can avoid these questions entirely by writing methods that only use exported functions from your package, so that all the methods will work from another package that imports yours.

Reference Class Generators

The call to setRefClass defines the specified class and returns a "generator function" object for that class. This object has class "refObjectGenerator"; it inherits from "function" via "classGeneratorFunction" and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class "refGeneratorSlot"). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing "refGeneratorSlot", not "refObjectGenerator".

The fields are def, the class definition, and className, the character string name of the class.

Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

$new(...) This method is equivalent to calling the generator function returned by setRefClass.

$help(topic) Prints brief help on the topic. The topics recognized are reference method names, quoted or not.

The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on "Writing Reference Methods" for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.

$methods(...) With no arguments, returns the names of the reference methods for this class. With one character string argument, returns the method of that name.

Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the methods argument to setRefClass(). Supplying methods in this way, rather than in the call to setRefClass(), is recommended for the sake of clearer source code.

All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods can not be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition.

The new methods can refer to any currently defined method by name (including other methods supplied in this call to $methods()). Note though that previously defined methods are not re-analyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply NULL as its new definition.

$fields() Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "activeBindingFunction".

$lock(...) The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error.

If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument).
All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

`$trace(what, ..., classMethod = FALSE)` Establish a traced version of method `what` for objects generated from this class. The generator object tracing works like the `$trace()` method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument `classMethod = TRUE` allows tracing on the methods of the generator object itself. By default, `what` is interpreted as the name of a method in the class for which this object is the generator.

`$accessors(...)` A number of systems using the OOP programming paradigm recommend or enforce getter and setter methods corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named abc by `x$getAbc()` and assign it by `x$setAbc(value)`, the `$accessors` method is a convenience function that creates such getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on “Reference Objects”.

**Implementation; Reference Classes as S4 Classes**

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an active binding. In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field.

As a related feature, the element in the `fields=` list supplied to `setRefClass` can be an accessor function, a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications, but not generally recommended as they blur the concept of fields as data within the object.

A field, say data, can be accessed generally by an expression of the form `x$data` for any object from the relevant class. In an internal method for this class, the field can be accessed by the name data. A field that is not locked can be set by an expression of the form `x$data <- value`. Inside an internal method, a field can be assigned by an expression of the form `x <<- value`. Note the non-local assignment operator. The standard R interpretation of this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object’s environment, with the same environment as the environment of the function.

Reference classes can have validity methods in the same sense as any S4 class (see `setValidity`). Such methods are often a good idea; they will be called by calling `validObject` and a validity method, if one is defined, will be called when a reference object is created (from version 3.4 of R on). Just remember that these are S4 methods. The function will be called with the object as its argument. Fields and methods must be accessed using `$`.

**Note: Slots.** Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes, and can include class-specific slots in the definition. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Slots will as always be treated functionally. Therefore, changes to the slots and the fields
will behave inconsistently, mixing the functional and reference paradigms for properties of the
same object, conceptually unclear and prone to errors. In addition, the initialization method for the
class will have to sort out fields from slots, with a good chance of creating anomalous behavior for
subclasses of this class.

Inheriting from a class union, however, is a reasonable strategy (with all members of the union
likely to be reference classes).

**Debugging**

The standard R debugging and tracing facilities can be applied to reference methods. Reference
methods can be passed to `debug` and its relatives from an object to debug further method invocations
on that object; for example, `debug(xx$edit)`.

Somewhat more flexible use is available for a reference method version of the `trace` function.
A corresponding `$trace()` reference method is available for either an object or for the reference
class generator (`xx$trace()` or `mEdit$trace()` in the example below). Using `$trace()` on an
object sets up a tracing version for future invocations of the specified method for that object. Using
`$trace()` on the generator for the class sets up a tracing version for all future objects from that
class (and sometimes for existing objects from the class if the method is not declared or previously
invoked).

In either case, all the arguments to the standard `trace` function are available, except for `signature=`
which is meaningless since reference methods can not be S4 generic functions. This includes the
typical style `trace(what, browser)` for interactive debugging and `trace(what, edit = TRUE)` toedit the reference method interactively.

**Examples**

```r
## a simple editor for matrix objects. Method $edit() changes some
## range of values; method $undo() undoes the last edit.

mEdit <- setRefClass("mEdit",
   fields = list( data = "matrix",
                  edits = "list"))

## The basic edit, undo methods

mEdit$methods(
   edit = function(i, j, value) {
      ## the following string documents the edit method
      'Replaces the range [i, j] of the
      object by value.
      
      backup <-
      list(i, j, data[i,j])
      data[i,j] <<- value
      edits <<- c(edits, list(backup))
      invisible(value)
   },
   undo = function() {
      'Undoes the last edit() operation
      and update the edits field accordingly.
      
      prev <- edits
```
if(length(prev)) prev <- prev[length(prev)]
else stop("No more edits to undo")
edit(prev[[1]], prev[[2]], prev[[3]])
## trim the edits list
length(edits) <<- length(edits) - 2
invisible(prev)
})

## A method to automatically print objects
mEdit$methods(
  show = function() {
    'Method for automatically printing matrix editors'
    cat("Reference matrix editor object of class",
        classLabel(class(.self)), "\n")
    cat("Data: \n")
    methods::show(data)
    cat("Undo list is of length", length(edits), "\n")
  }
)

xMat <- matrix(1:12, 4, 3)
xx <- mEdit(data = xMat)
xx$edit(2, 2, 0)
xx
xx$undo()
mEdit$help("undo")
stoptifnot(all.equal(xx$data, xMat))
utils::str(xx) # show fields and names of methods

## A method to save the object
mEdit$methods(
  save = function(file) {
    'Save the current object on the file
    in R external object format.
    '
    base::save(.self, file = file)
  }
)

tf <- tempfile()
xx$save(tf)

## Not run:
## Inheriting a reference class: a matrix viewer
mv <- setRefClass("matrixViewer",
  fields = c("viewerDevice", "viewerFile"),
  contains = "mEdit",
  methods = list(
    view = function() {
      dd <- dev.cur(); dev.set(viewerDevice)
      devAskNewPage(FALSE)
      matplot(data, main = paste("After", length(edits), "edits"))
      dev.set(dd),
      edit = # invoke previous method, then replot
        function(i, j, value) {
          callSuper(i, j, value)
## initialize and finalize methods

```r
mv$methods(initialize =
  function(file = "./matrixView.pdf", ...) {
    viewerFile <<- file
    pdf(viewerFile)
    viewerDevice <<- dev.cur()
    dev.set(dev.prev())
    callSuper(...)
  },
  finalize = function() {
    dev.off(viewerDevice)
  })
```  

## debugging an object: call browser() in method $edit()

```r
xx$trace(edit, browser)
```  

## debugging all objects from class mEdit in method $undo()

```r
mEdit$trace(undo, browser)
```  

## End(Not run)

---

### removeMethod

**Remove a Method**

**Description**

Remove the method for a given function and signature. Obsolete for ordinary applications: Method definitions in a package should never need to remove methods and it’s very bad practice to remove methods that were defined in other packages.

**Usage**

```r
removeMethod(f, signature, where)
```  

**Arguments**

- `f, signature, where`

  As for `setMethod()`.

**Value**

TRUE if a method was found to be removed.

**References**

representation

Construct a Representation or a Prototype for a Class Definition

Description

These are old utility functions to construct, respectively a list designed to represent the slots and superclasses and a list of prototype specifications. The `representation()` function is no longer useful, since the arguments `slots` and `contains` to `setClass` are now recommended.

The `prototype()` function may still be used for the corresponding argument, but a simple list of the same arguments works as well.

Usage

```r
representation(...) prototype(...)```

Arguments

... The call to `representation` takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to `prototype`, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The `representation` function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when `representation` is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to `prototype` are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of `representation` is just the list of arguments, after these have been checked for validity.

The value of `prototype` is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does not use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

  contains = "numeric",
  prototype = prototype(pi, comment = "Start with pi"))

S4 Classes that Contain S3 Classes

Description

A regular (S4) class may contain an S3 class, if that class has been registered (by calling setOldClass). The functions described here provide information about contained S3 classes. See the section ‘Functions’.

In modern R, these functions are not usually needed to program with objects from the S4 class. Standard computations work as expected, including method selection for both S4 and S3. To coerce an object to its contained S3 class, use either of the expressions:

as(object, S3Class); as(object, "S3")

where S3Class evaluates to the name of the contained class. These return slightly different objects, which in rare cases may need to be distinguished. See the section “Contained S3 Objects”.

Usage

S3Part(object, strictS3 = FALSE, S3Class)

S3Class(object)

isXS3Class(classDef)

slotsFromS3(object)
## the replacement versions of the functions are not recommended
## Create a new object from the class or use the replacement version of as().

\[
\text{S3Part(object, strictS3 = FALSE, needClass = ) <- value}
\]

\[
\text{S3Class(object) <- value}
\]

### Arguments

- **object**: an object from some class that extends a registered S3 class, or a basic vector, matrix or array object type.
  
  For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.

- **strictS3**: If TRUE, the value returned by S3Part will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by \texttt{setOldClass} as a proxy for an S3 class, rather than the underlying S3 object.

- **S3Class**: the character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from object, but an S3 superclass is allowed.

- **classDef**: a class definition object, as returned by \texttt{getClass}.

  The remaining arguments apply only to the replacement versions, which are not recommended.

- **needClass**: Require that the replacement value be this class or a subclass of it.

- **value**: For S3Part<-, the replacement value for the S3 part of the object.
  
  For S3Class<-, the character vector that will be used as a proxy for \texttt{class(x)} in S3 method dispatch.

### Functions

- **S3Part**: Returns an object from the S3 class that appeared in the \texttt{contains=} argument to \texttt{setClass}.
  
  If called with \texttt{strictS3 = TRUE}, S3Part() constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With \texttt{strictS3 = FALSE} the object returned is from the corresponding S4 class.

  A call to is equivalent coercing the object to class \texttt{"S3"} for the strict case, or to whatever the specific S3 class was, for the non-strict case. The \texttt{as()} calls are usually easier for readers to understand.

- **S3Class**: Returns the character vector of S3 class(es) stored in the object, if the class has the corresponding .S3Class slot. Currently, the function defaults to \texttt{class} otherwise.

- **isXS3Class**: Returns TRUE or FALSE according to whether the class defined by ClassDef extends S3 classes (specifically, whether it has the slot for holding the S3 class).

- **slotsFromS3**: returns a list of the relevant slot classes, or an empty list for any other object.
  
  The function slotsFromS3() is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when \texttt{setOldClass} is called with the S4Class argument. Usually, there is only one S3 slot, containing the S3 class, but the S4Class argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of \texttt{setOldClass}.
Contained S3 Objects

Registering an S3 class defines an S4 class. Objects from this class are essentially identical in content to an object from the S3 class, except for two differences. The value returned by `class()` will always be a single string for the S4 object, and `isS4()` will return TRUE or FALSE in the two cases. See the example below. It is barely possible that some S3 code will not work with the S4 object; if so, use `as(x, "S3")`.

Objects from a class that extends an S3 class will have some basic type and possibly some attributes. For an S3 class that has an equivalent S4 definition (e.g., "data.frame"), an extending S4 class will have a data part and slots. For other S3 classes (e.g., "lm") an object from the extending S4 class will be some sort of basic type, nearly always a vector type (e.g., "list" for "lm"), but the data part will not have a formal definition.

Registering an S3 class by a call to `setOldClass` creates a class of the same name with a slot ".S3Class" to hold the corresponding S3 vector of class strings. New S4 classes that extend such classes also have the same slot, set to the S3 class of the contained S3 object, which may be an (S3) subclass of the registered class. For example, an S4 class might contain the S3 class "lm", but an object from the class might contain an object from class "mlm", as in the "xlm" example below.

`R` is somewhat arbitrary about what it treats as an S3 class: "ts" is, but "matrix" and "array" are not. For classes that extend those, assuming they contain an S3 class is incorrect and will cause some confusion—not usually disastrous, but the better strategy is to stick to the explicit "class". Thus `as(x, "matrix")` rather than `as(x, "S3")` or `S3Part(x)`.

S3 and S4 Objects: Conversion Mechanisms

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by `isS4` and can be set on or off by `asS4`. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions `as(object, "S3")` and `as(object, "S4")` return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression `as(object, "S3")` can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by `class(object)`. If the registered class has known attribute/slots, these will also be provided.

Another use of `as(object, "S3")` is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression `as(object, "S4")` will use the attributes in the object to create an object from the S4 definition of `class(object)`. This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking `new` with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

`setOldClass`
Examples

## an "mlm" object, regressing two variables on two others

```r
sepal <- as.matrix(datasets::iris[, c("Sepal.Width", "Sepal.Length")])
fit <- lm(sepal ~ Petal.Length + Petal.Width + Species, data = datasets::iris)
class(fit) # S3 class: "mlm", "lm"
```

## a class that contains "mlm"

```r
myReg <- setClass("myReg", slots = c(title = "character"), contains = "mlm")
```

```r
fit2 <- myReg(fit, title = "Sepal Regression for iris data")
fit2 # shows the inherited "mlm" object and the title
```

```r
identical(S3Part(fit2), as(fit2, "mlm"))
```

```r
class(as(fit2, "mlm")) # the S4 class, "mlm"
class(as(fit2, "S3")) # the S3 class, c("mlm", "lm")
```

## An object may contain an S3 class from a subclass of that declared:

```r
xlm <- setClass("xlm", slots = c(eps = "numeric"), contains = "lm")
```

```r
xfit <- xlm(fit, eps = .Machine$double.eps)
```

```r
xfit@.S3Class # c("mlm", "lm")
```

**S4groupGeneric**

**S4 Group Generic Functions**

### Description

Methods can be defined for *group generic functions*. Each group generic function has a number of *member* generic functions associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the *methods* package, but the mechanism is available to any programmer, by calling `setGroupGeneric` (provided package *methods* is attached).

### Usage

```r
## S4 group generics:
Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
```
Summary(x, ..., na.rm = FALSE)
Complex(z)

Arguments
x, z, e1, e2 objects.
digits number of digits to be used in round or signif.
... further arguments passed to or from methods.
na.rm logical: should missing values be removed?

Details
Methods can be defined for the group generic functions by calls to `setMethod` in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see `Methods_Details`.

There are also S3 groups Math, Ops, Summary and Complex, see ?S3groupGeneric, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling `getGroupMembers`. For the group generic functions currently defined in this package the members are as follows:

Arith "+", "-", "/", "%/%", "^", "%%"
Compare "==", ">", "<", "!=", "<=", ">=", ">="
Logic "<<|".
Ops "Arith","Compare","Logic"
Math2 "round", "signif"
Summary "max", "min", "range", "prod", "sum", "any", "all"
Complex "Arg", "Conj", "Im", "Mod", "Re"

Note that Ops merely consists of three sub groups.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all works more or less as you might expect, admittedly via a bit of trickery in the background. See `Methods_Details` for details.

Note that two members of the Math group, `log` and `trunc`, have ... as an extra formal argument. Since methods for Math will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of the second reference.
SClassExtension-class

Class to Represent Inheritance (Extension) Relations

Description

An object from this class represents a single ‘is’ relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by setIs, from direct calls and from the contains= information in a call to setClass, and from class unions created by setClassUnion. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).

Slots

subClass, superClass: The classes being extended: corresponding to the from, and to arguments to setIs.

package: The package to which that class belongs.

coerce: A function to carry out the as() computation implied by the relation. Note that these functions should not be used directly. They only deal with the strict=TRUE calls to the as function, with the full method constructed from this mechanically.

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also

The function callGeneric is nearly always relevant when writing a method for a group generic. See the examples below and in section 10.5 of Software for Data Analysis.

See S3groupGeneric for S3 group generics.

Examples

```r
setClass("testComplex", slots = c(zz = "complex"))
## method for whole group "Complex"
setMethod("Complex", "testComplex",
  function(z) c("groupMethod", callGeneric(z@zz)))
## exception for Arg()
setMethod("Arg", "testComplex",
  function(z) c("ArgMethod", Arg(z@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```
selectSuperClasses

Super Classes (of Specific Kinds) of a Class

Description

Return superclasses of ClassDef, possibly only non-virtual or direct or simple ones. These functions are designed to be fast, and consequently only work with the contains slot of the corresponding class definitions.

Usage

```
selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE, 
                   directOnly = TRUE, simpleOnly = directOnly, 
                   where = topenv(parent.frame()))
```

```
.selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE, 
                    directOnly = TRUE, simpleOnly = directOnly)
```

Arguments

- **Class**: name of the class or (more efficiently) the class definition object (see `getClass`).
- **dropVirtual**: logical indicating if only non-virtual superclasses should be returned.
- **namesOnly**: logical indicating if only a vector names instead of a named list class-extensions should be returned.
- **directOnly**: logical indicating if only a `direct` super classes should be returned.
- **simpleOnly**: logical indicating if only simple class extensions should be returned.
- **where**: (only used when Class is not a class definition) environment where the class definition of Class is found.
- **ext**: for `.selectSuperClasses()` only, a `list` of class extensions, typically `getClassDef(..)@contains`.

**test**: The function that would test whether the relation holds. Except for explicitly specified `test` arguments to `setIs`, this function is trivial.

**replace**: The method used to implement `as(x, Class) <- value`.

**simple**: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.

**by**: If this relation has been constructed transitively, the first intermediate class from the subclass.

**dataPart**: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).

**distance**: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

Methods

No methods defined with class "SClassExtension" in the signature.

See Also

`is`, `as`, and the `classRepresentation` class.
Value

a character vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of getClass).

Note

The typical user level function is selectSuperClasses() which calls .selectSuperClasses(); i.e., the latter should only be used for efficiency reasons by experienced useRs.

See Also

is, getClass; further, the more technical class classRepresentation documentation.

Examples

setClass("Root")
setClass("Base", contains = "Root", slots = c(length = "integer"))
setClass("A", contains = "Base", slots = c(x = "numeric"))
setClass("B", contains = "Base", slots = c(y = "character"))
setClass("C", contains = c("A", "B"))

extends("C")  #--> "C"  "A"  "B"  "Base"  "Root"
selectSuperClasses("C")  # "A"  "B"
selectSuperClasses("C", directOnly=FALSE)  # "A"  "B"  "Base"  "Root"
selectSuperClasses("C", dropVirtual=TRUE, directOnly=FALSE)# ditto w/o "Root"

setAs Methods for Coercing an Object to a Class

Description

A call to setAs defines a method for coercing an object of class from to class to. The methods will then be used by calls to as for objects with class from, including calls that replace part of the object.

Methods for this purpose work indirectly, by defining methods for function coerce. The coerce function is not to be called directly, and method selection uses class inheritance only on the first argument.

Usage

setAs(from, to, def, replace, where = topenv(parent.frame()))

Arguments

from, to The classes between which the coerce methods def and replace perform coercion.
def function of one argument. It will get an object from class from and had better return an object of class to. The convention is that the name of the argument is from; if another argument name is used, setAs will attempt to substitute from.
replace if supplied, the function to use as a replacement method, when as is used on the left of an assignment. Should be a function of two arguments, from, value, although setAs will attempt to substitute if the arguments differ.

The remaining argument will not be used in standard applications.

where the position or environment in which to store the resulting methods. Do not use this argument when defining a method in a package. Only the default, the namespace of the package, should be used in normal situations.

Inheritance and Coercion

Objects from one class can turn into objects from another class either automatically or by an explicit call to the as function. Automatic conversion is special, and comes from the designer of one class of objects asserting that this class extends another class. The most common case is that one or more class names are supplied in the contains= argument to setClass, in which case the new class extends each of the earlier classes (in the usual terminology, the earlier classes are superclasses of the new class and it is a subclass of each of them).

This form of inheritance is called simple inheritance in R. See setClass for details. Inheritance can also be defined explicitly by a call to setIs. The two versions have slightly different implications for coerce methods. Simple inheritance implies that inherited slots behave identically in the subclass and the superclass. Whenever two classes are related by simple inheritance, corresponding coerce methods are defined for both direct and replacement use of as. In the case of simple inheritance, these methods do the obvious computation: they extract or replace the slots in the object that correspond to those in the superclass definition.

The implicitly defined coerce methods may be overridden by a call to setAs; note, however, that the implicit methods are defined for each subclass-superclass pair, so that you must override each of these explicitly, not rely on inheritance.

When inheritance is defined by a call to setIs, the coerce methods are provided explicitly, not generated automatically. Inheritance will apply (to the from argument, as described in the section below). You could also supply methods via setAs for non-inherited relationships, and now these also can be inherited.

For further on the distinction between simple and explicit inheritance, see setIs.

How Functions 'as' and 'setAs' Work

The function as turns object into an object of class Class. In doing so, it applies a “coerce method”, using S4 classes and methods, but in a somewhat special way. Coerce methods are methods for the function coerce or, in the replacement case the function `coerce<-`. These functions have two arguments in method signatures, from and to, corresponding to the class of the object and the desired coerce class. These functions must not be called directly, but are used to store tables of methods for the use of as, directly and for replacements. In this section we will describe the direct case, but except where noted the replacement case works the same way, using `coerce<->` and the replace argument to setAs, rather than coerce and the def argument.

Assuming the object is not already of the desired class, as first looks for a method in the table of methods for the function coerce for the signature c(from = class(object), to = Class), in the same way method selection would do its initial lookup. To be precise, this means the table of both direct and inherited methods, but inheritance is used specially in this case (see below).

If no method is found, as looks for one. First, if either Class or class(object) is a superclass of the other, the class definition will contain the information needed to construct a coerce method. In the usual case that the subclass contains the superclass (i.e., has all its slots), the method is constructed either by extracting or replacing the inherited slots. Non-simple extensions (the result of a call to setIs) will usually contain explicit methods, though possibly not for replacement.
If no subclass/superclass relationship provides a method, `as()` looks for an inherited method, but applying, inheritance for the argument from only, not for the argument to (if you think about it, you’ll probably agree that you wouldn’t want the result to be from some class other than the Class specified). Thus, `selectMethod("coerce", sig, useInherited=c(from=TRUE, to=FALSE))` replicates the method selection used by `as()`.

In nearly all cases the method found in this way will be cached in the table of coerce methods (the exception being subclass relationships with a test, which are legal but discouraged). So the detailed calculations should be done only on the first occurrence of a coerce from `class(object)` to `Class`.

Note that `coerce` is not a standard generic function. It is not intended to be called directly. To prevent accidentally caching an invalid inherited method, calls are routed to an equivalent call to `as`, and a warning is issued. Also, calls to `selectMethod` for this function may not represent the method that as will choose. You can only trust the result if the corresponding call to `as` has occurred previously in this session.

With this explanation as background, the function `setAs` does a fairly obvious computation: It constructs and sets a method for the function `coerce` with signature `c(from, to)`, using the `def` argument to define the body of the method. The function supplied as `def` can have one argument (interpreted as an object to be coerced) or two arguments (the from object and the to class). Either way, `setAs` constructs a function of two arguments, with the second defaulting to the name of the to class. The method will be called from as with the object as the from argument and no to argument, with the default for this argument being the name of the intended to class, so the method can use this information in messages.

The direct version of the `as` function also has a `strict=` argument that defaults to `TRUE`. Calls during the evaluation of methods for other functions will set this argument to `FALSE`. The distinction is relevant when the object being coerced is from a simple subclass of the to class; if `strict=FALSE` in this case, nothing need be done. For most user-written coerce methods, when the two classes have no subclass/superclass, the `strict=` argument is irrelevant.

The `replace` argument to `setAs` provides a method for `"coerce<"`. As with all replacement methods, the last argument of the method must have the name `value` for the object on the right of the assignment. As with the `coerce` method, the first two arguments are `from`, `to`; there is no `strict=` option for the replace case.

The function `coerce` exists as a repository for such methods, to be selected as described above by the `as` function. Actually dispatching the methods using `standardGeneric` could produce incorrect inherited methods, by using inheritance on the to argument; as mentioned, this is not the logic used for as. To prevent selecting and caching invalid methods, calls to `coerce` are currently mapped into calls to `as`, with a warning message.

### Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, `as(x, "numeric")` uses the existing `as.numeric` function. These built-in methods can be listed by `showMethods("coerce")`.

### References

### See Also

If you think of using `try(as(x, cl))`, consider `canCoerce(x, cl)` instead.
Examples

## using the definition of class "track" from \link{setClass}

setAs("track", "numeric", function(from) from@y)

t1 <- new("track", x=1:20, y=(1:20)^2)

as(t1, "numeric")

## The next example shows:
## 1. A virtual class to define setAs for several classes at once.
## 2. as() using inherited information

setClass("ca", slots = c(a = "character", id = "numeric"))

setClass("cb", slots = c(b = "character", id = "numeric"))

setClass("id")

setIs("ca", "id")

setIs("cb", "id")

setAs("id", "numeric", function(from) from@id)

CA <- new("ca", a = "A", id = 1)

CB <- new("cb", b = "B", id = 2)

setAs("cb", "ca", function(from, to )new(to, a=from@b, id = from@id))

as(CB, "numeric")

---

**setClass**  
Create a Class Definition

Description

Create a class definition and return a generator function to create objects from the class. Typical usage will be of the style:

```r
myClass <- setClass("myClass", slots= ...., contains=....)
```

where the first argument is the name of the new class and, if supplied, the arguments slots= and contains= specify the slots in the new class and existing classes from which the new class should inherit. Calls to setClass() are normally found in the source of a package; when the package is loaded the class will be defined in the package’s namespace. Assigning the generator function with the name of the class is convenient for users, but not a requirement.

Usage

```r
setClass(Class, representation, prototype, contains=character(),
validity, access, where, version, sealed, package,
S3methods = FALSE, slots)
```
**setClass**

**Arguments**

- **Class**
  - character string name for the class.

- **slots**
  - The names and classes for the slots in the new class. This argument must be supplied by name, `slots=`, in the call, for back compatibility with other arguments no longer recommended.
  - The argument must be vector with a names attribute, the names being those of the slots in the new class. Each element of the vector specifies an existing class; the corresponding slot must be from this class or a subclass of it. Usually, this is a character vector naming the classes. It’s also legal for the elements of the vector to be class representation objects, as returned by `getClass`.
  - As a limiting case, the argument may be an unnamed character vector; the elements are taken as slot names and all slots have the unrestricted class "ANY".

- **contains**
  - A vector specifying existing classes from which this class should inherit. The new class will have all the slots of the superclasses, with the same requirements on the classes of these slots. This argument must be supplied by name, `contains=`, in the call, for back compatibility with other arguments no longer recommended.
  - See the section ‘Virtual Classes’ for the special superclass "VIRTUAL".

- **prototype, where, validity, sealed, package**
  - *These arguments are currently allowed, but either they are unlikely to be useful or there are modern alternatives that are preferred.*
  - **prototype**: supplies an object with the default data for the slots in this class. A more flexible approach is to write a method for `initialize()`.
  - **where**: supplies an environment in which to store the definition. Should not be used: For calls to `setClass()` appearing in the source code for a package the definition will be stored in the namespace of the package.
  - **validity**: supplied a validity-checking method for objects from this class. For clearer code, use a separate call to `isValid()`.
  - **sealed**: if `TRUE`, the class definition will be sealed, so that another call to `setClass` will fail on this class name. But the definition is automatically sealed after the namespace is loaded, so explicit sealing it is not needed.
  - **package**: supplies an optional package name for the class, but the class attribute should be the package in which the class definition is assigned, as it is by default.

- **representation, access, version, S3methods**
  - *All these arguments are deprecated from version 3.0.0 of R and should be avoided.*
  - **representation** is an argument inherited from S that included both `slots` and `contains`, but the use of the latter two arguments is clearer and recommended.
  - **access** and **version** are included for historical compatibility with S-Plus, but ignored.
  - **S3methods** is a flag indicating that old-style methods will be written involving this class; ignored now.

**Value**

A generator function suitable for creating objects from the class is returned, invisibly. A call to this function generates a call to `new` for the class. The call takes any number of arguments, which will be passed on to the initialize method. If no `initialize` method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the slots and unnamed arguments that are objects from one of the contained classes.
setClass

Typically the generator function is assigned the name of the class, for programming clarity. This is not a requirement and objects from the class can also be generated directly from `new`. The advantages of the generator function are a slightly simpler and clearer call, and that the call will contain the package name of the class (eliminating any ambiguity if two classes from different packages have the same name).

If the class is virtual, an attempt to generate an object from either the generator or `new()` will result in an error.

**Basic Use: Slots and Inheritance**

The two essential arguments other than the class name are `slots` and `contains`, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The superclass information specifies which methods apply indirectly, through inheritance. See `Methods_Details` for inheritance in method selection.

The slots in a class definition will be the union of all the slots specified directly by `slots` and all the slots in all the contained classes. There can only be one slot with a given name. A class may override the definition of a slot with a given name, but only if the newly specified class is a subclass of the inherited one. For example, if the contained class had a slot a with class "ANY", then a subclass could specify a with class "numeric", but if the original specification for the slot was class "character", the new call to `setClass` would generate an error.

Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the "." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.

Some inherited classes will be treated specially—object types, S3 classes and a few special cases—whether inherited directly or indirectly. See the next three sections.

**Virtual Classes**

Classes exist for which no actual objects can be created, the virtual classes.

The most common and useful form of virtual class is the class union, a virtual class that is defined in a call to `setClassUnion()` rather than a call to `setClass()`. This call lists the members of the union—subclasses that extend the new class. Methods that are written with the class union in the signature are eligible for use with objects from any of the member classes. Class unions can include as members classes whose definition is otherwise sealed, including basic R data types.

Calls to `setClass()` will also create a virtual class, either when only the `Class` argument is supplied (no slots or superclasses) or when the `contains=` argument includes the special class name "VIRTUAL".

In the latter case, a virtual class may include slots to provide some common behavior without fully defining the object—see the class `traceable` for an example. Note that "VIRTUAL" does not carry over to subclasses; a class that contains a virtual class is not itself automatically virtual.

**Inheriting from Object Types**

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the "data part" of the class. This appears as a pseudo-slot, ".Data" and can be treated as a slot but actually determines the type of objects from this slot.
Objects from the new class try to inherit the built in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object \( x \) from the class, \( \text{typeof}(x) \) will be the contained basic type; and a special pseudo-slot, \( .Data \), will be shown with the corresponding class. See the "numWithId" example below.

Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does not contain one of these types or classes, \( \text{typeof}(x) \) will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalptr", and "name". These can not be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot, \( \cdot.xData \). See the example for class "stampedEnv" below. An object from such a class does not have a \( .Data \) pseudo-slot.

For most computations, these classes behave transparently as if they inherited directly from the anomalous type. S3 method dispatch and the relevant \( \text{as.type}() \) functions should behave correctly, but code that uses the type of the object directly will not. For example, \( \text{as.environment(e1)} \) would work as expected with the "stampedEnv" class, but \( \text{typeof(e1)} \) is "S4".

**Inheriting from S3 Classes**

Old-style S3 classes have no formal definition. Objects are “from” the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from an S3 class, providing that class has been registered as an old class (see \( \text{setOldClass} \)).

Broadly speaking, both S3 and S4 method dispatch try to behave sensibly with respect to inheritance in either system. Given an S4 object, S3 method dispatch and the \( \text{inherits}() \) function should use the S4 inheritance information. Given an S3 object, an S4 generic function will dispatch S4 methods using the S3 inheritance, provided that inheritance has been declared via \( \text{setOldClass} \). For details, see \( \text{setOldClass} \) and Section 10.8 of the reference.

**Classes and Packages**

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the \( \text{classRepresentation} \) object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass in a call to \( \text{setClass} \), a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be already defined in this package, in the imports directives of the package’s \( \text{DESCRIPTION} \) and \( \text{NAMESPACE} \) files or in the basic classes defined by the methods package. (The ‘methods’ package must be included in the imports directives for any package that uses S4 methods and classes, to satisfy the "CMD check" utility.)
If a package imports two classes of the same name from separate packages, the `packageSlot` of the name argument needs to be set to the package name of the particular class. This should be a rare occurrence.

Examples

```r
## A simple class with two slots
track <- setClass("track", slots = c(x="numeric", y="numeric"))
## an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

## A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve",
  slots = c(smooth = "numeric"),
  contains = "track")

## an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
  slots = c(x="numeric", y="matrix", smooth="matrix"),
  prototype = list(x=numeric(), y=matrix(0,0,0),
                  smooth= matrix(0,0,0)))

## A class that extends the built-in data type "numeric"
numWithId <- setClass("numWithId", slots = c(id = "character"),
                     contains = "numeric")
numWithId(1:3, id = "An Example")

## inherit from reference object of type "environment"
stampedEnv <- setClass("stampedEnv", contains = "environment",
                      slots = c(update = "POSIXct"))
setMethod("[[-", c("stampedEnv", "character", "missing"),
          function(x, i, j, ..., value) {
            ev <- as(x, "environment")
            ev[i] <- value # update the object in the environment
            x$update <- Sys.time() # and the update time
          })

e1 <- stampedEnv(update = Sys.time())

e1["noise"] <- rnorm(10)
```
setClassUnion

Classes Defined as the Union of Other Classes

Description

A class may be defined as the union of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

Usage

setClassUnion(name, members, where)
isClassUnion(Class)

Arguments

name the name for the new union class.
members the names of the classes that should be members of this union.
where where to save the new class definition. In calls from a package’s source code, should be omitted to save the definition in the package’s namespace.

Class the name or definition of a class.

Details

The classes in members must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

Class unions are the only way to create a new superclass of a class whose definition is sealed. The namespace of all packages is sealed when the package is loaded, protecting the class and other definitions from being overwritten from another class or from the global environment. A call to setIs that tried to define a new superclass for class "numeric", for example, would cause an error.

Class unions are the exception; the class union "maybeNumber" in the examples defines itself as a new superclass of "numeric". Technically, it does not alter the metadata object in the other package’s namespace and, of course, the effect of the class union depends on loading the package it belongs to. But, basically, class unions are sufficiently useful to justify the exemption.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class classRepresentation.

Examples

## a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
setClass("withId", contains = "maybeNumber", slots = c(id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%1 < .01, id = "Perfect squares")

## add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")

w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

## a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode", 
  c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode") ## TRUE

---

setGeneric

Create a Generic Version of a Function

Description

Create a generic version of the named function so that methods may be defined for it. A call to setMethod will call setGeneric automatically if applied to a non-generic function.

An explicit call to setGeneric is usually not required, but doesn’t hurt and makes explicit that methods are being defined for a non-generic function.

Standard calls will be of the form:

setGeneric(name)

where name specifies an existing function, possibly in another package. An alternative when creating a new generic function in this package is:

setGeneric(name, def)

where the function definition def specifies the formal arguments and becomes the default method.

Usage

setGeneric(name, def=, group=list(), valueClass=character(),
  where=, package=, signature=, useAsDefault=,
  genericFunction=, simpleInheritanceOnly = )

Arguments

name The character string name of the generic function.
def An optional function object, defining the non-generic version, to become the
default method. This is equivalent in effect to assigning `def` as the function and
then using the one-argument call to `setGeneric`. 

The following arguments are specialized, optionally used when creating a new
generic function with non-standard features. They should not be used when the
non-generic is in another package.

group The name of the group generic function to which this function belongs. See
`Methods_Details` for details of group generic functions in method selection and
`S4groupGeneric` for existing groups.

valueClass A character vector specifying one or more class names. The value returned
by the generic function must have (or extend) this class, or one of the classes;
otherwise, an error is generated.

signature The vector of names from among the formal arguments to the function, that will
be allowed in the signature of methods for this function, in calls to `setMethod`
By default and usually, this will be all formal arguments except `...`.

A non-standard signature for the generic function may be used to exclude argu-
ments that take advantage of lazy evaluation; in particular, if the argument may
not be evaluated then it cannot be part of the signature.

While `...` cannot be used as part of a general signature, it is possible to have this
as the only element of the signature. Methods will then be selected if their signature
matches all the `...` arguments. See the documentation for the `dotsMethods`
details. It is not possible to mix `...` and other arguments in the signature.
It’s usually a mistake to omit arguments from the signature in the belief that this
improves efficiency. For method selection, the arguments that are used in the
signatures for the `methods` are what counts, and then only seriously on the first
call to the function with that combination of classes.

simpleInheritanceOnly Supply this argument as `TRUE` to require that methods selected be inherited
through simple inheritance only; that is, from superclasses specified in the
contains= argument to `setClass`, or by simple inheritance to a class union
or other virtual class. Generic functions should require simple inheritance if
they need to be assured that they get the complete original object, not one that
has been transformed. Examples of functions requiring simple inheritance are
`initialize`, because by definition it must return an object from the same class
as its argument, and `show`, because it claims to give a full description of the
object provided as its argument.

useAsDefault Override the usual default method mechanism. Only relevant when defining a
nonstandard generic function. See the section ‘Specialized Local Generics’.

The remaining arguments are obsolete for normal applications.

package The name of the package with which this function is associated. Should be
determined automatically from the non-generic version.

where Where to store the resulting objects as side effects. The default, to store in the
package’s namespace, is the only safe choice.

genericFunction Obsolete.

Value

The `setGeneric` function exists for its side effect: saving the generic function to allow methods to
be specified later. It returns `name`. 
**Basic Use**

The `setGeneric` function is called to initialize a generic function as preparation for defining some methods for that function.

The simplest and most common situation is that `name` specifies an existing function, usually in another package. You now want to define methods for this function. In this case you should supply only `name`, for example:

```r
colSums
```

There must be an existing function of this name (in this case in package "base"). The non-generic function can be in the same package as the call, typically the case when you are creating a new function plus methods for it. When the function is in another package, it must be available by name, for example through an `importFrom()` directive in this package's `NAMESPACE` file. Not required for functions in "base", which are implicitly imported.

A generic version of the function will be created in the current package. The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example).

Two special types of non-generic should be noted. Functions that dispatch S3 methods by calling `UseMethod` are ordinary functions, not objects from the "genericFunction" class. They are made generic like any other function, but some special considerations apply to ensure that S4 and S3 method dispatch is consistent (see Methods_for_S3).

Primitive functions are handled in C code and don't exist as normal functions. A call to `setGeneric` is allowed in the simple form, but no actual generic function object is created. Method dispatch will take place in the C code. See the section on Primitive Functions for more details.

It's an important feature that the identical generic function definition is created in every package that uses the same `setGeneric()` call. When any of these packages is loaded into an R session, this function will be added to a table of generic functions, and will contain a methods table of all the available methods for the function.

Calling `setGeneric()` is not strictly necessary before calling `setMethod()`. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. In the case that the non-generic is in another package, does not dispatch S3 methods and is not a primitive, a message is printed noting the creation of the generic function the first time `setMethod` is called.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function. See the `asRObject()` example below. This case can be handled just like the previous examples, with only the difference that the non-generic function exists in the current package. Again, the non-generic version becomes the default method. For clarity it's best for the assignment to immediately precede the call to `setGeneric()` in the source code.

Exactly the same result can be obtained by supplying the default as the `def` argument instead of assigning it. In some applications, there will be no completely general default method. While there is a special mechanism for this (see the ‘Specialized Local Generics’ section), the recommendation is to provide a default method that signals an error, but with a message that explains as clearly as you can why a non-default method is needed.

**Specialized Local Generics**

The great majority of calls to `setGeneric()` should either have one argument to ensure that an existing function can have methods, or arguments `name` and `def` to create a new generic function and optionally a default method.

It is possible to create generic functions with nonstandard signatures, or functions that do additional computations besides method dispatch or that belong to a group of generic functions.
None of these mechanisms should be used with a non-generic function from a different package, because the result is to create a generic function that may not be consistent from one package to another. When any such options are used, the new generic function will be assigned with a package slot set to the current package, not the one in which the non-generic version of the function is found.

There is a mechanism to define a specialized generic version of a non-generic function, the implicitGeneric construction. This defines the generic version, but then reverts the function to its non-generic form, saving the implicit generic in a table to be activated when methods are defined. However, the mechanism can only legitimately be used either for a non-generic in the same package or by the "methods" package itself. And in the first case, there is no compelling reason not to simply make the function generic, with the non-generic as the default method. See implicitGeneric for details.

The body of a generic function usually does nothing except for dispatching methods by a call to standardGeneric. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls standardGeneric that is permissible. See the example "authorNames" below.

In this case, the def argument will define the nonstandard generic, not the default method. An existing non-generic of the same name and calling sequence should be pre-assigned. It will become the default method, as usual. (An alternative is the useAsDefault argument.)

By default, the generic function can return any object. If valueClass is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy is(object, Class) for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

If the def argument calls standardGeneric() (with or without additional computations) and there is no existing non-generic version of the function, the generic is created without a default method. This is not usually a good idea: better to have a default method that signals an error with a message explaining why the default case is not defined.

A new generic function can be created belonging to an existing group by including the group argument. The argument list of the new generic must agree with that of the group. See setGroupGeneric for defining a new group generic. For the role of group generics in dispatching methods, see GroupGenericFunctions and section 10.5 of the second reference.

Generic Functions and Primitive Functions

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see implicitGeneric), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Calling setGeneric() for the primitive functions in the base package differs in that it does not, in fact, generate an explicit generic function. Methods for primitives are selected and dispatched from the internal C code, to satisfy concerns for efficiency. The same is true for a few non-primitive functions that dispatch internally. These include unlist and as.vector.

Note, that the implementation restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class. Otherwise the internal C code will not look for methods. This is a desirable restriction in principle, since optional packages should not be allowed to change the behavior of basic R computations on existing data types.

To see the generic version of a primitive function, use getGeneric(name). The function isGeneric will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘internal generic’, plus %*%. 
setGroupGeneric

Create a Group Generic Version of a Function

Description

The setGroupGeneric function behaves like setGeneric except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a stop call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

All members of the group must have the identical argument list.

Examples

```r
## Specify that this package will define methods for plot()
setGeneric("plot")

## create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

### A non-standard generic function. It insists that the methods
### return a non-empty character vector (a stronger requirement than
### valueClass = "character" in the call to setGeneric)
setGeneric("authorNames",
    function(text) {
        value <- standardGeneric("authorNames")
        if(!(is(value, "character") && any(nchar(value)>0)))
            stop("authorNames methods must return non-empty strings")
        value
    })

## the asRObject generic function, from package XR
## Its default method just returns object
## See the reference, Chapter 12 for methods
setGeneric("asRObject", function(object, evaluator) {
    object
})
```
setIs

Specify a Superclass Explicitly

Description

setIs is an explicit alternative to the contains= argument to setClass. It is only needed to create relations with explicit test or coercion. These have not proved to be of much practical value, so this function should not likely be needed in applications.

Where the programming goal is to define methods for transforming one class of objects to another, it is usually better practice to call setAs(), which requires the transformations to be done explicitly.

Usage

setGroupGeneric(name, def=, group=list(), valueClass=character(),
knownMembers=list(), package=, where=)

Arguments

name the character string name of the generic function.
def A function object. There isn’t likely to be an existing nongeneric of this name, so some function needs to be supplied. Any known member or other function with the same argument list will do, because the group generic cannot be called directly.
group, valueClass arguments to pass to setGeneric.
knownMembers the names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.
package, where passed to setGeneric, but obsolete and to be avoided.

Value

The setGroupGeneric function exists for its side effect: saving the generic function to allow methods to be specified later. It returns name.

References

See Also

Methods_Details and the links there for a general discussion, dotsMethods for methods that dispatch on ..., and setMethod for method definitions.

Examples

## Not run:
## the definition of the "Logic" group generic in the methods package
setGroupGeneric("Logic", function(e1, e2) NULL,
knownMembers = c("&", "|"))
## End(Not run)
Usage

```r
setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
     by = character(), where = topenv(parent.frame()), classDef =,
     extensionObject = NULL, doComplete = TRUE)
```

Arguments

class1, class2  the names of the classes between which `is` relations are to be examined defined, or (more efficiently) the class definition objects for the classes.

coerce, replace  functions optionally supplied to coerce the object to class2, and to alter the object so that `is(object, class2)` is identical to value. See the details section below.

test  a conditional relationship is defined by supplying this function. Conditional relations are discouraged and are not included in selecting methods. See the details section below.

The remaining arguments are for internal use and/or usually omitted.

extensionObject  alternative to the `test`, `coerce`, `replace`, by arguments; an object from class `SClassExtension` describing the relation. (Used in internal calls.)

doComplete  when `TRUE`, the class definitions will be augmented with indirect relations as well. (Used in internal calls.)

by  In a call to `setIs`, the name of an intermediary class. Coercion will proceed by first coercing to this class and from there to the target class. (The intermediate coercions have to be valid.)

where  In a call to `setIs`, where to store the metadata defining the relationship. Default is the global environment for calls from the top level of the session or a source file evaluated there. When the call occurs in the top level of a file in the source of a package, the default will be the namespace or environment of the package. Other uses are tricky and not usually a good idea, unless you really know what you are doing.

classDef  Optional class definition for class, required internally when `setIs` is called during the initial definition of the class by a call to `setClass`. *Don’t use this argument, unless you really know why you’re doing so.*

Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the `contains=` argument in a call to `setClass`. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be simple, with important implications for method definition (see the section on this topic below).

2. Making `class1` a subclass of a virtual class either by a call to `setClassUnion` to make the subclass a member of a new class union, or by a call to `setIs` to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for
the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.

3. Supplying `coerce` and `replace` arguments to `setIs`. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to `setAs`. The difference between the two is simply that `setAs` will require a call to `as` for a conversion to take place, whereas after the call to `setIs`, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the `setAs` mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when `coerce=` and `replace=` arguments are supplied to `setIs`.

The `coerce` and `replace` arguments are functions that define how to coerce a `class1` object to `class2`, and how to replace the part of the subclass object that corresponds to `class2`. The first of these is a function of one argument which should be `from`, and the second of two arguments (`from`, `value`). For details, see the section on coerce functions below.

When `by` is specified, the coerce process first coerces to this class and then to `class2`. It’s unlikely you would use the `by` argument directly, but it is used in defining cached information about classes.

The value returned (invisibly) by `setIs` is the revised class definition of `class1`.

Coerce, replace, and test functions

The `coerce` argument is a function that turns a `class1` object into a `class2` object. The `replace` argument is a function of two arguments that modifies a `class1` object (the first argument) to replace the part of it that corresponds to `class2` (supplied as `value`, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression `as(object, class2) <- value`.

The easiest way to think of the `coerce` and `replace` functions is by thinking of the case that `class1` contains `class2` in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call `setIs`, but the analogy shows what happens when you do.)

The `coerce` function in this case would just make a `class2` object by extracting the corresponding slots from the `class1` object. The `replace` function would replace in the `class1` object the slots corresponding to `class2`, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the `setAs` function. (Unfortunately, argument `def` to that function corresponds to argument `coerce` here.)

The inheritance relationship can also be conditional, if a function is supplied as the `test` argument. This should be a function of one argument that returns `TRUE` or `FALSE` according to whether the object supplied satisfies the relation `is(object, class2)`. Conditional relations between classes are discouraged in general because they require a per-object calculation to determine their validity. They cannot be applied as efficiently as ordinary relations and tend to make the code that uses them harder to interpret. **NOTE: conditional inheritance is not used to dispatch methods.** Methods for conditional superclasses will not be inherited. Instead, a method for the subclass should be defined that tests the conditional relationship.
Inherited methods

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.

The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the contains= argument in a call to \texttt{setClass}, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to \texttt{setIs}, extra computations are required. This form of inheritance implies that the subclass does not just contain the slots of the superclass, but instead requires the explicit call to the coerce and/or replace method. To ensure correct computation, the inherited method is supplemented by calls to \texttt{as} before the body of the method is evaluated.

The calls to \texttt{as} generated in this case have the argument \texttt{strict = FALSE}, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It’s this option that allows simple subclass objects to be used without any change.) When you are writing your coerce method, you may want to take advantage of that option.

Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If \texttt{class2} is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of \texttt{class1}. But if \texttt{class2} is a class with many methods, you may find that you now inherit some undesirable methods for \texttt{class1}, in some cases, fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example initialize methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the \texttt{simpleInheritanceOnly} argument to \texttt{setGeneric} for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the \texttt{setIs} call and settle for explicit coercing defined by a call to \texttt{setAs}; or, define explicit methods involving \texttt{class1} to override the bad inherited methods. The first choice is the safer, when there are serious problems.

Examples

\begin{verbatim}
## Two examples of setIs() with coerce= and replace= arguments
## The first one works fairly well, because neither class has many
## inherited methods do be disturbed by the new inheritance

## The second example does NOT work well, because the new superclass,
## "factor", causes methods to be inherited that should not be.

## First example:
## a class definition (see \link{setClass} for class "track")
\end{verbatim}
setClass("trackCurve", contains = "track",
  slots = c(smooth = "numeric"))
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
  slots = c(x = "numeric", y = "matrix", smooth = "matrix"),
  prototype = structure(list(), x = numeric(), y = matrix(0, 0, 0),
                         smooth = matrix(0, 0, 0)))
## Automatically convert an object from class "trackCurve" into
## "trackMultiCurve", by making the y, smooth slots into 1-column matrices
setIs("trackCurve",
  "trackMultiCurve",
  coerce = function(obj) {
    new("trackMultiCurve",
        x = obj@x,
        y = as.matrix(obj@y),
        smooth = as.matrix(obj@smooth))
  },
  replace = function(obj, value) {
    obj@y <- as.matrix(value@y)
    obj@x <- value@x
    obj@smooth <- as.matrix(value@smooth)
    obj})

## Second Example:
## A class that adds a slot to "character"
setClass("stringsDated", contains = "character",
  slots = c(stamp = "POSIXt"))
## Convert automatically to a factor by explicit coerce
setIs("stringsDated", "factor",
  coerce = function(from) factor(from@.Data),
  replace = function(from, value) {
    from@.Data <- as.character(value); from })
ll <- sample(letters, 10, replace = TRUE)
ld <- new("stringsDated", ll, stamp = Sys.time())
levels(as(ld, "factor"))
levels(ld) # will be NULL--see comment in section on inheritance above.

## In contrast, a class that simply extends "factor"
## has no such ambiguities
setClass("factorDated", contains = "factor",
  slots = c(stamp = "POSIXt"))
fd <- new("factorDated", factor(ll), stamp = Sys.time())
identical(levels(fd), levels(as(fd, "factor")))
setLoadActions

Description

These functions provide a mechanism for packages to specify computations to be done during the loading of a package namespace. Such actions are a flexible way to provide information only available at load time (such as locations in a dynamically linked library).

A call to setLoadAction() or setLoadActions() specifies one or more functions to be called when the corresponding namespace is loaded, with the ... argument names being used as identifying names for the actions.

getLoadActions reports the currently defined load actions, given a package’s namespace as its argument.

hasLoadAction returns TRUE if a load action corresponding to the given name has previously been set for the where namespace.

evalOnLoad() and evalqOnLoad() schedule a specific expression for evaluation at load time.

Usage

setLoadAction(action, aname=, where=)

setLoadActions(..., .where=)

getLoadActions(where=)

hasLoadAction(aname, where=)

evalOnLoad(expr, where=, aname=)

evalqOnLoad(expr, where=, aname=)

Arguments

action, ... functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values.

If the elements of ... are named, these names will be used for the corresponding load metadata.

where, .where the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.

aname the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified (".1", etc.).

eexpr an expression to be evaluated in a load action in environment where. In the case of evalqOnLoad(), the expression is interpreted literally, in that of evalOnLoad() it must be precomputed, typically as an object of type "language".

Details

The evalOnLoad() and evalqOnLoad() functions are for convenience. They construct a function to evaluate the expression and call setLoadAction() to schedule a call to that function.
Each of the functions supplied as an argument to `setLoadAction()` or `setLoadActions()` is saved as metadata in the namespace, typically that of the package containing the call to `setLoadActions()`. When this package's namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to `setLoadActions()`. The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions (".1", etc.).

Multiple calls to `setLoadAction()` or `setLoadActions()` can be used in a package's code; the actions will be scheduled after any previously specified, except if the name given to `setLoadAction()` is that of an existing action. In typical applications, `setLoadActions()` is more convenient when calling from the package's own code to set several actions. Calls to `setLoadAction()` are more convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any compiled code, the call to `.onLoad()`, if any, and caching method and class definitions, but before the namespace is sealed. (Load actions are only called if methods dispatch is on.)

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by `setHook()`. User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load actions are normally part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

Value

`setLoadAction()` and `setLoadActions()` are called for their side effect and return no useful value.

`getLoadActions()` returns a named list of the actions in the supplied namespace.

`hasLoadAction()` returns `TRUE` if the specified action name appears in the actions for this package.

See Also

`setHook` for safer (since they are run after the namespace is sealed) and more comprehensive versions in the base package.

Examples

```r
## Not run:
## in the code for some package

## ... somewhere else
setLoadActions(function(ns)
```
setMethod

Create and Save a Method

Description

Create a method for a generic function, corresponding to a signature of classes for the arguments. Standard usage will be of the form:

```r
setMethod(f, signature, definition)
```

where `f` is the name of the function, `signature` specifies the argument classes for which the method applies and `definition` is the function definition for the method.

Usage

```r
setMethod(f, signature=character(), definition, 
where = topenv(parent.frame()), 
valueClass = NULL, sealed = FALSE)
```

Arguments

- **f**: The character-string name of the generic function. The unquoted name usually works as well (evaluating to the generic function), except for a few functions in the base package.

- **signature**: The classes required for some of the arguments. Most applications just require one or two character strings matching the first argument(s) in the signature. More complicated cases follow R’s rule for argument matching. See the details below; however, if the signature is not trivial, you should use `method.skeleton` to generate a valid call to `setMethod`.

- **definition**: A function definition, which will become the method called when the arguments in a call to `f` match the classes in `signature`, directly or through inheritance. The definition must be a function with the same formal arguments as the generic; however, `setMethod()` will handle methods that add arguments, if ... is a formal argument to the generic. See the Details section.

- **where**, **valueClass**, **sealed**

  **These arguments are allowed but either obsolete or rarely appropriate.**

  - **where**: where to store the definition; should be the default, the namespace for the package.
  - **valueClass**: Obsolete.
  - **sealed**: prevents the method being redefined, but should never be needed when the method is defined in the source code of a package.
Value

The function exists for its side-effect. The definition will be stored in a special metadata object and incorporated in the generic function when the corresponding package is loaded into an R session.

Method Selection: Avoiding Ambiguity

When defining methods, it’s important to ensure that methods are selected correctly; in particular, packages should be designed to avoid ambiguous method selection.

To describe method selection, consider first the case where only one formal argument is in the active signature; that is, there is only one argument, $x$ say, for which methods have been defined. The generic function has a table of methods, indexed by the class for the argument in the calls to `setMethod`. If there is a method in the table for the class of $x$ in the call, this method is selected.

If not, the next best methods would correspond to the direct superclasses of `class(x)`—those appearing in the `contains=` argument when that class was defined. If there is no method for any of these, the next best would correspond to the direct superclasses of the first set of superclasses, and so on.

The first possible source of ambiguity arises if the class has several direct superclasses and methods have been defined for more than one of those; R will consider these equally valid and report an ambiguous choice. If your package has the class definition for `class(x)`, then you need to define a method explicitly for this combination of generic function and class.

When more than one formal argument appears in the method signature, R requires the “best” method to be chosen unambiguously for each argument. Ambiguities arise when one method is specific about one argument while another is specific about a different argument. A call that satisfies both requirements is then ambiguous: The two methods look equally valid, which should be chosen? In such cases the package needs to add a third method requiring both arguments to match.

The most common examples arise with binary operators. Methods may be defined for individual operators, for special groups of operators such as `Arith` or for group `Ops`.

Exporting Methods

If a package defines methods for generic functions, those methods should be exported if any of the classes involved are exported; in other words, if someone using the package might expect these methods to be called. Methods are exported by including an `exportMethods()` directive in the `NAMESPACE` file for the package, with the arguments to the directive being the names of the generic functions for which methods have been defined.

Exporting methods is always desirable in the sense of declaring what you want to happen, in that you do expect users to find such methods. It can be essential in the case that the method was defined for a function that is not originally a generic function in its own package (for example, `plot()` in the `graphics` package). In this case it may be that the version of the function in the R session is not generic, and your methods will not be called.

Exporting methods for a function also exports the generic version of the function. Keep in mind that this does not conflict with the function as it was originally defined in another package; on the contrary, it’s designed to ensure that the function in the R session dispatches methods correctly for your classes and continues to behave as expected when no specific methods apply. See `Methods_Details` for the actual mechanism.

Details

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the
case of a package, the table object becomes part of the namespace or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the function originated. For example, generic functions for all the functions in package base will have "base" as the package name, although none of them is an S4 generic on that package. These include most of the base functions that are primitives, rather than true functions; see the section on primitive functions in the documentation for setGeneric for details.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument must not appear in the call in order to match this signature. Don't confuse these two: if an argument isn't mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below.

Old-style (S3) classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling setOldClass if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but only if the generic function must have some default expression for the same argument. (This restriction is imposed by the way R manages formal arguments.) If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to standardGeneric(f) occurs. Note that specifying class "missing" in the signature does not require any default expressions.

It is possible to have some differences between the formal arguments to a method supplied to setMethod and those of the generic. Roughly, if the generic has ... as one of its arguments, then the method may have extra formal arguments, which will be matched from the arguments matching ... in the call to f. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for f. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See Methods_Details and Section 10.7 of the reference for more details.

Examples

## examples for a simple class with two numeric slots.
## (Run example(setMethod) to see the class and function definitions)

## methods for plotting track objects
##
## First, with only one object as argument, plot the two slots
## y must be included in the signature, it would default to "ANY"
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(x@x, x@y, ...)
)

## plot numeric data on either axis against a track object
## (reducing the track object to the cumulative distance along the track)
## Using a short form for the signature, which matches like formal arguments
setMethod("plot", c("track", "numeric"),
  function(x, y, ...) plot(cumdist(x@x, x@y), y, xlab = "Distance",...)
)

## and similarly for the other axis
setMethod("plot", c("numeric", "track"),
  function(x, y, ...) plot(x, cumdist(y@x, y@y), ylab = "Distance",...)
)

t1 <- new("track", x=1:20, y=(1:20)^2)
plot(t1)
plot(qnorm(ppoints(20)), t1)

## Now a class that inherits from "track", with a vector for data at
## the points
setClass("trackData", contains = c("numeric", "track"))
tc1 <- new("trackData", t1, rnorm(20))

## a method for plotting the object
## This method has an extra argument, allowed because ... is an
## argument to the generic function.
setMethod("plot", c("trackData", "missing"),
  function(x, y, maxRadius = max(par("cin")), ...) {
    plot(x@x, x@y, type = "n", ...)
    symbols(x@x, x@y, type = "n", ...)
  }
)
## Without other methods for "trackData", methods for "track"
## will be selected by inheritance

```r
plot(qnorm(ppoints(20)), tc1)
```

## defining methods for primitive function.
## Although "[" and "length" are not ordinary functions
## methods can be defined for them.

```r
setMethod("[", "track",
  function(x, i, j, ...., drop) {
    x@x <- x@x[i]; x@y <- x@y[i]
    x
  })
```

```r
plot(t1[1:15])
```

```r
setMethod("length", "track", function(x)length(x@y))
length(t1)
```

## Methods for binary operators
## A method for the group generic "Ops" will apply to all operators
## unless a method for a more specific operator has been defined.

```r
setMethod("Ops", signature(e1 = "trackData"),
  function(e1, e2) callGeneric(e1@.Data, e2))
setMethod("Ops", signature(e2 = "trackData"),
  function(e1, e2) callGeneric(e1, e2@.Data))
```

## At this point, the choice of a method for a call with BOTH
## arguments from "trackData" is ambiguous. We must define a method.

```r
setMethod("Ops", signature(e1 = "trackData", e2 = "trackData"),
  function(e1, e2) callGeneric(e1@.Data, e2@.Data))
```

## (well, really we should only do this if the "track" part
## of the two arguments matched)

```r
tc1 +1
1/tc1
all(tc1 == tc1)
```

---

**setOldClass**

*Register Old-Style (S3) Classes and Inheritance*

**Description**

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. Simple usage will be of the form:

```r
setOldClass
```
**setOldClass**

where `Classes` is the character vector that would be the class attribute of the S3 object. Calls to `setOldClass()` in the code for a package allow the class to be used as a slot in formal (S4) classes and in signatures for methods (see Methods_for_S3). Formal classes can also contain a registered S3 class (see S3Part for details).

If the S3 class has a known set of attributes, an equivalent S4 class can be specified by `S4Class=` in the call to `setOldClass()`; see the section “Known Attributes”.

**Usage**

```
setOldClass(Classes, prototype, where, test = FALSE, S4Class)
```

**Arguments**

- **Classes**: A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the class attribute in S3 computations.
  
  In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.

- **S4Class**: optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus any S3 inheritance implied by multiple names in the `Classes` argument. See the section on “S3 classes with known attributes” below.

- **prototype, where, test**

  These arguments are currently allowed, but not recommended in typical applications.

  - **prototype**: An optional object to use as the prototype. If the S3 class is not to be VIRTUAL (the default), the use of `S4Class=` is preferred.

  - **where**: Where to store the class definitions. Should be the default (the package namespace) for normal use in an application package.

  - **test**: flag, if TRUE, arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. Such classes are inherently malformed, are rare, and should be avoided.

**Details**

The name (or each of the names) in `Classes` will be defined as an S4 class, extending class `oldClass`, which is the ‘root’ of all old-style classes. S3 classes with multiple names in their class attribute will have a corresponding inheritance as formal classes. See the “nlm” example.

S3 classes have no formal definition, and therefore no formally defined slots. If no S4 class is supplied as a model, the class created will be a virtual class. If a virtual class (any virtual class) is used for a slot in another class, then the initializing method for the class needs to put something legal in that slot; otherwise it will be set to NULL.

See Methods_for_S3 for the details of method dispatch and inheritance with mixed S3 and S4 methods.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects with the same initial string in the class attribute can have different strings following. Such classes are fortunately rare. They violate the basic idea of object-oriented programming and should be avoided. If you must deal with them, it is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call `setOldClass` with argument `test=TRUE`. 
Pre-Defined Old Classes

Many of the widely used S3 classes in the standard R distribution come pre-defined for use with S4. These don’t need to be explicitly declared in your package (although it does no harm to do so). The list .OldClassesList contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to setOldClass when creating the methods package; therefore, these classes can be used in setMethod calls, with the inheritance as implied by the list.

S3 Classes with known attributes

A further specification of an S3 class can be made if the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to setOldClass() can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument S4Class= to setOldClass().

See the definition of class "ts" in the examples below and the data.frame example in Section 10.2 of the reference. The call to setClass to create the S4 class can use the same class name, as here, so long as the call to setOldClass follows in the same package. For clarity it should be the next expression in the same file.

In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the structure class).

Failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., dimnames in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class "NULL", because attributes, unlike slots, can not have value NULL.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, "terms" in "data.frame" objects returned by model.frame). Validity checks by validObject ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

setClass, setMethod
Examples

```r
require(stats)

## "lm" and "mlm" are predefined; if they were not this would do it:
## Not run:
setOldClass(c("mlm", "lm"))
## End(Not run)

## Define a new generic function to compute the residual degrees of freedom
setGeneric("dfResidual",
  function(model) stop(gettextf("This function only works for fitted model objects, not class \%s", class(model))))

setMethod("dfResidual", "lm", function(model) model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

## two examples extending S3 class "lm": class "xlm" directly
## and "ylm" indirectly
setClass("xlm", slots = c(eps = "numeric"), contains = "lm")
setClass("ylm", slots = c(header = "character"), contains = "xlm")
ym1 = new("ylm", myLm, header = "Example", eps = 0.)
## for more examples, see ?\link{S3Class}.

## Not run:
## The code in R that defines "ts" as an S4 class
setClass("ts", contains = "structure", slots = c(tsp = "numeric"),
  prototype(NA, tsp = rep(1,3)))

## and now registers it as an S3 class
setOldClass("ts", S4Class = "ts", where = envir)
## End(Not run)
```

show

Show an Object

Description

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for `show` will usually be invoked for automatic printing (see the details).
Usage

show(object)

Arguments

object Any R object

Details

Objects from an S4 class (a class defined by a call to `setClass`) will be displayed automatically if by a call to `show`. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to `print`.

Methods defined for `show` will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Value

`show` returns an invisible `NULL`.

See Also

`showMethods` prints all the methods for one or more functions.

Examples

```r
## following the example shown in the setMethod documentation ...
setClass("track", slots = c(x="numeric", y="numeric"))
setClass("trackCurve", contains = "track", slots = c(smooth = "numeric"))
t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)
setMethod("show", "track",
  function(object)print(rbind(x = object@x, y=object@y))
)
## The method will now be used for automatic printing of t1

t1

x 1 2 3 4 5 6 7 8 9 10 11 12
y 1 4 9 16 25 36 49 64 81 100 121 144

## End(Not run)
## and also for tc1, an object of a class that extends "track"
tc1

x 13 14 15 16 17 18 19 20
y 169 196 225 256 289 324 361 400

## End(Not run)
```
showMethods

Show all the methods for the specified function(s) or class

Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

showMethods(f = character(), where = topenv(parent.frame()),
             classes = NULL, includeDefs = FALSE,
             inherited = !includeDefs,
             showEmpty, printTo = stdout(), fdef)

Arguments

f
  one or more function names. If omitted, all functions will be shown that match the other arguments.
  The argument can also be an expression that evaluates to a single generic function, in which case argument fdef is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for isDiagonal().

where
  Where to find the generic function, if not supplied as an argument. When f is missing, or length 0, this also determines which generic functions to examine. If where is supplied, only the generic functions returned by getGenerics(where) are eligible for printing. If where is also missing, all the cached generic functions are considered.

classes
  If argument classes is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

includeDefs
  If includeDefs is TRUE, include the definitions of the individual methods in the printout.

inherited
  logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See selectMethod if you want to know what method would be dispatched for particular classes of arguments.

showEmpty
  logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument f is not missing.
The connection on which the information will be shown; by default, on standard output.

Optionally, the generic function definition to use; if missing, one is found, looking in where if that is specified. See also comment in ‘Details’.

generic.function, class
See methods.

Details
See methods for a description of .S4methods.

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because f was missing, the functions are found and showMethods is recalled for each, including the generic as the argument fdef. In complicated situations, this can avoid some anomalous results.

Value
If printTo is FALSE, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via invisible.

See Also
setMethod, and GenericFunctions for other tools involving methods; selectMethod will show you the method dispatched for a particular function and signature of classes for the arguments. methods provides method discovery tools for light-weight interactive use.

Examples

```r
require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
# Function "plot":
# x = ANY, y = track
# x = track, y = missing
# x = track, y = ANY

require("Matrix")
showMethods("%*%")# many!
  methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
```
showMethods(Matrix:::isDiagonal) # a non-exported generic

## End(Not run)

if(no4 <- is.na(match("stats4", loadedNamespaces())))
  loadNamespace("stats4")
  showMethods(classes = "mle") # -> a method for show()
if(no4) unloadNamespace("stats4")
The Slots in an Object from a Formal Class

Description

These functions return or set information about the individual slots in an object.

Usage

object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
.hasSlot(object, name)

slotNames(x)
getSlots(x)

Arguments

object
An object from a formally defined class.

name
The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes).

In the case of the `slot` function, `name` can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is because the slot name has to be computed.

value
A new value for the named slot. The value must be valid for this slot in this object’s class.

check
In the replacement version of `slot`, a flag. If `TRUE`, check the assigned value for validity as the value of this slot. User’s code should not set this to `FALSE` in normal use, since the resulting object can be invalid.

x
either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, `slotNames` (only) uses `class(x)` instead.

Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The `@` extraction operator and `slot` function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for `slot` in the case `check=FALSE`). So long as slots are set without cheating, the extracted slots will be valid.
Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious
way is to assign a slot with check=FALSE. Also, slots in R are implemented as attributes, for the sake
of some back compatibility. The current implementation does not prevent attributes being assigned,
via attr<-, and such assignments are not checked for legitimate slot names.

Note that the "@" operators for extraction and replacement are primitive and actually reside in the
base package.

The replacement versions of "@" and slot() differ in the computations done to coerce the right
side of the assignment to the declared class of the slot. Both verify that the value provided is from
a subclass of the declared slot class. The slot() version will go on to call the coerce method if
there is one, in effect doing the computation as(value, slotClass, strict = FALSE). The "%" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "@" version saves an extra function call, but if empirical
evidence shows that a conversion is needed, either call as() before the replacement or use the
replacement version of slot().

Value

The "@" operator and the slot function extract or replace the formally defined slots for the object.

Functions slotNames and getSlots return respectively the names of the slots and the classes as-
sociated with the slots in the specified class definition. Except for its extended interpretation of x
(above), slotNames(x) is just names(getSlots(x)).

Examples

setClass("track", slots = c(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack)

getSlots("track") # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
slotNames(myTrack)
Description

The virtual class structure and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

Usage

```r
## The following class names can appear in method signatures,
## as the class in as() and is() expressions, and, except for
## the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., `function matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes "matrix" and "array" are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no "class" attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return `FALSE` for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the special treatment is that these two classes `may` be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a `.Data` slot with that class. This is the only use of `.Data` other than as a pseudo-class indicating the type of the object. In this case the type of the object will be the type of the contained matrix or array. See `Classes_Details` for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the `setOldClass` mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)
Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for `setOldClass` in the examples section for an abbreviated listing of how this is done). The S3 inheritance of "mts" in package `stats` is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for `initialize` that accept the same arguments as the basic generator functions, `matrix`, `array`, and `ts`, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to `new`; therefore, a such a class (what is called a “mixin” in some languages) uses the default method for `initialize`, with no special arguments.

**Extends**

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

**Methods**

`coerce` Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "matrix")` calls `as.matrix(x)`. If `strict = TRUE` in the call to `as()`, the method goes on to delete all other slots and attributes other than the `dim` and `dimnames`.

`Ops` Group methods (see, e.g., `S4groupGeneric`) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

Class `nonStructure`, which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

**Examples**

```
showClass("structure")
## explore a bit :
showClass("ts")
(ts0 <- new("ts"))
str(ts0)
```
testInheritedMethods (Ops) # six methods from these classes, but maybe many more

---

**testInheritedMethods**  
*Test for and Report about Selection of Inherited Methods*

**Description**

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified generic function. If method selection is ambiguous for some of these, a summary of the ambiguities is attached to the returned object. This test should be performed by package authors *before* releasing a package.

**Usage**

```r
testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE,  
groupMethods = TRUE, where = .GlobalEnv)
```

**Arguments**

- `f`  
  a generic function or the character string name of one. By default, all currently defined subclasses of all the method signatures for this generic will be examined. The other arguments are mainly options to modify which inheritance patterns will be examined.

- `signatures`  
  An optional set of subclass signatures to use instead of the relevant subclasses computed by `testInheritedMethods`. See the Details for how this is done. This argument might be supplied after a call with `test = FALSE`, to test selection in batches.

- `test`  
  optional flag to control whether method selection is actually tested. If `FALSE`, returns just the list of relevant signatures for subclasses, without calling `selectMethod` for each signature. If there are a very large number of signatures, you may want to collect the full list and then test them in batches.

- `virtual`  
  should virtual classes be included in the relevant subclasses. Normally not, since only the classes of actual arguments will trigger the inheritance calculation in a call to the generic function. Including virtual classes may be useful if the class has no current non-virtual subclasses but you anticipate your users may define such classes in the future.

- `groupMethods`  
  should methods for the group generic function be included?

- `where`  
  the environment in which to look for class definitions. Nearly always, use the default global environment after attaching all the packages with relevant methods and/or class definitions.

**Details**

The following description applies when the optional arguments are omitted, the usual case. First, the defining signatures for all methods are computed by calls to `findMethodSignatures`. From these all the known non-virtual subclasses are found for each class that appears in the signature of some method. These subclasses are split into groups according to which class they inherit from, and only one subclass from each group is retained (for each argument in the generic signature). So if a method was defined with class "vector" for some argument, one actual vector class is chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy,
nonvirtual class, ".Other", is used to correspond to all classes that have no superclasses among those being tested.

All combinations of retained subclasses for the arguments in the generic signature are then computed. Each row of the resulting matrix is a signature to be tested by a call to `selectMethod`. To collect information on ambiguous selections, `testInheritedMethods` establishes a calling handler for the special signal "ambiguousMethodSelection", by setting the corresponding option.

**Value**

An object of class "methodSelectionReport". The details of this class are currently subject to change. It has slots "target", "selected", "candidates", and "note", all referring to the ambiguous cases (and so of length 0 if there were none). These slots are intended to be examined by the programmer to detect and preferably fix ambiguous method selections. The object contains in addition slots "generic", the name of the generic function, and "allSelections", giving the vector of labels for all the signatures tested.

**References**

**Examples**

```r
## if no other attached packages have methods for `+` or its group
## generic functions, this returns a 16 by 2 matrix of selection
## patterns (in R 2.9.0)
testInheritedMethods("+")
```

**TraceClasses**

*Classes Used Internally to Control Tracing*

**Description**

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

**Usage**

```r
### Objects from the following classes are generated
### by calling trace() on an object from the corresponding
class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
```
### classes above

"traceable"

**Objects from the Class**

Objects will be created from these classes by calls to `trace`. (There is an `initialize` method for class "traceable", but you are unlikely to need it directly.)

**Slots**

- `.Data`: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.
- `original`: Object of the original class; e.g., "function" for class "functionWithTrace".

**Extends**

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

**Methods**

The point of the specific classes is that objects generated from them, by function `trace()`, remain callable or dispatchable, in addition to their new trace information.

**See Also**

function `trace`

---

**validObject**  
*Test the Validity of an Object*

**Description**

`validObject()` tests the validity of object related to its class definition; specifically, it checks that all slots specified in the class definition are present and that the object in the slot is from the required class or a subclass of that class.

If the object is valid, `TRUE` is returned; otherwise, an error is generated, reporting all the validity failures encountered. If argument `test` is `TRUE`, the errors are returned as a character vector rather than generating an error.

When an object from a class is initialized, the default method for `initialize()` calls `validObject`. A class definition may have a validity method, set by a call to the function `setValidity`, in the package or environment that defines the class (or via the validity argument to `setClass`). The method should be a function of one object that returns `TRUE` or a character-string description of the non-validity. If such a method exists, it will be called from `validObject` and any strings from failure will be included in the result or the error message. Any validity methods defined for superclasses (from the `contains=` argument to `setClass`), will also be called.
validObject

Usage

validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topenv(parent.frame()) )

getValidity(ClassDef)

Arguments

object any object, but not much will happen unless the object’s class has a formal definition.
test logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.
complete logical; if TRUE, validObject is called recursively for each of the slots. The default is FALSE.
Class the name or class definition of the class whose validity method is to be set.
ClassDef a class definition object, as from getClassDef.
method a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.
where an environment to store the modified class definition. Should be omitted, specifically for calls from a package that defines the class. The definition will be stored in the namespace of the package.

Details

Validity testing takes place ‘bottom up’, checking the slots, then the superclasses, then the object’s own validity method, if there is one.

For each slot and superclass, the existence of the specified class is checked. For each slot, the object in the slot is tested for inheritance from the corresponding class. If complete is TRUE, validObject is called recursively for the object in the slot.

Then, for each of the classes that this class extends (the ‘superclasses’), the explicit validity method of that class is called, if one exists. Finally, the validity method of object’s class is called, if there is one.

Value

validObject returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

Validity methods

A validity method must be a function of one argument; formally, that argument should be named object. If the argument has a different name, setValidity makes the substitution but in obscure cases that might fail, so it’s wiser to name the argument object.

A good method checks all the possible errors and returns a character vector citing all the exceptions found, rather than returning after the first one. validObject will accumulate these errors in its error message or its return value.
Note that validity methods do not have to check validity of superclasses: `validObject` calls such methods explicitly.

**References**

**See Also**

`setClass`; class `classRepresentation`.

**Examples**

```r
setClass("track", 
  slots = c(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
  if(length(object@x) == length(object@y)) TRUE
  else paste("Unequal x,y lengths: ", length(object@x), ", ", length(object@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad
t2 <- t1
t2@x <- 1:20
## This should generate an error
## Not run: try(validObject(t2))

setClass("trackCurve", contains = "track", 
  slots = c(smooth = "numeric"))
## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", slots = c(tr1 = "track", tr2 ="track"))
## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)
## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))
```
Chapter 8

The parallel package

<table>
<thead>
<tr>
<th>parallel-package</th>
<th>Support for Parallel Computation</th>
</tr>
</thead>
</table>

Description

Support for parallel computation, including random-number generation.

Details

This package was first included with R 2.14.0 in 2011.

There is support for multiple RNG streams with the "L'Ecuyer-CMRG" RNG: see nextRNGStream.

It contains functionality derived from and pretty much equivalent to that contained in packages multicore (formerly on CRAN, with some low-level functions renamed and not exported) and snow (for socket clusters only, but MPI clusters generated by snow are also supported). There have been many enhancements and bug fixes since 2011.

This package also provides makeForkCluster to create socket clusters by forking (not Windows).

For a complete list of exported functions, use library(help = "parallel").

Author(s)

Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <R-core@r-project.org>

See Also

Parallel computation involves launching worker processes: functions psnice and pskill in package tools provide means to manage such processes.
clusterApply

Apply Operations using Clusters

Description

These functions provide several ways to parallelize computations using a cluster.

Usage

clusterCall(cl = NULL, fun, ...)
clusterApply(cl = NULL, x, fun, ...)  
clusterApplyLB(cl = NULL, x, fun, ...)  
clusterEvalQ(cl = NULL, expr)  
clusterExport(cl = NULL, varlist, envir = .GlobalEnv)  
clusterMap(cl = NULL, Fun, ..., MoreArgs = NULL, RECYCLE = TRUE,  
SIMPLIFY = FALSE, USE.NAMES = TRUE,  
.scheduling = c("static", "dynamic"))  
clusterSplit(cl = NULL, seq)  
parLapply(cl = NULL, X, fun, ..., chunk.size = NULL)  
parSapply(cl = NULL, X, FUN, ..., simplify = TRUE,  
USE.NAMES = TRUE, chunk.size = NULL)  
parApply(cl = NULL, X, MARGIN, FUN, ..., chunk.size = NULL)  
parCapply(cl = NULL, x, FUN, ..., chunk.size = NULL)  
parLapplyLB(cl = NULL, X, fun, ..., chunk.size = NULL)  
parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE,  
USE.NAMES = TRUE, chunk.size = NULL)

Arguments

cl a cluster object, created by this package or by package snow. If NULL, use the  
registered default cluster.  
fun, FUN function or character string naming a function.  
expr expression to evaluate.  
seq vector to split.  
varlist character vector of names of objects to export.  
envir environment from which t export variables  
x a vector for clusterApply and clusterApplyLB, a matrix for parRapply and  
parCapply.  
... additional arguments to pass to fun or FUN: beware of partial matching to earlier  
arguments.  
MoreArgs additional arguments for fun.  
RECYCLE logical; if true shorter arguments are recycled.  
X A vector (atomic or list) for parLapply and parSapply, an array for parApply.  
chunk.size scalar number; number of invocations of fun or FUN in one chunk; a chunk is a  
unit for scheduling.
clusterApply

MARGIN vector specifying the dimensions to use.
simplify, USE.NAMES logical; see \texttt{sapply}.
SIMPLIFY logical; see \texttt{mapply}.
.scheduling should tasks be statically allocated to nodes or dynamic load-balancing used?

Details

\texttt{clusterCall} calls a function \texttt{fun} with identical arguments \ldots on each node. 
\texttt{clusterEvalQ} evaluates a literal expression on each cluster node. It is a parallel version of \texttt{evalq}, and is a convenience function invoking \texttt{clusterCall}. 
\texttt{clusterApply} calls \texttt{fun} on the first node with arguments \texttt{x[[1]]} and \ldots, on the second node with \texttt{x[[2]]} and \ldots, and so on, recycling nodes as needed. 
\texttt{clusterApplyLB} is a load balancing version of \texttt{clusterApply}. If the length \texttt{n} of \texttt{x} is not greater than the number of nodes \texttt{p}, then a job is sent to \texttt{n} nodes. Otherwise the first \texttt{p} jobs are placed in order on the \texttt{p} nodes. When the first job completes, the next job is placed on the node that has become free; this continues until all jobs are complete. Using \texttt{clusterApplyLB} can result in better cluster utilization than using \texttt{clusterApply}, but increased communication can reduce performance. Furthermore, the node that executes a particular job is non-deterministic. This means that simulations that assign RNG streams to nodes will not be reproducible. 
\texttt{clusterMap} is a multi-argument version of \texttt{clusterApply}, analogous to \texttt{mapply} and \texttt{Map}. If \texttt{RECYCLE} is true shorter arguments are recycled (and either none or all must be of length zero); otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length of the result is greater than the number of nodes. (\texttt{mapply} always uses \texttt{RECYCLE = TRUE}, and has argument \texttt{SIMPLIFY = TRUE}. \texttt{Map} always uses \texttt{RECYCLE = TRUE}.) 
\texttt{clusterExport} assigns the values on the master \texttt{R} process of the variables named in \texttt{varlist} to variables of the same names in the global environment (aka ‘workspace’) of each node. The environment on the master from which variables are exported defaults to the global environment. 
\texttt{clusterSplit} splits \texttt{seq} into a consecutive piece for each cluster and returns the result as a list with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in length: the computation is done on the master. 
\texttt{parLapply}, \texttt{parSapply}, and \texttt{parApply} are parallel versions of \texttt{lapply}, \texttt{sapply} and \texttt{apply}. Chunks of computation are statically allocated to nodes using \texttt{clusterApply}. By default, the number of chunks is the same as the number of nodes. \texttt{parLapplyLB}, \texttt{parSapplyLB} are load-balancing versions, intended for use when applying \texttt{FUN} to different elements of \texttt{X} takes quite variable amounts of time, and either the function is deterministic or reproducible results are not required. Chunks of computation are allocated dynamically to nodes using \texttt{clusterApplyLB}. From R 3.5.0, the default number of chunks is twice the number of nodes. Before R 3.5.0, the (fixed) number of chunks was the same as the number of nodes. As for \texttt{clusterApplyLB}, with load balancing the node that executes a particular job is non-deterministic and simulations that assign RNG streams to nodes will not be reproducible. 
\texttt{parRapply} and \texttt{parCapply} are parallel row and column \texttt{apply} functions for a matrix \texttt{x}; they may be slightly more efficient than \texttt{parApply} but do less post-processing of the result. 
A chunk size of \texttt{0} with static scheduling uses the default (one chunk per node). With dynamic scheduling, chunk size of \texttt{0} has the same effect as \texttt{1} (one invocation of \texttt{FUN/fun} per chunk).

Value

For \texttt{clusterCall}, \texttt{clusterEvalQ} and \texttt{clusterSplit}, a list with one element per node.
For `clusterApply` and `clusterApplyLB`, a list the same length as x.

`clusterMap` follows `mapply`.

`clusterExport` returns nothing.

`parLapply` returns a list the length of X.

`parSapply` and `parApply` follow `sapply` and `apply` respectively.

`parRapply` and `parCapply` always return a vector. If FUN always returns a scalar result this will be of length the number of rows or columns: otherwise it will be the concatenation of the returned values.

An error is signalled on the master if any of the workers produces an error.

### Note

These functions are almost identical to those in package `snow`.

Two exceptions: `parLapply` has argument X not x for consistency with `lapply`, and `parSapply` has been updated to match `sapply`.

### Author(s)

Luke Tierney and R Core.

Derived from the `snow` package.

### Examples

```r
## Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

clusterApply(cl, 1:2, get("+"), 3)
xx <- 1
clusterExport(cl, "xx")
clusterCall(cl, function(y) xx + y, 2)

## Use clusterMap like an mapply example
clusterMap(cl, function(x, y) seq_len(x) + y,
           c(a = 1, b = 2, c = 3), c(A = 10, B = 0, C = -10))

parSapply(cl, 1:20, get("+"), 3)

## A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
  ## set up each worker. Could also use clusterExport()
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  NULL
})
res <- clusterEvalQ(cl, boot(cd4, corr, R = 100,
                           sim = "parametric", ran.gen = cd4.rg, mle = cd4.mle))
library(boot)
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
        conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)
```
## or
```r
library(boot)
run1 <- function(...) {
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  boot(cd4, corr, R = 500, sim = "parametric",
       ran.gen = cd4.rg, mle = cd4.mle)
}
cl <- makeCluster(mc <- getOption("cl.cores", 2))
## to make this reproducible
clusterSetRNGStream(cl, 123)
```
cd4.boot <- do.call(c, parLapply(cl, seq_len(mc), run1))
```r
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
       conf = 0.9, h = atanh, hinv = tanh)
```
stopCluster(cl)
```

detectCores

Detect the Number of CPU Cores

**Description**

Attempt to detect the number of CPU cores on the current host.

**Usage**

```r
detectCores(all.tests = FALSE, logical = TRUE)
```

**Arguments**

- **all.tests** Logical: if true apply all known tests.
- **logical** Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE). Currently this is honoured only on macOS, Solaris and Windows.

**Details**

This attempts to detect the number of available CPU cores.

It has methods to do so for Linux, macOS, FreeBSD, OpenBSD, Solaris and Windows. detectCores(TRUE) could be tried on other Unix-alike systems.

**Value**

An integer, NA if the answer is unknown.

Exactly what this represents is OS-dependent: where possible by default it counts logical (e.g., hyperthreaded) CPUs and not physical cores or packages.

Under macOS there is a further distinction between ‘available in the current power management mode’ and ‘could be available this boot’, and this function returns the first.

On Windows: Only versions of Windows since XP SP3 are supported. Microsoft documents that with logical = FALSE it will report the number of cores on Vista or later, but the number of physical CPU packages on XP or Server 2003: however it reported correctly on the XP systems we tested.
On Sparc Solaris `logical = FALSE` returns the number of physical cores and `logical = TRUE` returns the number of available hardware threads. (Some Sparc CPUs have multiple cores per CPU, others have multiple threads per core and some have both.) For example, the UltraSparc T2 CPU in the former CRAN check server was a single physical CPU with 8 cores, and each core supports 8 hardware threads. So `detectCores(logical = FALSE)` returns 8, and `detectCores(logical = TRUE)` returns 64.

Where virtual machines are in use, one would hope that the result for `logical = TRUE` represents the number of CPUs available (or potentially available) to that particular VM.

**Note**

This is not suitable for use directly for the `mc.cores` argument of `mclapply` nor specifying the number of cores in `makeCluster`. First because it may return `NA`, second because it does not give the number of allowed cores, and third because on Sparc Solaris and some Windows boxes it is not reasonable to try to use all the logical CPUs at once.

**Author(s)**

Simon Urbanek and Brian Ripley

**Examples**

```r
detectCores()
detectCores(logical = FALSE)
```

### makeCluster

**Create a Parallel Socket Cluster**

**Description**

Creates a set of copies of \( \mathcal{R} \) running in parallel and communicating over sockets.

**Usage**

```r
makeCluster(spec, type, ...)
makePSOCKcluster(names, ...)
makeForkCluster(nnodes = getOption("mc.cores", 2L), ...)
stopCluster(cl = NULL)
setDefaultCluster(cl = NULL)
getDefaultCluster()
```

**Arguments**

- **spec**  
  A specification appropriate to the type of cluster.

- **names**  
  Either a character vector of host names on which to run the worker copies of \( \mathcal{R} \), or a positive integer (in which case that number of copies is run on ‘localhost’).

- **nnodes**  
  The number of nodes to be forked.

- **type**  
  One of the supported types: see ‘Details’.

- **...**  
  Options to be passed to the function spawning the workers. See ‘Details’.

- **cl**  
  An object of class "cluster".
makeCluster creates a cluster of one of the supported types. The default type, "PSOCK", calls makePSOCKcluster. Type "FORK" calls makeForkCluster. Other types are passed to package snow.

makePSOCKcluster is an enhanced version of makeSOCKcluster in package snow. It runs Rscript on the specified host(s) to set up a worker process which listens on a socket for expressions to evaluate, and returns the results (as serialized objects).

makeForkCluster is merely a stub on Windows. On Unix-alike platforms it creates the worker process by forking.

The workers are most often running on the same host as the master, when no options need be set. Several options are supported (mainly for makePSOCKcluster):

- **master**: The host name of the master, as known to the workers. This may not be the same as it is known to the master, and on private subnets it may be necessary to specify this as a numeric IP address. For example, macOS is likely to detect a machine as ‘somename.local’, a name known only to itself.

- **port**: The port number for the socket connection, default taken from the environment variable R_PARALLEL_PORT, then a randomly chosen port in the range 11000:11999.

- **timeout**: The timeout in seconds for that port. This is the maximum time of zero communication between master and worker before failing. Default is 30 days (and the POSIX standard only requires values up to 31 days to be supported).

- **setup_timeout**: The maximum number of seconds a worker attempts to connect to master before failing. Default is 2 minutes. The waiting time before the next attempt starts at 0.1 seconds and is incremented 50% after each retry.

- **outfile**: Where to direct the stdout and stderr connection output from the workers. "" indicates no redirection (which may only be useful for workers on the local machine). Defaults to ‘/dev/null’ (‘nul:’ on Windows). The other possibility is a file path on the worker’s host. Files will be opened in append mode, as all workers log to the same file.

- **homogeneous**: Logical, default true. See ‘Note’.

- **rscript**: See ‘Note’.

- **rscript_args**: Character vector of additional arguments for Rscript such as ‘--no-environ’.

- **renice**: A numerical ‘niceness’ to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see psnice for details.

- **rshcmd**: The command to be run on the master to launch a process on another host. Defaults to ssh.

- **user**: The user name to be used when communicating with another host.

- **manual**: Logical. If true the workers will need to be run manually.

- **methods**: Logical. If true (default) the workers will load the methods package: not loading it saves ca 30% of the startup CPU time of the cluster.

- **useXDR**: Logical. If true (default) serialization will use XDR: where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially faster if this is set to false.

- **setup_strategy**: Character. If "parallel" (default) workers will be started in parallel during cluster setup when this is possible, which is now for homogeneous "PSOCK" clusters with all workers started automatically (manual = FALSE) on the local machine. Workers will be started sequentially on other clusters, on all clusters with setup_strategy = "sequential" and on R 3.6.0 and older. This option is for expert use only (e.g. debugging) and may be removed in future versions of R.
Function `makeForkCluster` creates a socket cluster by forking (and hence is not available on Windows). It supports options `port`, `timeout` and `outfile`, and always uses `useXDR = FALSE`. It is strongly discouraged to use the "FORK" cluster with GUI front-ends or multi-threaded libraries. See `mcfork` for details.

It is good practice to shut down the workers by calling `stopCluster`: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function `setDefaultCluster` registers a cluster as the default one for the current session. Using `setDefaultCluster(NULL)` removes the registered cluster, as does stopping that cluster.

**Value**

For the cluster creators, an object of class `c("SOCKcluster", "cluster")`.

For the default cluster setter and getter, the registered default cluster or `NULL` if there is no such cluster.

**Note**

Option `homogeneous = TRUE` was for years documented as ‘Are all the hosts running identical setups?’, but this was apparently more restrictive than its author intended and not required by the code.

The current interpretation of `homogeneous = TRUE` is that `Rscript` can be launched using the same path on each worker. That path is given by the option `rscript` and defaults to the full path to `Rscript` on the master. (The workers are not required to be running the same version of R as the master, nor even as each other.) For `homogeneous = FALSE`, `Rscript` on the workers is found on their default shell’s path.

For the very common usage of running both master and worker on a single multi-core host, the default settings are the appropriate ones.

**Author(s)**

Luke Tierney and R Core.

Derived from the `snow` package.

---

### `mcaffinity`

**Get or Set CPU Affinity Mask of the Current Process**

**Description**

`mcaffinity` retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or hyperthread unit.)

**Usage**

```r
mcaffinity(affinity = NULL)
```

**Arguments**

- `affinity` specification of the CPUs to lock this process to (numeric vector) or `NULL` if no change is requested
**Details**

`mc_affinity` can be used to obtain (`affinity = NULL`) or set the CPU affinity mask of the current process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where no support is present at all `mc_affinity()` will return `NULL`. Some systems may take into account only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as the OS can handle) and the system will return back the actually present set.

**Value**

`NULL` if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the active affinity mask for this process (this may be different than `affinity`).

**Author(s)**

Simon Urbanek.

`mcparallel`

---

`mcchildren`  
*Low-level Functions for Management of Forked Processes*

**Description**

These are low-level support functions for the forking approach.

They are not available on Windows, and not exported from the namespace.

**Usage**

```r
children(select)  
readChild(child)  
readChildren(timeout = 0)  
selectChildren(children = NULL, timeout = 0)  
sendChildStdin(child, what)  
sendMaster(what, raw.asis = TRUE)  
mckill(process, signal = 2L)
```

**Arguments**

- `select` if omitted, all active children are returned, otherwise `select` should be a list of processes and only those from the list that are active will be returned.
- `child` child process (object of the class "childProcess") or a process ID (pid). See also ‘Details’.
- `timeout` timeout (in seconds, fractions supported) to wait for a response before giving up.
children list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.

what For sendChildStdin:
Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!)
For sendMaster:
Data to send to the master process. If what is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.

raw.asis logical, if TRUE and what is a raw vector then it is sent directly as-is to the master (default, suitable for arbitrary payload passing), otherwise raw vectors are serialized before sending just as any other objects (suitable for passing evaluation results).

process process (object of the class process) or a process ID (pid)

signal integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use tools::SIGTERM and so on.

Details

children returns currently active children.
readChild reads data (sent by sendMaster) from a given child process.
selectChildren checks children for available data.
readChildren checks all children for available data and reads from the first child that has available data.

sendChildStdin sends a string (or data) to one or more child’s standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify child as a list or a vector of process IDs.

sendMaster sends data from the child to the master process.
mckill sends a signal to a child process: it is equivalent to pskill in package tools.

Value

children returns a (possibly empty) list of objects of class "process", the process ID.
readChild and readChildren return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for readChildren).
selectChildren returns TRUE is the timeout was reached, FALSE if an error occurred (e.g., if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.

sendChildStdin returns a vector of TRUE values (one for each member of child) or throws an error.

sendMaster returns TRUE or throws an error.
mckill returns TRUE.
**mcfork**

**Warning**
This is a very low-level interface for expert use only: it not regarded as part of the \texttt{R} API and subject to change without notice.

\texttt{sendMaster}, \texttt{readChild} and \texttt{sendChildStdin} did not support long vectors prior to \texttt{R 3.4.0} and so were limited to $2^{31} - 1$ bytes (and still are on 32-bit platforms).

**Author(s)**
Simon Urbanek and \texttt{R} Core.

Derived from the \texttt{multicore} package formerly on CRAN.

**See Also**
\texttt{mcfork, sendMaster, mcparallel}

**Examples**
```
## Not run:
p <- mcparallel(scan(n = 1, quiet = TRUE))
sendChildStdin(p, "17.4\n")
mccollect(p)[[1]]
## End(Not run)
```

---

**mcfork**  
\textit{Fork a Copy of the Current R Process}

**Description**
These are low-level functions, not available on Windows, and not exported from the namespace. \texttt{mcfork} creates a new child process as a copy of the current \texttt{R} process. \texttt{mcexit} closes the current child process, informing the master process as necessary.

**Usage**
```
mcfork(estranged = FALSE)
mexit(exit.code = 0L, send = NULL)
```

**Arguments**
- \texttt{estranged} logical, if \texttt{TRUE} then the new process has no ties to the parent process, will not show in the list of children and will not be killed on exit.
- \texttt{exit.code} process exit code. By convention \texttt{0} signifies a clean exit, \texttt{1} an error.
- \texttt{send} if not \texttt{NULL} send this data before exiting (equivalent to using \texttt{sendMaster}).
Details

The mcfork function provides an interface to the fork system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see sendMaster) and child’s ’stdin’ is re-mapped to another pipe held by the master process (see sendChildStdin).

If you are not familiar with the fork system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.

In a nutshell fork spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes mcfork an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

mcexit is to be run in the child process. It sends send to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal SIGUSR1, as is done by the unexported function parallel:::rmChild.

Value

mcfork returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". If estranged is set to TRUE then the child process will be of the class "estrangedProcess" and cannot communicate with the master process nor will it show up on the list of children. These are lists with components pid (the process id of the other process) and a vector fd of the two file descriptor numbers for ends in the current process of the inter-process pipes.

mcexit never returns.

GUI/embedded environments

It is strongly discouraged to use mcfork and the higher-level functions which rely on it (e.g., mclapply, mcpparallel and pvec) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on macOS, but users of third-party front-ends should consult their documentation.

This can also apply to other connections (e.g., to an X server) created before forking, and to files opened by e.g. graphics devices.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

It is strongly discouraged to use mcfork and the higher-level functions in any multi-threaded R process (with additional threads created by a third-party library or package). Such use can lead to deadlocks or crashes, because the child process created by mcfork may not be able to access resources locked in the parent or may see an inconsistent version of global data (mcfork runs system call fork without exec).

If in doubt, it is safer to use a non-FORK cluster (see makeCluster, clusterApply).

Warning

This is a very low-level API for expert use only.

Examples
## This will work when run as an example, but not when pasted in.
p <- parallel:::mcfork()
if (inherits(p, "masterProcess")) {
  cat("I'm a child! ", Sys.getpid(), "\n")
  parallel:::mcexit("I was a child")
} cat("I'm the master\n")
unserialize(parallel:::readChildren(1.5))

---

mclapply
Parallel Versions of lapply and mapply using Forking

Description
mclapply is a parallelized version of lapply, it returns a list of the same length as X, each element
of which is the result of applying FUN to the corresponding element of X.
It relies on forking and hence is not available on Windows unless mc.cores = 1.
mcmapply is a parallelized version of mapply, and mcMap corresponds to Map.

Usage

mclapply(X, FUN, ..., 
  mc.preschedule = TRUE, mc.set.seed = TRUE, 
  mc.silent = FALSE, mc.cores =getOption("mc.cores", 2L), 
  mc.cleanup = TRUE, mc.allow.recursive = TRUE, affinity.list = NULL)

mcmapply(FUN, ..., 
  MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE, 
  mc.preschedule = TRUE, mc.set.seed = TRUE, 
  mc.silent = FALSE, mc.cores =getOption("mc.cores", 2L), 
  mc.cleanup = TRUE, affinity.list = NULL)

mcMap(f, ...)

Arguments

X a vector (atomic or list) or an expressions vector. Other objects (including
classed objects) will be coerced by as.list.
FUN the function to be applied to (mclapply) each element of X or (mcmapply) in parallel to ....
mclapply

f

the function to be applied in parallel to ... 

... For mclapply, optional arguments to FUN. For mcmaply and mcMap, vector or list inputs: see mapply.

MoreArgs, SIMPLIFY, USE.NAMES

see mapply.

mc.preschedule if set to TRUE then the computation is first divided to (at most) as many jobs are there are cores and then the jobs are started, each job possibly covering more than one value. If set to FALSE then one job is forked for each value of X. The former is better for short computations or large number of values in X, the latter is better for jobs that have high variance of completion time and not too many values of X compared to mc.cores.

mc.set.seed See mcparallel.

mc.silent if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel processes forked (‘stderr’ is not affected).

mc.cores The number of cores to use, i.e. at most how many child processes will be run simultaneously. The option is initialized from environment variable MC_CORES if set. Must be at least one, and parallelization requires at least two cores.

mc.cleanup if set to TRUE then all children that have been forked by this function will be killed (by sending SIGTERM) before this function returns. Under normal circumstances mclapply waits for the children to deliver results, so this option usually has only effect when mclapply is interrupted. If set to FALSE then child processes are collected, but not forcefully terminated. As a special case this argument can be set to the number of the signal that should be used to kill the children instead of SIGTERM.

mc.allow.recursive Unless true, calling mclapply in a child process will use the child and not fork again.

affinity.list a vector (atomic or list) containing the CPU affinity mask for each element of X. The CPU affinity mask describes on which CPU (core or hyperthread unit) a given item is allowed to run, see mcaffinity. To use this parameter prescheduling has to be deactivated (mc.preschedule = FALSE).

Details

mclapply is a parallelized version of lapply, provided mc.cores > 1: for mc.cores == 1 (and the affinity.list is NULL) it simply calls lapply.

By default (mc.preschedule = TRUE) the input X is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ...(core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of X. To ensure that no more than mc.cores jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using lapply. They are sequential for each forked process, but not all jobs as a whole. See mcparallel or the package’s vignette for ways to make the results reproducible with mc.preschedule = TRUE.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see ulimit -n or similar in your OS
**mclapply**

documentation) unless you raise the limit of permissible open file descriptors (fork will fail with error "unable to create a pipe").

Prior to R 3.4.0 and on a 32-bit platform, the serialized result from each forked process is limited to $2^{31} - 1$ bytes. (Returning very large results via serialization is inefficient and should be avoided.)

**affinity.list** can be used to run elements of X on specific CPUs. This can be helpful, if elements of X have a high variance of completion time or if the hardware architecture is heterogeneous. It also enables the development of scheduling strategies for optimizing the overall runtime of parallel jobs. If **affinity.list** is set, the mc.core parameter is replaced with the number of CPU ids used in the affinity masks.

**Value**

For **mclapply**, a list of the same length as X and named by X.

For **mcapply**, a list, vector or array: see **mapply**.

For **mcMap**, a list.

Each forked process runs its job inside **try(..., silent = TRUE)** so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of X and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed. If any forked process is killed or fails to deliver a result for any reason, values involved in the failure will be NULL. To allow detection of such errors, FUN should not return NULL. As of R 4.0, the return value of **mcapply** is always a list when it needs to contain "try-error" objects (SIMPLIFY is overridden to FALSE).

**Warning**

It is strongly discouraged to use these functions in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on macOS, but users of third-party front-ends should consult their documentation.

Note that **tcltk** counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

It is strongly discouraged to use these functions with multi-threaded libraries or packages (see **mcfork** for more details). If in doubt, it is safer to use a non-FORK cluster (see **makeCluster**, **clusterApply**).

ey <- simplify2array(mclapply(rep(4, 5), rnorm))
# use the same random numbers for all values
set.seed(1)
sey <- simplify2array(mclapply(rep(4, 5), rnorm, mc.preschedule = FALSE,
    mc.set.seed = FALSE))
```

```r
## Contrast this with the examples for clusterCall
library(boot)
cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
mc <- getOption("mc.cores", 2)
run1 <- function(...) boot(cd4, corr, R = 500, sim = "parametric",
    ran.gen = cd4.rg, mle = cd4.mle)
## To make this reproducible:
set.seed(123, "L'Ecuyer")
res <- mclapply(seq_len(mc), run1)
cd4.boot <- do.call(c, res)
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
    conf = 0.9, h = atanh, hinv = tanh)
```

```r
## Usage of the affinity.list parameter
A <- runif(2500000, 0, 100)
B <- runif(2500000, 0, 100)
C <- runif(5000000, 0, 100)
first <- function(i) head(sort(i), n = 1)
# Restrict all elements of X to run on CPU 1 and 2
affL <- list(c(1, 2), c(1, 2), c(1, 2))
mclapply(list(A, A, A), first, mc.preschedule = FALSE, affinity.list = affL)
```

```r
## Completion times are assumed to have a high variance
## To optimize the overall execution time elements of X are scheduled to suitable CPUs
## Assuming that the runtime for C is as long as the runtime of A plus B
## mapping: A to 1, B to 1, C to 2
X <- list(A, B, C)
affL <- c(1, 1, 2)
mclapply(X, first, mc.preschedule = FALSE, affinity.list = affL)
```

Description

These functions are based on forking and so are not available on Windows.
`mcparallel` starts a parallel R process which evaluates the given expression.
`mccollect` collects results from one or more parallel processes.
Usage

mcparallel(expr, name, mc.set.seed = TRUE, silent = FALSE,
    mc.affinity = NULL, mc.interactive = FALSE,
    detached = FALSE)

mccollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)

Arguments

expr expression to evaluate (do not use any on-screen devices or GUI elements in this code, see mcfork for the inadvisability of using mcparallel with GUI front-ends and multi-threaded libraries). Raw vectors are reserved for internal use and cannot be returned, but the expression may evaluate e.g. to a list holding a raw vector. NULL should not be returned because it is used by mccollect to signal an error.

name an optional name (character vector of length one) that can be associated with the job.

mc.set.seed logical: see section ‘Random numbers’.

silent if set to TRUE then all output on stdout will be suppressed (stderr is not affected).

mc.affinity either a numeric vector specifying CPUs to restrict the child process to (1-based) or NULL to not modify the CPU affinity

mc.interactive logical, if TRUE or FALSE then the child process will be set as interactive or non-interactive respectively. If NA then the child process will inherit the interactive flag from the parent.

detached logical, if TRUE then the job is detached from the current session and cannot deliver any results back - it is used for the code side-effect only.

jobs list of jobs (or a single job) to collect results for. Alternatively jobs can also be an integer vector of process IDs. If omitted collect will wait for all currently existing children.

wait if set to FALSE it checks for any results that are available within timeout seconds from now, otherwise it waits for all specified jobs to finish.

timeout timeout (in seconds) to check for job results – applies only if wait is FALSE.

intermediate FALSE or a function which will be called while collect waits for results. The function will be called with one parameter which is the list of results received so far.

Details

mcparallel evaluates the expr expression in parallel to the current R process. Everything is shared read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no side-effects of the expression affect the main process. The result of the parallel execution can be collected using mccollect function.

mccollect function collects any available results from parallel jobs (or in fact any child process). If wait is TRUE then collect waits for all specified jobs to finish before returning a list containing the last reported result for each job. If wait is FALSE then mccollect merely checks for any results available at the moment and will not wait for jobs to finish. If jobs is specified, jobs not listed there will not be affected or acted upon.

Note: If expr uses low-level multicore functions such as sendMaster a single job can deliver results multiple times and it is the responsibility of the user to interpret them correctly. mccollect will
return NULL for a terminating job that has sent its results already after which the job is no longer available.

Jobs are identified by process IDs (even when referred to as job objects), which are reused by the operating system. Detached jobs created by mcparallel can thus never be safely referred to by their process IDs nor job objects. Non-detached jobs are guaranteed to exist until collected by mccollect, even if crashed or terminated by a signal. Once collected by mccollect, a job is regarded as detached, and thus no longer be referred to by its process ID nor its job object.

With wait = TRUE, all jobs passed to mccollect are collected. With wait = FALSE, the collected jobs are given as names of the result vector, and thus in subsequent calls to mccollect these jobs must be excluded. Job objects should be used in preference of process IDs whenever accepted by the API.

The mc.affinity parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

Value

mcparallel returns an object of the class "parallelJob" which inherits from "childProcess" (see the ‘Value’ section of the help for mcfork). If argument name was supplied this will have an additional component name.

mccollect returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns NULL.

Random numbers

If mc.set.seed = FALSE, the child process has the same initial random number generator (RNG) state as the current R session. If the RNG has been used (or .Random.seed was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with mc.set.seed = TRUE is different only if RNGkind("L'Ecuyer-CMRG") has been selected. Then each time a child is forked it is given the next stream (see nextRNGStream). So if you select that generator, set a seed and call mc.reset.stream just before the first use of mcparallel the results of simulations will be reproducible provided the same tasks are given to the first, second, ...forked process.

Note

Prior to R 3.4.0 and on a 32-bit platform, the serialized result from each forked process is limited to $2^{31} - 1$ bytes. (Returning very large results via serialization is inefficient and should be avoided.)

Author(s)

Simon Urbanek and R Core.

Derived from the multicore package formerly on CRAN. (but with different handling of the RNG stream).

pvec, mclapply
Examples

```r
p <- mcparallel(1:10)
q <- mcparallel(1:20)
# wait for both jobs to finish and collect all results
res <- mccollect(list(p, q))

## IGNORE_RDIFF_BEGIN
## reports process ids, so not reproducible
p <- mcparallel(1:10)
mccollect(p, wait = FALSE, 10) # will retrieve the result (since it's fast)
mccollect(p, wait = FALSE) # will signal the job as terminating
mccollect(p, wait = FALSE) # there is no longer such a job
## IGNORE_RDIFF_END

# a naive parallel lapply can be created using mcparallel alone:
jobs <- lapply(1:10, function(x) mcparallel(rnorm(x), name = x))
mccollect(jobs)
```

Description

pvec parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn’t depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless mc.cores = 1.

Usage

```r
pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE,
     mc.cores = getOption("mc.cores", 2L), mc.cleanup = TRUE)
```

Arguments

- `v`: vector to operate on
- `FUN`: function to call on each part of the vector
- `...`: any further arguments passed to `FUN` after the vector
- `mc.set.seed`: See `mcparallel`.
- `mc.silent`: if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel processes forked (‘stderr’ is not affected).
- `mc.cores`: The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable MC_CORES if set.
- `mc.cleanup`: See the description of this argument in `mclapply`.
Details

`pvec` parallelizes `FUN(x, ...)` where `FUN` is a function that returns a vector of the same length as `x`. `FUN` must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which `FUN` is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between `pvec` and `mclapply` is that `mclapply` will run `FUN` on each element separately whereas `pvec` assumes that `c(FUN(x[1]), FUN(x[2]))` is equivalent to `FUN(x[1:2])` and thus will split into as many calls to `FUN` as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than `mclapply` but requires the above assumption on `FUN`.

If `mc.cores == 1` this evaluates `FUN(v, ...)` in the current process.

Value

The result of the computation – in a successful case it should be of the same length as `v`. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

Note

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as non-existent data. Therefore it is the responsibility of the user to check the length of the result to make sure it is of the correct size. `pvec` raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See `mcfork` for the inadvisability of using this with GUI front-ends and multi-threaded libraries.

`mcparallel`, `mclapply`, `parLapply`, `clusterMap`.

Examples

```r
x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))
```

# One use is to convert date strings to unix time in large datasets
# as that is a relatively slow operation.
# So let's get some random dates first
# (A small test only with 2 cores: set options("mc.cores")
# and increase N for a larger-scale test.)
N <- 1e5
dates <- sprintf('%04d-%02d-%02d', as.integer(2000+rnorm(N)),
                as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))
```
# But specifying the format is faster
system.time(a <- as.POSIXct(dates, format = "%Y-%m-%d"))

# pvec ought to be faster, but system overhead can be high
system.time(b <- pvec(dates, as.POSIXct, format = "%Y-%m-%d"))
stopifnot(all(a == b))

# using mclapply for this would much slower because each value
# will require a separate call to as.POSIXct()
# as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct, format = "%Y-%m-%d")))
stopifnot(all(a == c))

---

**RNGstreams**

*Implementation of Pierre L’Ecuyer’s RngStreams*

**Description**

This is an R re-implementation of Pierre L’Ecuyer’s ‘RngStreams’ multiple streams of pseudo-random numbers.

**Usage**

- `nextRNGStream(seed)`
- `nextRNGSubStream(seed)`
- `clusterSetRNGStream(cl = NULL, iseed)`
- `mc.reset.stream()`

**Arguments**

- `seed` An integer vector of length 7 as given by `.Random.seed` when the ‘L’Ecuyer-CMRG’ RNG is in use. See `RNG` for the valid values.
- `cl` A cluster from this package or package `snow`, or (if `NULL`) the registered cluster.
- `iseed` An integer to be supplied to `set.seed`, or `NULL` not to set reproducible seeds.

**Details**

The ‘RngStream’ interface works with (potentially) multiple streams of pseudo-random numbers: this is particularly suitable for working with parallel computations since each task can be assigned a separate RNG stream.

This uses as its underlying generator `RNGkind("L 'Ecuyer-CMRG")`, of L’Ecuyer (1999), which has a seed vector of 6 (signed) integers and a period of around $2^{191}$. Each ‘stream’ is a subsequence of the period of length $2^{127}$ which is in turn divided into ‘substreams’ of length $2^{76}$.

The idea of L’Ecuyer *et al* (2002) is to use a separate stream for each of the parallel computations (which ensures that the random numbers generated never get into to sync) and the parallel computations can themselves use substreams if required. The original interface stores the original seed of the first stream, the original seed of the current stream and the current seed: this could be implemented in R, but it is as easy to work by saving the relevant values of `.Random.seed`: see the examples.
clusterSetRNGStream selects the "L'Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by set.seed(iseed) (otherwise they are set from the current seed of the master process: after selecting the L’Ecuyer generator).

When not on Windows, Calling mc.reset.stream() after setting the L’Ecuyer random number generator and seed makes runs from mcparallel(mc.set.seed = TRUE) reproducible. This is done internally in mclapply and pvec. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

Value

For nextRNGStream and nextRNGSubStream, a value which can be assigned to .Random.seed.

Note

Interfaces to L’Ecuyer’s C code are available in CRAN packages rlecuyer and rstream.

splitIndices

Divide Tasks for Distribution in a Cluster

Description

This divides up 1:nx into ncl lists of approximately equal size, as a way to allocate tasks to nodes in a cluster.

It is mainly for internal use, but some package authors have found it useful.
splitIndices

Usage

splitIndices(nx, ncl)

Arguments

nx       Number of tasks.
ncl      Number of cluster nodes.

Value

A list of length ncl, each element being an integer vector.

Examples

splitIndices(20, 3)
Chapter 9

The splines package

splines-package  Regression Spline Functions and Classes

Description

Regression spline functions and classes.

Details

This package provides functions for working with regression splines using the B-spline basis, bs, and the natural cubic spline basis, ns.

For a complete list of functions, use library(help = "splines").

Author(s)

Douglas M. Bates <bates@stat.wisc.edu> and William N. Venables <Bill.Venables@csiro.au>

Maintainer: R Core Team <R-core@r-project.org>

asVector  Coerce an Object to a Vector

Description

This is a generic function. Methods for this function coerce objects of given classes to vectors.

Usage

asVector(object)

Arguments

object  An object.
Details

Methods for vector coercion in new classes must be created for the `asVector` generic instead of `as.vector`. The `as.vector` function is internal and not easily extended. Currently the only class with an `asVector` method is the `xyVector` class.

Value

a vector

Author(s)

Douglas Bates and Bill Venables

See Also

`xyVector`

Examples

```r
require(stats)
isp1 <- interpSpline( weight ~ height, women )
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)
```

---

backSpline  

Monotone Inverse Spline

Description

Create a monotone inverse of a monotone natural spline.

Usage

`backSpline(object)`

Arguments

- `object`  
an object that inherits from class `nbSpline` or `npolySpline`. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.

Value

An object of class `polySpline` that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by `object`. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.
Author(s)
Douglas Bates and Bill Venables

See Also
interpSpline

Examples

```r
require(graphics)
ispl <- interpSpline( women$height, women$weight )
bspl <- backSpline( ispl )
plot( bspl ) # plots over the range of the knots
points( women$weight, women$height )
```

bs
B-Spline Basis for Polynomial Splines

Description
Generate the B-spline basis matrix for a polynomial spline.

Usage

```r
bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,
   Boundary.knots = range(x))
```

Arguments

- `x`: the predictor variable. Missing values are allowed.
- `df`: degrees of freedom; one can specify `df` rather than `knots`; `bs()` then chooses `df-degree` (minus one if there is an intercept) knots at suitable quantiles of `x` (which will ignore missing values). The default, `NULL`, takes the number of inner knots as `length(knots)`. If that is zero as per default, that corresponds to `df = degree - intercept`.
- `knots`: the `internal` breakpoints that define the spline. The default is `NULL`, which results in a basis for ordinary polynomial regression. Typical values are the mean or median for one knot, quantiles for more knots. See also `Boundary.knots`.
- `degree`: degree of the piecewise polynomial—default is 3 for cubic splines.
- `intercept`: if TRUE, an intercept is included in the basis; default is `FALSE`.
- `Boundary.knots`: boundary points at which to anchor the B-spline basis (default the range of the non-NA data). If both `knots` and `Boundary.knots` are supplied, the basis parameters do not depend on `x`. Data can extend beyond `Boundary.knots`.

Details
bs is based on the function `splineDesign`. It generates a basis matrix for representing the family of piecewise polynomials with the specified interior knots and degree, evaluated at the values of `x`. A primary use is in modeling formulas to directly specify a piecewise polynomial term in a model.

When `Boundary.knots` are set `inside range(x)`, `bs()` now uses a ‘pivot’ inside the respective boundary knot which is important for derivative evaluation. In R versions ≤ 3.2.2, the boundary knot itself had been used as pivot, which lead to somewhat wrong extrapolations.
Value

A matrix of dimension c(length(x), df), where either df was supplied or if knots were supplied, df = length(knots) + degree plus one if there is an intercept. Attributes are returned that correspond to the arguments to bs, and explicitly give the knots, Boundary.knots etc for use by predict.bs().

Author(s)

Douglas Bates and Bill Venables. Tweaks by R Core, and a patch fixing extrapolation “outside” Boundary.knots by Trevor Hastie.

References

See Also

ns, poly, smooth.spline, predict.bs, SafePrediction

Examples

require(stats); require(graphics)
bs(women$height, df = 5)
summary(fm1 <- lm(weight ~ bs(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))

interpSpline
Create an Interpolation Spline

Description

Create an interpolation spline, either from x and y vectors (default method), or from a formula / data.frame combination (formula method).

Usage

interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
ord = 4L,
na.action = na.fail, sparse = FALSE)

Arguments

obj1

either a numeric vector of x values or a formula.

obj2

if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
ns

Generate a Basis Matrix for Natural Cubic Splines

Description

Generate the B-spline basis matrix for a natural cubic spline.

Usage

`ns(x, df = NULL, knots = NULL, intercept = FALSE, boundary.knots = range(x))`

Value

An object that inherits from (S3) class `spline`. The object can be in the B-spline representation, in which case it will be of class `nbSpline` for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class `npolySpline`.

Author(s)

Douglas Bates and Bill Venables

See Also

`splineKnots`, `splineOrder`, `periodicSpline`.

Examples

```r
require(graphics); require(stats)
ispl <- interpSpline( women$height, women$weight )
ispl2 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl, seq( 55, 75, length.out = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )
```
Arguments

- **x**: the predictor variable. Missing values are allowed.
- **df**: degrees of freedom. One can supply `df` rather than knots; `ns()` then chooses `df - 1 - intercept` knots at suitably chosen quantiles of `x` (which will ignore missing values). The default, `df = NULL`, sets the number of inner knots as `length(knots)`.
- **knots**: breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on `x`. Typical values are the mean or median for one knot, quantiles for more knots. See also `Boundary.knots`.
- **intercept**: if TRUE, an intercept is included in the basis; default is FALSE.
- **Boundary.knots**: boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both knots and `Boundary.knots` are supplied, the basis parameters do not depend on `x`. Data can extend beyond `Boundary.knots`.

Details

`ns` is based on the function `splineDesign`. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

Value

A matrix of dimension `length(x) * df` where either `df` was supplied or if `knots` were supplied, `df = length(knots) + 1 + intercept`. Attributes are returned that correspond to the arguments to `ns`, and explicitly give the knots, `Boundary.knots` etc for use by `predict.ns()`.

Examples

```r
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

### To see what knots were selected
attr(terms(fm1), "predvars")

### example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)");
ht <- seq(57, 73, length.out = 200); nD <- data.frame(height = ht)
```
periodicSpline

Create a Periodic Interpolation Spline

Description

Create a periodic interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Usage

periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4L)

Arguments

obj1       either a numeric vector of x values or a formula.
obj2       if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
knots      optional numeric vector of knot positions.
period      positive numeric value giving the period for the periodic spline. Defaults to 2 * pi.
ord         integer giving the order of the spline, at least 2. Defaults to 4. See splineOrder for a definition of the order of a spline.

Value

An object that inherits from class spline. The object can be in the B-spline representation, in which case it will be a pbSpline object, or in the piecewise polynomial representation (a ppolySpline object).

Author(s)

Douglas Bates and Bill Venables

See Also

splineKnots, interpSpline
Examples

```r
require(graphics); require(stats)
x <- seq(-pi, pi, length.out = 16)[-1]
y <- sin(x)
frm <- data.frame(x, y)
pispl <- periodicSpline(x, y, period = 2 * pi)
pispl
pispl2 <- periodicSpline(y ~ x, frm, period = 2 * pi)
stopifnot(all.equal(pispl, pispl2)) # pispl and pispl2 are the same

plot(pispl)        # displays over one period
points(y ~ x, col = "brown")
plot(predict(pispl, seq(-3*pi, 3*pi, length.out = 101)), type = "l")
```

---

**polySpline**

**Piecewise Polynomial Spline Representation**

**Description**

Create the piecewise polynomial representation of a spline object.

**Usage**

```r
polySpline(object, ...)
```

**Arguments**

- `object` An object that inherits from class `spline`.
- `...` Optional additional arguments. At present no additional arguments are used.

**Value**

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`interpSpline`, `periodicSpline`, `splineKnots`, `splineOrder`
Examples

```r
require(graphics)
ispl <- polySpline(interpSpline(weight ~ height, women, bSpline = TRUE))
## IGNORE_RDIFF_BEGIN
print(ispl) # print the piecewise polynomial representation
## IGNORE_RDIFF_END
plot(ispl)  # plots over the range of the knots
points(women$height, women$weight)
```

Description

Evaluate a predefined spline basis at given values.

Usage

```r
## S3 method for class 'bs'
predict(object, newx, ...)
## S3 method for class 'ns'
predict(object, newx, ...)
```

Arguments

- `object`: the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.
- `newx`: the x values at which evaluations are required.
- `...`: Optional additional arguments. At present no additional arguments are used.

Value

An object just like `object`, except evaluated at the new values of `x`.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.

See Also

- `bs`, `ns`, `poly`.

Examples

```r
require(stats)
basis <- ns(women$height, df = 5)
newX <- seq(58, 72, length.out = 51)
# evaluate the basis at the new data
predict(basis, newX)
```
**predict.bSpline**

*Evaluate a Spline at New Values of x*

**Description**

The `predict` methods for the classes that inherit from the virtual classes `bSpline` and `polySpline` are used to evaluate the spline or its derivatives. The `plot` method for a spline object first evaluates `predict` with the `x` argument missing, then plots the resulting `xyVector` with `type = "l"`.

**Usage**

```r
## S3 method for class 'bSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'nbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'pbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'npolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'ppolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
```

**Arguments**

- `object` An object that inherits from the `bSpline` or the `polySpline` class.
- `x` A numeric vector of `x` values at which to evaluate the spline. If this argument is missing a suitable set of `x` values is generated as a sequence of `nseg` segments spanning the range of the knots.
- `nseg` A positive integer giving the number of segments in a set of equally-spaced `x` values spanning the range of the knots in `object`. This value is only used if `x` is missing.
- `deriv` An integer between 0 and `splineOrder(object) - 1` specifying the derivative to evaluate.
- `...` further arguments passed to or from other methods.

**Value**

An `xyVector` with components

- `x` the supplied or inferred numeric vector of `x` values
- `y` the value of the spline (or its `deriv`'th derivative) at the `x` vector

**Author(s)**

Douglas Bates and Bill Venables

```

splineDesign

### Design Matrix for B-splines

**Description**

Evaluate the design matrix for the B-splines defined by knots at the values in x.

**Usage**

```r
splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
```

**Arguments**

- `knots`: a numeric vector of knot positions (which will be sorted increasingly if needed).
- `x`: a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless `outer.ok` is true, the values in x must be between the “inner” knots `knots[ord]` and `knots[length(knots) - (ord-1)]`.
- `ord`: a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.
- `derivs`: an integer vector with values between 0 and `ord - 1`, conceptually recycled to the length of x. The derivative of the given order is evaluated at the x positions. Defaults to zero (or a vector of zeroes of the same length as x).
- `outer.ok`: logical indicating if x should be allowed outside the inner knots, see the x argument.
- `sparse`: logical indicating if the result should inherit from class "sparseMatrix" (from package Matrix).
splineKnots

Knot Vector from a Spline

Value
A matrix with \(\text{length}(x)\) rows and \(\text{length}(\text{knots}) - \text{ord}\) columns. The \(i\)'th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the \(i\)'th value of \(x\). Each B-spline is defined by a set of \(\text{ord}\) successive knots so the total number of B-splines is \(\text{length}(\text{knots}) - \text{ord}\).

Note
The older \text{spline.des} function takes the same arguments but returns a list with several components including \text{knots}, \text{ord}, \text{derivs}, and \text{design}. The \text{design} component is the same as the value of the \text{splineDesign} function.

**Examples**
```r
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )
```

---

**splineOrder**  
*Determine the Order of a Spline*

**Description**
Return the order of a spline object.

**Usage**
```r
splineOrder(object)
```

**Arguments**
- `object`  
  An object that inherits from class "spline".

**Details**
The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

**Value**
A positive integer.

**Author(s)**
Douglas Bates and Bill Venables

**See Also**
- `splineKnots`, `interpSpline`, `periodicSpline`

**Examples**
```r
splineOrder( interpSpline( weight ~ height, women ) )
```
Construct an xyVector Object

Description

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as predict.spline is returned as an xyVector object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

Usage

xyVector(x, y)

Arguments

x a numeric vector
y a numeric vector of the same length as x

Value

An object of class xyVector with components

x a numeric vector
y a numeric vector of the same length as x

Author(s)

Douglas Bates and Bill Venables

Examples

require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ) )
class(weights)
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights

**.checkMFClasses**

*Functions to Check the Type of Variables passed to Model Frames*

---

**Description**

`.checkMFClasses` checks if the variables used in a predict method agree in type with those used for fitting.

`.MFclass` categorizes variables for this purpose.

`.getXlevels()` extracts factor levels from `factor` or `character` variables.

**Usage**

`.checkMFClasses(cl, m, ordNotOK = FALSE)`

`.MFclass(x)`

`.getXlevels(Terms, m)`

1291
acf

Auto- and Cross- Covariance and -Correlation Function Estimation

The function `acf` computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function `pacf` is the function used for the partial autocorrelations. Function `ccf` computes the cross-correlation or cross-covariance of two univariate series.
Usage

acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)

## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail,
    ...)  

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)

## S3 method for class 'acf'
x[i, j]

Arguments

x, y  a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an "acf" object.

lag.max  maximum lag at which to calculate the acf. Default is $10 \log_{10}(N/m)$ where $N$ is the number of observations and $m$ the number of series. Will be automatically limited to one less than the number of observations in the series.

type  character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial". Will be partially matched.

plot  logical. If TRUE (the default) the acf is plotted.

na.action  function to be called to handle missing values. na.pass can be used.

demean  logical. Should the covariances be about the sample means?

...  further arguments to be passed to plot.acf.

i  a set of lags (time differences) to retain.

j  a set of series (names or numbers) to retain.

Details

For type = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the na.action function passes through missing values (as na.pass does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to lag.max.

The generic function plot has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".
Value

An object of class "acf", which is a list with the following elements:

- \texttt{lag} A three dimensional array containing the lags at which the acf is estimated.
- \texttt{acf} An array with the same dimensions as \texttt{lag} containing the estimated acf.
- \texttt{type} The type of correlation (same as the \texttt{type} argument).
- \texttt{n.used} The number of observations in the time series.
- \texttt{series} The name of the series \texttt{x}.
- \texttt{snames} The series names for a multivariate time series.

The lag \( k \) value returned by \texttt{ccf(x, y)} estimates the correlation between \( x[t+k] \) and \( y[t] \).

The result is returned invisibly if \texttt{plot} is \texttt{TRUE}.

Author(s)

Original: Paul Gilbert, Martyn Plummer. Extensive modifications and univariate case of \texttt{pacf} by B. D. Ripley.

References

(This contains the exact definitions used.)

See Also

\texttt{plot.acf}, \texttt{ARMAacf} for the exact autocorrelations of a given ARMA process.

Examples

```r
require(graphics)

## Examples from Venables & Ripley
acf(lh)
acf(lh, type = "covariance")
pacf(lh)

acf(ldeaths)
acf(ldeaths, ci.type = "ma")
acf(ts.union(mdeaths, fdeaths))
ccf(mdeaths, fdeaths, ylab = "cross-correlation")
# (just the cross-correlations)

presidents # contains missing values
acf(presidents, na.action = na.pass)
pacf(presidents, na.action = na.pass)
```
acf2AR

**Compute an AR Process Exactly Fitting an ACF**

**Description**

Compute an AR process exactly fitting an autocorrelation function.

**Usage**

```r
acf2AR(acf)
```

**Arguments**

- `acf` An autocorrelation or autocovariance sequence.

**Value**

A matrix, with one row for the computed AR(p) coefficients for 1 <= p <= length(acf).

**See Also**

- `ARMAacf`, `ar.yw` which does this from an empirical ACF.

**Examples**

```r
(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
```

---

add1

**Add or Drop All Possible Single Terms to a Model**

**Description**

Compute all the single terms in the `scope` argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

**Usage**

```r
add1(object, scope, ...) 
## Default S3 method: 
add1(object, scope, scale = 0, test = c("none", "Chisq"), 
    k = 2, trace = FALSE, ...) 
## S3 method for class 'lm' 
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"), 
    x = NULL, k = 2, ...) 
## S3 method for class 'glm' 
add1(object, scope, scale = 0, 
```

...
test = c("none", "Rao", "LRT", "Chisq", "F"),
    x = NULL, k = 2, ...)

drop1(object, scope, ...)

## Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
    k = 2, trace = FALSE, ...)

## S3 method for class 'lm'
drop1(object, scope, scale = 0, all.cols = TRUE,
    test = c("none", "Chisq", "F"), k = 2, ...)

## S3 method for class 'glm'
drop1(object, scope, scale = 0,
    test = c("none", "Rao", "LRT", "Chisq", "F"),
    k = 2, ...)

Arguments

- **object**: a fitted model object.
- **scope**: a formula giving the terms to be considered for adding or dropping.
- **scale**: an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models or perhaps for `glm` fits with estimated dispersion. The $\chi^2$ test can be an exact test (`lm` models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method. For `glm` fits, you can also choose "LRT" and "Rao" for likelihood ratio tests and Rao’s efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution). Values can be abbreviated.
- **k**: the penalty constant in AIC / $C_p$.
- **trace**: if TRUE, print out progress reports.
- **x**: a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if `add1` is to be called repeatedly. **Warning**: no checks are done on its validity.
- **all.cols** (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.

Details

For `drop1` methods, a missing `scope` is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a `scope` formula . means ‘what is already there’.

The methods for `lm` and `glm` are more efficient in that they do not recompute the model matrix and call the fit methods directly.
The default output table gives AIC, defined as minus twice log likelihood plus 2p where p is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ C_p, RSS/scale + 2p − n. Where C_p is used, the column is labelled as Cp rather than AIC.

The F tests for the "glm" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of anova.glm.

Value

An object of class "anova" summarizing the differences in fit between the models.

Warning

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if na.action = na.omit, but this may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function nobs to check that the number of observations involved in the fitting process remained unchanged.

Note

These are not fully equivalent to the functions in S. There is no keep argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ C_p and Akaike’s AIC are used, not those of the authors of the models chapter of S.

Author(s)

The design was inspired by the S functions of the same names described in Chambers (1992).

```
addmargins \hspace{1cm} \textit{Puts Arbitrary Margins on Multidimensional Tables or Arrays}

\textbf{Description}

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

\textbf{Usage}

\begin{verbatim}
addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{A} \hspace{1cm} table or array. The function uses the presence of the \texttt{"dim"} and \texttt{"dimnames"} attributes of \texttt{A}.
  \item \texttt{margin} \hspace{1cm} vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in \texttt{margin}.
  \item \texttt{FUN} \hspace{1cm} list of the same length as \texttt{margin}, each element of the list being either a \texttt{function} or a list of functions. In the length-1 case, can be a function instead of a list of one. Names of the list elements will appear as levels in \texttt{dimnames} of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.
  \item \texttt{quiet} \hspace{1cm} logical which suppresses the message telling the order in which the margins were computed.
\end{itemize}

\textbf{Details}

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the \texttt{FUN} list.

\textbf{Value}

A \texttt{table} or \texttt{array} with the same number of dimensions as \texttt{A}, but with extra levels of the dimensions mentioned in \texttt{margin}. The number of levels added to each dimension is the length of the entries in \texttt{FUN}. A message with the order of computation of margins is printed.

\textbf{Author(s)}

Bendix Carstensen, Steno Diabetes Center \& Department of Biostatistics, University of Copenhagen, \url{https://BendixCarstensen.com}, autumn 2003. Margin naming enhanced by Duncan Murdoch.

print(tx, zero.print = ".")

aggregate

Compute Summary Statistics of Data Subsets

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

Usage

aggregate(x, ...)

# Default S3 method:
aggregate(x, ...)

aggregate

## S3 method for class 'data.frame'
aggregate(x, by, FUN, ..., simplify = TRUE, drop = TRUE)

## S3 method for class 'formula'
aggregate(formula, data, FUN, ..., subset, na.action = na.omit)

## S3 method for class 'ts'
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1, ts.eps = getOption("ts.eps"), ...)

Arguments

x an R object.

by a list of grouping elements, each as long as the variables in the data frame x. The elements are coerced to factors before use.

FUN a function to compute the summary statistics which can be applied to all data subsets.

simplify a logical indicating whether results should be simplified to a vector or matrix if possible.

drop a logical indicating whether to drop unused combinations of grouping values. The non-default case drop=FALSE has been amended for R 3.5.0 to drop unused combinations.

formula a formula, such as y ~ x or cbind(y1, y2) ~ x1 + x2, where the y variables are numeric data to be split into groups according to the grouping x variables (usually factors).

data a data frame (or list) from which the variables in formula should be taken.

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.

nfrequency new number of observations per unit of time; must be a divisor of the frequency of x.

ndeltat new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of x.

ts.eps tolerance used to decide if nfrequency is a sub-multiple of the original frequency.

... further arguments passed to or used by methods.

Details

aggregate is a generic function with methods for data frames and time series.

The default method, aggregate.default, uses the time series method if x is a time series, and otherwise coerces x to a data frame and calls the data frame method.

aggregate.data.frame is the data frame method. If x is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in x is split into subsets of cases (rows) of identical combinations of the components of by, and FUN is applied to each such subset with further arguments in ... passed to it. The result is reformatted into a data frame containing the variables in by and x. The ones arising from by contain the unique combinations of grouping values used for determining the subsets, and the ones arising from x
the corresponding summaries for the subset of the respective variables in x. If simplify is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the by variables will be omitted from the result. (Note that versions of R prior to 2.11.0 required FUN to be a scalar function.)

aggregate.formula is a standard formula interface to aggregate.data.frame.

aggregate.ts is the time series method, and requires FUN to be a scalar function. If x is not a time series, it is coerced to one. Then, the variables in x are split into appropriate blocks of length frequency(x) / nfrequency, and FUN is applied to each such block, with further (named) arguments in ... passed to it. The result returned is a time series with frequency nfrequency holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

FUN is passed to match.fun, and hence it can be a function or a symbol or character string naming a function.

Value

For the time series method, a time series of class "ts" or class c("mts", "ts").

For the data frame method, a data frame with columns corresponding to the grouping variables in by followed by aggregated columns from x. If the by has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named Group.i for by[[i]].

## Often followed by xtabs():
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)

## Compute the average annual approval ratings for American presidents.
aggregate(presidents, nfrequency = 1, FUN = mean)
# Give the summer less weight.
aggregate(presidents, nfrequency = 1, 
FUN = weighted.mean, w = c(1, 1, 0.5, 1))

---

### Description

Generic function calculating Akaike’s ‘An Information Criterion’ for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula \(-2\log\text{-likelihood} + k\#\text{par}\), where \#\text{par} represents the number of parameters in the fitted model, and \(k = 2\) for the usual AIC, or \(k = \log(n)\) (\(n\) being the number of observations) for the so-called BIC or SBC (Schwarz’s Bayesian criterion).

### Usage

- **AIC**
  - `AIC(object, ..., k = 2)`

- **BIC**
  - `BIC(object, ...)`

### Arguments

- **object**
  - A fitted model object for which there exists a `logLik` method to extract the corresponding log-likelihood, or an object inheriting from class `logLik`. 
optionally more fitted model objects.

k numeric, the penalty per parameter to be used; the default k = 2 is the classical AIC.

Details

When comparing models fitted by maximum likelihood to the same data, the smaller the AIC or BIC, the better the fit.

The theory of AIC requires that the log-likelihood has been maximized: whereas AIC can be computed for models not fitted by maximum likelihood, their AIC values should not be compared.

Examples of models not ‘fitted to the same data’ are where the response is transformed (accelerated-life models are fitted to log-times) and where contingency tables have been used to summarize data.

These are generic functions (with S4 generics defined in package stats4): however methods should be defined for the log-likelihood function \texttt{logLik} rather than these functions: the action of their default methods is to call \texttt{logLik} on all the supplied objects and assemble the results. Note that in several common cases \texttt{logLik} does not return the value at the MLE; see its help page.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally been used for different purposes and so \texttt{extractAIC} and AIC may give different values (and do for models of class "lm": see the help for \texttt{extractAIC}). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous).

BIC is defined as \( \text{AIC}(\text{object}, \ldots, k = \log(\text{nobs}(\text{object}))) \). This needs the number of observations to be known: the default method looks first for a \texttt{nobs} attribute on the return value from \texttt{logLik} method, then tries the \texttt{nobs} generic, and if neither succeed returns BIC as NA.

Value

If just one object is provided, a numeric value with the corresponding AIC (or BIC, or \ldots, depending on k).

If multiple objects are provided, a \texttt{data.frame} with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC or BIC.

Author(s)

Originally by José Pinheiro and Douglas Bates, more recent revisions by R-core.

\texttt{extractAIC}, \texttt{logLik}, \texttt{nobs}.

Examples

```r
lm1 <- lm(Fertility ~ . , data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),
               AIC(logLik(lm1))))
BIC(lm1)
```
lm2 <- update(lm1, . ~ . -Examination)
AIC(lm1, lm2)
BIC(lm1, lm2)

**alias**

*Find Aliases (Dependencies) in a Model*

**Description**

Find aliases (linearly dependent terms) in a linear model specified by a formula.

**Usage**

```r
alias(object, ...)
```

```r
## S3 method for class 'formula'
alias(object, data, ...)
```

```r
## S3 method for class 'lm'
alias(object, complete = TRUE, partial = FALSE,
partial.pattern = FALSE, ...)
```

**Arguments**

- `object` A fitted model object, for example from `lm` or `aov`, or a formula for `alias.formula`.
- `data` Optionally, a data frame to search for the objects in the formula.
- `complete` Should information on complete aliasing be included?
- `partial` Should information on partial aliasing be included?
- `partial.pattern` Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.

... further arguments passed to or from other methods.

**Details**

Although the main method is for class "lm", alias is most useful for experimental designs and so is used with fits from `aov`. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Some parts of the "lm" method require recommended package MASS to be installed.
Value

A list (of class "listof") containing components

- **Model**: Description of the model; usually the formula.
- **Complete**: A matrix with columns corresponding to effects that are linearly dependent on the rows.
- **Partial**: The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own `print` method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers *et al* (1992).

References

Examples

```r
op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op)  # reset
```

---

### anova

#### Anova Tables

**Description**

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

**Usage**

```r
anova(object, ...)
```

**Arguments**

- `object`: an object containing the results returned by a model fitting function (e.g., `lm` or `glm`).
- `...`: additional objects of the same type.
Value

This (generic) function returns an object of class anova. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, anova tests the models against one another in the order specified.

The print method for anova objects prints tables in a 'pretty' form.

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of na.action = na.omit is used.

anova.glm

Analysis of Deviance for Generalized Linear Model Fits

Description

Compute an analysis of deviance table for one or more generalized linear model fits.

Usage

## S3 method for class 'glm'
anova(object, ..., dispersion = NULL, test = NULL)

Arguments

object, ... objects of class glm, typically the result of a call to glm, or a list of objects for the "glmlist" method.
dispersion the dispersion parameter for the fitting family. By default it is obtained from the object(s).
test a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See stat.anova.

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.
The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., gaussian, quasibinomial and quasipoisson fits) the F test is most appropriate. Mallows' $C_p$ statistic is the residual deviance plus twice the estimate of $\sigma^2$ times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by \texttt{summary.glm}. As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

**Value**

An object of class "anova" inheriting from class "data.frame".

**Warning**

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of \texttt{na.action = na.omit} is used, and \texttt{anova} will detect this with an error.

**References**

**See Also**

\texttt{glm}, \texttt{anova}.

\texttt{drop1} for so-called ‘type II’ anova where each term is dropped one at a time respecting their hierarchy.

**Examples**

```r
## --- Continuing the Example from '?glm':

anova(glm.D93)
anova(glm.D93, test = "Cp")
anova(glm.D93, test = "Chisq")
glm.D93a <-
    update(glm.D93, ~treatment*outcome) # equivalent to Pearson Chi-square
anova(glm.D93, glm.D93a, test = "Rao")
```

\texttt{anova.lm} \hspace{1cm} \textit{ANOVA for Linear Model Fits}

**Description**

Compute an analysis of variance table for one or more linear model fits.
Usage

```r
## S3 method for class 'lm'
anova(object, ...)

## S3 method for class 'lmlist'
anova(object, ..., scale = 0, test = "F")
```

Arguments

- `object, ...` objects of class `lm`, usually, a result of a call to `lm`.
- `test` a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or `NULL` for no test.
- `scale` numeric. An estimate of the noise variance $\sigma^2$. If zero this will be estimated from the largest model considered.

Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows’ $C_p$ statistic is the residual sum of squares plus twice the estimate of $\sigma^2$ times the residual degrees of freedom.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used, and `anova.lmlist` will detect this with an error.

fit4 <- update(fit3, . ~ . + ddpi)
anova(fit0, fit1, fit2, fit3, fit4, test = "F")

anova(fit4, fit2, fit0, test = "F") # unconventional order

---

**anova.mlm**

*Comparisons between Multivariate Linear Models*

### Description

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

### Usage

```r
## S3 method for class 'mlm'
anova(object, ..., 
  test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy",
            "Spherical"),
  Sigma = diag(nrow = p), T = Thin.row(proj(M) - proj(X)),
  M = diag(nrow = p), X = ~0,
  idata = data.frame(index = seq_len(p)), tol = 1e-7)
```

### Arguments

- **object**: an object of class "mlm".
- **...**: further objects of class "mlm".
- **test**: choice of test statistic (see below). Can be abbreviated.
- **Sigma**: (only relevant if test == "Spherical"). Covariance matrix assumed proportional to Sigma.
- **T**: transformation matrix. By default computed from M and X.
- **M**: formula or matrix describing the outer projection (see below).
- **X**: formula or matrix describing the inner projection (see below).
- **idata**: data frame describing intra-block design.
- **tol**: tolerance to be used in deciding if the residuals are rank-deficient: see qr.
Details

The \texttt{anova.mlm} method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See \texttt{summary.manova} for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using \texttt{Sigma}. Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted $F$ tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix $T$ can be given directly or specified as the difference between two projections onto the spaces spanned by $M$ and $X$, which in turn can be given as matrices or as model formulas with respect to \texttt{idata} (the tests will be invariant to parametrization of the quotient space $M/X$).

As with \texttt{anova.lm}, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other \texttt{anova} methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in \texttt{R}.

### ansari.test

**Ansari-Bradley Test**

**Description**

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

**Usage**

ansari.test(x, ...)

## Default S3 method:
ansari.test(x, y,  
            alternative = c("two.sided", "less", "greater"),  
            exact = NULL, conf.int = FALSE, conf.level = 0.95,  
            ...)  

## S3 method for class 'formula'
ansari.test(formula, data, subset, na.action, ...)

**Arguments**

- **x** numeric vector of data values.
- **y** numeric vector of data values.
- **alternative** indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- **exact** a logical indicating whether an exact p-value should be computed.
- **conf.int** a logical indicating whether a confidence interval should be computed.
- **conf.level** confidence level of the interval.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
... further arguments to be passed to or from methods.

Details

Suppose that x and y are independent samples from distributions with densities \( f((t - m)/s)/s \) and \( f(t - m) \), respectively, where \( m \) is an unknown nuisance parameter and \( s \), the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that \( s = 1 \), the two-sided alternative being that \( s \neq 1 \) (the distributions differ only in variance), and the one-sided alternatives being \( s > 1 \) (the distribution underlying x has a larger variance, "greater") or \( s < 1 \) ("less").

By default (if exact is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for \( s \) are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

Value

A list with class "htest" containing the following components:

- statistic the value of the Ansari-Bradley test statistic.
- p.value the p-value of the test.
- null.value the ratio of scales \( s \) under the null, 1.
- alternative a character string describing the alternative hypothesis.
- method the string "Ansari-Bradley test".
- data.name a character string giving the names of the data.
- conf.int a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.)
- estimate an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)

Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that \( s \) is the ratio of scales and hence \( s^2 \) is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for \( s \) in the Ansari-Bradley test but for \( s^2 \) in the F test.

Examples

```r
## Hollander & Wolfe (1973, p. 86f):
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
           101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
                  100, 96, 108, 103, 104, 114, 114, 113, 110, 99)
ansari.test(ramsay, jung.parekh)
ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)
## try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```

---

**aov**  
*Fit an Analysis of Variance Model*

**Description**

Fit an analysis of variance model by a call to `lm` for each stratum.

**Usage**

```r
aov(formula, data = NULL, projections = FALSE, qr = TRUE, contrasts = NULL, ...)
```

**Arguments**

- `formula`  
  A formula specifying the model.

- `data`  
  A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.

- `projections`  
  Logical flag: should the projections be returned?

- `qr`  
  Logical flag: should the QR decomposition be returned?
contrasts A list of contrasts to be used for some of the factors in the formula. These are not used for any Error term, and supplying contrasts for factors only in the Error term will give a warning.

... Arguments to be passed to lm, such as subset or na.action. See ‘Details’ about weights.

Details
This provides a wrapper to lm for fitting linear models to balanced or unbalanced experimental designs.

The main difference from lm is in the way print, summary and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single Error term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a weights argument, but should not be used with an Error term, and are incompletely supported (e.g., not by model.tables).

Value
An object of class c("aov", "lm") or for multiple responses of class c("maov", "aov", "mlm", "lm") or for multiple error strata of class c("aovlist", "listof"). There are print and summary methods available for these.

Note
aov is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use lme in package nlme.

Balance can be checked with the replications function.

The default ‘contrasts’ in R are not orthogonal contrasts, and aov and its helper functions will work better with such contrasts: see the examples for how to select these.

Author(s)
The design was inspired by the S function of the same name described in Chambers et al (1992).

coefficients(npk.aov)

## to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
```

## IGNORE_RDIFF_BEGIN
```r
summary(npk.aovE)
## IGNORE_RDIFF_END
options(op) # reset to previous
```

approxfun

Interpolation Functions

Description

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

Usage

```r
approx (x, y = NULL, xout, method = "linear", n = 50,
yleft, yright, rule = 1, f = 0, ties = mean, na.rm = TRUE)

approxfun(x, y = NULL, method = "linear",
yleft, yright, rule = 1, f = 0, ties = mean, na.rm = TRUE)
```

Arguments

- **x, y**
  numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`.
- **xout**
  an optional set of numeric values specifying where interpolation is to take place.
- **method**
  specifies the interpolation method to be used. Choices are "linear" or "constant".
- **n**
  If `xout` is not specified, interpolation takes place at `n` equally spaced points spanning the interval `[min(x), max(x)]`. If `xout` is specified, interpolation takes place at the specified `xout`.
- **yleft**
  the value to be returned when input `x` values are less than `min(x)`. The default is defined by the value of `rule` given below.
- **yright**
  the value to be returned when input `x` values are greater than `max(x)`. The default is defined by the value of `rule` given below.
approxf

rule
an integer (of length 1 or 2) describing how interpolation is to take place outside the interval \([\min(x), \max(x)]\). If rule is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., rule = 2:1, if the left and right side extrapolation should differ.

f
for method = "constant" a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If \(y0\) and \(y1\) are the values to the left and right of the point then the value is \(y0\) if \(f = 0\), \(y1\) if \(f = 1\), and \(y0*(1-f)+y1*f\) for intermediate values. In this way the result is right-continuous for \(f = 0\) and left-continuous for \(f = 1\), even for non-finite \(y\) values.

ties
handling of tied \(x\) values. The string "ordered" or a function (or the name of a function) taking a single vector argument and returning a single number or a list of both, e.g., list("ordered", mean), see ‘Details’.

na.rm
logical specifying how missing values (NA’s) should be handled. Setting na.rm=FALSE will propagate NA’s in \(y\) to the interpolated values, also depending on the rule set. Note that in this case, NA’s in \(x\) are invalid, see also the examples.

Details
The inputs can contain missing values which are deleted (if na.rm is true, i.e., by default), so at least two complete \((x, y)\) pairs are required (for method = "linear", one otherwise). If there are duplicated (tied) \(x\) values and ties contains a function it is applied to the \(y\) values for each distinct \(x\) value to produce \((x,y)\) pairs with unique \(x\). Useful functions in this context include mean, min, and max.

If ties = "ordered" the \(x\) values are assumed to be already ordered (and unique) and ties are not checked but kept if present. This is the fastest option for large length(x).

If ties is a list of length two, ties[[2]] must be a function to be applied to ties, see above, but if ties[[1]] is identical to "ordered", the \(x\) values are assumed to be sorted and are only checked for ties. Consequently, ties = list("ordered", mean) will be slightly more efficient than the default ties = mean in such a case.

The first \(y\) value will be used for interpolation to the left and the last one for interpolation to the right.

Value
approx returns a list with components \(x\) and \(y\), containing \(n\) coordinates which interpolate the given data points according to the method (and rule) desired.

The function approxfun returns a function performing (linear or constant) interpolation of the given data points. For a given set of \(x\) values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning
The value returned by approxfun contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer for R >= 3.0.0.

References
See Also

`spline` and `splinefun` for spline interpolation.

Examples

```r
require(graphics)

x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "+")
points(approx(x, y, method = "constant"), col = 4, pch = "*")

f <- approxfun(x, y)

**ar**

*Fit Autoregressive Models to Time Series*

**Description**

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.

**Usage**

```r
ar(x, aic = TRUE, order.max = NULL,
   method = c("yule-walker", "burg", "ols", "mle", "yw"),
   na.action, series, ...)
```

```r
ar.burg(x, ...)
```

--

## Default S3 method:

```r
ar.burg(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series,
   var.method = 1, ...)
```

## S3 method for class 'mts'

```r
ar.burg(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series,
   var.method = 1, ...)
```

```r
ar.yw(x, ...)
```

--

## Default S3 method:

```r
ar.yw(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series, ...)
```

## S3 method for class 'mts'

```r
ar.yw(x, aic = TRUE, order.max = NULL,
   na.action = na.fail, demean = TRUE, series,
   var.method = 1, ...)
```

```r
ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
   demean = TRUE, series, ...)
```

## S3 method for class 'ar'

```r
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)
```
Arguments

- **x**: a univariate or multivariate time series.
- **aic**: logical. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order **order.max** is fitted.
- **order.max**: maximum order (or order) of model to fit. Defaults to the smaller of \( N - 1 \) and \( 10 \log_{10}(N) \) where \( N \) is the number of non-missing observations except for method = "mle" where it is the minimum of this quantity and 12.
- **method**: character string specifying the method to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".
- **na.action**: function to be called to handle missing values. Currently, via na.action = na.pass, only Yule-Walker method can handle missing values which must be consistent within a time point: either all variables must be missing or none.
- **demean**: should a mean be estimated during fitting?
- **series**: names for the series. Defaults to deparse1(substitute(x)).
- **var.method**: the method to estimate the innovations variance (see 'Details').
- **...**: additional arguments for specific methods.
- **object**: a fit from ar().
- **newdata**: data to which to apply the prediction.
- **n.ahead**: number of steps ahead at which to predict.
- **se.fit**: logical: return estimated standard errors of the prediction error?

Details

For definiteness, note that the AR coefficients have the sign in

\[
x_t = \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t
\]

ar is just a wrapper for the functions ar.yw, ar.burg, ar.ols and ar.mle.

Order selection is done by AIC if aic is true. This is problematic, as of the methods here only ar.mle performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In ar.yw the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of the residuals.

ar.burg allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that ar includes by default a constant in the model, by removing the overall mean of \( x \) before fitting the AR model, or (ar.mle) estimating a constant to subtract.
For `ar` and its methods a list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if `aic = TRUE`, otherwise it is `order.max`.
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean of the series used in fitting and for use in prediction.
- **x.intercept**: (ar.ols only.) The intercept in the model for `x - x.mean`.
- **aic**: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of ~1Inf.
- **n.used**: The number of observations in the time series, including missing.
- **n.obs**: The number of non-missing observations in the time series.
- **order.max**: The value of the `order.max` argument.
- **partialacf**: The estimate of the partial autocorrelation function up to lag `order.max`.
- **resid**: residuals from the fitted model, conditioning on the first `order` observations. The first `order` residuals are set to NA. If `x` is a time series, so is `resid`.
- **method**: The value of the `method` argument.
- **series**: The name(s) of the time series.
- **frequency**: The frequency of the time series.
- **call**: The matched call.
- **asy.var.coef**: (univariate case, `order > 0`.) The asymptotic-theory variance matrix of the coefficient estimates.

For `predict.ar`, a time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

**Note**

Only the univariate case of `ar.mle` is implemented.

Fitting by `method = "mle"` to long series can be very slow.

If `x` contains missing values, see `NA`, also consider using `arima()`, possibly with `method = "ML"`.

Martyn Plummer. Univariate case of `ar.yw`, `ar.mle` and C code for univariate case of `ar.burg` by B. D. Ripley.

**References**

ar.ols

Fit Autoregressive Models to Time Series by OLS

Description

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.

Usage

ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail, demean = TRUE, intercept = demean, series, ...)

Arguments

x  A univariate or multivariate time series.

aic   Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order order.max is fitted.

order.max   Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is the number of observations.

na.action   function to be called to handle missing values.

demean   should the AR model be for $x$ minus its mean?

intercept   should a separate intercept term be fitted?

series   names for the series. Defaults to \texttt{deparse1(substitute(x))}.

...   further arguments to be passed to or from methods.

See Also

\texttt{ar.ols, arima} for ARMA models; \texttt{acf2AR}, for AR construction from the ACF.

\texttt{arima.sim} for simulation of AR processes.

Examples

\begin{verbatim}
ar(lh)
ar(lh, method = "burg")
ar(lh, method = "ols")
ar(lh, FALSE, 4) # fit ar(4)

(sunspot.ar <- ar(sunspot.year))
predict(sunspot.ar, n.ahead = 25)
## try the other methods too

ar(ts.union(BJsales, BJsales.lead))
## Burg is quite different here, as is OLS (see ar.ols)
ar(ts.union(BJsales, BJsales.lead), method = "burg")
\end{verbatim}
Details

ar.ols fits the general AR model to a possibly non-stationary and/or multivariate system of series \( x \). The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

\[
x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + \epsilon_t
\]

where \( a_0 \) is zero unless intercept is true, and \( \mu \) is the sample mean if demean is true, zero otherwise.

Order selection is done by AIC if aic is true. This is problematic, as ar.ols does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if intercept is true and demean is false. Only use this if the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean (or zero if demean is false) of the series used in fitting and for use in prediction.
- **x.intercept**: The intercept in the model for \( x - x.mean \), or zero if intercept is false.
- **aic**: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.
- **n.used**: The number of observations in the time series.
- **order.max**: The value of the order.max argument.
- **partialacf**: NULL. For compatibility with ar.
- **resid**: Residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If \( x \) is a time series, so is resid.
- **method**: The character string "Unconstrained LS".
- **series**: The name(s) of the time series.
- **frequency**: The frequency of the time series.
- **call**: The matched call.
- **asy.se.coef**: The asymptotic-theory standard errors of the coefficient estimates.

ar.ols(x, order.max = 6, demean = FALSE, intercept = TRUE)

arima

ARIMA Modelling of Time Series

Description

Fit an ARIMA model to a univariate time series.

Usage

arima(x, order = c(0L, 0L, 0L),
seasonal = list(order = c(0L, 0L, 0L), period = NA),
xreg = NULL, include.mean = TRUE,
transform.pars = TRUE,
fixed = NULL, init = NULL,
method = c("CSS-ML", "ML", "CSS"), n.cond,
SSinit = c("Gardner1980", "Rossignol2011"),
optim.method = "BFGS",
optim.control = list(), kappa = 1e6)

Arguments

x a univariate time series

order A specification of the non-seasonal part of the ARIMA model: the three integer components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal A specification of the seasonal part of the ARIMA model, plus the period (which defaults to frequency(x)). This may be a list with components order and period, or just a numeric vector of length 3 which specifies the seasonal order. In the latter case the default period is used.

xreg Optionally, a vector or matrix of external regressors, which must have the same number of rows as x.
include.mean: Should the ARMA model include a mean/intercept term? The default is TRUE for undifferenced series, and it is ignored for ARIMA models with differencing.

transform.pars: logical; if true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for method = "CSS". For method = "ML", it has been advantageous to set transform.pars = FALSE in some cases, see also fixed.

fixed: optional numeric vector of the same length as the total number of coefficients to be estimated. It should be of the form

\[(\phi_1, \ldots, \phi_p, \theta_1, \ldots, \theta_q, \Phi_1, \ldots, \Phi_P, \Theta_1, \ldots, \Theta_Q, \mu),\]

where \(\phi_i\) are the AR coefficients, \(\theta_i\) are the MA coefficients, \(\Phi_i\) are the seasonal AR coefficients, \(\Theta_i\) are the seasonal MA coefficients and \(\mu\) is the intercept term.

Note that the \(\mu\) entry is required if and only if include.mean is TRUE. In particular it should not be present if the model is an ARIMA model with differencing. The entries of the fixed vector should consist of the values at which the user wishes to “fix” the corresponding coefficient, or NA if that coefficient should not be fixed, but estimated.

The argument transform.pars will be set to FALSE if any AR parameters are fixed. A warning will be given if transform.pars is set to (or left at its default) TRUE. It may be wise to set transform.pars = FALSE even when fixing MA parameters, especially at values that cause the model to be nearly non-invertible.

init: optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in fixed will be ignored.

method: fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood. Can be abbreviated.

n.cond: only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

SSinit: a string specifying the algorithm to compute the state-space initialization of the likelihood; see KalmanLike for details. Can be abbreviated.

optim.method: The value passed as the method argument to optim.

optim.control: List of control parameters for optim.

kappa: the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has

\[X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + \epsilon_t + b_1 \epsilon_{t-1} + \cdots + b_q \epsilon_{t-q}\]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if include.mean is true (the default for an ARMA model), this formula applies to \(X - m\) rather than \(X\). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an xreg term is included, a linear regression (with a constant term if include.mean is true and there is no differencing) is fitted with an ARMA model for the error term.
The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by \texttt{optim}. It will work best if the columns in \texttt{xreg} are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

\textbf{Value}

A list of class "Arima" with components:

- \texttt{coef}: a vector of AR, MA and regression coefficients, which can be extracted by the \texttt{coef} method.
- \texttt{sigma2}: the MLE of the innovations variance.
- \texttt{var.coef}: the estimated variance matrix of the coefficients \texttt{coef}, which can be extracted by the \texttt{vcov} method.
- \texttt{loglik}: the maximized log-likelihood (of the differenced data), or the approximation to it used.
- \texttt{arma}: A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- \texttt{aic}: the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.
- \texttt{residuals}: the fitted innovations.
- \texttt{call}: the matched call.
- \texttt{series}: the name of the series \texttt{x}.
- \texttt{code}: the convergence value returned by \texttt{optim}.
- \texttt{n.cond}: the number of initial observations not used in the fitting.
- \texttt{nobs}: the number of “used” observations for the fitting, can also be extracted via \texttt{nobs()} and is used by \texttt{BIC}.
- \texttt{model}: A list representing the Kalman Filter used in the fitting. See \texttt{KalmanLike}.

\textbf{Fitting methods}

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner \textit{et al} (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by \texttt{kappa}). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least $1e4$) are excluded from the likelihood calculations. (This gives comparable results to \texttt{arima0} in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If \texttt{transform.pars} is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if \texttt{transform.pars} is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation \texttt{n.cond} on, (where \texttt{n.cond} is at least the
maximum lag of an AR term), treating all earlier innovations to be zero. Argument \texttt{n.cond} can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

\textbf{Note}

The results are likely to be different from S-PLUS's \texttt{arima.mle}, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by \texttt{arima.mle} reverses the signs of the MA coefficients.

\texttt{arima} is very similar to \texttt{arima0} for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than \texttt{arima0}, particularly for seasonally differenced models.

### arima.sim

**Simulate from an ARIMA Model**

#### Description

Simulate from an ARIMA model.

#### Usage

```r
arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
    n.start = NA, start.innov = rand.gen(n.start, ...),
    ...)  
```

#### Arguments

- **model**: A list with component `ar` and/or `ma` giving the AR and MA coefficients respectively. Optionally a component `order` can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.
- **n**: length of output series, before un-differencing. A strictly positive integer.
- **rand.gen**: optional: a function to generate the innovations.
- **innov**: an optional times series of innovations. If not provided, `rand.gen` is used.
- **n.start**: length of ‘burn-in’ period. If NA, the default, a reasonable value is computed.
- **start.innov**: an optional times series of innovations to be used for the burn-in period. If supplied there must be at least `n.start` values (and `n.start` is by default computed inside the function).
- **...**: additional arguments for `rand.gen`. Most usefully, the standard deviation of the innovations generated by `rnorm` can be specified by `sd`.  

---
Details

See arima for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the order component of model, in the same way as for arima. Other aspects of the order component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the ‘burn-in’ period are generated by calling rand.gen.

Value

A time-series object of class "ts".

ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)

arima0

ARIMA Modelling of Time Series – Preliminary Version

Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

arima0(x, order = c(0, 0, 0),
       seasonal = list(order = c(0, 0, 0), period = NA),
       xreg = NULL, include.mean = TRUE, delta = 0.01,
       transform.pars = TRUE, fixed = NULL, init = NULL,
       method = c("ML", "CSS"), n.cond, optim.control = list())

## S3 method for class 'arima0'
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)
Arguments

- **x**: A univariate time series
- **order**: A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.
- **seasonal**: A specification of the seasonal part of the ARIMA model, plus the period (which defaults to \(frequency(x)\)). This should be a list with components `order` and `period`, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.
- **xreg**: Optionally, a vector or matrix of external regressors, which must have the same number of rows as `x`.
- **include.mean**: Should the ARIMA model include a mean term? The default is `TRUE` for undifferenced series, `FALSE` for differenced ones (where a mean would not affect the fit nor predictions).
- **delta**: A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.
- **transform.pars**: Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`.
- **fixed**: optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. `transform.pars = TRUE` will be overridden (with a warning) if any ARMA parameters are fixed.
- **init**: optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in `fixed` will be ignored.
- **method**: Fitting method: maximum likelihood or minimize conditional sum-of-squares. Can be abbreviated.
- **n.cond**: Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.
- **optim.control**: List of control parameters for `optim`.
- **object**: The result of an `arima0` fit.
- **newxreg**: New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.
- **n.ahead**: The number of steps ahead for which prediction is required.
- **se.fit**: Logical: should standard errors of prediction be returned?
- **...**: arguments passed to or from other methods.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true, this formula applies to \(X - m\) rather than \(X\). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.
Optimization is done by optim. It will work best if the columns in \texttt{xreg} are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so \texttt{predict.arima0} will give a warning for non-invertible MA models.

\textbf{Value}

For \texttt{arima0}, a list of class "arima0" with components:

- \texttt{coef}: a vector of AR, MA and regression coefficients,
- \texttt{sigma2}: the MLE of the innovations variance.
- \texttt{var.coef}: the estimated variance matrix of the coefficients \texttt{coef}.
- \texttt{loglik}: the maximized log-likelihood (of the differenced data), or the approximation to it used.
- \texttt{arma}: A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- \texttt{aic}: the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.
- \texttt{residuals}: the fitted innovations.
- \texttt{call}: the matched call.
- \texttt{series}: the name of the series \texttt{x}.
- \texttt{convergence}: the value returned by optim.
- \texttt{n.cond}: the number of initial observations not used in the fitting.

For \texttt{predict.arima0}, a time series of predictions, or if \texttt{se.fit = TRUE}, a list with components \texttt{pred}, the predictions, and \texttt{se}, the estimated standard errors. Both components are time series.

\textbf{Fitting methods}

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner \textit{et al} (1980). This has the option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument \texttt{delta} sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting \texttt{delta} to a negative value.

If \texttt{transform.pars} is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if \texttt{transform.pars} is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using \texttt{transform.pars = FALSE} and specifying a good set of initial values (often obtainable from a fit with \texttt{transform.pars = TRUE}).

Missing values are allowed, but any missing values will force \texttt{delta} to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation \texttt{n.cond} on, (where \texttt{n.cond} is at least the
maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The 'part log-likelihood' is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

This is a preliminary version, and will be replaced by arima.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS's arima.mle, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by arima.mle reverses the signs of the MA coefficients.

Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

Usage

ARMAacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)

Arguments

- **ar**: numeric vector of AR coefficients
- **ma**: numeric vector of MA coefficients
- **lag.max**: integer. Maximum lag required. Defaults to \( \max(p, q+1) \), where \( p, q \) are the numbers of AR and MA terms respectively.
- **pacf**: logical. Should the partial autocorrelations be returned?

Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags 0, \ldots, \( \max(p, q+1) \), and the remaining autocorrelations are given by a recursive filter.

Value

A vector of (partial) autocorrelations, named by the lags.

**ARMAtoMA**

Convert ARMA Process to Infinite MA Process

**Description**

Convert ARMA process to infinite MA process.

**Usage**

ARMAtoMA(ar = numeric(), ma = numeric(), lag.max)

**Arguments**

- **ar**: numeric vector of AR coefficients
- **ma**: numeric vector of MA coefficients
- **lag.max**: Largest MA(Inf) coefficient required.

**Value**

A vector of coefficients.

**References**

**See Also**

arima, ARMAacf.

**Examples**

ARMAtoMA(c(1.0, -0.25), 1.0, 10)

## Example from Brockwell & Davis (1991, p.92)
## answer (1 + 3n)*2^(-n)

n <- 1:10; (1 + 3*n)*2^(-n)
as.hclust

Convert Objects to Class hclust

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

as.hclust(x, ...)

Arguments

x Hierarchical clustering object
...

further arguments passed to or from other methods.

Details

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package cluster. The default method throws an error unless passed an "hclust" object.

Value

An object of class "hclust".

See Also

hclust, and from package cluster, diana and agnes

Examples

x <- matrix(rnorm(30), ncol = 3)
hc <- hclust(dist(x), method = "complete")

if(require("cluster", quietly = TRUE)) {# is a recommended package
  ag <- agnes(x, method = "complete")
hcag <- as.hclust(ag)
  mtext("agnes", side = 1)
}

op <- par(mfrow = c(1,2))
plot(hc); mtext("hclust", side = 1)
plot(hcag); mtext("agnes", side = 1)
detach("package:cluster")
}
asOneSidedFormula Convert to One-Sided Formula

Description
Names, expressions, numeric values, and character strings are converted to one-sided formulae. If `object` is a formula, it must be one-sided, in which case it is returned unaltered.

Usage
```
asOneSidedFormula(object)
```

Arguments
- `object`: a one-sided formula, an expression, a numeric value, or a character string.

Value
A one-sided formula representing `object`.

Author(s)
José Pinheiro and Douglas Bates

See Also
- `formula`

Examples
```
asOneSidedFormula("age")
asOneSidedFormula(~ age)
```

ave Group Averages Over Level Combinations of Factors

Description
Subsets of `x[]` are averaged, where each subset consist of those observations with the same factor levels.

Usage
```
ave(x, ..., FUN = mean)
```

Arguments
- `x`: A numeric.
- `...`: Grouping variables, typically factors, all of the same length as `x`.
- `FUN`: Function to apply for each factor level combination.
Value

A numeric vector, say \( y \) of length \( \text{length}(x) \). If \( \ldots \) is \( \text{g1} \), \( \text{g2} \), e.g., \( y[i] \) is equal to \( \text{FUN}(x[j], \ldots \) for all \( j \) with \( \text{g1}[j] == \text{g1}[i] \) and \( \text{g2}[j] == \text{g2}[i] \).

See Also

mean, median.

Examples

```r
require(graphics)
ave(1:3) # no grouping -> grand mean
attach(warpbreaks)
ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))
plot(breaks, main =
  "ave( Warpbreaks ) for wool x tension combinations")
lines(ave(breaks, wool, tension ), type = "s", col = "blue")
lines(ave(breaks, wool, tension, FUN = median), type = "s", col = "green")
legend(40, 70, c("mean", "median"), lty = 1,
  col = c("blue","green"), bg = "gray90")
detach()
```

bandwidth

**Bandwidth Selectors for Kernel Density Estimation**

Description

Bandwidth selectors for Gaussian kernels in `density`.

Usage

```r
bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
  tol = 0.1 * lower)

bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
  tol = 0.1 * lower)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
  method = c("ste", "dpi"), tol = 0.1 * lower)
```
Arguments

- `x`: numeric vector.
- `nb`: number of bins to use.
- `lower`, `upper`: range over which to minimize. The default is almost always satisfactory. `hmax` is calculated internally from a normal reference bandwidth.
- `method`: either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). Can be abbreviated.
- `tol`: for method "ste", the convergence tolerance for `uniroot`. The default leads to bandwidth estimates with only slightly more than one digit accuracy, which is sufficient for practical density estimation, but possibly not for theoretical simulation studies.

Details

- `bw.nrd0` implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s ‘rule of thumb’, Silverman (1986, page 48, eqn (3.31))) unless the quartiles coincide when a positive result will be guaranteed.
- `bw.nrd` is the more common variation given by Scott (1992), using factor 1.06.
- `bw.ucv` and `bw.bcv` implement unbiased and biased cross-validation respectively.
  The algorithm for method "ste" solves an equation (via `uniroot`) and because of that, enlarges the interval `c(lower, upper)` when the boundaries were not user-specified and do not bracket the root.
  The last three methods use all pairwise binned distances: they are of complexity $O(n^2)$ up to $n = nb/2$ and $O(n)$ thereafter. Because of the binning, the results differ slightly when `x` is translated or sign-flipped.

Value

A bandwidth on a scale suitable for the `bw` argument of `density`.

Note

Long vectors `x` are not supported, but neither are they by `density` and kernel density estimation and for more than a few thousand points a histogram would be preferred.

Author(s)

B. D. Ripley, taken from early versions of package `MASS`.

Bartlett Test of Homogeneity of Variances

Description

Performs Bartlett’s test of the null that the variances in each of the groups (samples) are the same.

Usage

bartlett.test(x, ...)

## Default S3 method:
bartlett.test(x, g, ...)

## S3 method for class 'formula'
bartlett.test(formula, data, subset, na.action, ...)

Arguments

x a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").
g a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
formula a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Examples

require(graphics)
plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw = "nrd"), col = 2)
lines(density(precip, bw = "ucv"), col = 3)
lines(density(precip, bw = "bcv"), col = 4)
lines(density(precip, bw = "SJ-ste"), col = 5)
lines(density(precip, bw = "SJ-dpi"), col = 6)
legend(55, 0.035,
legend = c("nrd0", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
col = 1:6, lty = 1)

bartlett.test

See Also
density.
bandwidth.rnd, ucv, bcv and width.SJ in package MASS, which are all scaled to the width argument of density and so give answers four times as large.
Details
If x is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, g is ignored, and one can simply use bartlett.test(x) to perform the test. If the samples are not yet contained in a list, use bartlett.test(list(x, ...)). Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value
A list of class "htest" containing the following components:

- statistic: Bartlett's K-squared test statistic.
- parameter: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value: the p-value of the test.
- method: the character string "Bartlett test of homogeneity of variances".
- data.name: a character string giving the names of the data.

References

Examples

```r
require(graphics)
plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)
```

Beta

The Beta Distribution

Description
Density, distribution function, quantile function and random generation for the Beta distribution with parameters shape1 and shape2 (and optional non-centrality parameter ncp).

Usage

dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)
Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **shape1, shape2**: non-negative parameters of the Beta distribution.
- **ncp**: non-centrality parameter.
- **log, log.p**: logical; if TRUE, probabilities p are given as \( \log(p) \).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Beta distribution with parameters shape1 = \( a \) and shape2 = \( b \) has density

\[
f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1-x)^{b-1}
\]

for \( a > 0, b > 0 \) and \( 0 \leq x \leq 1 \) where the boundary values at \( x = 0 \) or \( x = 1 \) are defined as by continuity (as limits).

The mean is \( a/(a + b) \) and the variance is \( ab/((a + b)^2(a + b + 1)) \). These moments and all distributional properties can be defined as limits (leading to point masses at 0, 1/2, or 1) when \( a \) or \( b \) are zero or infinite, and the corresponding \([dpqr]beta()\) functions are defined correspondingly.

pbeta is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

\[
B_x(a, b) = \int_0^x t^{a-1}(1-t)^{b-1} dt,
\]

and 6.6.2 \( I_x(a, b) = B_x(a, b) / B(a, b) \) where \( B(a, b) = B_1(a, b) \) is the Beta function (beta).

\( I_x(a, b) \) is pbeta(x, a, b).

The noncentral Beta distribution (with \( ncp = \lambda \)) is defined (Johnson et al, 1995, pp. 502) as the distribution of \( X / (X + Y) \) where \( X \sim \chi^2_{2a} (\lambda) \) and \( Y \sim \chi^2_{2b} \).

Value

dbeta gives the density, pbeta the distribution function, qbeta the quantile function, and rbeta generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rbeta, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \( ncp = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm as when \( ncp \) is omitted. This is to give consistent behaviour in extreme cases with values of \( ncp \) very near zero.
Source

• The central dbeta is based on a binomial probability, using code contributed by Catherine Loader (see dbinom) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson et al., 1995, pp. 502–3).

• The central pbeta for the default (log.p = FALSE) uses a C translation based on Didonato, A. and Morris, A., Jr. (1992) Algorithm 708: Significant digit computation of the incomplete beta function ratios, ACM Transactions on Mathematical Software, 18, 360–373. (See also Brown, B. and Lawrence Levy, L. (1994) Certification of algorithm 708: Significant digit computation of the incomplete beta, ACM Transactions on Mathematical Software, 20, 393–397.) We have slightly tweaked the original “TOMS 708” algorithm, and enhanced for log.p = TRUE. For that (log-scale) case, underflow to -Inf (i.e., P = 0) or 0 (i.e., P = 1) still happens because the original algorithm was designed without log-scale considerations. Underflow to -Inf now typically signals a warning.

binom.test

Exact Binomial Test

Description
Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli
experiment.
Usage
binom.test(x, n, p = 0.5,
alternative = c("two.sided", "less", "greater"),
conf.level = 0.95)
Arguments
x

number of successes, or a vector of length 2 giving the numbers of successes
and failures, respectively.

n

number of trials; ignored if x has length 2.


binom.test

p hypothesized probability of success.
alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
conf.level confidence level for the returned confidence interval.

Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least conf.level, but in general does not give the shortest-length confidence intervals.

Value

A list with class "htest" containing the following components:

statistic the number of successes.
parameter the number of trials.
p.value the p-value of the test.
conf.int a confidence interval for the probability of success.
estimate the estimated probability of success.
null.value the probability of success under the null, p.
alternative a character string describing the alternative hypothesis.
method the character string "Exact binomial test".
data.name a character string giving the names of the data.

References

See Also

prop.test for a general (approximate) test for equal or given proportions.

Examples

```
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
binom.test(c(682, 243), p = 3/4)
binom.test(682, 682 + 243, p = 3/4) # The same.
## => Data are in agreement with the null hypothesis.
```
The Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.

This is conventionally interpreted as the number of 'successes' in size trials.

Usage

dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
size number of trials (zero or more).
prob probability of success on each trial.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The binomial distribution with size = n and prob = p has density

\[
p(x) = \binom{n}{x} p^x (1 - p)^{n-x}
\]

for \( x = 0, \ldots, n \). Note that binomial coefficients can be computed by \texttt{choose} in R.

If an element of x is not integer, the result of \texttt{dbinom} is zero, with a warning.
p(x) is computed using Loader’s algorithm, see the reference below.
The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

dbinom gives the density, \texttt{pbinom} gives the distribution function, \texttt{qbinom} gives the quantile function and \texttt{rbinom} generates random deviates.

If size is not an integer, \texttt{NaN} is returned.
The length of the result is determined by \( n \) for \texttt{rbinom}, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

*Distributions* for other standard distributions, including 

dbinom for the negative binomial, and 

dpois for the Poisson distribution.

Examples

```
require(graphics)

# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(db

## Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot(k, db(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
     main = "db(k, log=TRUE) is better than log(db(k))")
lines(k, log(db(k, n, pi/10)), col = "red", lwd = 2)
## extreme points are omitted since db gives 0.
mtext("db(k, log=TRUE)", adj = 0)
mtext("extended range", adj = 0, line = -1, font = 4)
mtext("log(db(k))", col = "red", adj = 1)
```

Description

Plot a biplot on the current graphics device.

Usage

```
b

## Default S3 method:
b(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
x
```

```
Arguments

x The biplot, a fitted object. For biplot.default, the first set of points (a two-column matrix), usually associated with observations.
y The second set of points (a two-column matrix), usually associated with variables.
var.axes If TRUE the second set of points have arrows representing them as (unscaled) axes.
col A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the palette: if there it and the next colour as used, otherwise the first two colours of the palette are used.
cex The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.
xlabs A vector of character strings to label the first set of points: the default is to use the row dimname of x, or 1:n if the dimname is NULL.
ylabs A vector of character strings to label the second set of points: the default is to use the row dimname of y, or 1:n if the dimname is NULL.
expand An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.
arrow.len The length of the arrow heads on the axes plotted in var.axes is true. The arrow head can be suppressed by arrow.len = 0.
xlim, ylim Limits for the x and y axes in the units of the first set of variables.
main, sub, xlab, ylab, ... graphical parameters.

Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by biplot.princomp. The function biplot.default merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to biplot: the size of xlabs and ylabs is controlled by cex.

Side Effects

a plot is produced on the current graphics device.

References

See Also

biplot.princomp, also for examples.
Biplot for Principal Components

Description

Produces a biplot (in the strict sense) from the output of `princomp` or `prcomp`.

Usage

```r
## S3 method for class 'prcomp'
biplopt(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
## S3 method for class 'princomp'
biplopt(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

Arguments

- `x` an object of class "princomp".
- `choices` length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
- `scale` The variables are scaled by $\lambda^\text{scale}$ and the observations are scaled by $\lambda^{1-\text{scale}}$ where $\lambda$ are the singular values as computed by `princomp`. Normally $0 \leq \text{scale} \leq 1$, and a warning will be issued if the specified scale is outside this range.
- `pc.biplot` If true, use what Gabriel (1971) refers to as a "principal component biplot", with $\lambda = 1$ and observations scaled up by $\sqrt{n}$ and variables scaled down by $\sqrt{n}$. Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
- `...` optional arguments to be passed to `biplot.default`.

Details

This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

Side Effects

A plot is produced on the current graphics device.

References

See Also

`biplot.princomp`. 
Examples

```r
require(graphics)
biplot(princomp(USArrests))
```

### Description

Computes answers to a generalised *birthday paradox* problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the smallest number of observations needed to have at least a specified probability of coincidence.

### Usage

```r
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

### Arguments

- **classes**: How many distinct categories the people could fall into.
- **prob**: The desired probability of coincidence.
- **n**: The number of people.
- **coincident**: The number of people to fall in the same category.

### Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for `coincident > 2`. The approximation is very good for moderate values of `prob` but less good for very small probabilities.

### Value

- **qbirthday**: Minimum number of people needed for a probability of at least `prob` that `coincident` or more of them have the same one out of `classes` equiprobable labels.
- **pbirthday**: Probability of the specified coincidence.

### References

Examples

require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
pbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
pbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
pbirthday(1000, coincident = 100)

Box.test

Box-Pierce and Ljung-Box Tests

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

Usage

Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)

Arguments

x a numeric vector or univariate time series.
lag the statistic will be based on lag autocorrelation coefficients.
type test to be performed: partial matching is used.
fitdf number of degrees of freedom to be subtracted if x is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA(p, q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting fitdf = p+q, provided of course that lag > fitdf.
Value
A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- parameter: the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking fitdf into account).
- p.value: the p-value of the test.
- method: a character string indicating which type of test was performed.
- data.name: a character string giving the name of the data.

Note
Missing values are not handled.

Author(s)
A. Trapletti

References

Examples
```r
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

Description
Sets the "contrasts" attribute for the factor.

Usage
```r
C(object, contr, how.many, ...)
```

Arguments
- **object**: a factor or ordered factor
- **contr**: which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- **how.many**: the number of contrasts to set, by default one less than `nlevels(object)`
- **...**: additional arguments for the function `contr`
cancor

Details

For compatibility with S, contr can be treatment, helmert, sum or poly (without quotes) as shorthand for contr.treatment and so on.

Value

The factor object with the "contrasts" attribute set.

References

See Also

contrasts, contr.sum, etc.

Examples

## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)
## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
               C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)

cancor

Canonical Correlations

Description

Compute the canonical correlations between two data matrices.

Usage

cancor(x, y, xcenter = TRUE, ycenter = TRUE)

Arguments

x numeric matrix \((n \times p_1)\), containing the x coordinates.
y numeric matrix \((n \times p_2)\), containing the y coordinates.
xcenter  logical or numeric vector of length \( p_1 \), describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.

ycenter analogous to xcenter, but for the y values.

Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

Value

A list containing the following components:

- cor correlations.
- xcoef estimated coefficients for the x variables.
- ycoef estimated coefficients for the y variables.
- xcenter the values used to adjust the x variables.
- ycenter the values used to adjust the x variables.

References

See Also

qr, svd.

Examples

```r
## signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %*% cxy$xcoef, y %*% cxy$ycoef)[,1:3] - diag(cxy$cor)) < 1e-15)
all(abs(cor(x %*% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %*% cxy$ycoef) - diag(5)) < 1e-15)
```
Case and Variable Names of Fitted Models

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

Usage

```r
case.names(object, ...)  
## S3 method for class 'lm'
case.names(object, full = FALSE, ...)

variable.names(object, ...)  
## S3 method for class 'lm'
variable.names(object, full = FALSE, ...)
```

Arguments

- `object`: an R object, typically a fitted model.
- `full`: logical; if TRUE, all names (including zero weights, ...) are returned.
- `...`: further arguments passed to or from other methods.

Value

A character vector.

See Also

`lm`; further, `all.names`, `all.vars` for functions with a similar name but only slightly related purpose.

Examples

```r
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),  
paste("O", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww),  
correlation = TRUE)
variable.names(lmxy)
variable.names(lmxy, full = TRUE)  # includes the last
case.names(lmxy)
case.names(lmxy, full = TRUE)  # includes the 0-weight case
```
The Cauchy Distribution

Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter location and scale parameter scale.

Usage

dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P(X \leq x) \), otherwise, \( P(X > x) \).

Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location \( l \) and scale \( s \) has density

\[
f(x) = \frac{1}{\pi s} \left( 1 + \left( \frac{x - l}{s} \right)^2 \right)^{-1}
\]

for all \( x \).

Value

dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.

The length of the result is determined by n for rcauchy, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.

rcauchy uses inversion.

chisq.test

*Pearson’s Chi-squared Test for Count Data*

Description

chisq.test performs chi-squared contingency table tests and goodness-of-fit tests.

Usage

chisq.test(x, y = NULL, correct = TRUE, 
            p = rep(1/length(x), length(x)), rescale.p = FALSE, 
            simulate.p.value = FALSE, B = 2000)

Arguments

x a numeric vector or matrix. x and y can also both be factors.

y a numeric vector; ignored if x is a matrix. If x is a factor, y should be a factor of the same length.

correct a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all \(|O - E|\) differences; however, the correction will not be bigger than the differences themselves. No correction is done if simulate.p.value = TRUE.

p a vector of probabilities of the same length of x. An error is given if any entry of p is negative.

rescale.p a logical scalar; if TRUE then p is rescaled (if necessary) to sum to 1. If rescale.p is FALSE, and p does not sum to 1, an error is given.

simulate.p.value a logical indicating whether to compute p-values by Monte Carlo simulation.

B an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \( x \) is a matrix with one row or column, or if \( x \) is a vector and \( y \) is not given, then a **goodness-of-fit test** is performed (\( x \) is treated as a one-dimensional contingency table). The entries of \( x \) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \( p \), or are all equal if \( p \) is not given.

If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If `simulate.p.value` is `FALSE`, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if `correct` is `TRUE`, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with \( B \) replicates. In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \sum(x) \). This simulation is done in R and may be slow.

Value

A list with class "htest" containing the following components:

- **statistic** the value the chi-squared test statistic.
- **parameter** the degrees of freedom of the approximate chi-squared distribution of the test statistic, \( \text{NA} \) if the p-value is computed by Monte Carlo simulation.
- **p.value** the p-value for the test.
- **method** a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- **data.name** a character string giving the name(s) of the data.
- **observed** the observed counts.
- **expected** the expected counts under the null hypothesis.
- **residuals** the Pearson residuals, \((\text{observed} - \text{expected}) / \sqrt{\text{expected}}\).
- **stdres** standardized residuals, \((\text{observed} - \text{expected}) / \sqrt{\nu} \), where \( \nu \) is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where \( x \) is a matrix, \( n \times p \times (1 - p) \) otherwise).

Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

Examples

```r
## From Agresti(2007) p.39
M <- as.table(rbind(c(762, 327, 468), c(484, 239, 477)))
dimnames(M) <- list(gender = c("F", "M"),
                     party = c("Democrat","Independent", "Republican"))
(Xsq <- chisq.test(M)) # Prints test summary
Xsq$observed # observed counts (same as M)
Xsq$expected # expected counts under the null
Xsq$residuals # Pearson residuals
Xsq$stdres # standardized residuals

## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value # around 0.29!

## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x)) # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try(
  chisq.test(x, p = p) # gives an error
)
chisq.test(x, p = p, rescale.p = TRUE) # works
  p <- c(0.40,0.20,0.20,0.19,0.01) # Expected count in category 5
  # is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p) # maybe doubtful, but is ok!
  chisq.test(x, p = p, simulate.p.value = TRUE)

## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x)) # NOT 'chisq.test(x)'!
```

---

Chisquare: The (non-central) Chi-Squared Distribution
Description

Density, distribution function, quantile function and random generation for the chi-squared ($\chi^2$) distribution with $df$ degrees of freedom and optional non-centrality parameter $ncp$.

Usage

dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)

Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If length(n) > 1, the length is taken to be the number required.
- **df**: degrees of freedom (non-negative, but can be non-integer).
- **ncp**: non-centrality parameter (non-negative).
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The chi-squared distribution with $df = n \geq 0$ degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for $x > 0$, where $f_0(x) := \lim_{n \to 0} f_n(x) = \delta_0(x)$, a point mass at zero, is not a density function proper, but a "$\delta$ distribution".

The mean and variance are $n$ and $2n$.

The non-central chi-squared distribution with $df = n$ degrees of freedom and non-centrality parameter $ncp = \lambda$ has density

$$f(x) = f_{n,\lambda}(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for $x \geq 0$. For integer $n$, this is the distribution of the sum of squares of $n$ normals each with variance one, $\lambda$ being the sum of squares of the normal means; further, $E(X) = n + \lambda$, $Var(X) = 2(n + 2 \ast \lambda)$, and $E((X - E(X))^3) = 8(n + 3 \ast \lambda)$.

Note that the degrees of freedom $df = n$, can be non-integer, and also $n = 0$ which is relevant for non-centrality $\lambda > 0$, see Johnson et al (1995, chapter 29). In that (noncentral, zero df) case, the distribution is a mixture of a point mass at $x = 0$ (of size pchisq(0, df=0, ncp=ncp)) and a continuous part, and dchisq() is not a density with respect to that mixture measure but rather the limit of the density for $df \to 0$.

Note that ncp values larger than about $1e5$ (and even smaller) may give inaccurate results with many warnings for pchisq and qchisq.
Value

dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rchisq, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

Source

The central cases are computed via the gamma distribution.

The non-central dchisq and rchisq are computed as a Poisson mixture of central chi-squares (Johnson et al, 1995, p.436).

The non-central pchisq is for ncp < 80 computed from the Poisson mixture of central chi-squares and for larger ncp via a C translation of

which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).

The non-central qchisq is based on inversion of pchisq.

References

See Also

Distributions for other standard distributions.

A central chi-squared distribution with n degrees of freedom is the same as a Gamma distribution with shape $\alpha = n/2$ and scale $\sigma = 2$. Hence, see dgamma for the Gamma distribution.

The central chi-squared distribution with 2 d.f. is identical to the exponential distribution with rate 1/2: $\chi^2_2 = Exp(1/2)$, see dexp.

## "analytical" test
lam <- seq(0, 100, by = .25)
p00 <- pchisq(0, df = 0, ncp = lam)
p.0 <- pchisq(1e-300, df = 0, ncp = lam)
stopifnot(all.equal(p00, exp(-lam/2)),
         all.equal(p.0, exp(-lam/2)))

---

**cmdsclse**

Classical (Metric) Multidimensional Scaling

**Description**

Classical multidimensional scaling (MDS) of a data matrix. Also known as principal coordinates analysis (Gower, 1966).

**Usage**

```r
cmdsclse(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE,
         list. = eig || add || x.ret)
```
cmdscale

Arguments

d  a distance structure such as that returned by \texttt{dist} or a full symmetric matrix containing the dissimilarities.

k  the maximum dimension of the space which the data are to be represented in; must be in \{1, 2, \ldots, n - 1\}.

eig  indicates whether eigenvalues should be returned.

add  logical indicating if an additive constant \(c^*\) should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.

x.ret  indicates whether the doubly centred symmetric distance matrix should be returned.

list.  logical indicating if a \texttt{list} should be returned or just the \(n \times k\) matrix, see '\Value\':

Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call 'ordination'.)

A set of Euclidean distances on \(n\) points can be represented exactly in at most \(n - 1\) dimensions. \texttt{cmdscale} follows the analysis of Mardia (1978), and returns the best-fitting \(k\)-dimensional representation, where \(k\) may be less than the argument \(k\).

The representation is only determined up to location (\texttt{cmdscale} takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between \(R\) platforms (see \texttt{prcomp}).

When \(\text{add} = \text{TRUE}\), a minimal additive constant \(c^*\) is computed such that the dissimilarities \(d_{ij} + c^*\) are Euclidean and hence can be represented in \(n - 1\) dimensions. Whereas \(S\) (Becker et al, 1988) computes this constant using an approximation suggested by Torgerson, \(R\) uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than \(n - 1\) dimensions.

Value

If \,.\texttt{list} is false (as per default), a matrix with \(k\) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a \texttt{list} containing the following components.

- **points**: a matrix with up to \(k\) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

- **eig**: the \(n\) eigenvalues computed during the scaling process if \texttt{eig} is true. \textbf{NB}: versions of \(R\) before 2.12.1 returned only \(k\) but were documented to return \(n - 1\).

- **x**: the doubly centered distance matrix if \texttt{x.ret} is true.

- **ac**: the additive constant \(c^*\), 0 if \texttt{add} = \texttt{FALSE}.

- **GOF**: a numeric vector of length 2, equal to say \((g_1, g_2)\), where \(g_i = (\sum_{j=1}^{k} \lambda_j)/\sum_{j=1}^{n} T_i(\lambda_j)\), where \(\lambda_j\) are the eigenvalues (sorted in decreasing order), \(T_1(v) = \|v\|\), and \(T_2(v) = \max(v, 0)\).

Examples

require(graphics)

loc <- cmdscale(eurodist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
## note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
     main = "cmdscale(eurodist)"
     text(x, y, rownames(loc), cex = 0.6)

coef Extract Model Coefficients

description

coef is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

Usage

coef(object, ...)
coefficients(object, ...)
## Default S3 method:
coef(object, complete = TRUE, ...)
## S3 method for class 'aov'
coef(object, complete = FALSE, ...)
complete.cases

Arguments

object     an object for which the extraction of model coefficients is meaningful.
complete   for the default (used for lm, etc) and aov methods: logical indicating if the full
coefficient vector should be returned also in case of an over-determined system
where some coefficients will be set to NA, see also alias. Note that the default
differs for lm() and aov() results.
...         other arguments.

Details

All object classes which are returned by model fitting functions should provide a coef method or
use the default one. (Note that the method is for coef and not coefficients.)
The “aov” method does not report aliased coefficients (see alias) by default where complete = FALSE.
The complete argument also exists for compatibility with vcov methods, and coef and aov meth-
ods for other classes should typically also keep the complete = * behavior in sync. By that, with
p <- length(coef(obj, complete = TF)), dim(vcov(obj, complete = TF)) == c(p,p) will be
fulfilled for both complete settings and the default.

Value

Coefficients extracted from the model object object.
For standard model fitting classes this will be a named numeric vector. For "maov" objects (pro-
duced by aov) it will be a matrix.

References

See Also

fitted.values and residuals for related methods; glm, lm for model fitting.

Examples

x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))

---

complete.cases Find Complete Cases

Description

Return a logical vector indicating which cases are complete, i.e., have no missing values.

Usage

complete.cases(...) 

Arguments

... a sequence of vectors, matrices and data frames.
Value

A logical vector specifying which observations/rows have no missing values across the entire sequence.

Note

A current limitation of this function is that it uses low level functions to determine lengths and missingness, ignoring the class. This will lead to spurious errors when some columns have classes with `length` or `is.na` methods, for example "POSIXlt", as described in PR#16648.

See Also

`is.na`, `na.omit`, `na.fail`.

Examples

```r
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

---

**confint**

Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

Usage

```r
confint(object, parm, level = 0.95, ...)
```

Arguments

- **object**: a fitted model object.
- **parm**: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- **level**: the confidence level required.
- **...**: additional argument(s) for methods.
**Details**

`confint` is a generic function. The default method assumes normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.

There are stub methods in package `stats` for classes "glm" and "nls" which call those in package `MASS` (if installed): if the `MASS` namespace has been loaded, its methods will be used directly. (Those methods are based on profile likelihood.)

**Value**

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

**See Also**

`confint.glm` and `confint.nls` in package `MASS`.

**Examples**

```r
fit <- lm(100/mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")

## from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93) # needs MASS to be installed
confint.default(glm.D93) # based on asymptotic normality
```

---

**constrOptim**

*Linearity Constrained Optimization*

**Description**

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

**Usage**

```r
constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
outer.iterations = 100, outer.eps = 1e-05, ..., 
hessian = FALSE)
```

**Arguments**

- `theta` numeric (vector) starting value (of length \(p\)): must be in the feasible region.
- `f` function to minimise (see below).
- `grad` gradient of \(f\) (a `function` as well), or NULL (see below).

ui  constraint matrix \((k \times p)\), see below.

ci  constraint vector of length \(k\) (see below).

\(\mu\) (Small) tuning parameter.

control, method, hessian
	passed to optim.

outer.iterations
	iterations of the barrier algorithm.

outer.eps
	non-negative number; the relative convergence tolerance of the barrier algorithm.

... Other named arguments to be passed to \(f\) and \(\text{grad}\): needs to be passed through optim so should not match its argument names.

Details

The feasible region is defined by \(ui \%\%\theta - ci \geq 0\). The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then optim is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter \(\mu\) multiplies the barrier term. Its precise value is often relatively unimportant. As \(\mu\) increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any \texttt{optim} method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function \(f\) takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments \...
	will be passed to \texttt{optim} and then (if not used by \texttt{optim}) to \(f\). As with \texttt{optim}, the default is to minimise, but maximisation can be performed by setting \texttt{control$fnscale} to a negative value.

The gradient function \(\text{grad}\) must be supplied except with \texttt{method = "Nelder-Mead"}. It should take arguments matching those of \(f\) and return a vector containing the gradient.

Value

As for \texttt{optim}, but with two extra components: \texttt{barrier.value} giving the value of the barrier function at the optimum and \texttt{outer.iterations} gives the number of outer iterations (calls to \texttt{optim}). The \texttt{counts} component contains the sum of all \texttt{optim()}$counts.

contrast

Examples

```r
## from optim
fr <- function(x) { ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
     200 * (x2 - x1 * x1))
}
optim(c(-1.2,1), fr, grr)
#Box-constraint, optimum on the boundary
constrOptim(c(-1.2,0.9), fr, grr, ui = rbind(c(-1,0), c(0,-1)), ci = c(-1,-1))
  # x <= 0.9, y - x > 0.1
constrOptim(c(.5,0), fr, grr, ui = rbind(c(-1,0), c(1,-1)), ci = c(-0.9,0.1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value

# from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) {-sum(c(0,5,0)*b)+0.5*sum(b*b)}
Amat <- matrix(c(-4,-3,0,2,1,0,0,-2,1), 3, 3)
bvec <- c(-8, 2, 0)
constrOptim(c(2,-1,-1), fQP, NULL, ui = t(Amat), ci = bvec)
# derivative
gQP <- function(b) {-c(0, 5, 0) + b}
constrOptim(c(2,-1,-1), fQP, gQP, ui = t(Amat), ci = bvec)

## Now with maximisation instead of minimisation
hQP <- function(b) {sum(c(0,5,0)*b)-0.5*sum(b*b)}
constrOptim(c(2,-1,-1), hQP, NULL, ui = t(Amat), ci = bvec,
control = list(fnscale = -1))
```

contrast  (Possibly Sparse) Contrast Matrices

Description

Return a matrix of contrasts.

Usage

```r
contr.helmert(n, contrasts = TRUE, sparse = FALSE)
contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)
contr.sum(n, contrasts = TRUE, sparse = FALSE)
contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)
contr.SAS(n, contrasts = TRUE, sparse = FALSE)
```
Arguments

- **n**: a vector of levels for a factor, or the number of levels.
- **contrasts**: a logical indicating whether contrasts should be computed.
- **sparse**: logical indicating if the result should be sparse (of class `dgCMatrix`), using package `Matrix`.
- **scores**: the set of values over which orthogonal polynomials are to be computed.
- **base**: an integer specifying which group is considered the baseline group. Ignored if `contrasts` is FALSE.

Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with n levels. The returned value contains the computed contrasts. If the argument `contrasts` is FALSE a square indicator matrix (the dummy coding) is returned except for `contr.poly` (which includes the 0-degree, i.e. constant, polynomial when `contrasts` = FALSE).

- **contr.helmert**: returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. `contr.poly` returns contrasts based on orthogonal polynomials. `contr.sum` uses ‘sum to zero contrasts’.
- **contr.treatment**: contrasts each level with the baseline level (specified by `base`): the baseline level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for linear models as they are not orthogonal to the intercept.
- **contr.SAS**: is a wrapper for `contr.treatment` that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, `sparse` is an argument to all these contrast functions, however `sparse = TRUE` for `contr.poly` is typically pointless and is rarely useful for `contr.helmert`.

Value

A matrix with n rows and k columns, with k=n-1 if `contrasts` is TRUE and k=n if `contrasts` is FALSE.

References

See Also

- `contrasts`, `C`, and `aov.glm.lm`.

Examples

```r
(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal
```
contrasts

\[(cT. \leftarrow \text{contr.SAS}(5))\]
\[\text{all(crossprod(cT.) == diag(4))} \ # \ TRUE\]

\[\text{zapsmall(cP} \leftarrow \text{contr.poly}(3)) \ # \ \text{Linear and Quadratic}\]
\[\text{zapsmall(crossprod(cP), digits = 15)} \ # \ \text{orthonormal up to fuzz}\]

### Description
Set and view the contrasts associated with a factor.

### Usage
```r
contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many = NULL) <- value
```

### Arguments
- **x**: a factor or a logical variable.
- **contrasts**: logical. See ‘Details’.
- **sparse**: logical indicating if the result should be sparse (of class \text{dgCMatrix}, using package \text{Matrix}).
- **how.many**: integer number indicating how many contrasts should be made. Defaults to one less than the number of levels of \(x\). This need not be the same as the number of columns of \(value\).
- **value**: either a numeric matrix (or a sparse or dense matrix of a class extending \text{dMatrix} from package \text{Matrix}) whose columns give coefficients for contrasts in the levels of \(x\), or the (quoted) name of a function which computes such matrices.

### Details
If contrasts are not set for a factor the default functions from \text{options("contrasts")} are used.

A logical vector \(x\) is converted into a two-level factor with levels \(c(\text{FALSE}, \text{TRUE})\) (regardless of which levels occur in the variable).

The argument \text{contrasts} is ignored if \(x\) has a matrix \text{contrasts} attribute set. Otherwise if \text{contrasts} = \text{TRUE} it is passed to a contrasts function such as \text{contr.treatment} and if \text{contrasts} = \text{FALSE} an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument \text{contrasts} (always called with \text{contrasts} = \text{TRUE}) and optionally a logical argument \text{sparse}.

If \text{value} supplies more than \text{how.many} contrasts, the first \text{how.many} are used. If too few are supplied, a suitable contrast matrix is created by extending \text{value} after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

### References
convolve

Convolution of Sequences via FFT

Description
Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

Usage
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))

Arguments

- **x, y**: numeric sequences of the same length to be convolved.
- **conj**: logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
- **type**: character; partially matched to "circular", "open", "filter". For "circular", the two sequences are treated as circular, i.e., periodic. For "open" and "filter", the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of x with weights y.

Details
The Fast Fourier Transform, fft, is used for efficiency.

The input sequences x and y must have the same length if circular is true.

Note that the usual definition of convolution of two sequences x and y is given by convolve(x, rev(y), type = "o").
cophenetic

Description

Computes the cophenetic distances for a hierarchical clustering.

Value

If \( r \leftarrow \text{convolve}(x, y, \text{type} = \text{"open"}) \) and \( n \leftarrow \text{length}(x), m \leftarrow \text{length}(y) \), then

\[
 r_k = \sum_i x_{k-m+i}y_i 
\]

where the sum is over all valid indices \( i \), for \( k = 1, \ldots, n + m - 1 \).

If \( \text{type} = \text{"circular"}, n = m \) is required, and the above is true for \( i, k = 1, \ldots, n \) when \( x_j := x_{n+j} \) for \( j < 1 \).

References

See Also

fft, nextn, and particularly filter (from the stats package) which may be more appropriate.

Examples

```r
require(graphics)

x <- c(0,0,0,100,0,0,0)
y <- c(0,0,1,2,1,0,0)/4
zapsmall(convolve(x, y))  # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type = "f"))  # rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y),x)))

n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
Han <- function(y) # Hanning
  convolve(y, c(1,2,1)/4, type = "filter")
plot(x, y, main = "Using convolve(.) for Hanning filters")
lines(x[-c(1, n)], Han(y), col = "red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd = 2, col = "dark blue")
```
Usage

cophenetic(x)

## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram'
cophenetic(x)

Arguments

x an R object representing a hierarchical clustering. For the default method, an object of class "hclust" or with a method for as.hclust() such as "agnes" in package cluster.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class "dist".

### Correlation, Variance and Covariance (Matrices)

**Description**

var, cov and cor compute the variance of x and the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

cov2cor scales a covariance matrix into the corresponding correlation matrix efficiently.

**Usage**

```r
var(x, y = NULL, na.rm = FALSE, use)
cov(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cor(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cov2cor(V)
```

**Arguments**

- **x**
  - a numeric vector, matrix or data frame.
- **y**
  - NULL (default) or a vector, matrix or data frame with compatible dimensions to x. The default is equivalent to y = x (but more efficient).
- **na.rm**
  - logical. Should missing values be removed?
- **use**
  - an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
- **method**
  - a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman": can be abbreviated.
- **V**
  - symmetric numeric matrix, usually positive definite such as a covariance matrix.
Details

For `cov` and `cor` one must either give a matrix or data frame for `x` or give both `x` and `y`.

The inputs must be numeric (as determined by `is.numeric`; logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but `xtfrm` can be used to find a suitable prior transformation to numbers.

`var` is just another interface to `cov`, where `na.rm` is used to determine the default for use when that is unspecified. If `na.rm` is TRUE then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything".

If use is "everything", `NA`s will propagate conceptually, i.e., a resulting value will be `NA` whenever one of its contributing observations is `NA`.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives `NA`. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as `NA` entries if there are no complete pairs for that pair of variables. For `cov` and `var`, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) `var(double(0), use = *)` gives `NA` for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator `n - 1` is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return `NA` when there is only one observation (whereas S-PLUS has been returning `NaN`).

For `cor()`, if method is "kendall" or "spearman", Kendall's $\tau$ or Spearman's $\rho$ statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For `cov()`, a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes `cor(R(x), R(y))` (or `cov(., .)`) where `R(u) := rank(u, na.last = "keep")`. In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

When there are ties, Kendall's $\tau_b$ is computed, as proposed by Kendall (1945).

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using `sweep(..., FUN = "/")` twice. The `cov2cor` function is even a bit more efficient, and provided mostly for didactical reasons.

Value

For $r \leftarrow \text{cor}(\cdot, \text{use} = \"all.obs\")$, it is now guaranteed that $\text{all}(\text{abs}(r) \leq 1)$.

Note

Some people have noted that the code for Kendall’s tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function `cor.fk` in package `pcaPP`.

References

**See Also**
- `cor.test` for confidence intervals (and tests).
- `cov.wt` for weighted covariance computation.
- `sd` for standard deviation (vectors).

**Examples**

C2 <- cov(swM, use = "complete")
stopifnot(identical(C2, cov(swM, use = "na.or.complete")))
range(eigen(C2, only.values = TRUE)$values)  # 6.46 1930
```
C3 <- cov(swM, use = "pairwise")
range(eigen(C3, only.values = TRUE)$values) # 6.19 1938

## Kendall’s tau doesn’t change much:
symnum(Rc <- cor(swM, method = "kendall", use = "complete"))
symnum(Rp <- cor(swM, method = "kendall", use = "pairwise"))
symnum(R. <- cor(swiss, method = "kendall"))

## "pairwise" is closer componentwise,
symnum(abs(c(1 - Rp/R.)))
symnum(abs(c(1 - Rc/R.)))

## but "complete" is closer in Eigen space:
EV <- function(m) eigen(m, only.values=TRUE)$values
summary(abs(1 - EV(Rp)/EV(R.)) / abs(1 - EV(Rc)/EV(R.)))

---
cor.test  
Test for Association/Correlation Between Paired Samples

description

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s τ or Spearman’s ρ.

usage

cor.test(x, ...)

## Default S3 method:
cor.test(x, y,
  alternative = c("two.sided", "less", "greater"),
  method = c("pearson", "kendall", "spearman"),
  exact = NULL, conf.level = 0.95, continuity = FALSE, ...)

## S3 method for class 'formula'
cor.test(formula, data, subset, na.action, ...)

arguments

x, y
  numeric vectors of data values. x and y must have the same length.

alternative
  indicates the alternative hypothesis and must be one of "two.sided",
  "greater" or "less". You can specify just the initial letter. "greater"
  corresponds to positive association, "less" to negative association.

method
  a character string indicating which correlation coefficient is to be used for
  the test. One of "pearson", "kendall", or "spearman", can be abbreviated.

exact
  a logical indicating whether an exact p-value should be computed. Used for
  Kendall’s τ and Spearman’s ρ. See ‘Details’ for the meaning of NULL (the
  default).

conf.level
  confidence level for the returned confidence interval. Currently only used for
  the Pearson product moment correlation coefficient if there are at least 4
  complete pairs of observations.
The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range \([-1,1]\) with 0 indicating no association. These are sometimes referred to as tests of no correlation, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient \(\text{cor}(x, y)\) and follows a \(t\) distribution with \(\text{length}(x) - 2\) degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher’s Z transform.

If method is "kendall" or "spearman", Kendall’s \(\tau\) or Spearman’s \(\rho\) statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if exact is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89 for \(n < 1290\) and \(\text{exact} = \text{TRUE}\), otherwise via the asymptotic \(t\) approximation. Note that these are ‘exact’ for \(n < 10\), and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the degrees of freedom of the test statistic in the case that it follows a \(t\) distribution.
- **p.value**: the p-value of the test.
- **estimate**: the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
- **null.value**: the value of the association measure under the null hypothesis, always 0.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: a character string indicating how the association was measured.
- **data.name**: a character string giving the names of the data.
- **conf.int**: a confidence interval for the measure of association. Currently only given for Pearson’s product moment correlation coefficient in case of at least 4 complete pairs of observations.

Examples

```r
## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 80 such values) in
## 9 lots of canned tuna.

x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c(2.6, 3.1, 2.5, 5.0, 3.6, 4.0, 5.2, 2.8, 3.8)

## The alternative hypothesis of interest is that the
## Hunter L value is positively associated with the panel score.
cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972

## Compare this to

cor.test(x, y, method = "spearm", alternative = "g")
cor.test(x, y, alternative = "g")
```

cov.wt

**Weighted Covariance Matrices**

**Description**

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

**Usage**

```r
cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
method = c("unbiased", "ML"))
```
**cov.wt**

Arguments

- **x**: a matrix or data frame. As usual, rows are observations and columns are variables.
- **wt**: a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.
- **cor**: a logical indicating whether the estimated correlation weighted matrix will be returned as well.
- **center**: either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x.
- **method**: string specifying how the result is scaled, see ‘Details’ below. Can be abbreviated.

Details

By default, method = "unbiased". The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default (1/n) the conventional unbiased estimate of the covariance matrix with divisor (n − 1) is obtained. This differs from the behaviour in S-PLUS which corresponds to method = "ML" and does not divide.

Value

A list containing the following named components:

- **cov**: the estimated (weighted) covariance matrix
- **center**: an estimate for the center (mean) of the data.
- **n.obs**: the number of observations (rows) in x.
- **wt**: the weights used in the estimation. Only returned if given as an argument.
- **cor**: the estimated correlation matrix. Only returned if cor is TRUE.

See Also

- cov and var.

Examples

```r
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```
Plot Cumulative Periodogram

Description

Plots a cumulative periodogram.

Usage

\[
\text{cpgram}(\text{ts}, \text{taper} = 0.1, \\
\quad \text{main} = \text{paste("Series: ", \text{deparse1}(\text{substitute(ts))}, \\
\quad \text{ci.col} = "\text{blue}"))}
\]

Arguments

- \texttt{ts} : a univariate time series
- \texttt{taper} : proportion tapered in forming the periodogram
- \texttt{main} : main title
- \texttt{ci.col} : colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.

Note

From package \texttt{MASS}.

\text{cpgram(1h.ar$resid, main = "AR(3) fit to 1h")} \\
\text{cpgram(ldeaths)}
\]
cutree  

Cut a Tree into Groups of Data

Description

Cuts a tree, e.g., as resulting from hclust, into several groups either by specifying the desired number(s) of groups or the cut height(s).

Usage

cutree(tree, k = NULL, h = NULL)

Arguments

tree  a tree as produced by hclust. cutree() only expects a list with components merge, height, and labels, of appropriate content each.

k      an integer scalar or vector with the desired number of groups

h      numeric scalar or vector with heights where the tree should be cut. At least one of k or h must be specified, k overrides h if both are given.

Details

Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

Value

cutree returns a vector with group memberships if k or h are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of k or h, respectively (which are also used as column names).

References

table(grp2 = g24[,"2"], grp4 = g24[,"4"])

---
**decompose**

*Classical Seasonal Decomposition by Moving Averages*

**Description**

Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

**Usage**

```r
decompose(x, type = c("additive", "multiplicative"), filter = NULL)
```

**Arguments**

- `x` A time series.
- `type` The type of seasonal component. Can be abbreviated.
- `filter` A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If `NULL`, a moving average with symmetric window is performed.

**Details**

The additive model used is:

\[ Y_t = T_t + S_t + e_t \]

The multiplicative model used is:

\[ Y_t = T_t S_t e_t \]

The function first determines the trend component using a moving average (if `filter` is `NULL`, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if `x` covers an integer number of complete periods.

**Value**

An object of class "decomposed.ts" with following components:

- `x` The original series.
- `seasonal` The seasonal component (i.e., the repeated seasonal figure).
- `figure` The estimated seasonal figure only.
- `trend` The trend component.
- `random` The remainder part.
- `type` The value of `type`.

**Note**

The function `stl` provides a much more sophisticated decomposition.
**delete.response**

*Modify Terms Objects*

**Description**

delete.response returns a terms object for the same model but with no response variable.

drop.terms removes variables from the right-hand side of the model. There is also a " [. terms " method to perform the same function (with keep.response = TRUE).

reformulate creates a formula from a character vector. If length(termlabels) > 1, its elements are concatenated with +. Non-syntactic names (e.g. containing spaces or special characters; see make.names) must be protected with backticks (see examples). A non-parseable response still works for now, back compatibly, with a deprecation warning.

**Usage**

delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE, env = parent.frame())

drop.terms(termobj, dropx = NULL, keep.response = FALSE)
Arguments

termobj A terms object
termlabels character vector giving the right-hand side of a model formula. Cannot be zero-length.
response character string, symbol or call giving the left-hand side of a model formula, or NULL.
intercept logical: should the formula have an intercept?
env the environment of the formula returned.
dropx vector of positions of variables to drop from the right-hand side of the model.
keep.response Keep the response in the resulting object?

Value

delete.response and drop.terms return a terms object.
reformulate returns a formula.

See Also

terms

Examples

ff <- y ~ z + x + w
tt <- terms(ff)	tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[-1]
tt[2:3]
reformulate(attr(tt, "term.labels"))

## keep LHS :
reformulate("x*w", ff[[2]])

fS <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), fS[[2]])

## using non-syntactic names:
reformulate(c("P/E", "% Growth"), response = as.name("+-"))

x <- c("a name", "another name")
try( reformulate(x ) ) # -> Error ..... unexpected symbol

## rather backquote the strings in x :
reformulate(sprintf("`%s`", x))

stopifnot(identical( ~ var, reformulate("var")),
identical( ~ a + b + c, reformulate(letters[1:3])),
identical( ~ y ~ a + b, reformulate(letters[1:2], "y")))
Apply a Function to All Nodes of a Dendrogram

Description

Apply function FUN to each node of a dendrogram recursively. When y <- dendrapply(x, fn), then y is a dendrogram of the same graph structure as x and for each node, y.node[j] <- FUN(x.node[j], ...) (where y.node[j] is an (invalid!) notation for the j-th node of y).

Usage

dendrapply(X, FUN, ...)

Arguments

- **X**: an object of class "dendrogram".
- **FUN**: an R function to be applied to each dendrogram node, typically working on its attributes alone, returning an altered version of the same node.
- **...**: potential further arguments passed to FUN.

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually of the form FUN <- function(X) { attributes(X) <- ....; X }, i.e., returning the node with some attributes added or changed.

Note

The implementation is somewhat experimental and suggestions for enhancements (or nice examples of usage) are very welcome. The current implementation is recursive and inefficient for dendrograms with many non-leaves. See the ‘Warning’ in dendrogram.

dendrogram  General Tree Structures

### Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

### Usage

as.dendrogram(object, ...)
## S3 method for class 'hclust'
as.dendrogram(object, hang = -1, check = TRUE, ...)

## S3 method for class 'dendrogram'
as.hclust(x, ...)

## S3 method for class 'dendrogram'
plot(x, type = c("rectangle", "triangle"),
     center = FALSE,
     edge.root = is.leaf(x) || !is.null(attr(x,"edgetext")),
     nodePar = NULL, edgePar = list(),
     leaflab = c("perpendicular", "textlike", "none"),
     dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
     horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

## S3 method for class 'dendrogram'
cut(x, h, ...)

## S3 method for class 'dendrogram'
merge(x, y, ..., height,
adjust = c("auto", "add.max", "none")

### S3 method for class 'dendrogram'
nobs(object, ...)

### S3 method for class 'dendrogram'
print(x, digits, ...)

### S3 method for class 'dendrogram'
rev(x)

### S3 method for class 'dendrogram'
str(object, max.level = NA, digits.d = 3,
give.attr = FALSE, wid = getOption("width"),
nest.lev = 0, indent.str = "",
last.str = getOption("str.dendrogram.last"), stem = "--",
...)

is.leaf(object)

Arguments

object any R object that can be made into one of class "dendrogram".
x, y object(s) of class "dendrogram".
hang numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.
check logical indicating if object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of hclust(). The default is check=TRUE, e.g. for protecting against memory explosion with invalid inputs.
type type of plot.
center logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.
edge.root logical; if true, draw an edge to the root node.
nodePar a list of plotting parameters to use for the nodes (see points) or NULL by default which does not draw symbols at the nodes. The list may contain components named pch, cex, col, xpd, and/or bg each of which can have length two for specifying separate attributes for inner nodes and leaves. Note that the default of pch is 1:2, so you may want to use pch = NA if you specify nodePar.
edgePar a list of plotting parameters to use for the edge segments and labels (if there's an edgetext). The list may contain components named col, lty and lwd (for the segments), p.col, p.lwd, and p.lty (for the polygon around the text) and t.col for the text color. As with nodePar, each can have length two for differentiating leaves and inner nodes.

leaflab a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default). "textlike" writes text horizontally (in a rectangle), and "none" suppresses leaf labels.
dLeaf a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.
horiz logical indicating if the dendrogram should be drawn horizontally or not.
frame.plot logical indicating if a box around the plot should be drawn, see plot.default.

height at which the tree is cut.

height at which the two dendrograms should be merged. If not specified (or NULL), the default is ten percent larger than the (larger of the) two component heights.

adjust a string determining if the leaf values should be adjusted. The default, "auto", checks if the (first) two dendrograms both start at 1; if they do, code"add.max" is chosen, which adds the maximum of the previous dendrogram leaf values to each leaf of the "next" dendrogram. Specifying adjust to another value skips the check and hence is a tad more efficient.

xlim, ylim optional x- and y-limits of the plot, passed to plot.default. The defaults for these show the full dendrogram.

..., xlab, ylab, xaxt, yaxt graphical parameters, or arguments for other methods.

digits integer specifying the precision for printing, see print.default.

max.level, digits.d, give.attr, wid, nest.lev, indent.str arguments to str, see str.default(). Note that give.attr = FALSE still shows height and members attributes for each node.

last.str, stem strings used for str() specifying how the last branch (at each level) should start and the stem to use for each dendrogram branch. In some environments, using last.str = "" will provide much nicer looking output, than the historical default last.str = "-".

Details

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree z is z[[1]], the second branch of the corresponding subtree is z[[1]][[2]], or shorter z[[c(1,2)]] etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only members, height and leaf for leaves are compulsory:

members total number of leaves in the branch
height numeric non-negative height at which the node is plotted.

midpoint numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for plot(*, center = FALSE).

label character; the label of the node

x.member for cut()$upper, the number of former members; more generally a substitute for the members component used for 'horizontal' (when horiz = FALSE, else 'vertical') alignment.

edgetext character; the label for the edge leading to the node

nodePar a named list (of length-1 components) specifying node-specific attributes for points plotting, see the nodePar argument above.

edgePar a named list (of length-1 components) specifying attributes for segments plotting of the edge leading to the node, and drawing of the edgetext if available, see the edgePar argument above.

leaf logical, if TRUE, the node is a leaf of the tree.
cut.dendrogram() returns a list with components $upper and $lower, the first is a truncated version of the original tree, also of class dendrogram, the latter a list with the branches obtained from cutting the tree, each a dendrogram.

There are [[print]], and str methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class, i.e., returns a dendrogram even if only a leaf. On the other hand, [[(single bracket) extraction returns the underlying list structure.

Objects of class "hclust" can be converted to class "dendrogram" using method as.dendrogram(). and since R 2.13.0, there is also a as.hclust() method as an inverse.

rev.dendrogram simply returns the dendrogram x with reversed nodes, see also reorder.dendrogram.

The merge(x, y, ...) method merges two or more dendrograms into a new one which has x and y (and optional further arguments) as branches. Note that before R 3.1.2, adjust = "none" was used implicitly, which is invalid when, e.g., the dendrograms are from as.dendrogram(hclust(..)).

nobs(object) returns the total number of leaves (the members attribute, see above).
is.leaf(object) returns logical indicating if object is a leaf (the most simple dendrogram).

plotNode() and plotNodeLimit() are helper functions.

**Warning**

Some operations on dendrograms such as merge() make use of recursion. For deep trees it may be necessary to increase options("expressions"); if you do, you are likely to need to set the C stack size (Cstack_info()["size"]) larger than the default where possible.

**Note**

plot(): When using type = "triangle", center = TRUE often looks better.
str(d): If you really want to see the internal structure, use str(unclass(d)) instead.

**See Also**

dendrapply for applying a function to each node. order.dendrogram and reorder.dendrogram; further, the labels method.

**Examples**

```R
require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1) # "str()" method
str(dend1, max.level = 2, last.str = "\") # only the first two sub-levels
oo <- options(str.dendrogram.last = ")") # yet another possibility
str(dend1, max.level = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
     type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
     dLeaf = 1, edge.root = TRUE)
```
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
     horiz = TRUE)

## simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
## leaves are wrong horizontally in R 4.0 and earlier:
plot(dend2$upper)

## dend2$lower is *NOT* a dendrogram, but a list of .. :
plot(dend2$lower[[3]], nodePar = list(col = 4), horiz = TRUE, type = "tr")

## "inner" and "leaf" edges in different type & color :
plot(dend2$lower[[2]], nodePar = list(col = 1),
     edgePar = list(1ty = 1:2, col = 2:1), edge.root = TRUE)

par(op)
d3 <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

## merge() to join dendrograms:
(d13 <- merge(dend2$lower[[1]], dend2$lower[[3]]))

## merge() all parts back (using default 'height' instead of original one):
den.1 <- Reduce(merge, dend2$lower)

## or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
            dend2$lower[[4]])

## (with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) \rightarrow dendrogram with a 4-split")

## "Zoom" in to the first dendrogram :
plot(dend1, xlim = c(1,20), ylim = c(1,50))

nP <- list(col = 3:2, cex = c(2.0, 0.75), pch = 21:22,
           bg = c("light blue", "pink"),
           lab.cex = 0.75, lab.col = "tomato")
plot(d3, nodePar = nP, edgePar = list(col = "gray", lwd = 2), horiz = TRUE)

addE <- function(n) {
  if(is.leaf(n)) {
    if(is.leaf(n)) {
      attr(n, "edgePar") <- list(p.col = "plum")

plot(d3e, nodePar = nP)
plot(d3e, nodePar = nP, leaflab = "textlike")
density

Kernel Density Estimation

Description

The (S3) generic function density computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

density(x, ...)
## Default S3 method:
density(x, bw = \text{nrd0}, adjust = 1,
    kernel = \text{c("gaussian", \"epanechnikov\", \"rectangular\", \"triangular\", \"biweight\",
                       \"cosine\", \"optcosine\")},
    weights = \text{NULL}, window = kernel, width,
    give.Rkern = \text{FALSE}, subdensity = \text{FALSE},
    n = \text{512}, from, to, cut = \text{3}, na.rm = \text{FALSE}, ...)

Arguments

x
the data from which the estimate is to be computed. For the default method a numeric vector: long vectors are not supported.

bw
the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.)

bw can also be a character string giving a rule to choose the bandwidth. See \text{bw.nrd}.

The default, \text{\"nrd0\"}, has remained the default for historical and compatibility reasons, rather than as a general recommendation, where e.g., \text{\"SJ\"} would rather fit, see also Venables and Ripley (2002).

The specified (or computed) value of \text{bw} is multiplied by \text{adjust}.

adjust
the bandwidth used is actually \text{adjust*bw}. This makes it easy to specify values like ‘half the default’ bandwidth.

kernel, window
a character string giving the smoothing kernel to be used. This must partially match one of \text{\"gaussian\"}, \text{\"rectangular\"}, \text{\"triangular\"}, \text{\"epanechnikov\"}, \text{\"biweight\"}, \text{\"cosine\"} or \text{\"optcosine\"}, with default \text{\"gaussian\"}, and may be abbreviated to a unique prefix (single letter).

\text{\"cosine\"} is smoother than \text{\"optcosine\"}, which is the usual ‘cosine’ kernel in the literature and almost MSE-efficient. However, \text{\"cosine\"} is the version used by S.

weights
numeric vector of non-negative observation weights, hence of same length as \text{x}. The default \text{NULL} is equivalent to \text{weights = rep(1/\text{nx}, \text{nx})} where \text{nx} is the length of (the finite entries of) \text{x[\]}. If \text{na.rm = TRUE} and there are \text{NA}’s in \text{x}, they and the corresponding weights are removed before computations. In that case, when the original weights have summed to one, they are re-scaled to keep doing so.
density

width this exists for compatibility with S; if given, and bw is not, will set bw to width
if this is a character string, or to a kernel-dependent multiple of width if this is
numeric.
give.Rkern logical; if true, no density is estimated, and the 'canonical bandwidth’ of the
chosen kernel is returned instead.
subdensity used only when weights are specified which do not sum to one. When true, it
indicates that a “sub-density” is desired and no warning should be signalled. By
default, when false, a warning is signalled when the weights do not sum to one.
n the number of equally spaced points at which the density is to be estimated.
When n > 512, it is rounded up to a power of 2 during the calculations (as fft is
used) and the final result is interpolated by approx. So it almost always makes
sense to specify n as a power of two.
from,to the left and right-most points of the grid at which the density is to be estimated;
the defaults are cut * bw outside of range(x).
cut by default, the values of from and to are cut bandwidths beyond the extremes
of the data. This allows the estimated density to drop to approximately zero at
the extremes.
na.rm logical; if TRUE, missing values are removed from x. If FALSE any missing values
cause an error.
... further arguments for (non-default) methods.

Details

The algorithm used in density.default disperses the mass of the empirical distribution function
over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this ap-
proximation with a discretized version of the kernel and then uses linear approximation to evaluate
the density at the specified points.

The statistical properties of a kernel are determined by \( \sigma_K^2 = \int t^2 K(t) dt \) which is always
= 1 for our kernels (and hence the bandwidth bw is the standard deviation of the kernel) and
\( R(K) = \int K^2(t) dt \).

MSE-equivalent bandwidths (for different kernels) are proportional to \( \sigma_K R(K) \) which is scale in-
variant and for our kernels equal to \( R(K) \). This value is returned when give.Rkern = TRUE. See the
examples for using exact equivalent bandwidths.

Infinite values in x are assumed to correspond to a point mass at +/-Inf and the density estimate is
of the sub-density on (-Inf, +Inf).

Value

If give.Rkern is true, the number \( R(K) \), otherwise an object with class "density" whose under-
lying structure is a list containing the following components.

x the n coordinates of the points where the density is estimated.
y the estimated density values. These will be non-negative, but can be zero.
bw the bandwidth used.
n the sample size after elimination of missing values.
call the call which produced the result.
data.name the deparsed name of the x argument.
has.na logical, for compatibility (always FALSE).

The print method reports summary values on the x and y components.

deriv

### Symbolic and Algorithmic Derivatives of Simple Expressions

#### Description
Compute derivatives of simple expressions, symbolically and algorithmically.

#### Usage
```
D (expr, name)
deriv(expr, ...)  
deriv3(expr, ...)
```
## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr", hessian = FALSE, ...)
## S3 method for class 'formula'
deriv(expr, namevec, function.arg = NULL, tag = ".expr", hessian = FALSE, ...)
## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr", hessian = TRUE, ...)
## S3 method for class 'formula'
deriv3(expr, namevec, function.arg = NULL, tag = ".expr", hessian = TRUE, ...)

### Arguments

- **expr**: a *expression* or *call* or (except `D`) a formula with no lhs.
- **name, namevec**: character vector, giving the variable names (only one for `D()`) with respect to which derivatives will be computed.
- **function.arg**: if specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names `namevec` should be used.
- **tag**: character; the prefix to be used for the locally created variables in result.
- **hessian**: a logical value indicating whether the second derivatives should be calculated and incorporated in the return value.
- **...**: arguments to be passed to or from methods.

### Details

`D` is modelled after its S namesake for taking simple symbolic derivatives.

`deriv` is a *generic* function with a default and a *formula* method. It returns a *call* for computing the `expr` and its (partial) derivatives, simultaneously. It uses so-called *algorithmic derivatives*. If `function.arg` is a function, its arguments can have default values, see the `fx` example below.

Currently, `deriv.formula` just calls `deriv.default` after extracting the expression to the right of `~`.

`deriv3` and its methods are equivalent to `deriv` and its methods except that `hessian` defaults to TRUE for `deriv3`.

The internal code knows about the arithmetic operators `+`, `-`, `*`, `/`, and `^`, and the single-variable functions `exp`, `log`, `sin`, `cos`, `tan`, `sinh`, `cosh`, `sqr`, `pnorm`, `dnorm`, `asin`, `acos`, `atan`, `gamma`, `lgamma`, `digamma`, and `trigamma`, as well as `psigamma` for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.) Since R 3.4.0, the single-variable functions `log1p`, `expm1`, `log2`, `log10`, `cospi`, `sinpi`, `tanpi`, `factorial`, and `lfactorial` are supported as well.

### Value

`D` returns a call and therefore can easily be iterated for higher derivatives.

`deriv` and `deriv3` normally return an *expression* object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If `hessian` is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.
If `function.arg` is not `NULL`, `deriv` and `deriv3` return a function with those arguments rather than an expression.

**References**

**See Also**

`nlm` and `optim` for numeric minimization which could make use of derivatives,

**Examples**

```r
## formula argument :
dx2x <- deriv(~ x^2, "x") ; dx2x
## Not run: expression(
  .value <- x^2
  .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
  .grad[, "x"] <- 2 * x
  attr(.value, "gradient") <- .grad
  .value
)
## End(Not run)
mode(dx2x)
x <- -1:2
eval(dx2x)

## Something 'tougher':
trig.exp <- expression(sin(cos(x + y^2)))
( D.sc <- D(trig.exp, "x") )
all.equal(D(trig.exp[[1]], "x"), D.sc)

( dxy <- deriv(trig.exp, c("x", "y")) )
y <- 1
eval(dxy)
eval(D.sc)

## function returned:
deriv((y ~ sin(cos(x) * y)), c("x","y"), function.arg = TRUE)

## function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
  function(b0, b1, th, x = 1:7){} ) )
fx(2, 3, 4)

## First derivative
D(expression(x^2), "x")
stopifnot(D(as.name("x"), "x") == 1)

## Higher derivatives
deriv3(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
  c("b0", "b1", "th", "x"))
```
Higher derivatives:

```r
DD <- function(expr, name, order = 1) {
  if(order < 1) stop("'order' must be >= 1")
  if(order == 1) D(expr, name)
  else DD(D(expr, name), name, order - 1)
}
DD(expression(sin(x^2)), "x", 3)
```

showing the limits of the internal "simplify()":

```r
-sin(x^2) * (2 * x) * 2 + ((cos(x^2) * (2 * x) * (2 * x) + sin(x^2) * 2) * (2 * x) + sin(x^2) * (2 * x) * 2)
```

New (R 3.4.0, 2017):

```r
D(quote(log1p(x^2)), "x") ## log1p(x) = log(1 + x)
stopifnot(identical(D(quote(log1p(x^2)), "x"),
            D(quote(log(1+x^2)), "x")))
D(quote(expm1(x^2)), "x") ## expm1(x) = exp(x) - 1
stopifnot(identical(D(quote(expm1(x^2)), "x") -> Dex1,
            D(quote(exp(x^2)-1), "x")),
            identical(Dex1, quote(exp(x^2) * (2 * x))))
D(quote(sinpi(x^2)), "x") ## sinpi(x) = sin(pi*x)
D(quote(cospi(x^2)), "x") ## cospi(x) = cos(pi*x)
D(quote(tanpi(x^2)), "x") ## tanpi(x) = tan(pi*x)
stopifnot(identical(D(quote(log2 (x^2)), "x"),
            quote(2 * x/(x^2 * log(2)))),
            identical(D(quote(log10(x^2)), "x"),
            quote(2 * x/(x^2 * log(10)))))
```

---

**deviance**

<table>
<thead>
<tr>
<th>Model Deviance</th>
</tr>
</thead>
</table>

**Description**

Returns the deviance of a fitted model object.

**Usage**

`deviance(object, ...)`

**Arguments**

- `object` an object for which the deviance is desired.
- `...` additional optional argument.
Details

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

Value

The value of the deviance extracted from the object object.

References

See Also

df.residual, extractAIC, glm, lm.

---

df.residual     Residual Degrees-of-Freedom

Description

Returns the residual degrees-of-freedom extracted from a fitted model object.

Usage

df.residual(object, ...)

Arguments

object       an object for which the degrees-of-freedom are desired.
...
additional optional arguments.

Details

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the df.residual component.

Value

The value of the residual degrees-of-freedom extracted from the object x.

See Also

deviance, glm, lm.
**diffinv**

Discrete Integration: Inverse of Differencing

**Description**
Computes the inverse function of the lagged differences function `diff`.

**Usage**

```r
 diffinv(x, ...) 
```

### Default S3 method:
```r
 diffinv(x, lag = 1, differences = 1, xi, ...) 
```

### S3 method for class 'ts'
```r
 diffinv(x, lag = 1, differences = 1, xi, ...) 
```

**Arguments**
- `x` a numeric vector, matrix, or time series.
- `lag` a scalar lag parameter.
- `differences` an integer representing the order of the difference.
- `xi` a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
- `...` arguments passed to or from other methods.

**Details**
`diffinv` is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.

**Value**
A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of `x`.

**Author(s)**
A. Trapletti

**See Also**
- `diff`

**Examples**
```r
 s <- 1:10 
 d <- diff(s) 
 diffinv(d, xi = 1) 
```
Distance Matrix Computation

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

```
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)
```

```
as.dist(m, diag = FALSE, upper = FALSE)
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)
## S3 method for class 'dist'
print(x, diag = NULL, upper = NULL, digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dist'
as.matrix(x, ...)
```

Arguments

- **x**: a numeric matrix, data frame or "dist" object.
- **method**: the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- **diag**: logical value indicating whether the diagonal of the distance matrix should be printed by print.dist.
- **upper**: logical value indicating whether the upper triangle of the distance matrix should be printed by print.dist.
- **p**: The power of the Minkowski distance.
- **m**: An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using as.matrix(). (Only the lower triangle of the matrix is used, the rest is ignored).
- **digits, justify**: passed to format inside of print().
- **right, ...**: further arguments, passed to other methods.

Details

Available distance measures are (written for two vectors \(x\) and \(y\)):

- **euclidean**: Usual distance between the two vectors (2 norm aka \(L_2\)), \(\sqrt{\sum (x_i - y_i)^2}\).
- **maximum**: Maximum distance between two components of \(x\) and \(y\) (supremum norm)
**dist**

**manhattan:** Absolute distance between the two vectors (1 norm aka $L_1$).

**canberra:** $\sum_i |x_i - y_i|/(|x_i| + |y_i|)$. Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

This is intended for non-negative values (e.g., counts), in which case the denominator can be written in various equivalent ways; Originally, R used $x_i + y_i$, then from 1998 to 2017, $|x_i + y_i|$, and then the correct $|x_i| + |y_i|$.

**binary:** (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements are ‘on’ and zero elements are ‘off’. The distance is the proportion of bits in which only one is on amongst those in which at least one is on.

**minkowski:** The $p$ norm, the $p$th root of the sum of the $p$th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The "dist" method of as.matrix() and as.dist() can be used for conversion between objects of class "dist" and conventional distance matrices.

as.dist() is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using as.matrix(). Support for classes representing distances (also known as dissimilarities) can be added by providing an as.matrix() or, more directly, an as.dist method for such a class.

**Value**

`dist` returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say do. If n is the number of observations, i.e., `n <- attr(do, "Size")`, then for $i < j \leq n$, the dissimilarity between (row) i and j is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is $n \times (n - 1)/2$, i.e., of order $n^2$.

The object has the following attributes (besides "class" equal to "dist"):

- `Size` integer, the number of observations in the dataset.
- `Labels` optionally, contains the labels, if any, of the observations of the dataset.
- `Diag`, `Upper` logicals corresponding to the arguments `diag` and `upper` above, specifying how the object should be printed.
- `call` optionally, the `call` used to create the object.
- `method` optionally, the distance method used; resulting from `dist()`, the `match.arg()`ed method argument.

Examples

require(graphics)

x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"

dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables

## example of binary and canberra distances.

x <- c(0, 0, 1, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
## answer 0.4 = 2/5
dist(rbind(x, y), method = "canberra")
## answer 2 * (6/5)

## To find the names

labels(euroland)

## Examples involving "Inf":
## 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary") # warning, answer 0.5 = 2/4
## These all give "Inf":

stopifnot(Inf == dist(m2, method = "euclidean"),
Inf == dist(m2, method = "maximum"),
Inf == dist(m2, method = "manhattan"))

## "Inf" is same as very large number:

x1 <- x; x1[6] <- 1e100

stopifnot(dist(cbind(x1, y), method = "canberra") ==
print(dist(cbind(x1, y), method = "canberra")))

## 2)
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary" ) # warning; 0.5
dist(rbind(x, y), method = "canberra" ) # 3
dist(rbind(x, y), method = "maximum") # 1
dist(rbind(x, y), method = "manhattan") # 2.4
Distributions in the stats package

Description

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the stats package.

Details

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form dxxx, pxxx, qxxx and rxxx respectively.

For the beta distribution see dbeta.
For the binomial (including Bernoulli) distribution see dbinom.
For the Cauchy distribution see dcauchy.
For the chi-squared distribution see dchisq.
For the exponential distribution see dexp.
For the F distribution see df.
For the gamma distribution see dgamma.
For the geometric distribution see dgeom. (This is also a special case of the negative binomial.)
For the hypergeometric distribution see dhyper.
For the log-normal distribution see dlnorm.
For the multinomial distribution see dmultinom.
For the negative binomial distribution see dnbinom.
For the normal distribution see dnorm.
For the Poisson distribution see dpois.
For the Student’s t distribution see dt.
For the uniform distribution see dunif.
For the Weibull distribution see dweibull.
For less common distributions of test statistics see pbirthday, dsignrank, ptukey and dwilcox (and see the ‘See Also’ section of cor.test).

RNG about random number generation in R.

The CRAN task view on distributions, https://CRAN.R-project.org/view=Distributions, mentioning several CRAN packages for additional distributions.
dummy.coef  

Extract Coefficients in Original Coding

Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

Usage

dummy.coef(object, ...)

## S3 method for class 'lm'
dummy.coef(object, use.na = FALSE, ...)

## S3 method for class 'aovlist'
dummy.coef(object, use.na = FALSE, ...)

Arguments

object    a linear model fit.
use.na    logical flag for coefficients in a singular model. If use.na is true, undetermined coefficients will be missing; if false they will get one possible value.
...        arguments passed to or from other methods.

Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for contr.helmert or contr.sum) will be respected. There will be little point in using dummy.coef for contr.treatment contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as poly(x, 2). However, it is adequate for its main purpose, aov models.

Value

A list giving for each term the values of the coefficients. For a multistratum aov model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

Examples

```r
options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
```

**ecdf**  
*Empirical Cumulative Distribution Function*

**Description**

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an “ecdf” object.

**Usage**

```r
ecdf(x)
```

## S3 method for class 'ecdf'
```r
plot(x, ..., ylab="Fn(x)", verticals = FALSE, 
col.01line = "gray70", pch = 19)
```

## S3 method for class 'ecdf'
```r
print(x, digits= getOption("digits") - 2, ...)
```

## S3 method for class 'ecdf'
```r
summary(object, ...)
```

## S3 method for class 'ecdf'
```r
quantile(x, ...)
```

**Arguments**

- `x`, `object` numeric vector of the observations for `ecdf`; for the methods, an object inheriting from class "ecdf".
- `...` arguments to be passed to subsequent methods, e.g., `plot.stepfun` for the plot method.
- `ylab` label for the y-axis.
- `verticals` see `plot.stepfun`.
- `col.01line` numeric or character specifying the color of the horizontal lines at `y = 0` and `1`, see `colors`.
- `pch` plotting character.
- `digits` number of significant digits to use, see `print`.
Details

The e.c.d.f. (empirical cumulative distribution function) \( F_n \) is a step function with jumps \( i/n \) at observation values, where \( i \) is the number of tied observations at that value. Missing values are ignored.

For observations \( x = (x_1, x_2, \ldots, x_n) \), \( F_n \) is the fraction of observations less or equal to \( t \), i.e.,

\[
F_n(t) = \frac{\# \{x_i \leq t\}}{n} = \frac{1}{n} \sum_{i=1}^{n} 1[x_i \leq t].
\]

The function \texttt{plot.ecdf} which implements the \texttt{plot} method for \texttt{ecdf} objects, is implemented via a call to \texttt{plot.stepfun}; see its documentation.

Value

For \texttt{ecdf}, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a \texttt{knots()} method.

For the \texttt{summary} method, a summary of the knots of object with a "header" attribute.

The \texttt{quantile(obj, \ldots)} method computes the same quantiles as \texttt{quantile(x, \ldots)} would where \( x \) is the original sample.

Note

The objects of class "ecdf" are not intended to be used for permanent storage and may change structure between versions of \texttt{R} (and did at \texttt{R} 3.0.0). They can usually be re-created by

\[
\text{eval(attr(old_obj, "call"), environment(old_obj))}
\]

since the data used is stored as part of the object’s environment.

### eff.aovlist

**Compute Efficiencies of Multistratum Analysis of Variance**

**Description**

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

**Usage**

`eff.aovlist(aovlist)`

**Arguments**

- `aovlist` The result of a call to `aov` with an `Error` term.
Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g., treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

```
effects

Effects from Fitted Model

Description

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

Usage

effects(object, ...)

## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)

Arguments

object an R object; typically, the result of a model fitting function such as lm.
set.sign logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
...
arguments passed to or from other methods.

Details

For a linear model fitted by lm or aov, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first \( r \) (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

Value

A (named) numeric vector of the same length as residuals, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first \( r \) rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

c( round(ee - effects(lm(y+10 ~ I(x-3.8))), 3) )
# just the first is different
```

---

**embed**

**Embedding a Time Series**

Description

Embeds the time series \(x\) into a low-dimensional Euclidean space.

Usage

```r
embed(x, dimension = 1)
```

Arguments

- `x`: a numeric vector, matrix, or time series.
- `dimension`: a scalar representing the embedding dimension.

Details

Each row of the resulting matrix consists of sequences \(x[t]\), \(x[t-1]\), \ldots, \(x[t\text{-dimension}+1]\), where \(t\) is the original index of \(x\). If \(x\) is a matrix, i.e., \(x\) contains more than one variable, then \(x[t]\) consists of the \(t\)th observation on each variable.

Value

A matrix containing the embedded time series \(x\).

Author(s)

A. Trapletti, B.D. Ripley

Examples

```r
x <- 1:10
embed(x, 3)
```
**expand.model.frame**  
Add new variables to a model frame

**Description**
Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same `na.action` and `subset` arguments are applied and allows, for example, \( x \) to be recovered for a model using \( \sin(x) \) as a predictor.

**Usage**
```
expand.model.frame(model, extras,  
    envir = environment(formula(model)),  
    na.expand = FALSE)
```

**Arguments**
- `model` a fitted model  
- `extras` one-sided formula or vector of character strings describing new variables to be added  
- `envir` an environment to evaluate things in  
- `na.expand` logical; see below

**Details**
If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

**Value**
A data frame.

**See Also**
- `model.frame`  
- `predict`

**Examples**
```
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)  
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))  
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)  
expand.model.frame(model, "z", na.expand = FALSE) # = default  
expand.model.frame(model, "z", na.expand = TRUE)
```
The Exponential Distribution

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate \( \text{rate} \) (i.e., mean \( 1/\text{rate} \)).

Usage

\[
\begin{align*}
dexp(x, \text{rate} = 1, \log = \text{FALSE}) \\
pexp(q, \text{rate} = 1, \text{lower.tail = TRUE, log.p = FALSE}) \\
qexp(p, \text{rate} = 1, \text{lower.tail = TRUE, log.p = FALSE}) \\
rexp(n, \text{rate} = 1)
\end{align*}
\]

Arguments

- \( x, q \) vector of quantiles.
- \( p \) vector of probabilities.
- \( n \) number of observations. If length(\( n \)) > 1, the length is taken to be the number required.
- \( \text{rate} \) vector of rates.
- \( \log, \log.p \) logical; if TRUE, probabilities \( p \) are given as log(p).
- \( \text{lower.tail} \) logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If \( \text{rate} \) is not specified, it assumes the default value of 1.

The exponential distribution with rate \( \lambda \) has density

\[
f(x) = \lambda e^{-\lambda x}
\]

for \( x \geq 0 \).

Value

\( \text{dexp} \) gives the density, \( \text{pexp} \) gives the distribution function, \( \text{qexp} \) gives the quantile function, and \( \text{rexp} \) generates random deviates.

The length of the result is determined by \( n \) for \( \text{rexp} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is \( -\text{pexp}(t, \text{rate} = \text{FALSE, log = TRUE}) \).
Source

dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.

rexp uses

References

rsunif <- function(n) { n1 <- n+1
  cE <- cumsum(rexp(n1)); cE[seq_len(n)]/cE[n1] }
plot(rsunif(1000), ylim=0:1, pch=".")
abline(0,1/(1000+1), col=adjustcolor(1, 0.5))

extractAIC  

### Extract AIC from a Fitted Model

Description

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

Usage

extractAIC(fit, scale, k = 2, ...)

Arguments

- **fit**  
fitted model, usually the result of a fitter like lm.

- **scale**  
optional numeric specifying the scale parameter of the model, see scale in step. Currently only used in the "lm" method, where scale specifies the estimate of the error variance, and scale = 0 indicates that it is to be estimated by maximum likelihood.

- **k**  
numeric specifying the ‘weight’ of the equivalent degrees of freedom (≡ edf) part in the AIC formula.

- **...**  
further arguments (currently unused in base R).
Details

This is a generic function, with methods in base R for classes "aov", "glm" and "lm" as well as for "negbin" (package MASS) and "coxph" and "survreg" (package survival).

The criterion used is

\[ AIC = -2 \log L + k \times \text{edf}, \]

where \( L \) is the likelihood and edf the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of fit.

For linear models with unknown scale (i.e., for \( \text{lm} \) and \( \text{aov} \)), \( -2 \log L \) is computed from the deviance and uses a different additive constant to \( \logLik \) and hence \( \text{AIC} \). If \( RSS \) denotes the (weighted) residual sum of squares then extractAIC uses for \( -2 \log L \) the formulae \( RSS/s - n \) (corresponding to Mallows’ \( C_p \)) in the case of known scale \( s \) and \( n \log(RSS/n) \) for unknown scale. \( \text{AIC} \) only handles unknown scale and uses the formula \( n \log(RSS/n) + n + n \log 2\pi - \sum \log w \) where \( w \) are the weights. Further \( \text{AIC} \) counts the scale estimation as a parameter in the edf and extractAIC does not.

For \( \text{glm} \) fits the family’s \( \text{aic()} \) function is used to compute the \( \text{AIC} \): see the note under \( \logLik \) about the assumptions this makes.

\( k = 2 \) corresponds to the traditional \( \text{AIC} \), using \( k = \log(n) \) provides the BIC (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for \( \text{AIC} \) (usually via a method for \( \logLik \)). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as ‘free’. This is immaterial as extractAIC is only used to compare models of the same class (where only differences in \( \text{AIC} \) values are considered).

Value

A numeric vector of length 2, with first and second elements giving

- edf: the ‘equivalent degrees of freedom’ for the fitted model \( \text{fit} \).
- AIC: the (generalized) Akaike Information Criterion for \( \text{fit} \).

Note

This function is used in \( \text{add1, drop1 and step} \) and the similar functions in package \( \text{MASS} \) from which it was adopted.

extractAIC(glm.D93) #>> 5 15.129
Factanal

Factor Analysis

Description

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

Usage

```r
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
        subset, na.action, start = NULL,
        scores = c("none", "regression", "Bartlett"),
        rotation = "varimax", control = NULL, ...)
```

Arguments

- **x**: A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
- **factors**: The number of factors to be fitted.
- **data**: An optional data frame (or similar: see `model.frame`), used only if `x` is a formula. By default the variables are taken from `environment(formula)`.
- **covmat**: A covariance matrix, or a covariance list as returned by `cov.wt`. Of course, correlation matrices are covariance matrices.
- **n.obs**: The number of observations, used if `covmat` is a covariance matrix.
- **subset**: A specification of the cases to be used, if `x` is used as a matrix or formula.
- **na.action**: The `na.action` to be used if `x` is used as a matrix or formula.
- **start**: NULL or a matrix of starting values, each column giving an initial set of uniquenesses.
- **scores**: Type of scores to produce, if any. The default is none, "regression" gives Thompson’s scores, "Bartlett" given Bartlett’s weighted least-squares scores. Partial matching allows these names to be abbreviated.
- **rotation**: character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component loadings giving the rotated loadings, or just the rotated loadings.
- **control**: A list of control values.
  - `nstart`: The number of starting values to be tried if `start = NULL`. Default 1.
  - `trace`: logical. Output tracing information? Default FALSE.
  - `lower`: The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
  - `opt`: A list of control values to be passed to `optim`’s control argument.
  - `rotate`: a list of additional arguments for the rotation function.
- **...**: Components of `control` can also be supplied as named arguments to `factanal`.
Details

The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element vector \( x \), a \( p \times k \) matrix \( \Lambda \) of loadings, a \( k \)-element vector \( f \) of scores and a \( p \)-element vector \( e \) of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Psi \), the uniquenesses. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of \( x \),

\[ \Sigma = \Lambda \Lambda' + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( G \Lambda \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If \( covmat \) is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with \( data \) to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component correlation of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in \( start \) are tried in turn and the best fit obtained is used. If \( start = \text{NULL} \) then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then control$nstart - 1 \) other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in \([0, 1]\), but near-zero values are problematical, and the optimization is done with a lower bound of control$lower, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8).

Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[ \hat{f} = \Lambda \Sigma^{-1} x \]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see \( \text{napredict} \).

The print method (documented under \( \text{loadings} \)) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

Value

An object of class "factanal" with components

1. **loadings** A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class "loadings": see \( \text{loadings} \) for its print method.

2. **uniquenesses** The uniquenesses computed.
correlation
The correlation matrix used.
criteria
The results of the optimization: the value of the criterion (a linear function of the negative log-likelihood) and information on the iterations used.
factors
The argument factors.
dof
The number of degrees of freedom of the factor analysis model.
method
The method: always "mle".
rotmat
The rotation matrix if relevant.
scores
If requested, a matrix of scores. napredict is applied to handle the treatment of values omitted by the na.action.
n.obs
The number of observations if available, or NA.
call
The matched call.
na.action
If relevant.
STATISTIC, PVAL
The significance-test statistic and P value, if it can be computed.

Note
There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are 'Heywood cases' (with one or more uniquenesses essentially zero) are much more common than most texts and some other programs would lead one to believe.

**factor.scope**

*Compute Allowed Changes in Adding to or Dropping from a Formula*

**Description**

`add.scope` and `drop.scope` compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

**Usage**

```r
add.scope(terms1, terms2)
drop.scope(terms1, terms2)
factor.scope(factor, scope)
```

**Arguments**

- `terms1` the terms or formula for the base model.
- `terms2` the terms or formula for the upper (`add.scope`) or lower (`drop.scope`) scope. If missing for `drop.scope` it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.
- `factor` the "factor" attribute of the terms of the base object.
- `scope` a list with one or both components `drop` and `add` giving the "factor" attribute of the lower and upper scopes respectively.

**Details**

`factor.scope` is not intended to be called directly by users.

**Value**

For `add.scope` and `drop.scope` a character vector of terms labels. For `factor.scope`, a list with components `drop` and `add`, character vectors of terms labels.
See Also

add1, drop1.aov, lm

Examples

add.scope(~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c" "b:c"
drop.scope(~ a + b + c + a:b)
# [1] "c" "a:b"

family

Family Objects for Models

Description

Family objects provide a convenient way to specify the details of the models used by functions such as glm. See the documentation for glm for the details on how such model fitting takes place.

Usage

family(object, ...)

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")

Arguments

link

a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector, or an object of class "link-glm" (such as generated by make.link) provided it is not specified via one of the standard names given next.
The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit, (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt; and the inverse.gaussian family the links 1/mu^2, inverse, identity and log.
The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu^2 and sqrt, and the function power can be used to create a power link function.

variance

for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)"", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.
family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

For the binomial and quasibinomial families the response can be specified in one of three ways:

1. As a factor: 'success' is interpreted as the factor not having the first level (and hence usually of having the second level).
2. As a numerical vector with values between 0 and 1, interpreted as the proportion of successful cases (with the total number of cases given by the weights).
3. As a two-column integer matrix: the first column gives the number of successes and the second the number of failures.

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family character: the family name.
link character: the link name.
linkfun function: the link.
linkinv function: the inverse of the link function.
variance function: the variance as a function of the mean.
dev.resids function giving the deviance for each observation as a function of (y, mu, wt), used by the residuals method when computing deviance residuals.
aic function giving the AIC value if appropriate (but NA for the quasi- families). More precisely, this function returns $-2\ell + 2s$, where $\ell$ is the log-likelihood and $s$ is the number of estimated scale parameters. Note that the penalty term for the location parameters (typically the "regression coefficients") is added elsewhere, e.g., in glm.fit(), or AIC(), see the AIC example in glm. See logLik for the assumptions made about the dispersion parameter.

mu.eta function: derivative of the inverse-link function with respect to the linear predictor. If the inverse-link function is $\mu = g^{-1}(\eta)$ where $\eta$ is the value of the linear predictor, then this function returns $d(g^{-1})/d\eta = d\mu/d\eta$.

initialize expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and mustart (see glm).

validmu logical function. Returns TRUE if a mean vector mu is within the domain of variance.

valideta logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.
simulate (optional) function `simulate(object, nsim)` to be called by the "lm" method of `simulate`. It will normally return a matrix with `nsim` columns and one row for each fitted value, but it can also return a list of length `nsim`. Clearly this will be missing for 'quasi-' families.

**Note**

The link and variance arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). Additionally, they can be supplied as a length-one character vector giving the name of one of the options, or as a list (for `link`, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to `make.link` are accepted.

This is potentially ambiguous: supplying `link = logit` could mean the unquoted name of a link or the value of object `logit`. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via `logit[1]`.)

**Author(s)**

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

**See Also**

`glm, power, make.link`.

For binomial coefficients, `choose`; the binomial and negative binomial distributions, `Binomial` and `NegBinomial`.

**Examples**

```r
require(utils) # for str

nf <- gaussian()  # Normal family
nf
str(nf)

gf <- Gamma()
gf
str(gf)
gf$linkinv
gf$variance(-3:4) #== (.)^2

## Binomial with default 'logit' link: Check some properties visually:
bi <- binomial()
```
et <- seq(-10, 10, by=1/8)
plot(et, bi$mu.eta(et), type="l")
## show that mu.eta() is derivative of linkinv() :
lines((et[-1]+et[-length(et)])/2, col=adjustcolor("red", 1/4),
     diff(bi$linkinv(et))/diff(et), type="l", lwd=4)
## which here is the logistic density:
lines(et, dlogis(et), lwd=3, col=adjustcolor("blue", 1/4))
stopifnot(exprs = {
  all.equal(bi$mu.eta(et), dlogis(et))
  all.equal(bi$linkinv(et), plogis(et) -> m)
  all.equal(bi$linkfun(m ), qlogis(m))  # logit(.) == qlogis(.) !
})

## Data from example(glm) :
d.AD <- data.frame(treatment = gl(3,3),
                   outcome = gl(3,1,9),
                   counts = c(18,17,15, 20,10,20, 25,13,12))
glm.D93 <- glm(counts ~ outcome + treatment, d.AD, family = poisson())
## Quasipoisson: compare with above / example(glm) :
glm.qD93 <- glm(counts ~ outcome + treatment, d.AD, family = quasipoisson())
glm.qD93
anova (glm.qD93, test = "F")
summary(glm.qD93)
## for Poisson results (same as from 'glm.D93' !) use
anova (glm.qD93, dispersion = 1, test = "Chisq")
summary(glm.qD93, dispersion = 1)

## Example of user-specified link, a logit model for p^days
logexp <- function(days = 1)
{
  linkfun <- function(mu) qlogis(mu^(1/days))
  linkinv <- function(eta) plogis(eta)^days
  mu.eta <- function(eta) days * plogis(eta)^(days-1) *
             binomial()$mu.eta(eta)
  valideta <- function(eta) TRUE
  link <- paste0("logexp(" , days , ", ")"
  structure(list(linkfun = linkfun, linkinv = linkinv,
                mu.eta = mu.eta, valideta = valideta, name = link),
          class = "link-glm")
}
(bi3 <- binomial(logexp(3)))

## in practice this would be used with a vector of 'days', in
## which case use an offset of 0 in the corresponding formula
## to get the null deviance right.

## Binomial with identity link: often not a good idea, as both
## computationally and conceptually difficult:
binomial(link = "identity")  ## is exactly the same as
binomial(link = make.link("identity"))
## tests of quasi
x <- rnorm(100)
y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
# which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu^2", link = "log"))
## Not run: glm(y ~ x, family = quasi(variance = "mu^3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
# need to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))

### The F Distribution

**Description**

Density, distribution function, quantile function and random generation for the F distribution with df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

**Usage**

df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)

**Arguments**

- **x, q** vector of quantiles.
- **p** vector of probabilities.
- **n** number of observations. If length(n) > 1, the length is taken to be the number required.
- **df1, df2** degrees of freedom. Inf is allowed.
- **ncp** non-centrality parameter. If omitted the central F is assumed.
- **log, log.p** logical; if TRUE, probabilities p are given as log(p).
- **lower.tail** logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

**Details**

The F distribution with df1 = $n_1$ and df2 = $n_2$ degrees of freedom has density

$$f(x) = \frac{\Gamma(n_1/2 + n_2/2)}{\Gamma(n_1/2)\Gamma(n_2/2)} \left(\frac{n_1}{n_2}\right)^{n_1/2} x^{n_1/2 - 1} \left(1 + \frac{n_1 x}{n_2}\right)^{-(n_1 + n_2)/2}$$

for $x > 0$.

It is the distribution of the ratio of the mean squares of $n_1$ and $n_2$ independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of $m$ independent normals has a Student’s $t_m$ distribution, the square of a $t_m$ variate has a F distribution on 1 and $m$ degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and ncp is the sum of squares of the means. See Chisquare for further details on non-central distributions.
Value

df gives the density, pf gives the distribution function qf gives the quantile function, and rf generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rf, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

Source

For the central case of df, computed via a binomial probability, code contributed by Catherine Loader (see dbinom); for the non-central case computed via dbeta, code contributed by Peter Ruckdeschel.

For pf, via pbeta (or for large df2, via pchisq).

For qf, via qchisq for large df2, else via qbeta.

Examples

```r
## Equivalence of pt(.,nu) with pf(.^2, 1,nu):
x <- seq(0.001, 5, length.out = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
  ## upper tails:
  all.equal(2*pt(x, nu, lower.tail=FALSE),
    pf(x^2, 1,nu, lower.tail=FALSE)))
## the density of the square of a t_m is 2*dt(x, m)/(2*x)
## check this is the same as the density of F_.(1,m)
all.equal(df(x^2, 1, 5), dt(x, 5)/x)
## Identity: qf(2*p - 1, 1, df) == qt(p, df)^2 for p >= 1/2
```
\texttt{p <- seq(1/2, .99, length.out = 50); df <- 10}
\texttt{rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))}
\texttt{quantile(rel.err(qf(2*p - 1, df1 = 1, df2 = df), qt(p, df)^2), .90) \# \approx 7e-9}

---

\textbf{fft}

\textit{Fast Discrete Fourier Transform (FFT)}

\textbf{Description}

Computes the Discrete Fourier Transform (DFT) of an array with a fast algorithm, the “Fast Fourier Transform” (FFT).

\textbf{Usage}

\begin{verbatim}
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
\end{verbatim}

\textbf{Arguments}

- \texttt{z} a real or complex array containing the values to be transformed. Long vectors are not supported.
- \texttt{inverse} if \texttt{TRUE}, the unnormalized inverse transform is computed (the inverse has a + in the exponent of e, but here, we do not divide by \(1/\text{length(x)}\)).

\textbf{Value}

When \texttt{z} is a vector, the value computed and returned by \texttt{fft} is the unnormalized univariate discrete Fourier transform of the sequence of values in \texttt{z}. Specifically, \(y <- \text{fft}(z)\) returns

\[
y[h] = \sum_{k=1}^{n} z[k] \exp(-2\pi i(k - 1)(h - 1)/n)
\]

for \(h = 1, \ldots, n\) where \(n = \text{length(y)}\). If \texttt{inverse} is \texttt{TRUE}, \(\exp(-2\pi \ldots)\) is replaced with \(\exp(2\pi \ldots)\).

When \texttt{z} contains an array, \texttt{fft} computes and returns the multivariate (spatial) transform. If \texttt{inverse} is \texttt{TRUE}, the (unnormalized) inverse Fourier transform is returned, i.e., if \(y <- \text{fft}(z)\), then \(z = \text{fft}(y, \text{inverse} = \text{TRUE}) / \text{length(y)}\).

By contrast, \texttt{mvfft} takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

t <- fft(x)
fft(t), inverse = TRUE)/length(x)
## Slow Discrete Fourier Transform (DFT) - e.g., for checking the formula
fft0 <- function(z, inverse=FALSE) {
  n <- length(z)
  if(n == 0) return(z)
  k <- 0:(n-1)
  ff <- (if(inverse) 1 else -1) * 2*pi * 1i * k/n
  vapply(1:n, function(h) sum(z * exp(ff*(h-1))), complex(1))
}
relD <- function(x,y) 2* abs(x - y) / abs(x + y)
n <- 2^8
z <- complex(n, rnorm(n), rnorm(n))
## relative differences in the order of 4*10^{-14}:
summary(relD(fft(z), fft0(z)))
summary(relD(fft(z, inverse=TRUE), fft0(z, inverse=TRUE)))
```

---

**filter**

*Linear Filtering on a Time Series*

**Description**

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

**Usage**

```r
filter(x, filter, method = c("convolution", "recursive"),
sides = 2, circular = FALSE, init)
```
Arguments

- **x**: a univariate or multivariate time series.
- **filter**: a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
- **method**: Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used; if "recursive" an autoregression is used.
- **sides**: for convolution filters only. If `sides = 1` the filter coefficients are for past values only; if `sides = 2` they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
- **circular** for convolution filters only. If `TRUE`, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
- **init** for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in `x` but not in `filter` (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

\[ y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p} \]

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

\[ y_i = f_1 x_{i+o} + \cdots + f_p x_{i+(p-1)} \]

where `o` is the offset: see `sides` for how it is determined.

Value

A time series object.

Note

`convolve(, type = "filter")` uses the FFT for computations and so **may** be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. `filter` is faster for a filter of length 100 on a series of length 1000, for example.

See Also

`convolve`, `arima.sim`

Examples

```r
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)
filter(presidents, rep(1, 3))
```
ficher.test

Fisher’s Exact Test for Count Data

Description
Performs Fisher’s exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

Usage
ficher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
hybridPars = c(expect = 5, percent = 80, Emin = 1),
control = list(), or = 1, alternative = "two.sided",
conf.int = TRUE, conf.level = 0.95,
simulate.p.value = FALSE, B = 2000)

Arguments
x
either a two-dimensional contingency table in matrix form, or a factor object.
y
a factor object; ignored if x is a matrix.
workspace
an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than 2 × 2 tables. Since R version 3.5.0, this also increases the internal stack size which allows larger problems to be solved, however sometimes needing hours. In such cases, simulate.p.values=TRUE may be more reasonable.
hybrid
a logical. Only used for larger than 2 × 2 tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed.
hybridPars
a numeric vector of length 3, by default describing “Cochran’s conditions” for the validity of the chisquare approximation, see ‘Details’.
control
a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer ≥ 2 with default 30 used only for larger than 2 × 2 tables. This says how many times as much space should be allocated to paths as to keys: see file ‘fexact.c’ in the sources of this package.
or
the hypothesized odds ratio. Only used in the 2 × 2 case.
alternative
indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 × 2 case.
conf.int
logical indicating if a confidence interval for the odds ratio in a 2×2 table should be computed (and returned).
conf.level
confidence level for the returned confidence interval. Only used in the 2 × 2 case and if conf.int = TRUE.
simulate.p.value
a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than 2 × 2 tables.
B
an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \( x \) is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both \( x \) and \( y \) must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For \( 2 \times 2 \) cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1983, 1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from https://www.netlib.org/toms/643. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than \( 2^{31} - 1 \).)

For \( 2 \times 2 \) tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. 'Exact' inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so alternative = "greater" is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as 'more extreme' all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than \( 2 \times 2 \) tables and hybrid = TRUE, asymptotic chi-squared probabilities are only used if the 'Cochran conditions' (or modified version thereof) specified by hybridPars = c(expect = 5, percent = 80, Emin = 1) are satisfied, that is if no cell has expected counts less than 1 (= Emin) and more than 80% (= percent) of the cells have expected counts at least 5 (= expect), otherwise the exact calculation is used. A corresponding if() decision is made for all sub-tables considered. Accidentally, \( R \) has used 180 instead of 80 as percent, i.e., hybridPars[2] in \( R \) versions between 3.0.0 and 3.4.1 (inclusive), i.e., the 2nd of the hybridPars (all of which used to be hard-coded previous to \( R \) 3.5.0). Consequently, in these versions of \( R \), hybrid=TRUE never made a difference.

In the \( r \times c \) case with \( r > 2 \) or \( c > 2 \), internal tables can get too large for the exact test in which case an error is signalled. Apart from increasing workspace sufficiently, which then may lead to very long running times, using simulate.p.value = TRUE may then often be sufficient and hence advisable.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

Value

A list with class "htest" containing the following components:

- p.value: the p-value of the test.
- conf.int: a confidence interval for the odds ratio. Only present in the \( 2 \times 2 \) case and if argument conf.int = TRUE.
- estimate: an estimate of the odds ratio. Note that the conditional Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the \( 2 \times 2 \) case.
- null.value: the odds ratio under the null, or. Only present in the \( 2 \times 2 \) case.
- alternative: a character string describing the alternative hypothesis.
- method: the character string "Fisher’s Exact Test for Count Data".
- data.name: a character string giving the names of the data.

Convictions
fisher.test(Convictions, alternative = "less")
fisher.test(Convictions, conf.int = FALSE)
```
fitted  

\[
\text{fitted} \quad \text{Extract Model Fitted Values}
\]

**Description**

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)

Methods can make use of napredict methods to compensate for the omission of missing values. The default and nls methods do.

**Usage**

\[
fitted(object, \ldots)
fitted.values(object, \ldots)
\]

**Arguments**

- `object` an object for which the extraction of model fitted values is meaningful.
- `\ldots` other arguments.

**Value**

Fitted values extracted from the object object.

**References**

fisher.test(MP6)  
# Exactly the same p-value, as Cochran's conditions are never met:  
fisher.test(MP6, hybrid=TRUE)
```
fivenum  

Tukey Five-Number Summaries

Description

Returns Tukey’s five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

Usage

fivenum(x, na.rm = TRUE)

Arguments

x numeric, maybe including NAs and ±Inf s.
na.rm logical; if TRUE, all NA and NaNs are dropped, before the statistics are computed.

Value

A numeric vector of length 5 containing the summary information. See boxplot.stats for more details.

See Also

IQR, boxplot.stats, median, quantile, range.

Examples

fivenum(c(rnorm(100), -1:1/0))

fligner.test  

Fligner-Killeen Test of Homogeneity of Variances

Description

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

Usage

fligner.test(x, ...)

## Default S3 method:
fligner.test(x, g, ...)

## S3 method for class 'formula'
fligner.test(formula, data, subset, na.action, ...)

Arguments

x  a numeric vector of data values, or a list of numeric data vectors.
g  a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
formula  a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  an optional vector specifying a subset of observations to be used.
na.action  a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
...  further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use fligner.test(x) to perform the test. If the samples are not yet contained in a list, use fligner.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k-sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights \( a(i) = \text{qnorm}((1+i/(n+1))/2) \). The version implemented here uses median centering in each of the samples (F-K:med \( X^2 \) in the reference).

Value

A list of class "htest" containing the following components:

- statistic  the Fligner-Killeen:med \( X^2 \) test statistic.
- parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value  the p-value of the test.
- method  the character string "Fligner-Killeen test of homogeneity of variances".
- data.name  a character string giving the names of the data.

### Examples

```r
require(graphics)

plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

### formula

<table>
<thead>
<tr>
<th>Model Formulae</th>
</tr>
</thead>
<tbody>
<tr>
<td>formula</td>
</tr>
</tbody>
</table>

### Description

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when `object` already inherits from "formula".

### Usage

```r
formula(x, ...)  # R object, for DF2formula() a data.frame.
DF2formula(x, env = parent.frame())
as.formula(object, env = parent.frame())
## S3 method for class 'formula'
print(x, showEnv = !identical(e, .GlobalEnv), ...)
```

### Arguments

- `x`, `object`  
  - `R` object, for `DF2formula()` a `data.frame`.
- `...`  
  - further arguments passed to or from other methods.
- `env`  
  - the environment to associate with the result, if not already a formula.
- `showEnv`  
  - logical indicating if the environment should be printed as well.

### Details

The models fit by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The `~` operator is basic in the formation of such models. An expression of the form `y ~ model` is interpreted as a specification that the response `y` is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by `+` operators. The terms themselves consist of variable and factor names separated by `:` operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to `+` and `:`, a number of other operators are useful in model formulae. The `*` operator denotes factor crossing: `a*b` interpreted as `a+b+a:b`. The `^` operator indicates crossing to the specified degree. For example `(a+b+c)^2` is identical to `(a+b+c)*(a+b+c)` which in turn expands to a formula containing the main effects for `a` and `c` together with their second-order interactions. The `%in%` operator indicates that the terms on its left are nested within those on the right. For example `a + b %in% a` expands to the formula `a + a:b`. The `-` operator removes the specified terms, so that `(a+b+c)^2 - a:b` is identical to `a + b + c + b:c + a:c`. It can also used to remove the intercept term:
when fitting a linear model \( y \sim x - 1 \) specifies a line through the origin. A model with no intercept can be also specified as \( y \sim x + 0 \) or \( y \sim 0 + x \).

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula \( \log(y) \sim a + \log(x) \) is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula \( y \sim a + I(b+c) \), the term \( b+c \) is to be interpreted as the sum of \( b \) and \( c \).

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function `offset` to indicate terms with a fixed coefficient of one. Some functions accept other `specials` such as `strata` or `cluster` (see the `specials` argument of `terms.formula`).

There are two special interpretations of . in a formula. The usual one is in the context of a data argument of model fitting functions and means `all columns not otherwise in the formula`: see `terms.formula`. In the context of `update.formula, only`, it means `what was previously in this part of the formula`.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class "nls") or the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a `formula` parameter of the call (and evaluates its value) and finally a "formula" attribute.

There is a `formula` method for data frames. When there’s "terms" attribute with a formula, e.g., for a `model.frame()`, that formula is returned. If you’d like the previous (\( R \leq 3.5.x \)) behavior, use the auxiliary `DF2formula()` which does not consider a "terms" attribute. Otherwise, if there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by `+` form the RHS.

Value

All the functions above produce an object of class "formula" which contains a symbolic model formula.

Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied data argument.

Formulas created with the `~` operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment.

Note

In \( R \) versions up to 3.6.0, character \( x \) of length more than one were parsed as separate lines of \( R \) code and the first complete expression was evaluated into a formula when possible. This silently truncates such vectors of characters inefficiently and to some extent inconsistently as this behaviour had been undocumented. For this reason, such use has been deprecated. If you must work via character \( x \), do use a string, i.e., a character vector of length one.

E.g., `eval(call("~", quote(foo + bar)))` has been an order of magnitude more efficient than `formula(c("~", "foo + bar"))`.

Further, character "expressions" needing an `eval()` to return a formula are now deprecated.

formula(fm1)
```

friedman.test

Friedman Rank Sum Test

Description

Performs a Friedman rank sum test with unreplicated blocked data.

Usage

```r
friedman.test(y, ...)
```

## Default S3 method:
```r
defriedman.test(y, groups, blocks, ...)
```

## S3 method for class 'formula'
```r
friedman.test(formula, data, subset, na.action, ...)
```

Arguments

- `y` either a numeric vector of data values, or a data matrix.
- `groups` a vector giving the group for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `blocks` a vector giving the block for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `formula` a formula of the form `a ~ b | c`, where `a`, `b` and `c` give the data values and corresponding groups and blocks, respectively.
- `data` an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...` further arguments to be passed to or from methods.

Details

`friedman.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA’s are not allowed in `groups` or `blocks`; if `y` contains NA’s, corresponding blocks are removed.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of Friedman's chi-squared statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Friedman rank sum test".
- **data.name**: a character string giving the names of the data.

---

**ftable**

*Flat Contingency Tables*

### Description

Create ‘flat’ contingency tables.

### Usage

\[
\begin{verbatim}
ftable(x, ...)
\end{verbatim}
\]

### Default S3 method:

\[
\begin{verbatim}
ftable(..., exclude = c(NA, NaN), row.vars = NULL,
               col.vars = NULL)
\end{verbatim}
\]

### Arguments

- \(x, \ldots\)
  - \(R\) objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, or a contingency table object of class "table" or "ftable".

- \(exclude\)
  - values to use in the exclude argument of \texttt{factor} when interpreting non-factor objects.

- \(row.vars\)
  - a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the rows of the flat contingency table.

- \(col.vars\)
  - a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table.

### Details

\texttt{ftable} creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by \texttt{row.vars} and \texttt{col.vars}, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via \texttt{print.ftable}, the print method for objects of class "ftable") is often preferable to showing it as a higher-dimensional array.
ftable is a generic function. Its default method, ftable.default, first creates a contingency table in array form from all arguments except row.vars and col.vars. If the first argument is of class "table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the information it contains is converted to the usual array representation using as.ftable. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using table. Then, the arguments row.vars and col.vars are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to table to control how the variable names are displayed; see the last example below.

Function ftable.formula provides a formula method for creating flat contingency tables.

There are methods for as.table, as.matrix and as.data.frame.

Value

ftable returns an object of class "ftable", which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes "row.vars" and "col.vars".

See Also

ftable.formula for the formula interface (which allows a data = . argument); read.ftable for information on reading, writing and coercing flat contingency tables; table for ordinary cross-tabulation; xtabs for formula-based cross-tabulation.

Examples

## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
dnn = c("Cylinders", "V/S", "Transmission", "Gears"))
Usage

## S3 method for class 'formula'
ftable(formula, data = NULL, subset, na.action, ...)

Arguments

formula a formula object with both left and right hand sides specifying the column and
row variables of the flat table.
data a data frame, list or environment (or similar: see model.frame) containing the
variables to be cross-tabulated, or a contingency table (see below).
subset an optional vector specifying a subset of observations to be used. Ignored if
data is a contingency table.
na.action a function which indicates what should happen when the data contain
NA s. Ignored if data is a contingency table.
... further arguments to the default ftable method may also be passed as arguments,
see ftable.default.

Details

This is a method of the generic function ftable.
The left and right hand side of formula specify the column and row variables, respectively, of the
flat contingency table to be created. Only the + operator is allowed for combining the variables. A
. may be used once in the formula to indicate inclusion of all the remaining variables.

If data is an object of class "table" or an array with more than 2 dimensions, it is taken as
a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat
contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or
environment containing the variables to be cross-tabulated. In this case, na.action is applied to
the data to handle missing values, and, after possibly selecting a subset of the data as specified by
the subset argument, a contingency table is computed from the variables.
The contingency table is then collapsed to a flat table, according to the row and column variables
specified by formula.

Value

A flat contingency table which contains the counts of each combination of the levels of the variables,
collapsed into a matrix for suitably displaying the counts.

Examples

Titanic
x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
Gamma Distribution

Description
Density, distribution function, quantile function and random generation for the Gamma distribution with parameters shape and scale.

Usage

dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number required.
rate  an alternative way to specify the scale.
shape, scale  shape and scale parameters. Must be positive, scale strictly.
log, log.p  logical; if TRUE, probabilities/densities p are returned as log(p).
lower.tail  logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details
If scale is omitted, it assumes the default value of 1.
The Gamma distribution with parameters shape = $\alpha$ and scale = $\sigma$ has density

$$f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}$$

for $x \geq 0$, $\alpha > 0$ and $\sigma > 0$. (Here $\Gamma(\alpha)$ is the function implemented by R’s gamma() and defined in its help. Note that $\alpha = 0$ corresponds to the trivial distribution with all mass at point 0.)
The mean and variance are $E(X) = \alpha \sigma$ and $Var(X) = \alpha \sigma^2$.
The cumulative hazard $H(t) = -\log(1 - F(t))$ is

$$-\text{pgamma}(t, \ldots, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})$$

Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of $x$ so near zero that they will be represented as zero in computer arithmetic. So rgamma may well return values which will be represented as zero. (This will also happen for very large values of scale since the actual generation is done for scale = 1.)
Value
dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.
Invalid arguments will result in return value NaN, with a warning.
The length of the result is determined by n for rgamma, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note
The S (Becker et al, 1988) parametrization was via shape and rate: S had no scale parameter. It is an error to supply both scale and rate.
pgamma is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

\[ P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1}e^{-t}dt \]

\( P(a, x) \) is pgamma(x, a). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function \( \gamma(a, x) \) as \( \gamma(a, x) = \int_0^x t^{a-1}e^{-t}dt \), i.e., pgamma(x, a) * gamma(a). Yet other use the ‘upper’ incomplete gamma function,

\[ \Gamma(a, x) = \int_x^\infty t^{a-1}e^{-t}dt, \]

which can be computed by pgamma(x, a, lower = FALSE) * gamma(a).
Note however that pgamma(x, a, ...) currently requires \( a > 0 \), whereas the incomplete gamma function is also defined for negative \( a \). In that case, you can use gamma_inc(a, x) (for \( \Gamma(a, x) \)) from package gsl.
See also https://en.wikipedia.org/wiki/Incomplete_gamma_function, or https://dlmf.nist.gov/8.2#i.

Source
dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see dbinom).
pgamma uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.
qgamma is based on a C translation of
plus a final Newton step to improve the approximation.
rgamma for shape \( \geq 1 \) uses
and for \( 0 < \text{shape} < 1 \) uses

Geometric

The Geometric Distribution

Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter prob.

Usage

\[d\text{geom}(x, \text{prob}, \text{log} = \text{FALSE})\]

\[p\text{geom}(q, \text{prob}, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE})\]

\[q\text{geom}(p, \text{prob}, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE})\]

\[r\text{geom}(n, \text{prob})\]

Arguments

\[x, q\]

vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.

\[p\]

vector of probabilities.
Geometric

n number of observations. If \( \text{length}(n) > 1 \), the length is taken to be the number required.

prob probability of success in each trial. \( 0 < \text{prob} \leq 1 \).

log, log.p logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).

lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The geometric distribution with \( \text{prob} = p \) has density

\[
p(x) = p(1 - p)^x
\]

for \( x = 0, 1, 2, \ldots, 0 < p \leq 1 \).

If an element of \( x \) is not integer, the result of \( \text{dgeom} \) is zero, with a warning.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

dgeom gives the density, pgeom gives the distribution function, qgeom gives the quantile function, and rgeom generates random deviates.

Invalid \( \text{prob} \) will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for \( \text{rgeom} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

rgeom returns a vector of type integer unless generated values exceed the maximum representable integer when \( \text{double} \) values are returned since R version 4.0.0.

Source

dgeom computes via \( \text{dbinom} \), using code contributed by Catherine Loader (see \( \text{dbinom} \)).
pgeom and qgeom are based on the closed-form formulae.
rgeom uses the derivation as an exponential mixture of Poissons, see

Get Initial Parameter Estimates

Description

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

Usage

getInitial(object, data, ...)

Arguments

- **object**: a formula or a selfStart model that defines a nonlinear regression model
- **data**: a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
- **...**: optional additional arguments

Value

A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Examples

PurTrt <- Puromycin[ Puromycin$state == "treated", ]
print(getInitial( rate ~ SSmicmen( conc, Vm, K ), PurTrt ), digits = 3)
Description

`glm` is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage

```r
glm(formula, family = gaussian, data, weights, subset,  
    na.action, start = NULL, etastart, mustart, offset,  
    control = list(...), model = TRUE, method = "glm.fit",  
    x = FALSE, y = TRUE, singular.ok = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep.int(1, nobs),  
    start = NULL, etastart = NULL, mustart = NULL,  
    offset = rep.int(0, nobs), family = gaussian(),  
    control = list(), intercept = TRUE, singular.ok = TRUE)
```

## S3 method for class 'glm'

```r
weights(object, type = c("prior", "working"), ...)
```

Arguments

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- **family**: a description of the error distribution and link function to be used in the model. For `glm` this can be a character string naming a family function, a family function or the result of a call to a family function. For `glm.fit` only the third option is supported. (See `family` for details of family functions.)
- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame`) to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `glm` is called.
- **weights**: an optional vector of ‘prior weights’ to be used in the fitting process. Should be `NULL` or a numeric vector.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **na.action**: a function which indicates what should happen when the data contain `NA`s. The default is set by the na.action setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`. Another possible value is `NULL`, no action. Value `na.exclude` can be useful.
- **start**: starting values for the parameters in the linear predictor.
- **etastart**: starting values for the linear predictor.
- **mustart**: starting values for the vector of means.
offset: this can be used to specify an \textit{a priori} known component to be included in the linear predictor during fitting. This should be \texttt{NULL} or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See \texttt{model.offset}.

control: a list of parameters for controlling the fitting process. For \texttt{glm.fit} this is passed to \texttt{glm.control}.

model: a logical value indicating whether \textit{model frame} should be included as a component of the returned value.

method: the method to be used in fitting the model. The default method \texttt{"glm.fit"} uses iteratively reweighted least squares (IWLS): the alternative \texttt{"model.frame"} returns the model frame and does no fitting. User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as \texttt{glm.fit}. If specified as a character string it is looked up from within the \texttt{stats} namespace.

\texttt{x, y}: For \texttt{glm}: logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.

For \texttt{glm.fit}: \texttt{x} is a design matrix of dimension \(n \times p\), and \texttt{y} is a vector of observations of length \(n\).

\texttt{singular.ok}: logical; if \texttt{FALSE} a singular fit is an error.

\texttt{contrasts}: an optional list. See the \texttt{contrasts.arg} of \texttt{model.matrix.default}.

\texttt{intercept}: logical. Should an intercept be included in the \textit{null} model?

\texttt{object}: an object inheriting from class \texttt{"glm"}.

\texttt{type}: character, partial matching allowed. Type of weights to extract from the fitted model object. Can be abbreviated.

...: For \texttt{glm}: arguments to be used to form the default \texttt{control} argument if it is not supplied directly.

For \texttt{weights}: further arguments passed to or from other methods.

**Details**

A typical predictor has the form \(\text{response} \sim \text{terms}\) where \text{response} is the (numeric) response vector and \text{terms} is a series of terms which specifies a linear predictor for \text{response}. For \texttt{binomial} and \texttt{quasibinomial} families the response can also be specified as a \texttt{factor} (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form \texttt{first + second} indicates all the terms in \texttt{first} together with all the terms in \texttt{second} with any duplicates removed.

A specification of the form \texttt{first:second} indicates the set of terms obtained by taking the interactions of all terms in \texttt{first} with all terms in \texttt{second}. The specification \texttt{first*second} indicates the \textit{cross} of \texttt{first} and \texttt{second}. This is the same as \texttt{first + second + first:second}.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a \texttt{terms} object as the formula.

Non-\texttt{NULL} weights can be used to indicate that different observations have different dispersions (with the values in \texttt{weights} being inversely proportional to the dispersions); or equivalently, when the elements of \texttt{weights} are positive integers \(w_i\), that each response \(y_i\) is the mean of \(w_i\) unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.
**glm**

*glm.fit* is the workhorse function: it is not normally called directly but can be more efficient where the response vector, design matrix and family have already been calculated.

If more than one of *etastart*, *start* and *mustart* is specified, the first in the list will be used. It is often advisable to supply starting values for a *quasi* family, and also for families with unusual links such as gaussian("log").

All of *weights*, *subset*, *offset*, *etastart* and *mustart* are evaluated in the same way as variables in *formula*, that is first in *data* and then in the environment of *formula*.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

**Value**

*glm* returns an object of class inheriting from "glm" which inherits from the class "lm". See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function *summary* (i.e., *summary.glm*) can be used to obtain or print a summary of the results and the function *anova* (i.e., *anova.glm*) to produce an analysis of variance table.

The generic accessor functions *coefficients*, *effects*, *fitted.values* and *residuals* can be used to extract various useful features of the value returned by *glm*.

*weights* extracts a vector of weights, one for each case in the fit (after subsetting and *na.action*). An object of class "glm" is a list containing at least the following components:

- **coefficients**: a named vector of coefficients
- **residuals**: the *working* residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their *working* residuals are *NA*.
- **fitted.values**: the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
- **rank**: the numeric rank of the fitted linear model.
- **family**: the *family* object used.
- **linear.predictors**: the linear fit on link scale.
- **deviance**: up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
- **aic**: A version of Akaike’s *An Information Criterion*, minus twice the maximized log-likelihood plus twice the number of parameters, computed via the *aic* component of the family. For binomial and Poison families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is *NA*.
- **null.deviance**: The deviance for the null model, comparable with *deviance*. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
- **iter**: the number of iterations of IWLS used.
- **weights**: the *working* weights, that is the weights in the final iteration of the IWLS fit.
prior.weights  the weights initially supplied, a vector of 1s if none were.
df.residual  the residual degrees of freedom.
df.null  the residual degrees of freedom for the null model.
y  if requested (the default) the y vector used. (It is a vector even for a binomial model.)
x  if requested, the model matrix.
model  if requested (the default), the model frame.
converged  logical. Was the IWLS algorithm judged to have converged?
boundary  logical. Is the fitted value on the boundary of the attainable values?
call  the matched call.
formula  the formula supplied.
terms  the terms object used.
data  the data argument.
offset  the offset vector used.
control  the value of the control argument used.
method  the name of the fitter function used (when provided as a character string to glm()) or the fitter function (when provided as that).
contrasts  (where relevant) the contrasts used.
xlevels  (where relevant) a record of the levels of the factors used in fitting.
na.action  (where relevant) information returned by model.frame on the special handling of NAs.

In addition, non-empty fits will have components qr, R and effects relating to the final weighted linear fit.

Objects of class "glm" are normally of class c("glm", "lm"), that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as residuals and weights do **not** just pick out the component of the fit with the same name.

If a **binomial** glm model was specified by giving a two-column response, the weights returned by prior.weights are the total numbers of cases (factored by the supplied case weights) and the component y of the result is the proportion of successes.

**Fitting functions**

The argument method serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function glm.fit to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If glm.fit is supplied as a character string it is used to search for a function of that name, starting in the stats namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by glm.

**Author(s)**

The original R implementation of glm was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team. The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

glm.control

Auxiliary for Controlling GLM Fitting

Description

Auxiliary function for glm fitting. Typically only used internally by glm.fit, but may be used to construct a control argument to either function.

Usage

glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)

Arguments

epsilon positive convergence tolerance ϵ; the iterations converge when \(|dev − dev_{old}|/(|dev| + 0.1) < ϵ.|$
maxit integer giving the maximal number of IWLS iterations.
trace logical indicating if output should be produced for each iteration.

Details

The control argument of glm is by default passed to the control argument of glm.fit, which uses its elements as arguments to glm.control: the latter provides defaults and sanity checking.

If epsilon is small (less than $10^{-10}$) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When trace is true, calls to cat produce the output for each IWLS iteration. Hence, options(digits = *) can be used to increase the precision, see the example.

Value

A list with components named as the arguments.

**glm.summaries**

### Accessing Generalized Linear Model Fits

#### Description

These functions are all **methods** for class **glm** or **summary.glm** objects.

#### Usage

```r
## S3 method for class 'glm'
family(object, ...)

## S3 method for class 'glm'
residuals(object, type = c("deviance", "pearson", "working",
                          "response", "partial"), ...)
```

#### Arguments

- **object**: an object of class **glm**, typically the result of a call to **glm**.
- **type**: the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial". Can be abbreviated.
- **...**: further arguments passed to or from other methods.

#### Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the **na.action** argument of that fit. If **na.action** = **na.omit** omitted cases will not appear in the residuals, whereas if **na.action** = **na.exclude** they will appear, with residual value NA. See also **naresid**.

For fits done with **y = FALSE** the response values are computed from other components.

influence.measures for deletion diagnostics, including standardized (rstandard) and studentized (rstudent) residuals.

hclust  

Hierarchical Clustering

Description

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

Usage

hclust(d, method = "complete", members = NULL)

## S3 method for class 'hclust'
plot(x, labels = NULL, hang = 0.1, check = TRUE,
    axes = TRUE, frame.plot = FALSE, ann = TRUE,
    main = "Cluster Dendrogram",
    sub = NULL, xlab = NULL, ylab = "Height", ...)

Arguments

d  
a dissimilarity structure as produced by dist.

method  
the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward.D", "ward.D2", "single", "complete", "average" (= UPGMA), "mcquitty" (= WPGMA), "median" (= WPGMC) or "centroid" (= UPGMC).

members  
NULL or a vector with length size of d. See the ‘Details’ section.

x  
an object of the type produced by hclust.

hang  
The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.

check  
logical indicating if the x object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of hclust(). The default is check=TRUE, as invalid inputs may crash R due to memory violation in the internal C plotting code.
hclust

labels A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If \text{labels} = \text{FALSE} no labels at all are plotted.

axes, frame.plot, ann logical flags as in \text{plot.default}.

main, sub, xlab, ylab character strings for \text{title}. Sub and xlab have a non-NULL default when there’s a \text{tree$call}.

... Further graphical arguments. E.g., cex controls the size of the labels (if plotted) in the same way as \text{text}.

Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the \( n \) objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called \text{inversions or reversals} which are hard to interpret, but note the trichotomies in Legendre and Legendre (2012).

Two different algorithms are found in the literature for Ward clustering. The one used by option "ward.D" (equivalent to the only Ward option "ward" in R versions \( \leq 3.0.3 \)) \text{does not implement} Ward’s (1963) clustering criterion, whereas option "ward.D2" implements that criterion (Murtagh and Legendre 2014). With the latter, the dissimilarities are \text{squared} before cluster updating. Note that \text{agnes(*) method="ward"} corresponds to \text{hclust(*, "ward.D2")}.

If \text{members} != \text{NULL}, then \text{d} is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and \text{members} gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without \text{hclust} itself) only for a limited number of distance/linkage combinations, the simplest one being \text{squared} Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for \( n \) observations there are \( n - 1 \) merges, there are \( 2^{(n-1)} \) possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in \text{hclust} is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class \text{hclust} which describes the tree produced by the clustering process. The object is a list with components:
merge

an \( n - 1 \) by 2 matrix. Row \( i \) of \( \text{merge} \) describes the merging of clusters at step \( i \) of the clustering. If an element \( j \) in the row is negative, then observation \( -j \) was merged at this stage. If \( j \) is positive then the merge was with the cluster formed at the (earlier) stage \( j \) of the algorithm. Thus negative entries in \( \text{merge} \) indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

height

a set of \( n - 1 \) real values (non-decreasing for ultrametric trees). The clustering \( \text{height} \): that is, the value of the criterion associated with the clustering method for the particular agglomeration.

order

a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix \( \text{merge} \) will not have crossings of the branches.

labels

labels for each of the objects being clustered.

call

the call which produced the result.

method

the cluster method that has been used.

dist.method

the distance that has been used to create \( d \) (only returned if the distance object has a "method" attribute).

There are \texttt{print}, \texttt{plot} and \texttt{identify} (see \texttt{identify.hclust}) methods and the \texttt{rect.hclust()} function for \texttt{hclust} objects.

\textbf{Note}

Method "centroid" is typically meant to be used with \textit{squared} Euclidean distances.

\textbf{Author(s)}

The \texttt{hclust} function is based on Fortran code contributed to \texttt{STATLIB} by F. Murtagh.

require(graphics)

### Example 1: Violent crime rates by US state
hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

## Do the same with centroid clustering and *squared* Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hc1 <- hclust(dist(cent)^2, method = "cen", members = table(memb))

### Example 2: Straight-line distances among 10 US cities
## Compare the results of algorithms "ward.D" and "ward.D2"

mds2 <- -cmdscale(UScitiesD)
plot(mds2, type="n", axes=FALSE, ann=FALSE)
text(mds2, labels=rownames(mds2), xpd = NA)

hcity.D <- hclust(UScitiesD, "ward.D") # "wrong"
hcity.D2 <- hclust(UScitiesD, "ward.D2")
opar <- par(mfrow = c(1, 2))
plot(hcity.D, hang=-1)
plot(hcity.D2, hang=-1)
par(opar)
```

### Description

A heat map is a false color image (basically `image(t(x))`) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.
Usage

heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL,
       distfun = dist, hclustfun = hclust,
       reorderfun = function(d, w) reorder(d, w),
       add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
       scale = c("row", "column", "none"), na.rm = TRUE,
       margins = c(5, 5), ColSideColors, RowSideColors,
       cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
       labRow = NULL, labCol = NULL, main = NULL,
       xlab = NULL, ylab = NULL,
       keep.dendro = FALSE, verbose = getOption("verbose"), ...)

Arguments

x  numeric matrix of the values to be plotted.
Rowv  determines if and how the row dendrogram should be computed and reordered. Either a dendrogram or a vector of values used to reorder the row dendrogram or NA to suppress any row dendrogram (and reordering) or by default, NULL, see 'Details' below.
Colv  determines if and how the column dendrogram should be reordered. Has the same options as the Rowv argument above and additionally when x is a square matrix, Colv = "Rowv" means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either).
distfun function used to compute the distance (dissimilarity) between both rows and columns. Defaults to dist.
hclustfun function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to hclust. Should take as argument a result of distfun and return an object to which as.dendrogram can be applied.
reorderfun function(d, w) of dendrogram and weights for reordering the row and column dendrograms. The default uses reorder.dendrogram.
add.expr expression that will be evaluated after the call to image. Can be used to add components to the plot.
symm logical indicating if x should be treated symmetrically; can only be true when x is a square matrix.
revC logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
scale character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.
na.rm logical indicating whether NA's should be removed.
margins numeric vector of length 2 containing the margins (see par(mar = *)) for column and row names, respectively.
ColSideColors (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.
RowSideColors (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.
heatmap

cexRow, cexCol  positive numbers, used as cex.axis in for the row or column axis labeling. The
defaults currently only use number of rows or columns, respectively.
labRow, labCol  character vectors with row and column labels to use; these default to
               rownames(x) or colnames(x), respectively.
main, xlab, ylab main, x- and y-axis titles; defaults to none.
keep.dendro    logical indicating if the dendrogram(s) should be kept as part of the result (when
               Rowv and/or Colv are not NA).
verbose        logical indicating if information should be printed.
...            additional arguments passed on to image, e.g., col specifying the colors.

Details

If either Rowv or Colv are dendrograms they are honored (and not reordered). Otherwise, dendro-
grams are computed as dd <- as.dendrogram(hclustfun(distfun(X))) where X is either x or
t(x).

If either is a vector (of ‘weights’) then the appropriate dendrogram is reordered according to the
supplied values subject to the constraints imposed by the dendrogram, by reorder(dd, Rowv), in
the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram
is by the mean value of the rows/columns, i.e., in the case of rows, Rowv <- rowMeans(x, na.rm =
na.rm). If either is NA, no reordering will be done for the corresponding side.

By default (scale = "row") the rows are scaled to have mean zero and standard deviation one.
There is some empirical evidence from genomic plotting that this is useful.

Value

Invisibly, a list with components

rowInd         row index permutation vector as returned by order.dendrogram.
colInd         column index permutation vector.
Rowv           the row dendrogram; only if input Rowv was not NA and keep.dendro is true.
Colv           the column dendrogram; only if input Colv was not NA and keep.dendro is true.

Note

Unless Rowv = NA (or Colv = NA), the original rows and columns are reordered in any case to
match the dendrogram, e.g., the rows by order.dendrogram(Rowv) where Rowv is the (possibly
reorder()ed) row dendrogram.

heatmap() uses layout and draws the image in the lower right corner of a 2x2 layout. Consequen-
tially, it can not be used in a multi column/row layout, i.e., when par(mfrow = *) or (mfcol = *)
has been called.

HoltWinters

Holt-Winters Filtering

Description

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

Usage

HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
seasonal = c("additive", "multiplicative"),
start.periods = 2, l.start = NULL, b.start = NULL,
s.start = NULL,
optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
optim.control = list())

Arguments

x An object of class ts
alpha alpha parameter of Holt-Winters Filter.
beta beta parameter of Holt-Winters Filter. If set to FALSE, the function will do
exponential smoothing.
gamma gamma parameter used for the seasonal component. If set to FALSE, an non-
seasonal model is fitted.
seasonal Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if gamma is non-zero).
start.periods Start periods used in the autodetection of start values. Must be at least 2.
l.start Start value for level (a[0]).
b.start Start value for trend (b[0]).
s.start Vector of start values for the seasonal component (s[1][0] ... s[p][0])
optim.start Vector with named components alpha, beta, and gamma containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case.
optim.control Optional list with additional control parameters passed to optim if this is used. Ignored in the one-parameter case.

Details

The additive Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t + h] = a[t] + hb[t] + s[t - p + 1 + (h - 1) \mod p], \]

where \(a[t], b[t]\) and \(s[t]\) are given by

\[ a[t] = \alpha(Y[t] - s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \]
\[ b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \]
\[ s[t] = \gamma(Y[t] - a[t]) + (1 - \gamma)s[t - p] \]

The multiplicative Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t + h] = (a[t] + hb[t]) \times s[t - p + 1 + (h - 1) \mod p]. \]

where \(a[t], b[t]\) and \(s[t]\) are given by

\[ a[t] = \alpha(Y[t]/s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \]
\[ b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \]
\[ s[t] = \gamma(Y[t]/a[t]) + (1 - \gamma)s[t - p] \]
The data in \( x \) are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of \( \alpha \) and/or \( \beta \) and/or \( \gamma \) by minimizing the squared one-step prediction error if they are NULL (the default). \texttt{optimize} will be used for the single-parameter case, and \texttt{optim} otherwise.

For seasonal models, start values for \( a \), \( b \) and \( s \) are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function \texttt{decompose}) on the \texttt{start.periods} first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for \( a \) and \( b \) are \( x[2] \) and \( x[2] - x[1] \), respectively. For level-only models (ordinary exponential smoothing), the start value for \( a \) is \( x[1] \).

### Value

An object of class “\texttt{HoltWinters}”, a list with components:

- \texttt{fitted}: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time \( t \) and not at the end of the series).
- \texttt{x}: The original series
- \texttt{alpha}: \( \alpha \) used for filtering
- \texttt{beta}: \( \beta \) used for filtering
- \texttt{gamma}: \( \gamma \) used for filtering
- \texttt{coefficients}: A vector with named components \( a, b, s1, \ldots, sp \) containing the estimated values for the level, trend and seasonal components
- \texttt{seasonal}: The specified seasonal parameter
- \texttt{SSE}: The final sum of squared errors achieved in optimizing
- \texttt{call}: The call used

Hypergeometric

The Hypergeometric Distribution

Description

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

Usage

```r
dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)
```

Arguments

- `x, q` vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
- `m` the number of white balls in the urn.
- `n` the number of black balls in the urn.
- `k` the number of balls drawn from the urn, hence must be in \(0, 1, \ldots, m + n\).
- `p` probability, it must be between 0 and 1.
- `nn` number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).
The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters $m, n$ and $k$ (named $Np$, $N - Np$, and $n$, respectively in the reference below, where $N := m + n$ is also used in other references) is given by

$$p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}$$

for $x = 0, \ldots, k$.

Note that $p(x)$ is non-zero only for $\max(0, k-n) \leq x \leq \min(k, m)$.

With $p := m/(m+n)$ (hence $Np = N \times p$ in the reference’s notation), the first two moments are mean

$$E[X] = \mu = kp$$

and variance

$$\text{Var}(X) = kp(1-p) \frac{m+n-k}{m+n-1},$$

which shows the closeness to the Binomial$(k, p)$ (where the hypergeometric has smaller variance unless $k = 1$).

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

In rhyper(), if one of $m, n, k$ exceeds .Machine$integer.max, currently the equivalent of qhyper(runif(nn), m,n,k) is used which is comparably slow while instead a binomial approximation may be considerably more efficient.

**Value**

dhyper gives the density, phyper gives the distribution function, qhyper gives the quantile function, and rhyper generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by $n$ for rhyper, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than $n$ are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Source**

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).

phyper is based on calculating dhyper and phyper(...)/dhyper(...) (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion (of an earlier phyper() algorithm).

rhyper is based on a corrected version of

**References**

identify.hclust

Description

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL, 

Arguments

x  
an object of the type produced by hclust.

FUN  
(optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).

N  
the maximum number of clusters to be identified.

MAXCLUSTER  
the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).

DEV.FUN  
(optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.

...  
further arguments to FUN.

Details

By default clusters can be identified using the mouse and an invisible list of indices of the respective data points is returned.

If FUN is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for FUN can be specified using DEV.FUN.

The identification process is terminated by pressing any mouse button other than the first, see also identify.

Distributions for other standard distributions.

Examples

m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k)))  # FALSE
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)
influence.measures

Regression Deletion Diagnostics

Description

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

Usage

influence.measures(model, infl = influence(model))

rstandard(model, ...)
## S3 method for class 'lm'
rstandard(model, infl = lm.influence(model, do.coef = FALSE),
  sd = sqrt(deviance(model)/df.residual(model)),
  type = c("sd.1", "predictive"), ...)
## S3 method for class 'glm'
rstandard(model, infl = influence(model, do.coef = FALSE),
  type = c("deviance", "pearson"), ...)
rstudent(model, ...)  
## S3 method for class 'lm'  
rstudent(model, infl = lm.influence(model, do.coef = FALSE),  
res = infl$wt.res, ...)  
## S3 method for class 'glm'  
rstudent(model, infl = influence(model, do.coef = FALSE), ...)  

dffits(model, infl = , res = )  

dfbeta(model, ...)  
## S3 method for class 'lm'  
dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)  

dfbetas(model, ...)  
## S3 method for class 'lm'  
dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)  

covratio(model, infl = lm.influence(model, do.coef = FALSE),  
res = weighted.residuals(model))  

cooks.distance(model, ...)  
## S3 method for class 'lm'  
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),  
res = weighted.residuals(model),  
sd = sqrt(deviance(model)/df.residual(model)),  
hat = infl$hat, ...)  
## S3 method for class 'glm'  
cooks.distance(model, infl = influence(model, do.coef = FALSE),  
res = infl$pear.res,  
dispersion = summary(model)$dispersion,  
hat = infl$hat, ...)  

hatvalues(model, ...)  
## S3 method for class 'lm'  
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)  

hat(x, intercept = TRUE)  

Arguments  
model an R object, typically returned by lm or glm.  
infl influence structure as returned by lm.influence or influence (the latter only for the glm method of rstudent and cooks.distance).  
res (possibly weighted) residuals, with proper default.  
sd standard deviation to use, see default.  
dispersion dispersion (for glm objects) to use, see default.  
hat hat values $H_{ii}$, see default.  
type type of residuals for rstandard, with different options and meanings for lm and glm. Can be abbreviated.  
x the X or design matrix.
influence.measures

intercept  should an intercept column be prepended to x?

...  further arguments passed to or from other methods.

Details

The primary high-level function is `influence.measures` which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook's distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Note that for multivariate `lm()` models (of class "mlm"), these functions return 3d arrays instead of matrices, or matrices instead of vectors.

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook's distances are scaled as $F$ rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional `infl`, `res` and `sd` arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence` or the generic `influence`) are already available.

Note that cases with `weights == 0` are dropped from all these functions, but that if a linear model has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded during fitting.

For linear models, `rstandard(*, type = "predictive")` provides leave-one-out cross validation residuals, and the “PRESS” statistic (PREdictive Sum of Squares, the same as the CV score) of model model is

$$\text{PRESS} \leftarrow \sum (rstandard(model, \text{type} = \text{"pred"})^2)$$

The function `hat()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

Note

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized linear models.

---

**integrate**

**Integration of One-Dimensional Functions**

**Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.

**Usage**

```r
integrate(f, lower, upper, ..., subdivisions = 100L,
rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```

**Arguments**

- **f**
  - an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
- **lower, upper**
  - the limits of integration. Can be infinite.
- **...**
  - additional arguments to be passed to f.
- **subdivisions**
  - the maximum number of subintervals.
- **rel.tol**
  - relative accuracy requested.
- **abs.tol**
  - absolute accuracy requested.
- **stop.on.error**
  - logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the message component.
- **keep.xy**
  - unused. For compatibility with S.
- **aux**
  - unused. For compatibility with S.

**Details**

Note that arguments after ... must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn's Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature.

rel.tol cannot be less than max(50*.Machine$double.eps, 0.5e-28) if abs.tol <= 0.

Note that the comments in the C source code in `<R>/src/appl/integrate.c` give more details, particularly about reasons for failure (internal error code ier >= 1).

In R versions ≤ 3.2.x, the first entries of lower and upper were used whereas an error is signalled now if they are not of length one.
Value

A list of class "integrate" with components

value the final estimate of the integral.
abs.error estimate of the modulus of the absolute error.
subdivisions the number of subintervals produced in the subdivision process.
message "OK" or a character string giving the error message.
call the matched call.

Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

f must accept a vector of inputs and produce a vector of function evaluations at those points. The Vectorize function may be helpful to convert f to this form.

Source

Based on QUADPACK routines dqags and dqagi by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

**interaction.plot**  
*Two-way Interaction Plot*

### Description

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

### Usage

```r
interaction.plot(x.factor, trace.factor, response, fun = mean,
                 type = c("l", "p", "b", "o", "c"), legend = TRUE,
                 trace.label = deparse1(substitute(trace.factor)),
                 fixed = FALSE,
                 xlab = deparse1(substitute(x.factor)), ylab = ylabel,
                 ylim = range(cells, na.rm = TRUE),
                 lty = nc:1, col = 1, pch = c(1:9, 0, letters),
                 xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
                 xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
                 ...) 
```

### Arguments

- **x.factor**: a factor whose levels will form the x axis.
- **trace.factor**: another factor whose levels will form the traces.
- **response**: a numeric variable giving the response.
- **fun**: the function to compute the summary. Should return a single real value.
- **type**: the type of plot (see `plot.default`): lines or points or both.
- **legend**: logical. Should a legend be included?
- **trace.label**: overall label for the legend.
- **fixed**: logical. Should the legend be in the order of the levels of `trace.factor` or in the order of the traces at their right-hand ends?
- **xlab, ylab**: the x and y label of the plot each with a sensible default.
- **ylim**: numeric of length 2 giving the y limits for the plot.
- **lty**: line type for the lines drawn, with sensible default.
interaction.plot

`col` the color to be used for plotting.

`pch` a vector of plotting symbols or characters, with sensible default.

`xpd` determines clipping behaviour for the `legend` used, see `par(xpd)`. Per default, the legend is *not* clipped at the figure border.

`leg.bg`, `leg.bty` arguments passed to `legend()`.

`xtick` logical. Should tick marks be used on the x axis?

`xaxt`, `axes`, ... graphics parameters to be passed to the plotting routines.

**Details**

By default the levels of `.factor` are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If `.factor` is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting). The graphics parameters `xlab`, `ylab`, `ylim`, `lty`, `col` and `pch` are given suitable defaults (and `xlim` and `xaxs` are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

**Note**

Some of the argument names and the precise behaviour are chosen for S-compatibility.

**References**

**Examples**

```r
require(graphics)

with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed = TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, leg.bty = "o")
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis = 0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos,
    levels = sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})
```
The Interquartile Range

**Description**
computes interquartile range of the x values.

**Usage**
IQR(x, na.rm = FALSE, type = 7)

**Arguments**
- x
  a numeric vector.
- na.rm
  logical. Should missing values be removed?
- type
  an integer selecting one of the many quantile algorithms, see quantile.

**Details**
Note that this function computes the quartiles using the quantile function rather than following Tukey’s recommendations, i.e., IQR(x) = quantile(x, 3/4) - quantile(x, 1/4).

For normally $N(m, 1)$ distributed $X$, the expected value of IQR($X$) is $2\times qnorm(3/4) = 1.3490$, i.e., for a normal-consistent estimate of the standard deviation, use IQR(x) / 1.349.

**Examples**
IQR(rivers)
is.empty.model

Test if a Model’s Formula is Empty

Description

R’s formula notation allows models with no intercept and no predictors. These require special handling internally. is.empty.model() checks whether an object describes an empty model.

Usage

is.empty.model(x)

Arguments

x

A terms object or an object with a terms method.

Value

TRUE if the model is empty

See Also

lm, glm

Examples

y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))

isoreg

Isotonic / Monotone Regression

Description

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

Usage

isoreg(x, y = NULL)

Arguments

x, y

coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see xy.coords.
Details

The algorithm determines the convex minorant \( m(x) \) of the cumulative data (i.e., \( \text{cumsum}(y) \)) which is piecewise linear and the result is \( m'(x) \), a step function with level changes at locations where the convex \( m(x) \) touches the cumulative data polygon and changes slope. \( \text{as.stepfun()} \) returns a \textit{stepfun} object which can be more parsimonious.

Value

\texttt{isoreg()} returns an object of class \texttt{isoreg} which is basically a list with components:

\begin{itemize}
  \item \texttt{x} original (constructed) abscissa values \( x \).
  \item \texttt{y} corresponding \( y \) values.
  \item \texttt{yf} fitted values corresponding to \textit{ordered} \( x \) values.
  \item \texttt{yc} cumulative \( y \) values corresponding to \textit{ordered} \( x \) values.
  \item \texttt{iKnots} integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.
  \item \texttt{isOrd} logical indicating if original \( x \) values were ordered increasingly already.
  \item \texttt{ord} \( \text{if(!isOrd)}: \) integer permutation \textit{order}(\( x \)) of \textit{original} \( x \).
  \item \texttt{call} the call to \texttt{isoreg()} used.
\end{itemize}

Note

The code should be improved to accept \textit{weights} additionally and solve the corresponding weighted least squares problem. ‘Patches are welcome!’

the plotting method \texttt{plot.isoreg} with more examples; \texttt{isoMDS()} from the \texttt{MASS} package internally uses isotonic regression.

Examples

\begin{verbatim}
require(graphics)
(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(fi3 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %g\n",
          1 - sum(residuals(ir4)^2) / ((10-1)*var(y4))))

## If you are interested in the knots alone :
\end{verbatim}
KalmanLike

## Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x., y))
stopifnot(all.equal(with(m, yf[iKnots]),
                     as.vector(tapply(y, x., mean))))

KalmanLike 
Kalman Filtering

Description

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

Usage

KalmanLike(y, mod, nit = 0L, update = FALSE)
KalmanRun(y, mod, nit = 0L, update = FALSE)
KalmanSmooth(y, mod, nit = 0L)
KalmanForecast(n.ahead = 10L, mod, update = FALSE)

makeARIMA(phi, theta, Delta, kappa = 1e6,
          SSinit = c("Gardner1980", "Rossignol2011"),
          tol = .Machine$double.eps)

Arguments

y
mod
nit
update
n.ahead
phi, theta
Delta
kappa
SSinit
tol

a univariate time series.
a list describing the state-space model: see ‘Details’.
the time at which the initialization is computed. nit = 0L implies that the initialization is for a one-step prediction, so Pn should not be computed at the first step.
if TRUE the update mod object will be returned as attribute "mod" of the result.
the number of steps ahead for which prediction is required.
numeric vectors of length ≥ 0 giving AR and MA parameters.
vector of differencing coefficients, so an ARMA model is fitted to y[t] - Delta[1]*y[t-1] - ....
the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
a string specifying the algorithm to compute the Pn part of the state-space initialization; see ‘Details’.
tolerance eventually passed to solve.default when SSinit = "Rossignol2011".
Details

These functions work with a general univariate state-space model with state vector ‘\(a\)’, transitions ‘\(a \leftarrow T a + R e\)’, \(e \sim \mathcal{N}(0, \kappa Q)\) and observation equation ‘\(y = Z a + \text{eta}\)’, \((\text{eta} \equiv \eta)\), \(\eta \sim \mathcal{N}(0, \kappa h)\).

The likelihood is a profile likelihood after estimation of \(\kappa\).

The model is specified as a list with at least components

- \(T\) the transition matrix
- \(Z\) the observation coefficients
- \(h\) the observation variance
- \(V \equiv \text{RQR}\)
- \(a\) the current state estimate
- \(P\) the current estimate of the state uncertainty matrix \(Q\)
- \(Pn\) the estimate at time \(t - 1\) of the state uncertainty matrix \(Q\) (not updated by KalmanForecast).

KalmanSmooth is the workhorse function for tsSmooth. makeARIMA constructs the state-space model for an ARIMA model, see also arima.

KalmanLike

For KalmanLike, a list with components Lik (the log-likelihood less some constants) and s2, the estimate of \(\kappa\).

For KalmanRun, a list with components values, a vector of length 2 giving the output of KalmanLike, resid (the residuals) and states, the contemporaneous state estimates, a matrix with one row for each observation time.

For KalmanSmooth, a list with two components. Component smooth is a \(n \times p\) matrix of state estimates based on all the observations, with one row for each time. Component var is a \(n \times p \times p\) array of variance matrices.

For KalmanForecast, a list with components pred, the predictions, and var, the unscaled variances of the prediction errors (to be multiplied by \(s2\)).

For makeARIMA, a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

Examples

```r
## an ARIMA fit
fit3 <- arima(presidents, c(3, 0, 0))
predict(fit3, 12)
## reconstruct this
pr <- KalmanForecast(12, fit3$model)
pr$pred + fit3$coef[4]
sqrt(pr$var * fit3$sigma2)
## and now do it year by year
mod <- fit3$model
for(y in 1:3) {
  pr <- KalmanForecast(4, mod, TRUE)
  print(list(pred = pr$pred + fit3$coef["intercept"],
            se = sqrt(pr$var * fit3$sigma2)))
  mod <- attr(pr, "mod")
}
```

kernapply

*Apply Smoothing Kernel*

Description

kernapply computes the convolution between an input sequence and a specific kernel.

Usage

```r
kernapply(x, ...)
```

## Default S3 method:
```r
t kernapply(x, k, circular = FALSE, ...)
```

## S3 method for class 'ts'
```r
t kernapply(x, k, circular = FALSE, ...)
```

## S3 method for class 'vector'
```r
t kernapply(x, k, circular = FALSE, ...)
```

## S3 method for class 'tskernel'
```r
t kernapply(x, k, ...)
```
Arguments

- \( x \): an input vector, matrix, time series or kernel to be smoothed.
- \( k \): smoothing "tskernel" object.
- `circular`: a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
- `...`: arguments passed to or from other methods.

Value

A smoothed version of the input sequence.

Note

This uses \texttt{fft} to perform the convolution, so is fastest when \( \text{NROW}(x) \) is a power of 2 or some other highly composite integer.

---

*kernel Smoothing Kernel Objects*

Description

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are \texttt{print}, \texttt{plot} and \texttt{[} methods for these kernel objects.

Usage

```
kernel(coef, m = 2, r, name)
df.kernel(k) bandwidth.kernel(k) is.tskernel(k)
```
Arguments

- **coef**: the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").
- **m**: the kernel dimension(s) if `coef` is a name. When `m` has length larger than one, it means the convolution of kernels of dimension `m[j]`, for `j` in `1:length(m)`. Currently this is supported only for the named "*daniell" kernels.
- **name**: the name the kernel will be called.
- **r**: the kernel order for a Fejer kernel.
- **k, x**: a "tskernel" object.
- **type, xlab, ylab, main, ...**: arguments passed to `plot.default`.

Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS).

The `[]` method allows natural indexing of kernel objects with indices in `(-m) : m`. The normalization is such that for `k <- kernel(*)`, `sum(k[ -k$m : k$m ])` is one.

`df.kernel` returns the ‘equivalent degrees of freedom’ of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and `bandwidth.kernel` returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

Value

`kernel()` returns an object of class "tskernel" which is basically a list with the two components `coef` and the kernel dimension `m`. An additional attribute is "name".

spectrum(sunspot.year, kernel = kernel("daniell", c(11,7,3)), log = "no")

---

### kmeans

#### K-Means Clustering

**Description**

Perform k-means clustering on a data matrix.

**Usage**

```r
kmeans(x, centers, iter.max = 10, nstart = 1,
  algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
    "MacQueen"), trace=FALSE)
```

**Arguments**

- `x`: numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
- `centers`: either the number of clusters, say \( k \), or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in \( x \) is chosen as the initial centres.
- `iter.max`: the maximum number of iterations allowed.
- `nstart`: if `centers` is a number, how many random sets should be chosen?
- `algorithm`: character: may be abbreviated. Note that "Lloyd" and "Forgy" are alternative names for one algorithm.
- `object`: an R object of class "kmeans", typically the result of `ob <- kmeans(...)`.  
- `method`: character: may be abbreviated. "centers" causes fitted to return cluster centers (one for each input point) and "classes" causes fitted to return a vector of class assignments.
- `trace`: logical or integer number, currently only used in the default method ("Hartigan-Wong"): if positive (or true), tracing information on the progress of the algorithm is produced. Higher values may produce more tracing information.

---

... not used.
**Details**

The data given by $x$ are clustered by the $k$-means method, which aims to partition the points into $k$ groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use $k$-means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts ($nstart > 1$) is often recommended. In rare cases, when some of the points (rows of $x$) are extremely close, the algorithm may not converge in the “Quick-Transfer” stage, signalling a warning (and returning `ifault = 4`). Slight rounding of the data may be advisable in that case.

For ease of programmatic exploration, $k = 1$ is allowed, notably returning the center and `withinss`.

Except for the Lloyd–Forgy method, $k$ clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

**Value**

kmeans returns an object of class "kmeans" which has a print and a fitted method. It is a list with at least the following components:

- `cluster` A vector of integers (from 1:k) indicating the cluster to which each point is allocated.
- `centers` A matrix of cluster centres.
- `totss` The total sum of squares.
- `withinss` Vector of within-cluster sum of squares, one component per cluster.
- `tot.withinss` Total within-cluster sum of squares, i.e. sum(withinss).
- `betweenss` The between-cluster sum of squares, i.e. totss-tot.withinss.
- `size` The number of points in each cluster.
- `iter` The number of (outer) iterations.

colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex = 2)

# sum of squares
ss <- function(x) sum(scale(x, scale = FALSE)*2)

## cluster centers "fitted" to each obs.:
fitted.x <- fitted(cl); head(fitted.x)
resid.x <- x - fitted(cl)

## Equalities : ----------------------------------
cbind(cl[c("betweens", "tot.withinss", "totss")], # the same two columns
c(ss(fitted.x), ss(resid.x), ss(x)))
stopifnot(all.equal(cl$totss, ss(x)),
          all.equal(cl$tot.withinss, ss(resid.x)),
          these three are the same:
          all.equal(cl$betweens, ss(fitted.x)),
          all.equal(cl$betweens, cl$totss - cl$tot.withinss),
          # and hence also
          all.equal(ss(x), ss(fitted.x) + ss(resid.x))
)

kmeans(x, 1)$withinss # trivial one-cluster, (its W.SS == ss(x))

## random starts do help here with too many clusters
## (and are often recommended anyway!):
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)

kruskal.test

Kruskal-Wallis Rank Sum Test

Description

Performs a Kruskal-Wallis rank sum test.

Usage

kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...)

## S3 method for class 'formula'
kruskal.test(formula, data, subset, na.action, ...)
kruskal.test

Arguments

- **x**: a numeric vector of data values, or a list of numeric data vectors. Non-numeric elements of a list will be coerced, with a warning.
- **g**: a vector or factor object giving the group for the corresponding elements of x. Ignored with a warning if x is a list.
- **formula**: a formula of the form response ~ group where response gives the data values and group a vector or factor of the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
- ...: further arguments to be passed to or from methods.

Details

kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of x are the same in each group (sample). The alternative is that they differ in at least one.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use kruskal.test(x) to perform the test. If the samples are not yet contained in a list, use kruskal.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list with class "htest" containing the following components:

- **statistic**: the Kruskal-Wallis rank sum statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Kruskal–Wallis rank sum test".
- **data.name**: a character string giving the names of the data.

require(graphics)
boxplot(Ozone ~ Month, data = airquality)
ks.test(Ozone ~ Month, data = airquality)

ks.test

Kolmogorov-Smirnov Tests

Description

Perform a one- or two-sample Kolmogorov-Smirnov test.

Usage

ks.test(x, y, ..., alternative = c("two.sided", "less", "greater"),
        exact = NULL)

Arguments

x

a numeric vector of data values.

y

either a numeric vector of data values, or a character string naming a cumulative
distribution function or an actual cumulative distribution function such as pnorm. Only continuous CDFs are valid.

... parameters of the distribution specified (as a character string) by y.

alternative indicates the alternative hypothesis and must be one of "two.sided" (default), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be given in full. See 'Details' for the meanings of the possible values.

exact NULL or a logical indicating whether an exact p-value should be computed. See 'Details' for the meaning of NULL. Not available in the two-sample case for a one-sided test or if ties are present.
Details

If y is numeric, a two-sample test of the null hypothesis that x and y were drawn from the same continuous distribution is performed.

Alternatively, y can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample test is carried out of the null that the distribution function which generated x is distribution y with parameters specified by . . . .

The presence of ties always generates a warning, since continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from x and (in the two-sample case) y.

The possible values "two.sided", "less" and "greater" of alternative specify the null hypothesis that the true distribution function of x is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of y (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being $D^+ = \max_u [F_X(u) - F_Y(u)]$. Thus in the two-sample case alternative = "greater" includes distributions for which x is stochastically smaller than y (the CDF of x lies above and hence to the left of that for y), in contrast to t.test or wilcox.test.

Exact p-values are not available for the two-sample case if one-sided or in the presence of ties. If exact = NULL (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case and there are no ties, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a single-sample test is used, the parameters specified in . . . must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in ks.test.

Value

A list with class "htest" containing the following components:

- statistic the value of the test statistic.
- p.value the p-value of the test.
- alternative a character string describing the alternative hypothesis.
- method a character string indicating what type of test was performed.
- data.name a character string giving the name(s) of the data.

---

**ksmooth**

*Kernel Regression Smoother*

**Description**

The Nadaraya–Watson kernel regression estimate.

**Usage**

```r
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
        range.x = range(x),
        n.points = max(100L, length(x)), x.points)
```

**Arguments**

- `x`: input x values. Long vectors are supported.
- `y`: input y values. Long vectors are supported.
- `kernel`: the kernel to be used. Can be abbreviated.
- `bandwidth`: the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at ±0.25*bandwidth.
range.x  the range of points to be covered in the output.
n.points  the number of points at which to evaluate the fit.
x.points  points at which to evaluate the smoothed fit. If missing, n.points are chosen uniformly to cover range.x. Long vectors are supported.

Value
A list with components

x  values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
y  fitted values corresponding to x.

Note
This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as KernSmooth.

Examples
require(graphics)
with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})

lag  Lag a Time Series

Description
Compute a lagged version of a time series, shifting the time base back by a given number of observations.

lag is a generic function; this page documents its default method.

Usage
lag(x, ...)

## Default S3 method:
lag(x, k = 1, ...)

Arguments

x  A vector or matrix or univariate or multivariate time series
k  The number of lags (in units of observations).
...  further arguments to be passed to or from methods.
**Description**
Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

**Usage**
```r
call = function(x, lags = 1, layout = NULL, set.lags = 1:lags, 
    main = NULL, asp = 1, 
    diag = TRUE, diag.col = "gray", type = "p", oma = NULL, 
    ask = NULL, do.lines = (n <= 150), labels = do.lines, 
    ...)```

**Arguments**
- **x**: time-series (univariate or multivariate)
- **lags**: number of lag plots desired, see arg `set.lags`.
- **layout**: the layout of multiple plots, basically the `mfrow par()` argument. The default uses about a square layout (see `n2mfrow`) such that all plots are on one page.
- **set.lags**: vector of positive integers allowing specification of the set of lags used; defaults to `1:lags`.
- **main**: character with a main header title to be done on the top of each page.
- **asp**: Aspect ratio to be fixed, see `plot.default`.
lag.plot

- **diag**: logical indicating if the x=y diagonal should be drawn.
- **diag.col**: color to be used for the diagonal if(diag).
- **type**: plot type to be used, but see `plot.ts` about its restricted meaning.
- **oma**: outer margins, see `par`.
- **ask**: logical or `NULL`; if true, the user is asked to confirm before a new page is started.
- **do.lines**: logical indicating if lines should be drawn.
- **labels**: logical indicating if labels should be used.
- **...**: Further arguments to `plot.ts`. Several graphical parameters are set in this function and so cannot be changed: these include `xlab`, `ylab`, `mgp`, `col.lab` and `font.lab`: this also applies to the arguments `xy.labels` and `xy.lines`.

**Details**

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, `par(mfrow)` and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If `ask = NULL`, `par(ask = TRUE)` will be called if more than one page of plots is to be produced and the device is interactive.

**Note**

It is more flexible and has different default behaviour than the S version. We use `main` = instead of `head` = for internal consistency.

**Author(s)**

Martin Maechler

**See Also**

- `plot.ts` which is the basic work horse.

**Examples**

```r
require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
         main = "New Haven Temperatures", col.main = "blue")

## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)

## no lines for long series :
lag.plot(sqrt(sunspots), set.lags = c(1:4, 9:12), pch = ".", col = "gold")
```
Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Currently by default (iter = 1) the initial median-median line is not iterated (as opposed to Tukey’s “resistant line” in the references).

Usage

```r
line(x, y, iter = 1)
```

Arguments

- `x, y` the arguments can be any way of specifying x-y pairs. See `xy.coords`.
- `iter` positive integer specifying the number of “polishing” iterations. Note that this was hard coded to 1 in R versions before 3.5.0, and more importantly that such simple iterations may not converge, see Siegel’s 9-point example.

Details

Cases with missing values are omitted.

Contrary to the references where the data is split in three (almost) equally sized groups with symmetric sizes depending on n and n % 3 and computes medians inside each group, the `line()` code splits into three groups using all observations with `x[.] <= q1` and `x[.] >= q2`, where q1, q2 are (a kind of) quantiles for probabilities `p = 1/3` and `p = 2/3` of the form `(x[j1]+x[j2])/2` where `j1 = floor(p*(n-1))` and `j2 = ceiling(p*(n-1)), n = length(x)`.

Long vectors are not supported yet.

Value

An object of class “tukeyline”.

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

References

lm.

There are alternatives for robust linear regression more robust and more (statistically) efficient, see rlm() from MASS, or lmrob() from robustbase.

Examples

```r
require(graphics)

plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))

## Andrew Siegel's pathological 9-point data, y-values multiplied by 3:
d.AS <- data.frame(x = c(-4:3, 12), y = 3*c(rep(0,6), -5, 5, 1))
cAS <- with(d.AS, t(sapply(1:10,
  function(it) line(x,y, iter=it)$coefficients)))
dimnames(cAS) <- list(paste("it =", format(1:10)), c("intercept", "slope"))
cAS
## iterations started to oscillate, repeating iteration 7,8 indefinitely
```

listof

A Class for Lists of (Parts of) Model Fits

Description

Class "listof" is used by aov and the "lm" method of alias for lists of model fits or parts thereof. It is simply a list with an assigned class to control the way methods, especially printing, act on it.

It has a coef method in this package (which returns an object of this class), and [ and print methods in package base.

lm

Fitting Linear Models

Description

lm is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although aov may provide a more convenient interface for these).

Usage

```r
lm(formula, data, subset, weights, na.action, 
  method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE, 
  singular.ok = TRUE, contrasts = NULL, offset, ...)
```
Arguments

**formula** an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.

**data** an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `lm` is called.

**subset** an optional vector specifying a subset of observations to be used in the fitting process.

**weights** an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights weights (that is, minimizing sum(w*e^2)); otherwise ordinary least squares is used. See also ‘Details’.

**na.action** a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ’factory-fresh’ default is `na.omit`. Another possible value is NULL, no action. Value `na.exclude` can be useful.

**method** the method to be used; for fitting, currently only `method = "qr"` is supported; `method = "model.frame"` returns the model frame (the same as with `model = TRUE`, see below).

**model, x, y, qr** logicals. If `TRUE` the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.

**singular.ok** logical. If `FALSE` (the default in S but not in R) a singular fit is an error.

**contrasts** an optional list. See the `contrasts.arg` of `model.matrix.default`.

**offset** this can be used to specify an *a priori* known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector or matrix of extents matching those of the response. One or more offset terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See `model.offset`.

**...** additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for `lm` are specified symbolically. A typical model has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with duplicates removed. A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the cross of `first` and `second`. This is the same as `first + second + first:second`.

If the formula includes an `offset`, this is evaluated and subtracted from the response.

If `response` is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See `model.matrix` for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula (see `aov` and `demo(glm.vr)` for an example).
A formula has an implied intercept term. To remove this use either \( y \sim x - 1 \) or \( y \sim 0 + x \). See \texttt{formula} for more details of allowed formulae.

Non-NULL \texttt{weights} can be used to indicate that different observations have different variances (with the values in \texttt{weights} being inversely proportional to the variances); or equivalently, when the elements of \texttt{weights} are positive integers \( w_i \), that each response \( y_i \) is the mean of \( w_i \) unit-weight observations (including the case that there are \( w_i \) observations equal to \( y_i \) and the data have been summarized). However, in the latter case, notice that within-group variation is not used. Therefore, the sigma estimate and residual degrees of freedom may be suboptimal; in the case of replication weights, even wrong. Hence, standard errors and analysis of variance tables should be treated with care.

\texttt{lm} calls the lower level functions \texttt{lm.fit}, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of \texttt{weights}, \texttt{subset} and \texttt{offset} are evaluated in the same way as variables in \texttt{formula}, that is first in \texttt{data} and then in the environment of \texttt{formula}.

\section*{Value}

\texttt{lm} returns an object of \texttt{class} "\texttt{lm}" or for multiple responses of class \texttt{c("mlm", "lm")}.

The functions \texttt{summary} and \texttt{anova} are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions \texttt{coefficients}, \texttt{effects}, \texttt{fitted.values} and \texttt{residuals} extract various useful features of the value returned by \texttt{lm}.

An object of class "\texttt{lm}" is a list containing at least the following components:

\begin{itemize}
  \item \texttt{coefficients} a named vector of coefficients
  \item \texttt{residuals} the residuals, that is response minus fitted values.
  \item \texttt{fitted.values} the fitted mean values.
  \item \texttt{rank} the numeric rank of the fitted linear model.
  \item \texttt{weights} (only for weighted fits) the specified weights.
  \item \texttt{df.residual} the residual degrees of freedom.
  \item \texttt{call} the matched call.
  \item \texttt{terms} the \texttt{terms} object used.
  \item \texttt{contrasts} (only where relevant) the contrasts used.
  \item \texttt{xlevels} (only where relevant) a record of the levels of the factors used in fitting.
  \item \texttt{offset} the offset used (missing if none were used).
  \item \texttt{y} if requested, the response used.
  \item \texttt{x} if requested, the model matrix used.
  \item \texttt{model} if requested (the default), the model frame used.
  \item \texttt{na.action} (where relevant) information returned by \texttt{model.frame} on the special handling of NAs.
\end{itemize}

In addition, non-null fits will have components \texttt{assign}, \texttt{effects} and (unless not requested) \texttt{qr} relating to the linear fit, for use by extractor functions such as \texttt{summary} and \texttt{effects}. 

Using time series

Considerable care is needed when using lm with time series.

Unless na.action = NULL, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by ts.intersect(..., dframe = TRUE), then apply a suitable na.action to that data frame and call lm with na.action = NULL so that residuals and fitted values are time series.

Note

Offsets specified by offset will not be included in predictions by predict.lm, whereas those specified by an offset term in the formula will be.

Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

**lm.fit**

*Fitter Functions for Linear Models*

**Description**

These are the basic computing engines called by `lm` used to fit linear models. These should usually *not* be used directly unless by experienced users. `.lm.fit()` is bare bone wrapper to the innermost QR-based C code, on which `glm.fit` and `lsfit` are based as well, for even more experienced users.

**Usage**

```r
lm.fit (x, y, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

```r
lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

```r
.lm.fit(x, y, tol = 1e-7)
```

**Arguments**

- **x**: design matrix of dimension n * p.
- **y**: vector of observations of length n, or a matrix with n rows.
- **w**: vector of weights (length n) to be used in the fitting process for the `wfit` functions. Weighted least squares is used with weights w, i.e., \( \sum(w \cdot e^2) \) is minimized.
- **offset**: (numeric of length n). This can be used to specify an *a priori* known component to be included in the linear predictor during fitting.
- **method**: currently, only method = "qr" is supported.
- **tol**: tolerance for the `qr` decomposition. Default is 1e-7.
- **singular.ok**: logical. If FALSE, a singular model is an error.
- **...**: currently disregarded.

**Value**

A *list* with components (for `lm.fit` and `lm.wfit`)

- **coefficients**: p vector
- **residuals**: n vector or matrix
fitted.values  n vector or matrix

effects  n vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.

weights  n vector — only for the *wfit* functions.

rank  integer, giving the rank

df.residual  degrees of freedom of residuals

qr  the QR decomposition, see qr.

Fits without any columns or non-zero weights do not have the effects and qr components.

.lm.fit() returns a subset of the above, the qr part unwrapped, plus a logical component pivoted indicating if the underlying QR algorithm did pivot.

See Also

lm which you should use for linear least squares regression, unless you know better.

Examples

require(utils)

set.seed(129)

n <- 7 ; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x = X, y = y, w = w))

str(lm. <- lm.fit (x = X, y = y))

if(require("microbenchmark")) {
  mb <- microbenchmark(lm(y~X), lm.fit(X,y), .lm.fit(X,y))
  print(mb)
  boxplot(mb, notch=TRUE)
}

lm.influence  Regression Diagnostics

Description

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.
Usage

influence(model, ...)  
## S3 method for class 'lm'
influence(model, do.coef = TRUE, ...)
influence(model, do.coef = TRUE, ...)

## S3 method for class 'glm'
influence(model, do.coef = TRUE, ...)

lm.influence(model, do.coef = TRUE)

Arguments

model an object as returned by \texttt{lm} or \texttt{glm}.
do.coef logical indicating if the changed coefficients (see below) are desired. These need \(O(n^2p)\) computing time.

... further arguments passed to or from other methods.

Details

The \texttt{influence.measures()} and other functions listed in \texttt{See Also} provide a more user oriented way of computing a variety of regression diagnostics. These all build on \texttt{lm.influence}. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in \texttt{sigma} and \texttt{coefficients} are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.) \texttt{naresid} is applied to the results and so will fill in with NAs if the fit had \texttt{na.action = na.exclude}.

Value

A list containing the following components of the same length or number of rows \(n\), which is the number of non-zero weights. Cases omitted in the fit are omitted unless a \texttt{na.action} method was used (such as \texttt{na.exclude}) which restores them.

hat a vector containing the diagonal of the ‘hat’ matrix.
coefficients (unless \texttt{do.coef} is false) a matrix whose \(i\)-th row contains the change in the estimated coefficients which results when the \(i\)-th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.
sigma a vector whose \(i\)-th element contains the estimate of the residual standard deviation obtained when the \(i\)-th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)
wt.res a vector of weighted (or for class \texttt{glm} rather deviance) residuals.

Note

The coefficients returned by the \texttt{R} version of \texttt{lm.influence} differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need \(O(np^2)\) computing time, they can be omitted by \texttt{do.coef = FALSE}. (Prior to \texttt{R 4.0.0}, this was much worse, using an \(O(n^2p)\) algorithm.)

Note that cases with weights == 0 are dropped (contrary to the situation in S).

If a model has been fitted with \texttt{na.action = na.exclude} (see \texttt{na.exclude}), cases excluded in the fit are considered here.
References

See the list in the documentation for `influence.measures`.

See Also

`summary.lm` for `summary` and related methods;  
`influence.measures`,  
`hat` for the hat matrix diagonals,  
`dfbetas`, `dffits`, `covratio`, `cooks.distance`, `lm`.

Examples

```r
## Analysis of the life-cycle savings data  
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,  
data = LifeCycleSavings),  
correlation = TRUE)
utils::str(lmI <- lm.influence(lm.SR))
## For more "user level" examples, use example(influence.measures)
```

Description

All these functions are methods for class "lm" objects.

Usage

```r
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object,  
type = c("working", "response", "deviance", "pearson",  
"partial"),  
...)

## S3 method for class 'lm'
labels(object, ...)
```

Arguments

- `object, x` an object inheriting from class `lm`, usually the result of a call to `lm` or `aov`.
- `...` further arguments passed to or from other methods.
- `type` the type of residuals which should be returned. Can be abbreviated.
Details

The generic accessor functions coef, effects, fitted and residuals can be used to extract various useful features of the value returned by lm.

The working and response residuals are ‘observed - fitted’. The deviance and pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized rstudent residuals, and the weighted.residuals).

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

The “lm” method for generic labels returns the term labels for estimable terms, that is the names of the terms with an least one estimable coefficient.

qqnorm(residuals(lm.D90))
```

loadings

Print Loadings in Factor Analysis

Description

Extract or print loadings in factor analysis (or principal components analysis).
Usage

loadings(x, ...)

## S3 method for class 'loadings'
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)

## S3 method for class 'factanal'
print(x, digits = 3, ...)

Arguments

x an object of class "factanal" or "princomp" or the loadings component of such an object.
digits number of decimal places to use in printing uniquenesses and loadings.
cutoff loadings smaller than this (in absolute value) are suppressed.
sort logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.

... further arguments for other methods, ignored for loadings.

Details

'Loadings' is a term from factor analysis, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by princomp in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The print method for class "factanal" calls the "loadings" method to print the loadings, and so passes down arguments such as cutoff and sort.

The signs of the loadings vectors are arbitrary for both factor analysis and PCA.

Note

There are other functions called loadings in contributed packages which are S3 or S4 generic: the ... argument is to make it easier for this one to become a default method.

factanal, princomp

loessLocal Polynomial Regression Fitting

Description

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.
Usage

loess(formula, data, weights, subset, na.action, model = FALSE,
      span = 0.75, enp.target, degree = 2,
      parametric = FALSE, drop.square = FALSE, normalize = TRUE,
      family = c("gaussian", "symmetric"),
      method = c("loess", "model.frame"),
      control = loess.control(...), ...)

Arguments

formula  a formula specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.
data an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which loess is called.
weights optional weights for each case.
subset an optional specification of a subset of the data to be used.
na.action the action to be taken with missing values in the response or predictors. The default is given by getOption("na.action").
model should the model frame be returned?
span the parameter $\alpha$ which controls the degree of smoothing.
enp.target an alternative way to specify span, as the approximate equivalent number of parameters to be used.
degree the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the ‘Note’.)
parametric should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.
drop.square for fits with more than one predictor and degree = 2, should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for parametric.
normalize should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others known to be on a common scale.
family if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey’s biweight function. Can be abbreviated.
method fit the model or just extract the model frame. Can be abbreviated.
control control parameters: see loess.control.
... control parameters can also be supplied directly (if control is not specified).

Details

Fitting is done locally. That is, for the fit at point $x$, the fit is made using points in a neighbourhood of $x$, weighted by their distance from $x$ (with differences in ‘parametric’ variables being ignored when computing the distance). The size of the neighbourhood is controlled by $\alpha$ (set by span or
enp.target). For $\alpha < 1$, the neighbourhood includes proportion $\alpha$ of the points, and these have tricubic weighting (proportional to $(1 - (\text{dist}/\text{maxdist})^3)^3$). For $\alpha > 1$, all points are used, with the ‘maximum distance’ assumed to be $\alpha^{2/p}$ times the actual maximum distance for $p$ explanatory variables.

For the default family, fitting is by (weighted) least squares. For family="symmetric" a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See loess.control for details.

**Value**

An object of class "loess".

**Note**

As this is based on c1oess, it is similar to but not identical to the loess function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of loess is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

degree = 0, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

**Author(s)**

B. D. Ripley, based on the c1oess package of Cleveland, Grosse and Shyu.

**Source**

The 1998 version of c1oess package of Cleveland, Grosse and Shyu. A later version is available as dloess at https://www.netlib.org/a/.

**References**

**See Also**

loess.control, predict.loess.

lowess, the ancestor of loess (with different defaults!).

**Examples**

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE) # to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars, control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
Description

Set control parameters for loess fits.

Usage

loess.control(surface = c("interpolate", "direct"),
              statistics = c("approximate", "exact", "none"),
              trace.hat = c("exact", "approximate"),
              cell = 0.2, iterations = 4, iterTrace = FALSE, ...)

Arguments

surface  should the fitted surface be computed exactly ("direct") or via interpolation from a kd tree? Can be abbreviated.
statistics should the statistics be computed exactly, approximately or not at all? Exact computation can be very slow. Can be abbreviated.
trace.hat Only for the (default) case (surface = "interpolate", statistics = "approximate"): should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points. Can be abbreviated.
cell if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than floor(n*span*cell) points are subdivided.
iterations the number of iterations used in robust fitting, i.e. only if family is "symmetric".
iterTrace logical (or integer) determining if tracing information during the robust iterations (iterations ≥ 2) is produced.
... further arguments which are ignored.

Value

A list with components

surface
statistics
trace.hat
cell
iterations
iterTrace

with meanings as explained under ‘Arguments’.

loess
The Logistic Distribution

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.
The Logistic distribution with location = $\mu$ and scale = $\sigma$ has distribution function

$$F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}$$

and density

$$f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}$$

It is a long-tailed distribution with mean $\mu$ and variance $\pi^2/3\sigma^2$.

Value

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.
The length of the result is determined by n for rlogis, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.
**Note**

qlogis(p) is the same as the well known ‘logit’ function, \( \logit(p) = \log \frac{p}{1-p} \), and plogis(x) has consequently been called the ‘inverse logit’.

The distribution function is a rescaled hyperbolic tangent, \( p\logis(x) = \frac{1 + \tanh(x/2)}{2} \), and it is called a sigmoid function in contexts such as neural networks.

**Source**

[dpq]logis are calculated directly from the definitions.

rlogis uses inversion.

**References**

**See Also**

Distributions for other standard distributions.

**Examples**

```r
var(rlogis(4000, 0, scale = 5)) # approximately (+/- 3)
pi^2/3 * 5^2
```

---

**logLik**

**Extract Log-Likelihood**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS, "multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.

**Usage**

```r
logLik(object, ...)  
```

### S3 method for class 'lm'

```r
logLik(object, REML = FALSE, ...)  
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.</td>
</tr>
<tr>
<td>...</td>
<td>some methods for this generic function require additional arguments.</td>
</tr>
<tr>
<td>REML</td>
<td>an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.</td>
</tr>
</tbody>
</table>
Details

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by AIC, assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on using the family’s aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

Value

Returns an object of class logLik. This is a number with at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if REML = TRUE).

fm1 <- lm(distance ~ Sex * age, Orthodont)
```
loglin

logLik(fm1)
logLik(fm1, REML = TRUE)

---

loglin  
*Fitting Log-Linear Models*

**Description**

`loglin` is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

**Usage**

```r
loglin(table, margin, start = rep(1, length(table)), fit = FALSE,
eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```

**Arguments**

- `table`: a contingency table to be fit, typically the output from `table`.
- `margin`: a list of vectors with the marginal totals to be fit. (Hierarchical) log-linear models can be specified in terms of these marginal totals which give the ‘maximal’ factor subsets contained in the model. For example, in a three-factor model, `list(c(1, 2), c(1, 3))` specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as ‘[12][13]’). The names of factors (i.e., `names(dimnames(table))`) may be used rather than numeric indices.
- `start`: a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in `table` which should be preserved in the fit. In this case, the corresponding entries in `start` should be zero and the others can be taken as one.
- `fit`: a logical indicating whether the fitted values should be returned.
- `eps`: maximum deviation allowed between observed and fitted margins.
- `iter`: maximum number of iterations.
- `param`: a logical indicating whether the parameter values should be returned.
- `print`: a logical. If TRUE, the number of iterations and the final deviation are printed.

**Details**

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.
Note that the IPF steps are applied to the factors in the order given in margin. Hence if the model is decomposable and the order given in margin is a running intersection property ordering then IPF will converge in one iteration.

Package MASS contains loglm, a front-end to loglin which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as lm or glm.

**Value**

A list with the following components.

- **lrt**  the Likelihood Ratio Test statistic.
- **pearson**  the Pearson test statistic (X-squared).
- **df**  the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
- **margin**  list of the margins that were fit. Basically the same as the input margin, but with numbers replaced by names where possible.
- **fit**  An array like table containing the fitted values. Only returned if fit is TRUE.
- **param**  A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if param is TRUE.

**Author(s)**

Kurt Hornik

**References**

**See Also**

- loglm in package MASS for a user-friendly wrapper.
- glm for another way to fit log-linear models.

**Examples**

```r
## Model of joint independence of sex from hair and eye color.
fm <- loglin(HairEyeColor, list(c(1, 2), c(1, 3), c(2, 3)))
fm
1 - pchisq(fm$lrt, fm$df)
## Model with no three-factor interactions fits well.
```
Lognormal

The Log Normal Distribution

Description

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to meanlog and standard deviation equal to sdlog.

Usage

dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
meanlog, sdlog mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The log normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x) - \mu)^2/2\sigma^2}$$

where $\mu$ and $\sigma$ are the mean and standard deviation of the logarithm. The mean is $E(X) = exp(\mu + 1/2\sigma^2)$, the median is $med(X) = exp(\mu)$, and the variance $Var(X) = exp(2\mu + \sigma^2)(exp(\sigma^2) - 1)$ and hence the coefficient of variation is $\sqrt{exp(\sigma^2) - 1}$ which is approximately $\sigma$ when that is small (e.g., $\sigma < 1/2$).

Value

dlnorm gives the density, plnorm gives the distribution function, qlnorm gives the quantile function, and rlnorm generates random deviates.

The length of the result is determined by n for rlnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is -plnorm(t, r, lower = FALSE, log = TRUE).
Source

`dlnorm` is calculated from the definition (in ‘Details’). `[pqr]lnorm` are based on the relationship to the normal.

Consequently, they model a single point mass at \( \exp(\text{meanLog}) \) for the boundary case \( \text{sdLog} = 0 \).

References

See Also

*Distributions* for other standard distributions, including `dnorm` for the normal distribution.

Examples

```r
dlnorm(1) == dnorm(0)
```

Description

This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

Usage

```r
lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))
```

Arguments

- `x, y` vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see `xy.coords`.
- `f` the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.
- `iter` the number of ‘robustifying’ iterations which should be performed. Using smaller values of `iter` will make lowess run faster.
- `delta` See ‘Details’. Defaults to 1/100th of the range of `x`. 
Details

lowess is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file `src/library/stats/src/lowess.doc`. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the $\text{floor}(f \times n)$th nearest neighbour, and tricubic weighting is used for $x$ which fall within the neighbourhood.

The initial fit is done using weighted least squares. If $\text{iter} > 0$, further weighted fits are done using the product of the weights from the proximity of the $x$ values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff $6$ times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within delta of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

Value

lowess returns a list containing components $x$ and $y$ which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function lines: see the examples.

References

See Also

lowess, a newer formula based version of lowess (with different defaults!).

Examples

```r
require(graphics)

plot(cars, main = "lowess(cars)"
lines(lowess(cars), col = 2)
lines(lowess(cars, f = .2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ",.2"))), lty = 1, col = 2:3)
```

ls.diag

**Compute Diagnostics for lsfit Regression Results**

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.
Usage

ls.diag(ls.out)

Arguments

ls.out Typically the result of lsfit()

Value

A list with the following numeric components.

- std.dev The standard deviation of the errors, an estimate of \( \sigma \).
- hat diagonal entries \( h_{ii} \) of the hat matrix \( H \)
- std.res standardized residuals
- stud.res studentized residuals
- cooks Cook’s distances
- dfits DFITS statistics
- correlation correlation matrix
- std.err standard errors of the regression coefficients
- cov.scaled Scaled covariance matrix of the coefficients
- cov.unscaled Unscaled covariance matrix of the coefficients

References

See Also

hat for the hat matrix diagonals, ls.print, lm.influence, summary.lm, anova.

Examples

```r
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")
```
**ls.print**

*Print lsfit Regression Results*

**Description**

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if `print.it` is `TRUE`.

**Usage**

```r
ls.print(ls.out, digits = 4, print.it = TRUE)
```

**Arguments**

- `ls.out`: Typically the result of `lsfit()`
- `digits`: The number of significant digits used for printing
- `print.it`: a logical indicating whether the result should also be printed

**Value**

A list with the components

- `summary`: The ANOVA table of the regression
- `coef.table`: matrix with regression coefficients, standard errors, t- and p-values

**Note**

Usually you would use `summary(lm(...))` and `anova(lm(...))` to obtain similar output.

**See Also**

- `ls.diag, lsfit`, also for examples; `lm, lm.influence` which usually are preferable.

---

**lsfit**

*Find the Least Squares Fit*

**Description**

The least squares estimate of $\beta$ in the model

$$ Y = X\beta + \epsilon $$

is found.

**Usage**

```r
lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07,
      yname = NULL)
```
Arguments

x  a matrix whose rows correspond to cases and whose columns correspond to variables.
y  the responses, possibly a matrix if you want to fit multiple left hand sides.
wt an optional vector of weights for performing weighted least squares.
intercept whether or not an intercept term should be used.
tolerance the tolerance to be used in the matrix decomposition.
yname names to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the \( j \)th case specified by the \( j \)th entry in \( \text{wt} \).

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

Value

A list with the following named components:

- coef  the least squares estimates of the coefficients in the model (\( \beta \) as stated above).
- residuals residuals from the fit.
- intercept indicates whether an intercept was fitted.
- qr  the QR decomposition of the design matrix.

References

See Also

`lm` which usually is preferable: `ls.print`, `ls.diag`.

Examples

```r
##-- Using the same data as the lm(.) example:
lS9 <- lsfit(x = unclass(gl(2, 10)), y = weight)
lS.print(lS9)
```
Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage

\[
\text{mad}(x, \text{center} = \text{median}(x), \text{constant} = 1.4826, \text{na.rm} = \text{FALSE}, \\
\text{low} = \text{FALSE}, \text{high} = \text{FALSE})
\]

Arguments

- **x**: a numeric vector.
- **center**: Optionally, the centre: defaults to the median.
- **constant**: scale factor.
- **na.rm**: if TRUE then NA values are stripped from x before computation takes place.
- **low**: if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
- **high**: if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.

Details

The actual value calculated is \( \text{constant} \times c\text{Median}(\text{abs}(x - \text{center})) \) with the default value of center being median(x), and cMedian being the usual, the ‘low’ or ‘high’ median, see the arguments description for low and high above.

In the case of \( n = 1 \) non-missing values and default center, the result is 0, consistent with “no deviation from the center”.

The default constant = 1.4826 (approximately \( 1/\Phi^{-1}(\frac{3}{4}) = 1/qnorm(3/4) \)) ensures consistency, i.e.,

\[
E[\text{mad}(X_1, \ldots, X_n)] = \sigma
\]

for \( X_i \) distributed as \( N(\mu, \sigma^2) \) and large \( n \).

If na.rm is TRUE then NA values are stripped from x before computation takes place. If this is not done then an NA value in x will cause mad to return NA.

See Also

- IQR which is simpler but less robust, median, var.
Examples

mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
  mad(c(1:8, 100), constant = 1)   # = 2; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
  mad(x, constant = 1, low = TRUE),
  mad(x, constant = 1, high = TRUE))

mahalanobis

Mahalanobis Distance

Description

Returns the squared Mahalanobis distance of all rows in x and the vector μ = center with respect to Σ = cov. This is (for vector x) defined as

\[ D^2 = (x - \mu)' \Sigma^{-1} (x - \mu) \]

Usage

mahalanobis(x, center, cov, inverted = FALSE, ...)

Arguments

x vector or matrix of data with, say, p columns.
center mean vector of the distribution or second data vector of length p or recyclable to that length. If set to FALSE, the centering step is skipped.
cov covariance matrix (p × p) of the distribution.
inverted logical. If TRUE, cov is supposed to contain the inverse of the covariance matrix.
... passed to solve for computing the inverse of the covariance matrix (if inverted is false).

See Also
cov, var

Examples

require(graphics)
ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), 1:2, S)
x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))
  # Here, D^2 = usual squared Euclidean distances
Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
make.link

Description

This function is used with the family functions in glm(). Given the name of a link, it returns a link function, an inverse link function, the derivative $d\mu/d\eta$ and a function for domain checking.

Usage

make.link(link)

Arguments

link character; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse".

Value

A object of class "link-glm", a list with components

- linkfun Link function function(mu)
- linkinv Inverse link function function(eta)
- mu.eta Derivative function(eta) $d\mu/d\eta$
- valideta function(eta){ TRUE if eta is in the domain of linkinv }
- name a name to be used for the link

See Also

power, glm, family.

Examples

utils::str(make.link("logit"))
makepredictcall  Utility Function for Safe Prediction

Description

A utility to help `model.frame.default` create the right matrices when predicting from models with terms like (univariate) poly or ns.

Usage

`makepredictcall(var, call)`

Arguments

- `var`  A variable.
- `call`  The term in the formula, as a call.

Details

This is a generic function with methods for `poly`, `bs` and `ns`: the default method handles `scale`. If `model.frame.default` encounters such a term when creating a model frame, it modifies the `predvars` attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example `makepredictcall.ns` adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the `terms` attribute of the model frame, or copy the `predvars` attribute of the `terms` attribute of the model frame to your `terms` object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

Value

A replacement for `call` for the `predvars` attribute of the terms.

See Also

`model.frame`, `poly`, `scale`; `bs` and `ns` in package `splines`. `cars` for an example of prediction from a polynomial fit.

Examples

```r
require(graphics)

## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
nd <- data.frame(height = ht)
pfm <- predict(fm, nd)
lines(ht, pfm)
pf2 <- predict(update(fm, ~ stats::poly(height, 2)), nd)
stopifnot(all.equal(pfm, pf2)) ## was off (rel.diff. 0.0766) in R <= 3.5.0

## see also example(cars)
```
manova

### Multivariate Analysis of Variance

**Description**

A class for the multivariate analysis of variance.

**Usage**

```r
manova(...)```

**Arguments**

... Arguments to be passed to `aov`.

**Details**

Class "manova" differs from class "aov" in selecting a different summary method. Function `manova` calls `aov` and then add class "manova" to the result object for each stratum.

**Value**

See `aov` and the comments in 'Details' here.

**References**

**See Also**

`aov`, `summary.manova`, the latter containing more examples.

**Examples**

```r
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
nkp2 <- within(npk, foo <- rnorm(24))
(npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, nkp2))
summary(npk2.aov)

(npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), nkp2))
summary(npk2.aovE)
```
mantelhaen.test  Cochran-Mantel-Haenszel Chi-Squared Test for Count Data

Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

mantelhaen.test(x, y = NULL, z = NULL,
   alternative = c("two.sided", "less", "greater"),
   correct = TRUE, exact = FALSE, conf.level = 0.95)

Arguments

x  either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.

y  a factor object with at least 2 levels; ignored if x is an array.

z  a factor object with at least 2 levels identifying to which stratum the corresponding elements in x and y belong; ignored if x is an array.

alternative  indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by K case.

correct  a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by K case.

exact  a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by K case.

conf.level  confidence level for the returned confidence interval. Only used in the 2 by 2 by K case.

Details

If x is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA's are not allowed. Otherwise, x, y and z must have the same length. Triples containing NA's are removed. All variables must take at least two different values.

Value

A list with class "htest" containing the following components:

statistic  Only present if no exact test is performed. In the classical case of a 2 by 2 by K table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.

parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.

p.value  the p-value of the test.
mantelhaen.test

conf.int a confidence interval for the common odds ratio. Only present in the 2 by 2 by K case.

estimate an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by K case.

null.value the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by K case.

alternative a character string describing the alternative hypothesis. Only present in the 2 by 2 by K case.

method a character string indicating the method employed, and whether or not continuity correction was used.

data.name a character string giving the names of the data.

Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by K case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

```
## => p = 0.020

### UC Berkeley Student Admissions

mantelhaen.test(UCBAdmissions)

### No evidence for association between admission and gender

when adjusted for department. However,

apply(UCBAdmissions, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))

### This suggests that the assumption of homogeneous (conditional)

odds ratios may be violated. The traditional approach would be

### using the Woolf test for interaction:

woolf <- function(x) {
  x <- x + 1 / 2
  k <- dim(x)[3]
  or <- apply(x, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
  w <- apply(x, 3, function(x) 1 / sum(1 / x))
  1 - pchisq(sum(w * (log(or) - weighted.mean(log(or), w)) ^ 2), k - 1)
}

woolf(UCBAdmissions)

### => p = 0.003, indicating that there is significant heterogeneity.

### (And hence the Mantel-Haenszel test cannot be used.)

### Job Satisfaction example.

Satisfaction <-

as.table(array(c(1, 2, 0, 0, 3, 3, 1, 2,
  11, 17, 8, 4, 2, 3, 5, 2,
  1, 0, 0, 0, 1, 3, 0, 1,
  2, 5, 7, 9, 1, 1, 3, 6),
  dim = c(4, 4, 2),
  dimnames =
  list(Income =
    c("<5000", "5000-15000",
    "15000-25000", ">25000"),
    "Job Satisfaction" =
    c("V_D", "L_S", "M_S", "V_S"),
    Gender = c("Female", "Male")))

### (Satisfaction categories abbreviated for convenience.)

ftable(. ~ Gender + Income, Satisfaction)

### See Table 7.8 in Agresti (2002), p. 288.

mantelhaen.test(Satisfaction)

### mauchly.test

#### Mauchly's Test of Sphericity

**Description**

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

**Usage**

mauchly.test(object, ...)

### S3 method for class 'mlm'
mauchly.test(object, ...)  
## S3 method for class 'SSD'  
mauchly.test(object, Sigma = diag(nrow = p),  
    T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,  
    idata = data.frame(index = seq_len(p)), ...)  

Arguments  

object: object of class SSD or mlm.  
Sigma: matrix to be proportional to.  
T: transformation matrix. By default computed from M and X.  
M: formula or matrix describing the outer projection (see below).  
X: formula or matrix describing the inner projection (see below).  
idata: data frame describing intra-block design.  
...: arguments to be passed to or from other methods.

Details  

Mauchly’s test test for whether a covariance matrix can be assumed to be proportional to a given matrix.  

This is a generic function with methods for classes "mlm" and "SSD".  

The basic method is for objects of class SSD the method for mlm objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.  

The T argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).  

The common use of this test is in repeated measurements designs, with X = ~1. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.  

Notice that the defaults involve p, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the stats namespace, namely proj which calculates projection matrices from design matrices or model formulas and Thin.row which removes linearly dependent rows from a matrix until it has full row rank.

Value  

An object of class "htest"  

Note  

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

### traditional test of intrasubj. contrasts
mauchly.test(mlmfit, X = ~1)

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0,4,8)),
                      noise = gl(2, 3, 6, labels = c("A","B")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)

---------------------------------------------------------------------
mcnemar.test  
McNemar’s Chi-squared Test for Count Data
---------------------------------------------------------------------

Description

Performs McNemar's chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage

mcnemar.test(x, y = NULL, correct = TRUE)

Arguments

x  
either a two-dimensional contingency table in matrix form, or a factor object.

y  
a factor object; ignored if x is a matrix.

correct  
a logical indicating whether to apply continuity correction when computing the test statistic.

Details

The null is that the probabilities of being classified into cells \([i,j]\) and \([j,i]\) are the same.
If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.
Continuity correction is only used in the 2-by-2 case if correct is TRUE.

Value

A list with class "htest" containing the following components:

statistic  
the value of McNemar’s statistic.

parameter  
the degrees of freedom of the approximate chi-squared distribution of the test statistic.
### median

- **p.value**: the p-value of the test.
- **method**: a character string indicating the type of test performed, and whether continuity correction was used.
- **data.name**: a character string giving the name(s) of the data.

## Presidential Approval Ratings.
## Approval of the President's performance in office in two surveys,
## one month apart, for a random sample of 1600 voting-age Americans.
Performance <- matrix(c(794, 86, 150, 570),
nrow = 2,
dimnames = list("1st Survey" = c("Approve", "Disapprove"),
                "2nd Survey" = c("Approve", "Disapprove")))
mcnemar.test(Performance)
## => significant change (in fact, drop) in approval ratings
```

---

### median

**Median Value**

### Description

Compute the sample median.

### Usage

```r
median(x, na.rm = FALSE, ...)
```

### Arguments

- **x**: an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed.
- **na.rm**: a logical value indicating whether NA values should be stripped before the computation proceeds.
- **...**: potentially further arguments for methods; not used in the default method.

### Details

This is a generic function for which methods can be written. However, the default method makes use of `is.na`, `sort` and `mean` from package **base** all of which are generic, and so the default method will work for most classes (e.g., "Date") for which a median is a reasonable concept.
Value

The default method returns a length-one object of the same type as \( x \), except when \( x \) is logical or integer of even length, when the result will be double.

If there are no values or if \( \text{na.rm} = \text{FALSE} \) and there are NA values the result is NA of the same type as \( x \) (or more generally the result of \( x[\text{FALSE}][\text{NA}] \)).

References

See Also

`quantile` for general quantiles.

Examples

```r
median(1:4)  # = 2.5 [even number]
median(c(1:3, 100, 1000))  # = 3 [odd, robust]
```

Description

Fits an additive model (two-way decomposition) using Tukey’s *median polish* procedure.

Usage

```r
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, 
            na.rm = FALSE)
```

Arguments

- `x` a numeric matrix.
- `eps` real number greater than 0. A tolerance for convergence: see ‘Details’.
- `maxiter` the maximum number of iterations
- `trace.iter` logical. Should progress in convergence be reported?
- `na.rm` logical. Should missing values be removed?

Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than eps or until there have been maxiter iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if trace.iter is TRUE. If na.rm is FALSE the presence of any NA value in \( x \) will cause an error, otherwise NA values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via the generics `print` and `plot`. 
model.extract

Value
An object of class medpolish with the following named components:

- overall: the fitted constant term.
- row: the fitted row effects.
- col: the fitted column effects.
- residuals: the residuals.
- name: the name of the dataset.

## Check decomposition:
all(dates ==
    med.d$overall + outer(med.d$row, med.d$col, "+") + med.d$residuals)
```

model.extract

**Extract Components from a Model Frame**

**Description**

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

**Usage**

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```
Arguments

frame, x, data  A model frame.

component  literal character string or name. The name of a component to extract, such as "weights", "subset".

type  One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".

Details

model.extract is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the etastart and mustart components of a glm fit.

model.extract(m, "offset") and model.extract(m, "response") are equivalent to model.offset(m) and model.response(m) respectively. model.offset sums any terms specified by offset terms in the formula or by offset arguments in the call producing the model frame: it does check that the offset is numeric.

model.weights is slightly different from model.extract(, "weights") in not naming the vector it returns.

Value

The specified component of the model frame, usually a vector. model.response() now drops a possible "Asis" class (stemming from I(.)).

See Also

model.frame, offset

Examples

a <- model.frame(chbind(ncases,ncontrols) ~ agegp + tobgp + alcgp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcgp,
                  data = esoph, weights = ncases+ncontrols)
model.response(a)
(mw <- model.extract(a, "weights"))
stopifnot(identical(unname(mw), model.weights(a)))

a <- model.frame(chbind(ncases,ncontrols) ~ agegp,
                  something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
model.frame

Usage

model.frame(formula, ...)

## Default S3 method:
model.frame(formula, data = NULL,
             subset = NULL, na.action = na.fail,
             drop.unused.levels = FALSE, xlev = NULL, ...)

## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)

Arguments

formula a model formula or terms object or an R object.
data a data.frame, list or environment (or object coercible by as.data.frame to a
data.frame), containing the variables in formula. Neither a matrix nor an array
will be accepted.
subset a specification of the rows to be used: defaults to all rows. This can be any
valid indexing vector (see [.data.frame) for the rows of data or if that is not
supplied, a data frame made up of the variables used in formula.
na.action how NAs are treated. The default is first, any na.action attribute of data, second
a na.action setting of options, and third na.fail if that is unset. The 'factory-
fresh' default is na.omit. Another possible value is NULL.
drop.unused.levels
should factors have unused levels dropped? Defaults to FALSE.
xlev a named list of character vectors giving the full set of levels to be assumed for
each factor.
... for model.frame methods, a mix of further arguments such as data, na.action,
subset to pass to the default method. Any additional arguments (such as offset
and weights or other named arguments) which reach the default method are
used to create further columns in the model frame, with parenthesised names
such as "(offset)". For get_all_vars, further named columns to include in the model frame.

Details

Exactly what happens depends on the class and attributes of the object formula. If this is an object
of fitted-model class such as "lm", the method will either return the saved model frame used when
fitting the model (if any, often selected by argument model = TRUE) or pass the call used when fitting
on to the default method. The default method itself can cope with rather standard model objects
such as those of class "lqs" from package MASS if no other arguments are supplied.
The rest of this section applies only to the default method.
If either formula or data is already a model frame (a data frame with a "terms" attribute) and the other is missing, the model frame is returned. Unless formula is a terms object, as.formula and then terms is called on it. (If you wish to use the keep.order argument of terms.formula, pass a terms object rather than a formula.)

Row names for the model frame are taken from the data argument if present, then from the names of the response in the formula (or rownames if it is a matrix), if there is one.

All the variables in formula, subset and in ... are looked for first in data and then in the environment of formula (see the help for formula() for further details) and collected into a data frame. Then the subset expression is evaluated, and it is used as a row index to the data frame. Then the na.action function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the drop.unused.levels and xlev arguments: if xlev specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Unless na.action = NULL, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by ~. Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

get_all_vars returns a data.frame containing the variables used in formula plus those specified in ... which are recycled to the number of data frame rows. Unlike model.frame.default, it returns the input variables and not those resulting from function calls in formula.

Value

A data.frame containing the variables used in formula plus those specified in .... It will have additional attributes, including "terms" for an object of class "terms" derived from formula, and possibly "na.action" giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by na.pass).

model.matrix for the 'design matrix', formula for formulas and expand.model.frame for model.frame manipulation.

Examples

data.class(model.frame(dist ~ speed, data = cars))

## get_all_vars(): new var.s are recycled (iff length matches: 50 = 2*25)
cars <- get_all_vars(sqrt(dist) ~ I(speed/2), data = cars, newVar = 2:3)
stopifnot(is.data.frame(ncars),
identical(cars, ncars[,names(cars)]),
ncol(ncars) == ncol(cars) + 1)
model.matrix

Construct Design Matrices

Description

model.matrix creates a design (or model) matrix, e.g., by expanding factors to a set of dummy variables (depending on the contrasts) and expanding interactions similarly.

Usage

model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL, ...)

Arguments

object an object of an appropriate class. For the default method, a model formula or a terms object.
data a data frame created with model.frame. If another sort of object, model.frame is called first.
contrasts.arg a list, whose entries are values (numeric matrices, functions or character strings naming functions) to be used as replacement values for the contrasts replacement function and whose names are the names of columns of data containing factors.
xlev to be used as argument of model.frame if data is such that model.frame is called.
... further arguments passed to or from other methods.

Details

model.matrix creates a design matrix from the description given in terms(object), using the data in data which must supply variables with the same names as would be created by a call to model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables"). If data is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors. After coercion, all the variables used on the right-hand side of the formula must be logical, integer, numeric or factor.

If contrasts.arg is specified for a factor it overrides the default factor coding for that variable and any "contrasts" attribute set by C or contrasts. Whereas invalid contrasts.arg have been ignored always, they are warned about since R version 3.6.0.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in ~ a + b + b:a the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.
Value

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the term.labels attribute of the terms structure corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

`model.frame`, `model.extract`, `terms`, `sparse.model.matrix` from package Matrix for creating sparse model matrices, which may be more efficient in large dimensions.

Examples

```r
ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts") # typically 'treatment' (for unordered factors)
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts.arg = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts.arg = list(a = "contr.sum", b = contr.poly))
m.orth <- model.matrix(~a+b, dd, contrasts.arg = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal
# invalid contrasts. ignored with a warning:
stopifnot(identical(
  model.matrix(~ a + b, dd),
  model.matrix(~ a + b, dd, contrasts.arg = "contr.FOO")))
```

---

**model.tables**

*Compute Tables of Results from an Aov Model Fit*

Description

Computes summary tables for model fits, especially complex aov fits.
Usage

model.tables(x, ...)

## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist'
model.tables(x, type = "effects", se = FALSE, ...)

Arguments

x a model object, usually produced by aov
type type of table: currently only "effects" and "means" are implemented. Can be abbreviated.
se should standard errors be computed?
cterms A character vector giving the names of the terms for which tables should be computed. The default is all tables.
... further arguments passed to or from other methods.

Details

For type = "effects" give tables of the coefficients for each term, optionally with standard errors.
For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.
The "aov" method cannot be applied to components of a "aovlist" fit.

Value

An object of class "tables.aov", as list which may contain components
tables A list of tables for each requested term.
n The replication information for each term.
se Standard error information.

Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly.
Weighted aov fits are not supported.

See Also

aov, proj, replications, TukeyHSD, se.contrast

Examples

options(contrasts = c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")
monthplot

Plot a Seasonal or other Subseries from a Time Series

Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

Usage

monthplot(x, ...)

## S3 method for class 'stl'
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal", ...)

## S3 method for class 'StructTS'
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

## S3 method for class 'ts'
monthplot(x, labels = NULL, times = time(x), phase = cycle(x), ylab = deparse1(substitute(x)), ...)

## Default S3 method:
monthplot(x, labels = 1L:12L, ylab = deparse1(substitute(x)), times = seq_along(x), phase = (times - 1L)%/%length(labels) + 1L, base = mean, axes = TRUE, type = c("l", "h"), box = TRUE, add = FALSE, col = par("col"), lty = par("lty"), lwd = par("lwd"), col.base = col, lty.base = lty, lwd.base = lwd, ...)

Arguments

x

Time series or related object.

labels

Labels to use for each 'season'.

ylab

y label.

times

Time of each observation.

phase

Indicator for each 'season'.

base

Function to use for reference line for subseries.

choice

Which series of an stl or StructTS object?

... Arguments to be passed to the default method or graphical parameters.

axes

Should axes be drawn (ignored if add = TRUE)?

type

Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines.

box

Should a box be drawn (ignored if add = TRUE)?

add

Should thus just add on an existing plot.
monthplot

col, lty, lwd  Graphics parameters for the series.

col.base, lty.base, lwd.base
  Graphics parameters for the segments used for the reference lines.

Details

These functions extract subseries from a time series and plot them all in one frame. The \texttt{ts}, \texttt{stl}, and \texttt{StructTS} methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to \texttt{length(labels)}.

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test

Mood Two-Sample Test of Scale

Description

Performs Mood's two-sample test for a difference in scale parameters.

Usage

mood.test(x, y, alternative = c("two.sided", "less", "greater"), ...)

## Default S3 method:
mood.test(x, y, alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula'
mood.test(formula, data, subset, na.action, ...)

Arguments

x, y numeric vectors of data values.
alternative indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
... further arguments to be passed to or from methods.

Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.
p.value the p-value of the test.
alternative a character string describing the alternative hypothesis. You can specify just the initial letter.
Multinom

method: the character string "Mood two-sample test of scale".

data.name: a character string giving the names of the data.

References

Examples

```r
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
           101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```

---

**Multinom**

*The Multinomial Distribution*

**Description**

Generate multinomially distributed random number vectors and compute multinomial probabilities.

**Usage**

```r
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

**Arguments**

- `x`: vector of length `K` of integers in `0:size`.
- `n`: number of random vectors to draw.
- `size`: integer, say `N`, specifying the total number of objects that are put into `K` boxes in the typical multinomial experiment. For `dmultinom`, it defaults to `sum(x)`.
- `prob`: numeric non-negative vector of length `K`, specifying the probability for the `K` classes; is internally normalized to sum 1. Infinite and missing values are not allowed.
- `log`: logical; if `TRUE`, log probabilities are computed.
Details

If \( x \) is a \( K \)-component vector, \( \text{dmultinom}(x, \text{prob}) \) is the probability

\[
P(X_1 = x_1, \ldots, X_K = x_k) = C \times \prod_{j=1}^{K} \pi_j^{x_j}
\]

where \( C \) is the ‘multinomial coefficient’ \( C = N!/(x_1! \cdots x_K!) \) and \( N = \sum_{j=1}^{K} x_j \).

By definition, each component \( X_j \) is binomially distributed as \( \text{Bin}(\text{size}, \text{prob}[j]) \) for \( j = 1, \ldots, K \).

The \( \text{rmultinom}() \) algorithm draws binomials \( X_j \) from \( \text{Bin}(n_j, P_j) \) sequentially, where \( n_1 = N \) (\( N := \text{size} \)), \( P_1 = \pi_1 \) (\( \pi \) is prob scaled to sum 1), and for \( j \geq 2 \), recursively, \( n_j = N - \sum_{k=1}^{j-1} X_k \) and \( P_j = \pi_j/(1 - \sum_{k=1}^{j-1} \pi_k) \).

Value

For \( \text{rmultinom}() \), an integer \( K \times n \) matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to \( \text{size} \). Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

dmultinom is currently not vectorized at all and has no C interface (API); this may be amended in the future.

See Also

\( \text{Distributions} \) for standard distributions, including \( \text{dbinom} \) which is a special case conceptually.

Examples

```r
\text{rmultinom}(10, \text{size} = 12, \text{prob} = \text{c}(0.1,0.2,0.8))

\text{pr} <- \text{c}(1,3,6,10) \# normalization not necessary for generation
\text{rmultinom}(10, 20, \text{prob} = \text{pr})

## all possible outcomes of Multinom(N = 3, K = 3)
\text{X} <- \text{t(as.matrix(expand.grid(0:3, 0:3)))]; X} <- \text{X[}, \text{colSums(X)} <= 3\text{]} \text{X} <- \text{rbind(X, 3:3 - colSums(X)); dimnames(X)} <- \text{list(letters[1:3], NULL)} \text{X}
\text{round(apply(X, 2, function(x) dmultinom(x, \text{prob} = \text{c}(1,2,5))), 3)}
```

\( \text{na.action} \)

\( \text{NA Action} \)

Description

Extract information on the NA action used to create an object.

Usage

\( \text{na.action(object, \ldots)} \)
Arguments

object  any object whose NA action is given.
...     further arguments special methods could require.

Details

`na.action` is a generic function, and `na.action.default` its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When `model.frame` is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.

Value

Information from the action which was applied to object if NAs were handled specially, or NULL.

References

See Also

`options("na.action")`, `na.omit`, `na.fail`, also for `na.exclude`, `na.pass`.

Examples

```r
na.action(na.omit(c(1, NA)))
```

---

```r
na.contiguous
Find Longest Contiguous Stretch of non-NAs
```

Description

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

Usage

```r
na.contiguous(object, ...)
```

Arguments

object  a univariate or multivariate time series.
...     further arguments passed to or from other methods.

Value

A time series without missing values. The class of `object` will be preserved.

See Also

`na.omit` and `na.omit.ts`; `na.fail`
Examples

na.contiguous(presidents)

---

na.fail

**Handle Missing Values in Objects**

**Description**

These generic functions are useful for dealing with NAs in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

**Usage**

```r
na.fail(object, ...)
na.omit(object, ...)
na.exclude(object, ...)
na.pass(object, ...)
```

**Arguments**

- `object`  
  an R object, typically a data frame

- `...`  
  further arguments special methods could require.

**Details**

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

**References**

**See Also**

`na.action`, `options` with argument `na.action` for setting NA actions; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.
Examples

```r
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF)) #> Error: missing values in ...

options("na.action")
```

---

**naprint**

*Adjust for Missing Values*

**Description**

Use missing value information to report the effects of an `na.action`.

**Usage**

```r
naprint(x, ...)
```

**Arguments**

- `x`: An object produced by an `na.action` function.
- `...`: further arguments passed to or from other methods.

**Details**

This is a generic function, and the exact information differs by method. `naprint.omit` reports the number of rows omitted: `naprint.default` reports an empty string.

**Value**

A character string providing information on missing values, for example the number.

---

**naresid**

*Adjust for Missing Values*

**Description**

Use missing value information to adjust residuals and predictions.

**Usage**

```r
naresid(omit, x, ...)
napredict(omit, x, ...)
```
**Arguments**

- **omit**: an object produced by an `na.action` function, typically the “na.action” attribute of the result of `na.omit` or `na.exclude`.
- **x**: a vector, data frame, or matrix to be adjusted based upon the missing value information.
- **...**: further arguments passed to or from other methods.

**Details**

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages `MASS`, `rpart` and `survival`. Also used for the scores returned by `factanal`, `prcomp` and `princomp`.

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values, predictions and `weights`.

**Value**

These return a similar object to `x`.

**Note**

In the early 2000s, packages `rpart` and `survival` contained versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

---

**NegBinomial**

*The Negative Binomial Distribution*

**Description**

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

**Usage**

```r
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

**Arguments**

- **x**: vector of (non-negative integer) quantiles.
- **q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If `length(n) > 1`, the length is taken to be the number required.
**NegBinomial**

`size` target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer.

`prob` probability of success in each trial. $0 < \text{prob} \leq 1$.

`mu` alternative parametrization via mean: see ‘Details’.

`log, log.p` logical; if TRUE, probabilities p are given as log(p).

`lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

**Details**

The negative binomial distribution with $\text{size} = n$ and $\text{prob} = p$ has density

$$p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x$$

for $x = 0, 1, 2, \ldots, n > 0$ and $0 < p \leq 1$.

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is $\mu = n(1 - p)/p$ and variance $n(1 - p)/p^2$.

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see `pgamma`) with scale parameter $(1 - \text{prob})/\text{prob}$ and shape parameter `size`. (This definition allows non-integer values of `size`.)

An alternative parametrization (often used in ecology) is by the mean $\mu$ (see above), and `size`, the dispersion parameter, where $\text{prob} = \text{size}/(\text{size} + \mu)$. The variance is $\mu + \mu^2/\text{size}$ in this parametrization.

If an element of `x` is not integer, the result of `dnbinom` is zero, with a warning.

The case `size == 0` is the distribution concentrated at zero. This is the limiting distribution for `size` approaching zero, even if `mu` rather than `prob` is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of `mu`.

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

**Value**

`dnbinom` gives the density, `pnbinom` gives the distribution function, `qnbinom` gives the quantile function, and `rnbinom` generates random deviates.

Invalid `size` or `prob` will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rnbinom`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

`rnbinom` returns a vector of type `integer` unless generated values exceed the maximum representable integer when `double` values are returned since R version 4.0.0.

**Source**

`dnbinom` computes via binomial probabilities, using code contributed by Catherine Loader (see `dbinom`).

`pnbinom` uses `pbeta`.
qnbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

**See Also**

*Distributions* for standard distributions, including *dbinom* for the binomial, *dpois* for the Poisson and *dgeom* for the geometric distribution, which is a special case of the negative binomial.

**Examples**

```r
require(graphics)
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:8, size = 2, prob = 1/2) # -- theoretically integer

## Cumulative ("p") = Sum of discrete prob.s ("d"); Relative error :
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) / pnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dnbinom(x, s, prob = 0.4)),
      xlab = "x", ylab = "s", zlab = "density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")
image (x, size, log10(dnb), main = paste("log [", tit, "]")
contour(x, size, log10(dnb), add = TRUE)

## Alternative parametrization
x1 <- rnbinom(500, mu = 4, size = 1)
x2 <- rnbinom(500, mu = 4, size = 10)
x3 <- rnbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
        beside = TRUE, col = c("red","blue","cyan"),
        names.arg = round(h1$breaks[-length(h1$breaks)]))
```

**nextn**

*Find Highly Composite Numbers*

**Description**

nextn returns the smallest integer, greater than or equal to n, which can be obtained as a product of powers of the values contained in factors.

nextn() is intended to be used to find a suitable length to zero-pad the argument of *fft* so that the transform is computed quickly. The default value for factors ensures this.
Usage

```r
nextn(n, factors = c(2,3,5))
```

Arguments

- `n`: a vector of integer numbers (of type "integer" or "double").
- `factors`: a vector of positive integer factors (at least 2 and preferably relative prime, see the note).

Value

A vector of the same length as `n`, of type "integer" when the values are small enough (determined before computing them) and "double" otherwise.

Note

If the factors in `factors` are not relative prime, i.e., have themselves a common factor larger than one, the result may be wrong in the sense that it may not be the smallest integer. E.g., `nextn(91, c(2,6))` returns 128 instead of 96 as `nextn(91, c(2,3))` returns.

When the resulting `N <- nextn(..)` is larger than $2^{53}$, a warning with the true 64-bit integer value is signalled, as integers above that range may not be representable in double precision.

If you really need to deal with such large integers, it may be advisable to use package `gmp`.

See Also

- `convolve`, `fft`.

Examples

```r
nextn(1001) # 1024
table(nextn(599:630))
n <- 1:100 ; plot(n, nextn(n) - n, type = "o", lwd=2, cex=1/2)
```

**nlm**

Non-Linear Minimization

Description

This function carries out a minimization of the function `f` using a Newton-type algorithm. See the references for details.

Usage

```r
nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),
    fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,
    stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),
    steptol = 1e-6, iterlim = 100, check.analyicals = TRUE)
```
Arguments

*f* the function to be minimized, returning a single numeric value. This should be a function with first argument a vector of the length of *p* followed by any other arguments specified by the ... argument.

If the function value has an attribute called `gradient` or both `gradient` and `hessian` attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. `deriv` returns a function with suitable `gradient` attribute and optionally a `hessian` attribute.

*p* starting parameter values for the minimization.

... additional arguments to be passed to *f*.

`hessian` if TRUE, the hessian of *f* at the minimum is returned.

`typsize` an estimate of the size of each parameter at the minimum.

`fscale` an estimate of the size of *f* at the minimum.

`print.level` this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.

`ndigit` the number of significant digits in the function *f*.

`gradtol` a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in *f* in each direction *p[i]* divided by the relative change in *p[i]*.

`stepmax` a positive scalar which gives the maximum allowable scaled step length. `stepmax` is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. `stepmax` would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.

`steptol` A positive scalar providing the minimum allowable relative step length.

`iterlim` a positive integer specifying the maximum number of iterations to be performed before the program is terminated.

`check.analyticals` a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.

Details

Note that arguments after ... must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if `check.analyticals = TRUE` (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

The C code for the “perturbed” cholesky, `choldc()` has had a bug in all R versions before 3.4.1.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not NA and not NaN) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.
**Value**

A list containing the following components:

- **minimum**: the value of the estimated minimum of f.
- **estimate**: the point at which the minimum value of f is obtained.
- **gradient**: the gradient at the estimated minimum of f.
- **hessian**: the hessian at the estimated minimum of f (if requested).
- **code**: an integer indicating why the optimization process terminated.
  - 1: relative gradient is close to zero, current iterate is probably solution.
  - 2: successive iterates within tolerance, current iterate is probably solution.
  - 3: last global step failed to locate a point lower than estimate. Either estimate is an approximate local minimum of the function or steptol is too small.
  - 4: iteration limit exceeded.
  - 5: maximum step size stepmax exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or stepmax is too small.
- **iterations**: the number of iterations performed.

**Source**

The current code is by Saikat DebRoy and the R Core team, using a C translation of Fortran code by Richard H. Jones.

**References**

**See Also**

- `optim` and `nlminb`.
- `constrOptim` for constrained optimization, `optimize` for one-dimensional minimization and `uniroot` for root finding. `deriv` to calculate analytical derivatives.

For nonlinear regression, `nls` may be better.

**Examples**

```r
f <- function(x) sum((x-1:length(x))^2)
nlm(f, c(10,10))
nlm(f, c(10,10), print.level = 2)
utils::str(nlm(f, c(5), hessian = TRUE))

f <- function(x, a) sum((x-a)^2)
nlm(f, c(10,10), a = c(3,5))
f <- function(x, a)
{
  res <- sum((x-a)^2)
}
```
```r
attr(res, "gradient") <- 2*(x-a)
res
}
nlm(f, c(10,10), a = c(3,5))
```

## more examples, including the use of derivatives.
## Not run: demo(nlm)

---

### nlminb

**Optimization using PORT routines**

#### Description

Unconstrained and box-constrained optimization using PORT routines.

For historical compatibility.

#### Usage

```r
nlminb(start, objective, gradient = NULL, hessian = NULL, ..., scale = 1, control = list(), lower = -Inf, upper = Inf)
```

#### Arguments

- **start**: numeric vector, initial values for the parameters to be optimized.
- **objective**: Function to be minimized. Must return a scalar value. The first argument to `objective` is the vector of parameters to be optimized, whose initial values are supplied through `start`. Further arguments (fixed during the course of the optimization) to `objective` may be specified as well (see `...`).
- **gradient**: Optional function that takes the same arguments as `objective` and evaluates the gradient of `objective` at its first argument. Must return a vector as long as `start`.
- **hessian**: Optional function that takes the same arguments as `objective` and evaluates the hessian of `objective` at its first argument. Must return a square matrix of order `length(start)`. Only the lower triangle is used.
- **...**: Further arguments to be supplied to `objective`.
- **scale**: See PORT documentation (or leave alone).
- **control**: A list of control parameters. See below for details.
- **lower, upper**: vectors of lower and upper bounds, replicated to be as long as `start`. If unspecified, all parameters are assumed to be unconstrained.

#### Details

Any names of `start` are passed on to `objective` and where applicable, `gradient` and `hessian`. The parameter vector will be coerced to double.

If any of the functions returns `NA` or `NaN` this is an error for the gradient and Hessian, and such values for function evaluation are replaced by `+Inf` with a warning.
**Value**

A list with components:

- **par**: The best set of parameters found.
- **objective**: The value of objective corresponding to par.
- **convergence**: An integer code. 0 indicates successful convergence.
- **message**: A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
- **iterations**: Number of iterations performed.
- **evaluations**: Number of objective function and gradient function evaluations

**Control parameters**

Possible names in the control list and their default values are:

- **eval.max**: Maximum number of evaluations of the objective function allowed. Defaults to 200.
- **iter.max**: Maximum number of iterations allowed. Defaults to 150.
- **trace**: The value of the objective function and the parameters is printed every trace'th iteration. Defaults to 0 which indicates no trace information is to be printed.
- **abs.tol**: Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.
- **rel.tol**: Relative tolerance. Defaults to 1e-10.
- **x.tol**: X tolerance. Defaults to 1.5e-8.
- **xf.tol**: False convergence tolerance. Defaults to 2.2e-14.
- **step.min**, **step.max**: Minimum and maximum step size. Both default to 1.0.
- **sing.tol**: Singular convergence tolerance; defaults to rel.tol.
- **scale.init**: ...
- **diff.g**: An estimated bound on the relative error in the objective function value.

### nls

**Nonlinear Least Squares**
**nls**

**Description**

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

**Usage**

```r
nls(formula, data, start, control, algorithm, trace, subset, weights, na.action, model, lower, upper, ...)```

**Arguments**

- `formula`: a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.
- `data`: an optional data frame in which to evaluate the variables in `formula` and `weights`. Can also be a list or an environment, but not a matrix.
- `start`: a named list or named numeric vector of starting estimates. When `start` is missing (and `formula` is not a self-starting model, see `selfStart`), a very cheap guess for `start` is tried (if `algorithm` != "plinear").
- `control`: an optional list of control settings. See `nls.control` for the names of the settable control values and their effect.
- `algorithm`: character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references. Can be abbreviated.
- `trace`: logical value indicating if a trace of the iteration progress should be printed. Default is `FALSE`. If `TRUE` the residual (weighted) sum-of-squares, the convergence criterion and the parameter values are printed at the conclusion of each iteration. Note that `format()` is used, so these mostly depend on `getOption("digits")`. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.
- `subset`: an optional vector specifying a subset of observations to be used in the fitting process.
- `weights`: an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.
- `na.action`: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The 'factory-fresh' default is `na.omit`. Value `na.exclude` can be useful.
- `model`: logical. If true, the model frame is returned as part of the object. Default is `FALSE`.
- `lower`, `upper`: vectors of lower and upper bounds, replicated to be as long as `start`. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.
- `...`: Additional optional arguments. None are used at present.
Details

An `nls` object is a type of fitted model object. It has methods for the generic functions `anova`, `coef`, `confint`, `deviance`, `df.residual`, `fitted`, `formula`, `logLik`, `predict`, `print`, `profile`, `residuals`, `summary`, `vcov` and `weights`.

Variables in `formula` (and `weights` if not missing) are looked for first in `data`, then the environment of `formula` and finally along the search path. Functions in `formula` are searched for first in the environment of `formula` and then along the search path.

Arguments `subset` and `na.action` are supported only when all the variables in the formula taken from `data` are of the same length; other cases give a warning.

Note that the `anova` method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

- `m` an `nlsModel` object incorporating the model.
- `data` the expression that was passed to `nls` as the data argument. The actual data values are present in the `environment` of the `m` components, e.g., `environment(m$conv)`.
- `call` the matched call with several components, notably `algorithm`.
- `na.action` the "na.action" attribute (if any) of the model frame.
- `dataClasses` the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.
- `model` if `model = TRUE`, the model frame.
- `weights` if `weights` is supplied, the weights.
- `convInfo` a list with convergence information.
- `control` the control list used, see the `control` argument.
- `convergence`, `message` for an `algorithm = "port"` fit only, a convergence code (0 for convergence) and message.

To use these is deprecated, as they are available from `convInfo` now.

Warning

The default settings of `nls` generally fail on artificial “zero-residual” data problems.

The `nls` function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

\[ y = f(x, \theta) + \epsilon \]

(with \( \text{var}(\epsilon) > 0 \)). It fails to indicate convergence on data of the form

\[ y = f(x, \theta) \]

because the criterion amounts to comparing two components of the round-off error. To avoid a zero-divide in computing the convergence testing value, a positive constant `scaleOffset` should be added to the denominator sum-of-squares; it is set in `control`, as in the example below; this does not yet apply to `algorithm = "port"`.

The `algorithm = "port"` code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.
Note

Setting `warnOnly = TRUE` in the `control` argument (see `nls.control`) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, but not for inference.

Author(s)

Douglas M. Bates and Saikat DebRoy: David M. Gay for the Fortran code used by `algorithm = "port"`.

`summary.nls`, `predict.nls`, `profile.nls`.

Self starting models (with ‘automatic initial values’): `selfStart`.

Examples

```r
require(graphics)
DNase1 <- subset(DNase, Run == 1)

## using a selfStart model
fm1DNase1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
summary(fm1DNase1)
## the coefficients only:
coef(fm1DNase1)
## including their SE, etc:
coef(summary(fm1DNase1))

## using conditional linearity
fm2DNase1 <- nls(density ~ 1/(1 + exp((xmid - log(conc))/scal)),
data = DNase1,
start = list(xmid = 0, scal = 1),
algorithm = "plinear")
summary(fm2DNase1)

## without conditional linearity
fm3DNase1 <- nls(density ~ Asym/(1 + exp((xmid - log(conc))/scal)),
data = DNase1,
start = list(Asym = 3, xmid = 0, scal = 1))
summary(fm3DNase1)

## using Port's nl2sol algorithm
fm4DNase1 <- nls(density ~ Asym/(1 + exp((xmid - log(conc))/scal)),
data = DNase1,
start = list(Asym = 3, xmid = 0, scal = 1),
algorithm = "port")
```
## weighted nonlinear regression

```r
Treated <- Puromycin[Puromycin$state == "treated", ]
weighted.MM <- function(resp, conc, Vm, K)
{
  pred <- (Vm * conc)/(K + conc)
  (resp - pred) / sqrt(pred)
}
Pur.wt <- nls( ~ weighted.MM(rate, conc, Vm, K), data = Treated,
  start = list(Vm = 200, K = 0.1))
summary(Pur.wt)

lisTreat <- with(Treated,
  list(conc1 = conc[1], conc.1 = conc[-1], rate = rate))
weighted.MM1 <- function(resp, conc1, conc.1, Vm, K)
{
  conc <- c(conc1, conc.1)
  pred <- (Vm * conc)/(K + conc)
  (resp - pred) / sqrt(pred)
}
Pur.wt1 <- nls( ~ weighted.MM1(rate, conc1, conc.1, Vm, K),
  data = lisTreat, start = list(Vm = 200, K = 0.1))
stopifnot(all.equal(coef(Pur.wt), coef(Pur.wt1)))
```

```
weighted.MM.grad <- function(resp, conc1, conc.1, Vm, K)
{
  conc <- c(conc1, conc.1)
  K.conc <- K+conc
dy.dV <- conc/K.conc
dy.dK <- -Vm*dy.dV/K.conc
pred <- Vm*dy.dV
pred.5 <- sqrt(pred)
dev <- (resp - pred) / pred.5
Ddev <- -0.5*(resp+pred)/(pred.5*pred)
attr(dev, "gradient") <- Ddev * cbind(Vm = dy.dV, K = dy.dK)
dev
}
Pur.wt.grad <- nls( ~ weighted.MM.grad(rate, conc1, conc.1, Vm, K),
  data = lisTreat, start = list(Vm = 200, K = 0.1))
```
rbind(coef(Pur.wt), coef(Pur.wt1), coef(Pur.wt.grad))

## In this example, there seems no advantage to providing the gradient.
## In other cases, there might be.

## The two examples below show that you can fit a model to
## artificial data with noise but not to artificial data
## without noise.
x <- 1:10
y <- 2*x + 3  # perfect fit
## terminates in an error, because convergence cannot be confirmed:
try(nls(y ~ a + b*x, start = list(a = 0.12345, b = 0.54321)))
## adjusting the convergence test by adding 'scaleOffset' to its denominator RSS:
nls(y ~ a + b*x, start = list(a = 0.12345, b = 0.54321),
   control = list(scaleOffset = 1, printEval=TRUE))
## Alternatively jittering the "too exact" values, slightly:
set.seed(27)
yeps <- y + rnorm(length(y), sd = 0.01)  # added noise
nls(yeps ~ a + b*x, start = list(a = 0.12345, b = 0.54321))

## the nls() internal cheap guess for starting values can be sufficient:
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x))
plot(x,y, main = "nls(*), data, true function and fit, n=100")
curve(100 + 10 * exp(x / 2), col = 4, add = TRUE)
lines(x, predict(nlmod), col = 2)

## Here, requiring close convergence, must use more accurate numerical differentiation,
## as this typically gives Error: "step factor .. reduced below 'minFactor' .."
## IGNORE_RDIFF_BEGIN
try(nlm1 <- update(nlmod, control = list(tol = 1e-7)))
o2 <- options(digits = 10)  # more accuracy for 'trace'
## central differencing works here typically (PR#18165: not converging on *some*):
ctr2 <- nls.control(nDcentral=TRUE, tol = 8e-8, warnOnly = TRUE ||
                    (grepl("aarch64.*linux", R.version$platform) && grepl(""MixOS", osVersion) )
)(nlm2 <- update(nlmod, control = ctr2, trace = TRUE)); options(o2)
## --> convergence tolerance 4.997e-8 (in 11 iter.)
## IGNORE_RDIFF_END

## The muscle dataset in MASS is from an experiment on muscle
## contraction on 21 animals. The observed variables are Strip
## (identifier of muscle), Conc (Cacl concentration) and Length
## (resulting length of muscle section).
## IGNORE_RDIFF_BEGIN
if(requireNamespace("MASS", quietly = TRUE)) withAutoprint{
## The non linear model considered is
## Length = alpha + beta*exp(-Conc/theta) + error
## where theta is constant but alpha and beta may vary with Strip.
## nls.control

Control the Iterations in nls

**Description**

Allow the user to set some characteristics of the `nls` nonlinear least squares algorithm.

**Usage**

```r
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
             printEval = FALSE, warnOnly = FALSE, scaleOffset = 0,
             nDcentral = FALSE)
```

**Arguments**

- `maxiter`  
  A positive integer specifying the maximum number of iterations allowed.

- `tol`  
  A positive numeric value specifying the tolerance level for the relative offset convergence criterion.

- `minFactor`  
  A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.

- `printEval`  
  A logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.

- `warnOnly`  
  A logical specifying whether `nls()` should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of `maxiter` iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below `minFactor`. 

**Examples**

```r
with(MASS::muscle, table(Strip)) # 2, 3 or 4 obs per strip

## We first use the plinear algorithm to fit an overall model,
## ignoring that alpha and beta might vary with Strip.
musc.1 <- nls(Length ~ cbind(1, exp(-Conc/th)), MASS::muscle,
              start = list(th = 1), algorithm = "plinear")
summary(musc.1)

## Then we use nls' indexing feature for parameters in non-linear
## models to use the conventional algorithm to fit a model in which
## alpha and beta vary with Strip. The starting values are provided
## by the previously fitted model.
## Note that with indexed parameters, the starting values must be
## given in a list (with names):
# b <- coef(musc.1)
musc.2 <- nls(Length ~ a[Strip] + b[Strip]*exp(-Conc/th), MASS::muscle,
              start = list(a = rep(b[2], 21), b = rep(b[3], 21), th = b[1]))
summary(musc.2)
```
scaleOffset  a constant to be added to the denominator of the relative offset convergence criterion calculation to avoid a zero divide in the case where the fit of a model to data is very close. The default value of 0 keeps the legacy behaviour of nls(). A value such as 1 seems to work for problems of reasonable scale with very small residuals.

nDcentral  only when numerical derivatives are used: logical indicating if central differences should be employed, i.e., numericDeriv(*, central=TRUE) be used.

Value
A list with components
maxiter
tol
minFactor
printEval
warnOnly
scaleOffset
nDcentral
with meanings as explained under ‘Arguments’.

Author(s)
Douglas Bates and Saikat DebRoy; John C. Nash for part of the scaleOffset option.

NLSstAsymptotic  Fit the Asymptotic Regression Model

Description
Fits the asymptotic regression model, in the form \( b0 + b1 \times (1 - \exp(-\exp(lrc) \times x)) \) to the xy data. This can be used as a building block in determining starting estimates for more complicated models.

Usage
NLSstAsymptotic(xy)
NLSstClosestX

**Description**
Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

**Usage**
```r
NLSstClosestX(xy, yval)
```

**Arguments**
- `xy` a sortedXyData object
- `yval` a numeric value on the y scale

**Value**
A single numeric value on the x scale.

**Author(s)**
José Pinheiro and Douglas Bates

**See Also**

NLSstClosestX(DN.srt, 1.0)

---

NLSstLfAsymptote  Horizontal Asymptote on the Left Side

Description

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

Usage

NLSstLfAsymptote(xy)

Arguments

xy a sortedXyData object

Value

A single numeric value estimating the horizontal asymptote for small x.

Author(s)

José Pinheiro and Douglas Bates

See Also

sortedXyData, NLSstClosestX, NLSstRtAsymptote, selfStart

Examples

DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2)
NLSstLfAsymptote( DN.srt )
NLSstRtAsymptote  *Horizontal Asymptote on the Right Side*

**Description**

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of \(x\)) of the graph of \(y\) versus \(x\) from the \(xy\) object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

\[
\text{NLSstRtAsymptote}(xy)
\]

**Arguments**

- \(xy\)
  - a sortedXyData object

**Value**

A single numeric value estimating the horizontal asymptote for large \(x\).

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

- sortedXyData, NLSstClosestX, NLSstRtAsymptote, selfStart

**Examples**

\[
\begin{align*}
\text{DNase.2} & <- \text{DNase}\{\text{DNase$Run} == "2", \}\} \\
\text{DN.srt} & <- \text{sortedXyData}\{\text{expression(log(conc)), expression(density), DNase.2}\} \\
\text{NLSstRtAsymptote} & (\text{DN.srt})
\end{align*}
\]

---

nobs  *Extract the Number of Observations from a Fit.*

**Description**

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see \(\text{AIC}\)).

**Usage**

\[
\text{nobs}(\text{object}, \ldots)
\]

### Default S3 method:

\[
\text{nobs}(\text{object, use.fallback = FALSE, \ldots})
\]
Normal

The Normal Distribution

Description
Density, distribution function, quantile function and random generation for the normal distribution
with mean equal to mean and standard deviation equal to sd.

Usage

dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
mean vector of means.
sd vector of standard deviations.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X ≤ x] otherwise, P[X > x].
Details

If `mean` or `sd` are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

\[ f(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{-(x-\mu)^2/2\sigma^2} \]

where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

The length of the result is determined by `n` for rnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

For `sd = 0` this gives the limit as `sd` decreases to 0, a point mass at `mu`. `sd < 0` is an error and returns NaN.

Source

For pnorm, based on

For qnorm, the code is a C translation of

which provides precise results up to about 16 digits.

For rnorm, see RNG for how to select the algorithm and for references to the supplied methods.

curve(-x*dnorm(x), col=3, lty=3, lwd=2, add=TRUE)
##
## IGNORE_RDIFF_BEGIN
# shows 1.609e-8 on most platforms
all.equal(attr(nD,"gradient"),
  with(myenv, cbind(-dnorm(x), -x*dnorm(x))))
## IGNORE_RDIFF_END
```

Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage

```r
offset(object)
```

Arguments

- `object`: An offset to be included in a model frame

Details

There can be more than one offset in a model formula, but `-` is not supported for offset terms (and is equivalent to `+`).
oneway.test

Value
The input value.

See Also
model.offset, model.frame.
For examples see glm and Insurance in package MASS.

---

Test for Equal Means in a One-Way Layout

Description
Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage
oneway.test(formula, data, subset, na.action, var.equal = FALSE)

Arguments
formula a formula of the form lhs ~ rhs where lhs gives the sample values and rhs the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
var.equal a logical variable indicating whether to treat the variances in the samples as equal. If TRUE, then a simple F test for the equality of means in a one-way analysis of variance is performed. If FALSE, an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Details
If the right-hand side of the formula contains more than one term, their interaction is taken to form the grouping.

Value
A list with class "htest" containing the following components:

- statistic the value of the test statistic.
- parameter the degrees of freedom of the exact or approximate F distribution of the test statistic.
- p.value the p-value of the test.
- method a character string indicating the test performed.
- data.name a character string giving the names of the data.

---

optim

**General-purpose Optimization**

**Description**

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

**Usage**

```r
optim(par, fn, gr = NULL, ..., method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN", "Brent"), lower = -Inf, upper = Inf, control = list(), hessian = FALSE)
optimHess(par, fn, gr = NULL, ..., control = list())
```

**Arguments**

- `par`: Initial values for the parameters to be optimized over.
- `fn`: A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
- `gr`: A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used.
- `...`: Further arguments to be passed to fn and gr.
- `method`: The method to be used. See 'Details'. Can be abbreviated.
- `lower, upper`: Bounds on the variables for the "L-BFGS-B" method, or bounds in which to search for method "Brent".
- `control`: a list of control parameters. See 'Details'.
- `hessian`: Logical. Should a numerically differentiated Hessian matrix be returned?
Details

Note that arguments after ... must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnscale` is negative. `optim$Hess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et. al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to `temp / log(((t-1) %/% tmax) * tmax + exp(1))`, where `t` is the current iteration step and `temp` and `tmax` are specifiable via `control`, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using `optimize()`. It can be useful in cases where `optim()` is used inside other functions where only method can be specified, such as in `mle` from package `stats4`.

Function `fn` can return `NA` or `Inf` if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. (Except for method "L-BFGS-B" where the values should always be finite.)

`optim` can be used recursively, and for a single parameter as well as many. It also accepts a zero-length `par`, and just evaluates the function with that argument.

The `control` argument is a list that can supply any of the following components:

- `trace` Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

- `fnscale` An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on `fn(par)/fnscale`. 

parscale A vector of scaling values for the parameters. Optimization is performed on
par/parscale and these should be comparable in the sense that a unit change in any ele-
ment produces about a unit change in the scaled value. Not used (nor needed) for method =
"Brent".
ndeps A vector of step sizes for the finite-difference approximation to the gradient, on
par/parscale scale. Defaults to 1e-3.
maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and
500 for "Nelder-Mead".
For "SANN" maxit gives the total number of function evaluations: there is no other stopping
criterion. Defaults to 10000.
abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance
for reaching zero.
reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the
value by a factor of reltol * (abs(val) + reltol) at a step. Defaults to
sqrt(.Machine$double.eps), typically about 1e-8.
alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. alpha is the reflection
factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).
REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if
control$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or
every 100 temperatures for "SANN".
warn.1d.NelderMead a logical indicating if the (default) "Nelder-Mead" method should sig-
nal a warning when used for one-dimensional minimization. As the warning is sometimes
inappropriate, you can suppress it by setting this option to false.
type for the conjugate-gradients method. Takes value 1 for the Fletcher–Reeves update, 2 for
Polak–Ribiere and 3 for Beale–Sorenson.
lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It de-
defaults to 5.
factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduc-
tion in the objective is within this factor of the machine tolerance. Default is 1e7, that is a
tolerance of about 1e-8.
pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected
gradient in the current search direction. This defaults to zero, when the check is suppressed.
temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults
to 10.
tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults to
10.

Any names given to par will be copied to the vectors passed to fn and gr. Note that no other
attributes of par are copied over.
The parameter vector passed to fn has special semantics and may be shared between calls: the
function should not change or copy it.

Value

For optim, a list with components:

par The best set of parameters found.
value The value of fn corresponding to par.
counts A two-element integer vector giving the number of calls to fn and gr respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to fn to compute a finite-difference approximation to the gradient.

convergence An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are:

1 indicates that the iteration limit maxit had been reached.
10 indicates degeneracy of the Nelder–Mead simplex.
51 indicates a warning from the "L-BFGS-B" method; see component message for further details.
52 indicates an error from the "L-BFGS-B" method; see component message for further details.

message A character string giving any additional information returned by the optimizer, or NULL.

hessian Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

For optimHess, the description of the hessian component applies.

Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses optimize and needs bounds to be available; "BFGS" often works well enough if not.

Source

The code for methods "Nelder–Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file ‘opt/lbfgs_bcm.shar’: another version is in ‘toms/778’).

The code for method "SANN" was contributed by A. Trapletti.

---

**optimize**  
One Dimensional Optimization

**Description**

The function optimize searches the interval from lower to upper for a minimum or maximum of the function f with respect to its first argument.

optimise is an alias for optimize.
Usage

optimize(f, interval, ..., lower = min(interval), upper = max(interval),
  maximum = FALSE,
  tol = .Machine$double.eps^0.25)

optimise(f, interval, ..., lower = min(interval), upper = max(interval),
  maximum = FALSE,
  tol = .Machine$double.eps^0.25)

Arguments

f the function to be optimized. The function is either minimized or maximized
over its first argument depending on the value of maximum.

interval a vector containing the end-points of the interval to be searched for the mini-
mum.

... additional named or unnamed arguments to be passed to f.

lower the lower end point of the interval to be searched.

upper the upper end point of the interval to be searched.

maximum logical. Should we maximize or minimize (the default)?

tol the desired accuracy.

Details

Note that arguments after ... must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation,
and was designed for use with continuous functions. Convergence is never much slower than that
for a Fibonacci search. If f has a continuous second derivative which is positive at the minimum
(which is not at lower or upper), then convergence is superlinear, and usually of the order of about
1.324.

The function f is never evaluated at two points closer together than \( \epsilon |x_0| + (tol/3) \), where \( \epsilon \) is
approximately \( \sqrt{\text{sqrt}(\text{.Machine$double.eps})} \) and \( x_0 \) is the final abscissa \( \text{optimize()} \text{minimum}. \)

If f is a unimodal function and the computed values of f are always unimodal when separated by at
least \( \epsilon |x| + (tol/3) \), then \( x_0 \) approximates the abscissa of the global minimum of f on the interval
lower, upper with an error less than \( \epsilon |x_0| + tol \).

If f is not unimodal, then \( \text{optimize()} \) may approximate a local, but perhaps non-global, minimum
to the same accuracy.

The first evaluation of f is always at \( x_1 = a + (1 - \phi)(b - a) \) where \( (a,b) = (\text{lower}, \text{upper}) \) and
\( \phi = (\sqrt{5} - 1)/2 = 0.61803... \) is the golden section ratio. Almost always, the second evaluation is
at \( x_2 = a + \phi(b - a) \). Note that a local minimum inside \( [x_1, x_2] \) will be found as solution, even
when f is constant in there, see the last example.

f will be called as \( f(x, \ldots) \) for a numeric value of x.

The argument passed to f has special semantics and used to be shared between calls. The function
should not copy it.

Value

A list with components minimum (or maximum) and objective which give the location of the mini-
mum (or maximum) and the value of the function at that point.

**order.dendrogram**  
Ordering or Labels of the Leaves in a Dendrogram

**Description**

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

**Usage**

```r
order.dendrogram(x)
```  
```r
labels(object, ...)
```

**Arguments**

- `x, object` a dendrogram (see `as.dendrogram`).
- `...` additional arguments
Details

The indices or labels for the leaves in left to right order are retrieved.

Value

A vector with length equal to the number of leaves in the dendrogram is returned. From \( r \leftarrow \text{order.dendrogram}() \), each element is the index into the original data (from which the dendrogram was computed).

Author(s)

R. Gentleman (\texttt{order.dendrogram}) and Martin Maechler (\texttt{labels.dendrogram}).

See Also

\texttt{reorder}, \texttt{dendrogram}.

Examples

```r
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same:
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
rownames(USArrests)[order.dendrogram(d2)]))
```

---

**p.adjust**

*Adjust P-values for Multiple Comparisons*

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

```r
p.adjust(p, method = p.adjust.methods, n = length(p))
```

Arguments

- **p**: numeric vector of p-values (possibly with \texttt{NAs}). Any other \texttt{R} object is coerced by \texttt{as.numeric}.
- **method**: correction method, a \texttt{character} string. Can be abbreviated.
- **n**: number of comparisons, must be at least \texttt{length(p)}; only set this (to non-default) when you know what you are doing!
**Details**

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the \texttt{p.adjust.methods} vector for the benefit of methods that need to have the method as an option and pass it on to \texttt{p.adjust}.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" methods of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set \( n \) larger than \( \text{length}(p) \) which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

**Value**

A numeric vector of corrected p-values (of the same length as \( p \), with names copied from \( p \)).

**References**

See Also
pairwise.* functions such as `pairwise.t.test`.

Examples

```r
require(graphics)
set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))
round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[, "none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
## or a bit nicer: noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

## Can work with NA's:
pN <- p; iN <- c(46, 47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))
## The smallest 20 P-values all affected by the NA's:
round((pN.a / p.adj)[1:20, 1, 4])
```

---

**Pair**

Construct paired-data object

**Description**
Combines two vectors into an object of class “Pair”

**Usage**

`Pair(x, y)`

**Arguments**

- `x` Vector. 1st element of pair.
- `y` Vector. 2nd element of pair. Should be same length as `x`
pairwise.prop.test

Value
A 2-column matrix of class "Pair"

Note
Mostly designed as part of the formula interface to paired tests.

See Also
t.test and wilcox.test

pairwise.prop.test Pairwise comparisons for proportions

Description
Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

Usage
pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)

Arguments
x Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
n Vector of counts of trials; ignored if x is a matrix.
... Additional arguments to pass to prop.test

Value
Object of class "pairwise.htest"

See Also
prop.test, p.adjust

Examples
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
pairwise.prop.test(smokers, patients)
pairwise.t.test  

**Pairwise t tests**

**Description**
Calculate pairwise comparisons between group levels with corrections for multiple testing

**Usage**

```r
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
                 pool.sd = !paired, paired = FALSE,
                 alternative = c("two.sided", "less", "greater"),
                 ...)  
```

**Arguments**

- `x`: response vector.
- `g`: grouping vector or factor.
- `pool.sd`: switch to allow/disallow the use of a pooled SD
- `paired`: a logical indicating whether you want paired t-tests.
- `alternative`: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". Can be abbreviated.
- `...`: additional arguments to pass to `t.test`.

**Details**

The `pool.sd` switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call `t.test`, so extra arguments are ignored. Pooling does not generalize to paired tests so `pool.sd` and `paired` cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

**Value**

Object of class "pairwise.htest"

**See Also**

`t.test`, `p.adjust`

**Examples**

```r
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adjust.method = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```
pairwise.table

**Description**

Creates table of p values for pairwise comparisons with corrections for multiple testing.

**Usage**

```r
pairwise.table(compare.levels, level.names, p.adjust.method)
```

**Arguments**

- `compare.levels`: a function to compute (raw) p value given indices `i` and `j`.
- `level.names`: names of the group levels
- `p.adjust.method`: a character string specifying the method for multiple testing adjustment; almost always one of `p.adjust.methods`. Can be abbreviated.

**Details**

Functions that do multiple group comparisons create separate `compare.levels` functions (assumed to be symmetrical in `i` and `j`) and passes them to this function.

**Value**

Table of p values in lower triangular form.

**See Also**

- `pairwise.t.test`

---

pairwise.wilcox.test

**Description**

Calculate pairwise comparisons between group levels with corrections for multiple testing.

**Usage**

```r
pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods, paired = FALSE, ...)
```
Arguments

- **x**: response vector.
- **g**: grouping vector or factor.
- **p.adjust.method**: method for adjusting p values (see `p.adjust`). Can be abbreviated.
- **paired**: a logical indicating whether you want a paired test.
- **...**: additional arguments to pass to `wilcox.test`.

Details

Extra arguments that are passed on to `wilcox.test` may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

`wilcox.test`, `p.adjust`

Examples

```r
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adjust.method = "bonf")
detach()
```

plot.acf

Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

```r
## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
     ylim = NULL, main = NULL,
     ci.col = "blue", ci.type = c("white", "ma"),
     max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
     mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
     oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
     mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
     xpd = par("xpd"),
     cex.main = if(nser > 2) 1 else par("cex.main"),
     verbose = getOption("verbose"),
     ...)
```
 Arguments

x: an object of class "acf".

 ci: coverage probability for confidence interval. Plotting of the confidence interval is suppressed if ci is zero or negative.

type: the type of plot to be drawn, default to histogram like vertical lines.

xlab: the x label of the plot.

ylab: the y label of the plot.

ylim: numeric of length 2 giving the y limits for the plot.

main: overall title for the plot.

 ci.col: colour to plot the confidence interval lines.

 ci.type: should the confidence limits assume a white noise input or for lag k an MA(k-1) input? Can be abbreviated.

 max.mfrow: positive integer; for multivariate x indicating how many rows and columns of plots should be put on one page, using par(mfrow = c(m,m)).

ask: logical; if TRUE, the user is asked before a new page is started.

 mar, oma, mgp, xpd, cex.main: graphics parameters as in par(*), by default adjusted to use smaller than default margins for multivariate x only.

verbose: logical. Should R report extra information on progress?

... graphics parameters to be passed to the plotting routines.

 Note

The confidence interval plotted in plot.acf is based on an uncorrelated series and should be treated with appropriate caution. Using ci.type = "ma" may be less potentially misleading.

 See Also

acf which calls plot.acf by default.

 Examples

require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7)  # squeeze onto 1 page
acf(z7)  # multi-page
Description

The plot method for density objects.

Usage

## S3 method for class 'density'
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
      zero.line = TRUE, ...)

Arguments

x a "density" object.
main, xlab, ylab, type
plotting parameters with useful defaults.
...
... further plotting parameters.
zero.line logical; if TRUE, add a base line at \( y = 0 \)

Value

None.

See Also
density.

plot.HoltWinters

Plot function for HoltWinters objects

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE,
     separator = TRUE, col = 1, col.predicted = 2,
     col.intervals = 4, col.separator = 1, lty = 1,
     lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
     ylab = "Observed / Fitted",
     main = "Holt-Winters filtering",
     ylim = NULL, ...)
**plot.isoreg**

**Arguments**

- `x` Object of class "HoltWinters"
- `predicted.values` Predicted values as returned by `predict.HoltWinters`
- `intervals` If TRUE, the prediction intervals are plotted (default).
- `separator` If TRUE, a separating line between fitted and predicted values is plotted (default).
- `col, lty` Color/line type of original data (default: black solid).
- `col.predicted, lty.predicted` Color/line type of fitted and predicted values (default: red solid).
- `col.intervals, lty.intervals` Color/line type of prediction intervals (default: blue solid).
- `col.separator, lty.separator` Color/line type of observed/predicted values separator (default: black dashed).
- `ylab` Label of the y-axis.
- `main` Main title.
- `ylim` Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any.
- `...` Other graphics parameters.

**plot.isoreg**  
*Plot Method for isoreg Objects*

**Description**

The `plot` and `lines` method for R objects of class `isoreg`.
Usage

## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...
## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
      do.points = FALSE, cex = 1.5, pch = 13, ...)

Arguments

x
   an isoreg object.

plot.type
   character indicating which type of plot is desired. The first (default) only draws
   the data and the fit, where the others add a plot of the cumulative data and fit.
   Can be abbreviated.

main
   main title of plot, see title.

main2
   title for second (cumulative) plot.

xlab, ylab
   x- and y- axis annotation.

par.fit
   a list of arguments (for points and lines) for drawing the fit.

mar, mgp
   graphical parameters, see par, mainly for the case of two plots.

grid
   logical indicating if grid lines should be drawn. If true, grid() is used for the
   first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative
   plot.

do.points
   for lines(): logical indicating if the step points should be drawn as well (and
   as they are drawn in plot()).

col, lwd, cex, pch
   graphical arguments for lines(), where cex and pch are only used when
   do.points is TRUE.

...
   further arguments passed to and from methods.

See Also

isoreg for computation of isoreg objects.

Examples

require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>)")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^(1:9), c(1,0,4,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.type = "r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)), plot.type = "r")

---

**plot.lm**

*Plot Diagnostics for an lm Object*

**Description**

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of $\sqrt{|\text{residuals}|}$ against fitted values, a Normal Q-Q plot, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.

**Usage**

```r
## S3 method for class 'lm'
plot(x, which = c(1,2,3,5),
caption = list("Residuals vs Fitted", "Normal Q-Q", "Scale-Location", "Cook's distance", "Residuals vs Leverage", expression("Cook's dist vs Leverage* " * h[iii] / (1 - h[iii]))),
panel = if(add.smooth) function(x, y, ...) 
panel.smooth(x, y, iter=iter.smooth, ...) else points,
sub.caption = NULL, main = ",
ask = prod(par("mfcol")) < length(which) && dev.interactive(), ...
, id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qline = TRUE, cook.levels = c(0.5, 1.0),
cook.col = 8, cook.lty = 2, cook.legendChanges = list(),
add.smooth = getOption("add.smooth"),
iter.smooth = if(isGlm) 0 else 3,
label.pos = c(4,2),
cex.caption = 1, cex.oma.main = 1.25,
extend.ylim.f = 0.08
)
```

**Arguments**

- `x` *lm* object, typically result of *lm* or *glm*.
- `which` a subset of the numbers 1:6, by default 1:3, 5, referring to
2. "Normal Q-Q" plot, an enhanced `qqnorm(resid(.))`
3. "Scale-Location"
4. "Cook's distance"
5. "Residuals vs Leverage"
6. "Cook's dist vs Lev./(1-Lev.)"

, see also 'Details' below.

caption captions to appear above the plots; character vector or list of valid graphics annotations, see `as.graphicsAnnot`, of length 6, the j-th entry corresponding to which[j], see also the default vector in 'Usage'. Can be set to "" or NA to suppress all captions.

panel panel function. The useful alternative to `points, panel.smooth` can be chosen by `add.smooth = TRUE`.

sub.caption common title—above the figures if there are more than one; used as sub (s.title) otherwise. If NULL, as by default, a possible abbreviated version of `deparse(x$call)` is used.

main title to each plot—in addition to caption.

ask logical; if TRUE, the user is asked before each plot, see `par(ask=.)`.

... other parameters to be passed through to plotting functions.

id.n number of points to be labelled in each plot, starting with the most extreme.

labels.id vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.

cex.id magnification of point labels.

qcline logical indicating if a `qqline()` should be added to the normal Q-Q plot.

cook.levels levels of Cook’s distance at which to draw contours.

cook.col, cook.lty color and line type to use for these contour lines.

cook.legendChanges a list (or NULL to suppress the call) of arguments to `legend` which should be modified from (or added to) the `plot.lm()` default list(x = "bottomleft", legend = "Cook’s distance = c", lty = cook.lty, col = cook.col, text.col = cook.col, bty = "n", adj = 0.1, y.intersp = 1/8)

add.smooth logical indicating if a smoother should be added to most plots; see also panel above.

iter.smooth the number of robustness iterations, the argument `iter` in `panel.smooth()`; the default uses no such iterations for `glm` fits which is particularly desirable for the (predominant) case of binary observations, but also for other models where the response distribution can be highly skewed.

label.pos positioning of labels, for the left half and right half of the graph respectively, for plots 1-3, 5, 6.

cex.caption controls the size of caption.

cex oma.main controls the size of the sub.caption only if that is above the figures when there is more than one.

extend.ylim.f a numeric vector of length 1 or 2, to be used in `ylim <- extendrange(r=ylim, f = *)` for plots 1 and 5 when `id.n` is non-empty.
Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot (which=3), also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ($\sqrt{|E|}$ is much less skewed than $|E|$ for Gaussian zero-mean $E$).

The ‘S-L’, the Q-Q, and the Residual-Leverage (which=5) plot use standardized residuals which have identical variance (under the hypothesis). They are given as $R_i/(s \times \sqrt{1-h_{ii}})$ where the ‘leverages’ $h_{ii}$ are the diagonal entries of the hat matrix, influence()$hat$ (see also hat), and where the Residual-Leverage plot uses the standardized Pearson residuals (residuals.glm(type = "pearson")) for $R_i$.

The Residual-Leverage plot (which=5) shows contours of equal Cook’s distance, for values of cook.levels (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced aov situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) (= “leverage*”), contours of standardized residuals (rstandard(.)) that are equal in magnitude are lines through the origin. These lines are labelled with the magnitudes. The x-axis is labeled with the (non equidistant) leverages $h_{ii}$.

Notice that some plots may not make much sense for the glm case; e.g., the normal Q-Q plot only makes sense if the distribution is approximately normal.

plot(lm.SR, which=5, cook.lty="dotdash",
     cook.legendChanges = list(x = "bottomright"))
plot(lm.SR, which=5, cook.legendChanges= NULL)# no "legend"

par(opar) # reset par()

plot.ppr

### S3 method for class 'ppr'
plot(x, ask, type = "o", cex = 1/2,
     main = quote(bquote("term"[.(i)]: \[ \hat{beta}[.(i)] == .(bet.i)])),
     xlab = quote(bquote(bold(alpha)[.(i)]^T * bold(x))),
     ylab = "", ...)
plot.profile.nls

Arguments

x an R object of class "ppr" as produced by a call to ppr.
ask the graphics parameter ask: see par for details. If set to TRUE will ask between the plot of each cross-section.
type the type of line (see plot.default) to draw.
cex plot symbol expansion factor (relative to par("cex")).
main, xlab, ylab axis annotations, see also title. Can be an expression (depending on i and bet.i), as by default which will be evaluated.
... further graphical parameters, passed to plot().

Value
None

Side Effects
A series of plots are drawn on the current graphical device, one for each term in the fit.

See Also
ppr, par

Examples
require(graphics)

par(mfrow = c(3,2)) # maybe: , pty = "s"
rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
   data = rock1, nterms = 2, max.terms = 5)
plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)
plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)"
plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
   main = "update(..., sm.method="gcv", gcvpen=2")"

plot.profile.nls  Plot a profile.nls Object

Description
Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with nls and profiled with profile.nls.

Usage
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
   absVal = TRUE, ylab = NULL, lty = 2, ...)
Arguments

x  an object of class "profile.nls"
levels  levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly.
conf  a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to c(0.99, 0.95, 0.90, 0.80, 0.50).
absVal  a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.
lty  the line type to be used for axis and dropped lines.

ylab, ...  other arguments to the plot.default function can be passed here (but not xlab, xlim, ylim nor type).

Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the palette. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

mtext("BOD data - confidence levels of 50%, 80%, 90% and 95%",
     side = 1, outer = TRUE)
par(opar)
Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

Usage

```r
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...) 
```

```r
plot.spec.phase(x, ci = 0.95,
     xlab = "frequency", ylab = "phase",
     ylim = c(-pi, pi), type = "l",
     main = NULL, ci.col = "blue", ci.lty = 3,...)
```

```r
plot.spec.coherency(x, ci = 0.95,
     xlab = "frequency",
     ylab = "squared coherency",
     ylim = c(0, 1), type = "l",
     main = NULL, ci.col = "blue", ci.lty = 3,...)
```

Arguments

- **x**: an object of class "spec".
- **add**: logical. If TRUE, add to already existing plot. Only valid for `plot.type = "marginal"`.
- **ci**: coverage probability for confidence interval. Plotting of the confidence intervals is omitted unless `ci` is strictly positive.
- **log**: If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless `options(ts.S.compat = TRUE)` has been set, when it is "dB". Only valid for `plot.type = "marginal"`.
- **xlab**: the x label of the plot.
- **ylab**: the y label of the plot. If missing a suitable label will be constructed.
- **type**: the type of plot to be drawn, defaults to lines.
- **ci.col**: colour for plotting confidence bar or confidence intervals for coherency and phase.
- **ci.lty**: line type for confidence intervals for coherency and phase.
- **main**: overall title for the plot. If missing, a suitable title is constructed.
sub a sub title for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.

plot.type For multivariate time series, the type of plot required. Only the first character is needed.

ylim, ... Graphical parameters.

See Also
spectrum

plot.stepfun

Plot Step Functions

Description
Method of the generic plot for stepfun objects and utility for plotting piecewise constant functions.

Usage
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
xlab = "x", ylab = "f(x)", main = NULL,
add = FALSE, verticals = TRUE, do.points = (n < 1000),
pch = par("pch"), col = par("col"),
col.points = col, cex.points = par("cex"),
col.hor = col, col.vert = col,
lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun'
lines(x, ...)

Arguments
x an R object inheriting from "stepfun".

xval numeric vector of abscissa values at which to evaluate x. Defaults to knots(x) restricted to xlim.

xlim, ylim limits for the plot region: see plot.window. Both have sensible defaults if omitted.

xlab, ylab labels for x and y axis.

main main title.

add logical; if TRUE only add to an existing plot.

verticals logical; if TRUE, draw vertical lines at steps.

do.points logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000.

pch character; point character if do.points.

col default color of all points and lines.

col.points character or integer code; color of points if do.points.
plot.stepfun
cex.points  numeric; character expansion factor if do.points.
col.hor    color of horizontal lines.
col.vert   color of vertical lines.
lty, lwd    line type and thickness for all lines.
...         further arguments of plot(.), or if(add) segments(.).

Value

A list with two components

t  abscissa (x) values, including the two outermost ones.
y  y values ‘in between’ the t[].

plot.ts

Plotting Time-Series Objects

Description

Plotting method for objects inheriting from class "ts".

Usage

## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
     xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
     mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
     oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts'
lines(x, ...)

Arguments

x, y
time series objects, usually inheriting from class "ts".

plot.type
for multivariate time series, should the series by plotted separately (with a common time axis) or on a single plot? Can be abbreviated.

xy.labels
logical, indicating if text() labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.

xy.lines
logical, indicating if lines should be drawn for an x-y plot. Defaults to the value of xy.labels if that is logical, otherwise to TRUE.

panel
a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for plot.type = "multiple". The default is lines.

nc
the number of columns to use when type = "multiple". Defaults to 1 for up to 4 series, otherwise to 2.

yax.flip
logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when type = "multiple".

mar.multi, oma.multi
the (default) par settings for plot.type = "multiple". Modify with care!

axes
logical indicating if x- and y- axes should be drawn.

...
additional graphical arguments, see plot, plot.default and par.

Details

If y is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on plot.type.

If y is present, both x and y must be univariate, and a scatter plot y ~ x will be drawn, enhanced by using text if xy.labels is TRUE or character, and lines if xy.lines is TRUE.
See Also

ts for basic time series construction and access functionality.

Examples

```r
require(graphics)

## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
       start = c(1961, 1), frequency = 12)
plot(z, yax.flip = TRUE)
plot(z, axes = FALSE, ann = FALSE, frame.plot = TRUE,
     mar.multi = c(0,0,0,0), oma.multi = c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...)")

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b")  # multiple
plot(z, plot.type = "single", lty = 1:3, col = 4:2)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")

## xy.lines and xy.labels are FALSE for large series:
plot(lag(sunspots, 1), sunspots, pch = ".")
SMI <- EuStockMarkets[, "SMI"]
plot(lag(SMI, 1), SMI, pch = ".")
plot(lag(SMI, 20), SMI, pch = ".", log = "xy",
     main = "4 weeks lagged SMI stocks -- log scale", xy.lines = TRUE)
```

---

**Poisson**

**The Poisson Distribution**

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter lambda.

### Usage

```r
dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)
```

### Arguments

- `x` : vector of (non-negative integer) quantiles.
- `q` : vector of quantiles.
- `p` : vector of probabilities.
- `n` : number of random values to return.
lambda vector of (non-negative) means.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Poisson distribution has density

\[
p(x) = \frac{\lambda^x e^{-\lambda}}{x!}
\]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).

Note that \( \lambda = 0 \) is really a limit case (setting \( 0^0 = 1 \)) resulting in a point mass at 0, see also the example.

If an element of \( x \) is not integer, the result of \( \text{dpois} \) is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference in \( \text{dbinom} \).

The quantile is right continuous: \( \text{qpois}(p, \lambda) \) is the smallest integer \( x \) such that \( P(X \leq x) \geq p \).

Setting \( \text{lower.tail} = \text{FALSE} \) allows to get much more precise results when the default, \( \text{lower.tail} = \text{TRUE} \) would return 1, see the example below.

Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.
Invalid \( \lambda \) will result in return value \( \text{NaN} \), with a warning.

The length of the result is determined by \( n \) for \( rpois \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

\( rpois \) returns a vector of type integer unless generated values exceed the maximum representable integer when \( \text{double} \) values are returned since R version 4.0.0.

Source

dpois uses C code contributed by Catherine Loader (see \( \text{dbinom} \)).
ppois uses \( \text{pgamma} \).
qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rpois uses

See Also

\( \text{Distributions} \) for other standard distributions, including \( \text{dbinom} \) for the binomial and \( \text{dnbinom} \) for the negative binomial distribution.

\( \text{poisson.test} \).
Examples

```r
require(graphics)

-\log(dpois(0:7, lambda = 1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))

1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
   ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation

c <- 2
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type = "s", ylab = "F(x)", main = "Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type = "s", ylab = "F(x)",
    main = "Binomial(100, 0.01) CDF")

## The (limit) case lambda = 0 :
stopifnot(identical(dpois(0,0), 1),
           identical(ppois(0,0), 1),
           identical(qpois(1,0), 0))
```

### poisson.test

#### Exact Poisson tests

**Description**

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

**Usage**

`poisson.test(x, T = 1, r = 1, alternative = c("two.sided", "less", "greater"),
             conf.level = 0.95)`

**Arguments**

- `x` number of events. A vector of length one or two.
- `T` time base for event count. A vector of length one or two.
- `r` hypothesized rate or rate ratio
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.

**Details**

Confidence intervals are computed similarly to those of `binom.test` in the one-sample case, and using `binom.test` in the two sample case.
Value

A list with class "htest" containing the following components:

- **statistic**: the number of events (in the first sample if there are two.)
- **parameter**: the corresponding expected count
- **p.value**: the p-value of the test.
- **conf.int**: a confidence interval for the rate or rate ratio.
- **estimate**: the estimated rate or rate ratio.
- **null.value**: the rate or rate ratio under the null, \( r \).
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate.
- **data.name**: a character string giving the names of the data.

Note

The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the \( T \) argument.

The one-sample case is effectively the binomial test with a very large \( n \). The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

See Also

- `binom.test`

Examples

```r
### These are paraphrased from data sets in the ISwR package

## SMR, Welsh Nickel workers
poisson.test(137, 24.19893)

## eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
```

---

**poly**

*Compute Orthogonal Polynomials*

Description

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points \( x \): these are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.
Usage

poly(x, ..., degree = 1, coefs = NULL, raw = FALSE, simple = FALSE)
polym(..., degree = 1, coefs = NULL, raw = FALSE)

## S3 method for class 'poly'
predict(object, newdata, ...)

Arguments

x, newdata a numeric vector at which to evaluate the polynomial. x can also be a matrix. Missing values are not allowed in x.
degree the degree of the polynomial. Must be less than the number of unique points when raw is false, as by default.
coefs for prediction, coefficients from a previous fit.
raw if true, use raw and not orthogonal polynomials.
simple logical indicating if a simple matrix (with no further attributes but dimnames) should be returned. For speedup only.
object an object inheriting from class "poly", normally the result of a call to poly with a single vector argument.
... poly, polym: further vectors.
predict.poly: arguments to be passed to or from other methods.

Details

Although formally degree should be named (as it follows ...), an unnamed second argument of length 1 will be interpreted as the degree, such that poly(x, 3) can be used in formulas.
The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.
poly using ... is just a convenience wrapper for polym: coef is ignored. Conversely, if polym is called with a single argument in ..., it is a wrapper for poly.

Value

For poly and polym() (when simple=FALSE and coefs=NULL as per default):
A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless raw = TRUE) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials and class c("poly", "matrix").
For poly(*, simple=TRUE), polym(*, coefs=<non-NULL>), and predict.poly(): a matrix.

Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

Author(s)

R Core Team. Keith Jewell (Campden BRI Group, UK) contributed improvements for correct prediction on subsets.
power

Create a Power Link Object

Description

Creates a link object based on the link function $\eta = \mu^\lambda$.

Usage

power(lambda = 1)

Arguments

lambda a real number.

Details

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

Value

A list with components linkfun, linkinv, mu.eta, and valideta. See make.link for information on their meaning.
power.anova.test

References

See Also

`make.link`, `family`

To raise a number to a power, see `Arithmetic`.

To calculate the power of a test, see various functions in the `stats` package, e.g., `power.t.test`.

Examples

```r
power()
quasi(link = power(1/3))[c("linkfun", "linkinv")]
```

power.anova.test  
*Power Calculations for Balanced One-Way Analysis of Variance Tests*

Description

Compute power of test or determine parameters to obtain target power.

Usage

```r
power.anova.test(groups = NULL, n = NULL, 
between.var = NULL, within.var = NULL, 
sig.level = 0.05, power = NULL)
```

Arguments

- `groups`  
  Number of groups
- `n`  
  Number of observations (per group)
- `between.var`  
  Between group variance
- `within.var`  
  Within group variance
- `sig.level`  
  Significance level (Type I error probability)
- `power`  
  Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-NULL default so `NULL` must be explicitly passed if you want it computed.

Value

Object of class "`power.htest"", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.
power.prop.test

Power Calculations for Two-Sample Test for Proportions

Description

Compute the power of the two-sample test for proportions, or determine parameters to obtain a target power.

Usage

```r
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05, power = NULL, alternative = c("two.sided", "one.sided"), strict = FALSE, tol = .Machine$double.eps^0.25)
```

Arguments

- `n`: number of observations (per group)
- `p1`: probability in one group
- `p2`: probability in other group
- `sig.level`: significance level (Type I error probability)
- `power`: power of test (1 minus Type II error probability)
- `alternative`: one- or two-sided test. Can be abbreviated.
- `strict`: use strict interpretation in two-sided case
- `tol`: numerical tolerance used in root finding, the default providing (at least) four significant digits.

Examples

```r
power.anova.test(groups = 4, n = 5, between.var = 1, within.var = 3)
#  Power = 0.3535594

power.anova.test(groups = 4, between.var = 1, within.var = 3, power = .80)
#  n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
  between.var = var(groupmeans),
  within.var = 500, power = .90) #  n = 15.18834
```
Details

Exactly one of the parameters n, p1, p2, power, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has a non-NULL default so NULL must be explicitly passed if you want it computed.

If strict = TRUE is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Note that not all conditions can be satisfied, e.g., for

```
power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8, strict=TRUE)
```

there is no proportion p2 between p1 = 0.9 and 1, as you’d need a sample size of at least n = 74 to yield the desired power for (p1, p2) = (0.9, 1).

For these impossible conditions, currently a warning (warning) is signalled which may become an error (stop) in the future.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of p1 and p2 is computed, then p1 < p2 is assumed and will hold, but if you specify both, p2 ≤ p1 is allowed.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

See Also

prop.test, uniroot

Examples

```
power.prop.test(n = 50, p1 = .50, p2 = .75)  ## => power = 0.740
power.prop.test(p1 = .50, p2 = .75, power = .90)  ## =>  n =  76.7
power.prop.test(n = 50, p1 = .5, power = .90)   ## =>  p2 = 0.8026
power.prop.test(n = 50, p1 = .5, p2 = .9, power = .90, sig.level=NULL)  ## =>  sig.l = 0.00131
power.prop.test(p1 = .5, p2 = 0.501, sig.level=.001, power=0.90)  ## =>  n = 10451937
```

```
try(
  power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8)
) # a warning (which may become an error)
## Reason:
power.prop.test(  p1=0.90, p2= 1.0, power=0.8)  ##--> n =  73.37
```
power.t.test

Description

Compute the power of the one- or two-sample t test, or determine parameters to obtain a target power.

Usage

```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05,
             power = NULL,
             type = c("two.sample", "one.sample", "paired"),
             alternative = c("two.sided", "one.sided"),
             strict = FALSE, tol = .Machine$double.eps^0.25)
```

Arguments

- `n`: number of observations (per group)
- `delta`: true difference in means
- `sd`: standard deviation
- `sig.level`: significance level (Type I error probability)
- `power`: power of test (1 minus Type II error probability)
- `type`: string specifying the type of t test. Can be abbreviated.
- `alternative`: one- or two-sided test. Can be abbreviated.
- `strict`: use strict interpretation in two-sided case
- `tol`: numerical tolerance used in root finding, the default providing (at least) four significant digits.

Details

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that the last two have non-NULL defaults, so `NULL` must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve the power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.
Author(s)
Peter Dalgaard. Based on previous work by Claus Ekstrøm

t.test, uniroot

Examples
power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")

Description
Computes the Phillips-Perron test for the null hypothesis that \( x \) has a unit root against a stationary alternative.

Usage
PP.test(x, lshort = TRUE)

Arguments
x
a numeric vector or univariate time series.
lshort
a logical indicating whether the short or long version of the truncation lag parameter is used.

Details
The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate \( \sigma^2 \) the Newey-West estimator is used. If \( lshort \) is TRUE, then the truncation lag parameter is set to \( \text{trunc}(4*(n/100)^{0.25}) \), otherwise \( \text{trunc}(12*(n/100)^{0.25}) \) is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee et al (1993).

Missing values are not handled.

Value
A list with class "htest" containing the following components:
statistic
the value of the test statistic.
parameter
the truncation lag parameter.
p.value
the p-value of the test.
method
a character string indicating what type of test was performed.
data.name
a character string giving the name of the data.
ppoints

Author(s)
A. Trapletti

References

Examples
```r
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

ppoints

Ordinates for Probability Plotting

Description
Generates the sequence of probability points \((1:m - a)/(m + (1-a) \cdot a)\) where \(m\) is either \(n\), if `length(n)==1`, or `length(n)`.

Usage
```r
ppoints(n, a = if(n <= 10) 3/8 else 1/2)
```

Arguments
- `n`: either the number of points generated or a vector of observations.
- `a`: the offset fraction to be used; typically in \((0, 1)\).

Details
If \(0 < a < 1\), the resulting values are within \((0, 1)\) (excluding boundaries). In any case, the resulting sequence is symmetric in \([0, 1]\), i.e., \(p + \text{rev}(p) == 1\).

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of \(a\) follows the documentation of the function of the same name in Becker *et al* (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also `quantile`).

The probability points for the continuous sample quantile types 5 to 9 (see `quantile`) can be obtained by taking `a` as, respectively, 1/2, 0, 1, 1/3, and 3/8.

ppr

Projection Pursuit Regression

Description

Fit a projection pursuit regression model.

Usage

ppr(x, ...)

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
    contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcvspine"),
    bass = 0, span = 0, df = 5, gcvpen = 1, trace = FALSE, ...)

ppr

Projection Pursuit Regression

Description

Fit a projection pursuit regression model.

Usage

ppr(x, ...)

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
    contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcvspine"),
    bass = 0, span = 0, df = 5, gcvpen = 1, trace = FALSE, ...)

Arguments

- **formula**: a formula specifying one or more numeric response variables and the explanatory variables.
- **x**: numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
- **y**: numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
- **nterms**: number of terms to include in the final model.
- **data**: a data frame (or similar: see `model.frame`) from which variables specified in `formula` are preferentially to be taken.
- **weights**: a vector of weights $w_i$ for each case.
- **ww**: a vector of weights for each response, so the fit criterion is the sum over case $i$ and responses $j$ of $w_i \cdot w_{ij} \cdot (y_{ij} - \hat{y}_{ij})^2$ divided by the sum of $w_i$.
- **subset**: an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: a function to specify the action to be taken if NAs are found. The default action is given by `getOption("na.action")`. (NOTE: If given, this argument must be named.)
- **contrasts**: the contrasts to be used when any factor explanatory variables are coded.
- **max.terms**: maximum number of terms to choose from when building the model.
- **optlevel**: integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.
- **sm.method**: the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother `supsmu`. The alternatives are to use the smoothing spline code underlying `smooth.spline`, either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV. Can be abbreviated.
- **bass**: super smoother bass tone control used with automatic span selection (see `supsmu`); the range of values is 0 to 10, with larger values resulting in increased smoothing.
- **span**: super smoother span control (see `supsmu`). The default, 0, results in automatic span selection by local cross validation. span can also take a value in (0, 1].
- **df**: if `sm.method` is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.
- **gcvpen**: if `sm.method` is "gcv spline" this is the penalty used in the GCV selection for each degree of freedom used.
- **trace**: logical indicating if each spline fit should produce diagnostic output (about lambda and df), and the supsmu fit about its steps.
- **...**: arguments to be passed to or from other methods.
- **model**: logical. If true, the model frame is returned.
Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS’s pprreg. This code is extremely sensitive to the compiler used.

The algorithm first adds up to max. terms ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until nterms terms are left.

The levels of optimization (argument optlevel) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

Value

A list with the following components, many of which are for use by the method functions.

call the matched call
p the number of explanatory variables (after any coding)
q the number of response variables
mu the argument nterms
ml the argument max.terms
gof the overall residual (weighted) sum of squares for the selected model
gofn the overall residual (weighted) sum of squares against the number of terms, up to max. terms. Will be invalid (and zero) for less than nterms.
df the argument df
edf if sm.method is "spline" or "gcvspline" the equivalent number of degrees of freedom for each ridge term used.
xnames the names of the explanatory variables
ynames the names of the response variables
alpha a matrix of the projection directions, with a column for each ridge term
beta a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
yb the weighted means of each response
ys the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.
fitted.values the fitted values, as a matrix if q > 1.
residuals the residuals, as a matrix if q > 1.
smod internal work array, which includes the ridge functions evaluated at the training set points.
model (only if model = TRUE) the model frame.

Source

Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the MASS package.

prcomp

Principal Components Analysis

Description

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

Usage

```r
prcomp(x, ...)  
```

## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,  
tol = NULL, rank. = NULL, ...)

## S3 method for class 'prcomp'
predict(object, newdata, ...)
```

Arguments

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.  
- **subset**: an optional vector used to select rows (observations) of the data matrix `x`.  
- **na.action**: a function which indicates what should happen when the data contain `NA`s. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The 'factory-fresh' default is `na.omit`.  
- **...**: arguments passed to or from other methods. If `x` is a formula one might specify `scale.` or `tol`.  
- **x**: a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.  
- **retx**: a logical value indicating whether the rotated variables should be returned.  
- **center**: a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.  
- **scale.**: a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is `FALSE` for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.  
- **tol**: a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to `tol` times the standard deviation of the first component.) With the default null setting, no components are omitted (unless `rank.` is specified
less than \( \min(dim(x)) \). Other settings for \( \text{tol} \) could be \( \text{tol} = 0 \) or \( \text{tol} = \sqrt{\text{.Machine}\$\text{double\.eps}} \), which would omit essentially constant components.

rank. optionally, a number specifying the maximal rank, i.e., maximal number of principal components to be used. Can be set as alternative or in addition to \( \text{tol} \), useful notably when the desired rank is considerably smaller than the dimensions of the matrix.

object object of class inheriting from "prcomp"

newdata An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, \( \text{newdata} \) must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using \( \text{eigen} \) on the covariance matrix. This is generally the preferred method for numerical accuracy. The print method for these objects prints the results in a nice format and the plot method produces a scree plot.

Unlike \( \text{princomp} \), variances are computed with the usual divisor \( N - 1 \).

Note that \( \text{scale} = \text{TRUE} \) cannot be used if there are zero or constant (for \( \text{center} = \text{TRUE} \)) variables.

Value

\( \text{prcomp} \) returns a list with class "prcomp" containing the following components:

- **sdev** the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
- **rotation** the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function \( \text{princomp} \) returns this in the element \( \text{loadings} \).
- **x** if \( \text{retx} \) is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the \( \text{rotation} \) matrix) is returned. Hence, \( \text{cov}(x) \) is the diagonal matrix \( \text{diag}(sdev^2) \). For the formula method, \( \text{napredict}() \) is applied to handle the treatment of values omitted by the \( \text{na.action} \).
- **center**, \( \text{scale} \) the centering and scaling used, or \( \text{FALSE} \).

Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of \( \mathcal{R} \).

**predict**

*Model Predictions*

**Description**

predict is a generic function for predictions from the results of various model fitting functions. The function invokes particular *methods* which depend on the *class* of the first argument.

**Usage**

```
predict(object, ...)
```

**Arguments**

- `object` a model object for which prediction is desired.
- `...` additional arguments affecting the predictions produced.
Details

Most prediction methods which are similar to those for linear models have an argument \texttt{newdata} specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in \texttt{newdata} to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package \texttt{stats} have an argument \texttt{n.ahead} specifying how many time steps ahead to predict.

Many methods have a logical argument \texttt{se.fit} saying if standard errors are to be returned.

Value

The form of the value returned by \texttt{predict} depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

References

See Also

\texttt{predict.glm, predict.lm, predict.loess, predict.nls, predict.poly, predict.princomp, predict.smooth.spline}.

\texttt{SafePrediction} for prediction from (univariable) polynomial and spline fits.

Examples

```
require(utils)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
# Output will depend on what namespaces are (or have been) loaded.
## IGNORE_RDIFF_BEGIN
for(fn in methods("predict"))
  try({
    f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn)))
    cat(fn, ":\n\t", deparse(args(f)), "\n"
  }, silent = TRUE)
## IGNORE_RDIFF_END
```

\begin{verbatim}
predict.Arima                  Forecast from ARIMA fits
\end{verbatim}

Description

Forecast from models fitted by \texttt{arima}. 
Usage

## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
       se.fit = TRUE, ...)

Arguments

object    The result of an arima fit.
n.ahead   The number of steps ahead for which prediction is required.
newxreg   New values of xreg to be used for prediction. Must have at least n.ahead rows.
se.fit    Logical: should standard errors of prediction be returned?
...        arguments passed to or from other methods.

Details

Finite-history prediction is used, via KalmanForecast. This is only statistically efficient if the MA part of the fit is invertible, so predict.Arima will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

Value

A time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

References

See Also

arima

Examples

od <- options(digits = 5) # avoid too much spurious accuracy
predict(arima(lh, order = c(3,0,0)), n.ahead = 12)

(fit <- arima(USAccDeaths, order = c(0,1,1),
              seasonal = list(order = c(0,1,1))))
predict(fit, n.ahead = 6)
options(od)
**Description**

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

**Usage**

```r
## S3 method for class 'glm'
predict(object, newdata = NULL,
type = c("link", "response", "terms"),
se.fit = FALSE, dispersion = NULL, terms = NULL,
na.action = na.pass, ...)
```

**Arguments**

- `object`: a fitted object of class inheriting from "glm".
- `newdata`: optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
- `type`: the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and `type = "response"` gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.
  
  The value of this argument can be abbreviated.
- `se.fit`: logical switch indicating if standard errors are required.
- `dispersion`: the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by `summary` applied to the object is used.
- `terms`: with `type = "terms"` by default all terms are returned. A character vector specifies which terms are to be returned
- `na.action`: function determining what should be done with missing values in `newdata`. The default is to predict NA.
- `...`: further arguments passed to or from other methods.

**Details**

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also `napredict`.
predict.HoltWinters

Value

If `se.fit = FALSE`, a vector or matrix of predictions. For `type = "terms"` this is a matrix with a column per term, and may have an attribute "constant".

If `se.fit = TRUE`, a list with components

- **fit**: Predictions, as for `se.fit = FALSE`
- **se.fit**: Estimated standard errors.
- **residual.scale**: A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

## example from Venables and Ripley (2002, pp. 190-2.)
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20-numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
summary(budworm.lg)

plot(c(1,32), c(0,1), type = "n", xlab = "dose", ylab = "prob", log = "x")
text(2^ldose, numdead/20, as.character(sex))
ld <- seq(0, 5, 0.1)
lines(2^ld, predict(budworm.lg, data.frame(ldose = ld, sex = factor(rep("M", length(ld)), levels = levels(sex))), type = "response"))
lines(2^ld, predict(budworm.lg, data.frame(ldose = ld, sex = factor(rep("F", length(ld)), levels = levels(sex))), type = "response"))
```

---

**predict.HoltWinters**  
*Prediction Function for Fitted Holt-Winters Models*

Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.
Usage

```r
## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
         level = 0.95, ...)
```

Arguments

- `object`: An object of class `HoltWinters`.
- `n.ahead`: Number of future periods to predict.
- `prediction.interval`: logical. If `TRUE`, the lower and upper bounds of the corresponding prediction intervals are computed.
- `level`: Confidence level for the prediction interval.
- `...`: arguments passed to or from other methods.

Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

predict.lm

Predict method for Linear Model Fits

Description

Predicted values based on linear model object.

Usage

## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, type = c("response", "terms"),
        terms = NULL, na.action = na.pass,
        pred.var = res.var/weights, weights = 1, ...)

Arguments

- **object**: Object of class inheriting from "lm"
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- **se.fit**: A switch indicating if standard errors are required.
- **scale**: Scale parameter for std.err. calculation.
- **df**: Degrees of freedom for scale.
- **interval**: Type of interval calculation. Can be abbreviated.
- **level**: Tolerance/confidence level.
- **type**: Type of prediction (response or model term). Can be abbreviated.
- **terms**: If type = "terms", which terms (default is all terms), a character vector.
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
- **pred.var**: the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.
- **weights**: variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata.
- **...**: further arguments passed to or from other methods.

Details

predict.lm produces predicted values, obtained by evaluating the regression function in the frame newdata (which defaults to model.frame(object)). If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if newdata is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.
If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the predictions, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with value NA. See also napredict.

The prediction intervals are for a single observation at each case in newdata (or by default, the data used for the fit) with error variance(s) pred.var. This can be a multiple of res.var, the estimated value of $\sigma^2$: the default is to assume that future observations have the same error variance as those used for fitting. If weights is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, weights defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and newdata is given, the default is to assume constant prediction variance, with a warning.

Value

predict.lm produces a vector of predictions or a matrix of predictions and bounds with column names fit, lwr, and upr if interval is set. For type = "terms" this is a matrix with a column per term and may have an attribute "constant".

If se.fit is TRUE, a list with the following components is returned:

- fit: vector or matrix as above
- se.fit: standard error of predicted means
- residual.scale: residual standard deviations
- df: degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if res.var is not obtained from the fit.

predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
```
pred.w.plim <- predict(lm(y ~ x), new, interval = "prediction")
pred.w.clim <- predict(lm(y ~ x), new, interval = "confidence")
matplot(new$x, cbind(pred.w.clim, pred.w.plim[, -1]),
1ty = c(1, 2, 2, 3, 3), type = "l", ylab = "predicted y")

## Prediction intervals, special cases
## The first three of these throw warnings
w <- 1 + x^2
fit <- lm(y ~ x, weights = w)
wfit <- lm(y ~ x, weights = w)
predict(fit, interval = "prediction")
predict(wfit, interval = "prediction")
predict(wfit, new, interval = "prediction", weights = (new$x)^2)
predict(wfit, new, interval = "prediction", weights = -x^2)

##-- From aov(.) example ---- predict(.. terms)
npk.aov <- aov(yield ~ block + N*P*K, npk)
(termL <- attr(terms(npk.aov), "term.labels"))
(pt <- predict(npk.aov, type = "terms"))
pt. <- predict(npk.aov, type = "terms", terms = termL[1:4])
stopifnot(all.equal(pt[,1:4], pt,,
tolerance = 1e-12, check.attributes = FALSE))

predict.loess

Predict Loess Curve or Surface

Description

Predictions from a loess fit, optionally with standard errors.

Usage

## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
na.action = na.pass, ...)

Arguments

object an object fitted by loess.
newdata an optional data frame in which to look for variables with which to predict,
or a matrix or vector containing exactly the variables needs for prediction. If missed, the original data points are used.
se should standard errors be computed?
na.action function determining what should be done with missing values in data frame newdata. The default is to predict NA.
... arguments passed to or from other methods.
Details

The standard errors calculation se = TRUE is slower than prediction, notably as it needs a relatively large workspace (memory), notably matrices of dimension \( N \times N f \) where \( f = \text{span} \), i.e., se = TRUE is \( O(N^2) \) and hence stops when the sample size \( N \) is larger than about 40'600 (for default \( \text{span} = 0.75 \)).

When the fit was made using surface = "interpolate" (the default), predict.loess will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

Value

If se = FALSE, a vector giving the prediction for each row of newdata (or the original data). If se = TRUE, a list containing components

- fit: the predicted values.
- se: an estimated standard error for each predicted value.
- residual.scale: the estimated scale of the residuals used in computing the standard errors.
- df: an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals.

If newdata was the result of a call to expand.grid, the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since loess does not support extrapolation.

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Author(s)

B. D. Ripley, based on the cloess package of Cleveland, Grosse and Shyu.

    control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
predict.nls

Predicting from Nonlinear Least Squares Fits

Description

predict.nls produces predicted values, obtained by evaluating the regression function in the frame newdata. If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present se.fit and interval are ignored.

Usage

## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, ...)

Arguments

object An object that inherits from class nls.
newdata A named list or data frame in which to look for variables with which to predict. If newdata is missing the fitted values at the original data points are returned.
se.fit A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.
scale A numeric scalar. If it is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
df A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.
interval A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
level A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
... Additional optional arguments. At present no optional arguments are used.

Value

predict.nls produces a vector of predictions. When implemented, interval will produce a matrix of predictions and bounds with column names fit, lwr, and upr. When implemented, if se.fit is TRUE, a list with the following components will be returned:

- fit vector or matrix as above
- se.fit standard error of predictions
- residual.scale residual standard deviations
- df degrees of freedom for residual
Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

predict.smooth.spline  Predict from Smoothing Spline Fit

Description

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

Usage

## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)

Arguments

object a fit from smooth.spline.
x the new values of x.
deriv integer; the order of the derivative required.
... further arguments passed to or from other methods.

Value

A list with components

x The input x.
y The fitted values or derivatives at x.
See Also

  }
detach(); par(op)
```

---

**preplot**

Pre-computations for a Plotting Object

**Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```r
preplot(object, ...)
```

**Arguments**

- `object` a fitted model object.
- `...` additional arguments for specific methods.
Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

Value

An object set up to make a plot that describes object.

princomp

Principal Components Analysis

Description

princomp performs a principal components analysis on the given numeric data matrix and returns the results as an object of class princomp.

Usage

princomp(x, ...)

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
               subset = rep_len(TRUE, nrow(as.matrix(x))), fix_sign = TRUE, ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)

Arguments

formula a formula with no response variable, referring only to numeric variables.
data an optional data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector used to select rows (observations) of the data matrix x.
na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit.
x a numeric matrix or data frame which provides the data for the principal components analysis.
cor a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
scores a logical value indicating whether the score on each principal component should be calculated.
princomp

covmat: a covariance matrix, or a covariance list as returned by `cov.wt` (and `cov.mve` or `cov.mcd` from package MASS). If supplied, this is used rather than the covariance matrix of x.

fix_sign: Should the signs of the loadings and scores be chosen so that the first element of each loading is non-negative?

...: arguments passed to or from other methods. If x is a formula one might specify cor or scores.

object: Object of class inheriting from "princomp".

newdata: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

princomp is a generic function with "formula" and "default" methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use `svd` on x, as is done in `prcomp`.

Note that the default calculation uses divisor N for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (screeplot). There is also a `biplot` method.

If x is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

princomp only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

Value

princomp returns a list with class "princomp" containing the following components:

- `sdev`: the standard deviations of the principal components.
- `loadings`: the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see `loadings` for its print method.
- `center`: the means that were subtracted.
- `scale`: the scalings applied to each variable.
- `n.obs`: the number of observations.
- `scores`: if `scores = TRUE`, the scores of the supplied data on the principal components. These are non-null only if x was supplied, and if covmat was also supplied if it was a covariance list. For the formula method, `napredict()` is applied to handle the treatment of values omitted by the `na.action`.
- `call`: the matched call.
- `na.action`: If relevant.

Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R: `fix_sign = TRUE` alleviates that.

Examples

```r
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests)) # inappropriate
princomp(USArrests, cor = TRUE) # ^= prcomp(USArrests, scale=TRUE)
## Similar, but different:
## The standard deviations differ by a factor of sqrt(49/50)

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr) # note that blank entries are small but not zero
## The signs of the columns of the loadings are arbitrary
plot(pc.cr) # shows a screeplot.
biplot(pc.cr)

## Formula interface
princomp(~ ., data = USArrests, cor = TRUE)

## NA-handling
USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,
                  data = USArrests, na.action = na.exclude, cor = TRUE)
pc.cr$scores[1:5, ]

## (Simple) Robust PCA:
## Classical:
(pc.cl <- princomp(stackloss))
## Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))
```

Print Methods for Hypothesis Tests and Power Calculation Objects

Description

Printing objects of class "htest" or "power.htest", respectively, by simple `print` methods.

Usage

```r
## S3 method for class 'htest'
print(x, digits = getOption("digits"), prefix = "\t", ...)

## S3 method for class 'power.htest'
print(x, digits = getOption("digits"), ...)
```
Arguments

- **x**: object of class "htest" or "power.htest".
- **digits**: number of significant digits to be used.
- **prefix**: string, passed to `strwrap` for displaying the method component of the htest object.
- **...**: further arguments to be passed to or from methods.

Details

Both `print` methods traditionally have not obeyed the `digits` argument properly. They now do, the `htest` method mostly in expressions like `max(1, digits - 2)`.

A `power.htest` object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned ‘name = value’ format.

Value

the argument `x`, invisibly, as for all `print` methods.

Author(s)

Peter Dalgaard

See Also

`power.t.test`, `power.prop.test`

Examples

```r
(ptt <- power.t.test(n = 20, delta = 1))
print(ptt, digits = 4) # using less digits than default
print(ptt, digits = 12) # using more
```

---

**print.ts**  
*Printing and Formatting of Time-Series Objects*

Description

Notably for calendar related time series objects, `format` and `print` methods showing years, months and or quarters respectively.

Usage

```r
## S3 method for class 'ts'
print(x, calendar, ...)
.preformat.ts(x, calendar, ...)
```
Arguments

x  
a time series object.

calendar  
enable/disable the display of information about month names, quarter names or year when printing. The default is TRUE for a frequency of 4 or 12, FALSE otherwise.

...  
additional arguments to print (or format methods).

Details

The print method for "ts" objects prints a header (basically of tsp(x)), if calendar is false, and then prints the result of .preformat.ts(x, *), which is typically a matrix with rownames built from the calendar times where applicable.

See Also

print, ts.

Examples

print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

print(sunsp.1 <- window(sunspot.month, end=c(1756, 12)))
m <- .preformat.ts(sunsp.1) # a character matrix

Description

Utility function to be used in higher-level print methods, such as those for summary.lm, summary.glm and anova. The goal is to provide a flexible interface with smart defaults such that often, only x needs to be specified.

Usage

printCoefmat(x, digits = max(3, getOption("digits") - 2),
signif.stars = getOption("show.signif.stars"),
signif.legend = signif.stars,
dig.tst = max(1, min(5, digits - 1)),
cs.ind = 1L:k, tst.ind = k + 1L,
zap.ind = integer(), P.values = NULL,
has.Pvalue = nc >= 4L && length(cn <- colnames(x)) &&
    substr(cn[nc], 1L, 3L) %in% c("Pr", "p-v"),
eps.Pvalue = .Machine$double.eps,
na.print = "NA", quote = FALSE, right = TRUE, ...)
printCoefmat

Arguments

- **x**: a numeric matrix like object, to be printed.
- **digits**: minimum number of significant digits to be used for most numbers.
- **signif.stars**: logical; if TRUE, P-values are additionally encoded visually as 'significance stars' in order to help scanning of long coefficient tables. It defaults to the `show.signif.stars` slot of `options`.
- **signif.legend**: logical; if TRUE, a legend for the 'significance stars' is printed provided `signif.stars = TRUE`.
- **dig.tst**: minimum number of significant digits for the test statistics, see `tst.ind`.
- **cs.ind**: indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.
- **tst.ind**: indices (integer) of column numbers for test statistics.
- **zap.ind**: indices (integer) of column numbers which should be formatted by `zapsmall`, i.e., by 'zapping' values close to 0.
- **P.values**: logical or NULL; if TRUE, the last column of x is formatted by `format.pval` as P values. If P.values = NULL, the default, it is set to TRUE only if `options("show.coef.Pvalue")` is TRUE and x has at least 4 columns and the last column name of x starts with "Pr("
- **has.Pvalue**: logical; if TRUE, the last column of x contains P values; in that case, it is printed if and only if P.values (above) is true.
- **eps.Pvalue**: number, ...
- **na.print**: a character string to code NA values in printed output.
- **quote, right, ...**: further arguments passed to `print.default`.

Value

Invisibly returns its argument, x.

Author(s)

Martin Maechler

- `print.summary.lm`, `format.pval`, `format`.

Examples

```r
cmat <- cbind(rnorm(3, 10), sqrt(rchisq(3, 12)))
cmat <- cbind(cmat, cmat[, 1]/cmat[, 2])
cmat <- cbind(cmat, 2*pnorm(-cmat[, 3]))
colnames(cmat) <- c("Estimate", "Std.Err", "Z value", "Pr(z)")
printCoefmat(cmat[, 1:3])
printCoefmat(cmat)
op <- options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits = 2)
printCoefmat(cmat, digits = 2, P.values = TRUE)
options(op) # restore
```
Profile the objective function near the solution represented by `fitted`.

See documentation on method functions for further details.

**Usage**

```r
profile(fitted, ...)```

**Arguments**

- `fitted`: the original fitted model object.
- `which`: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
- `maxpts`: maximum number of points to be used for profiling each parameter.
- `alphamax`: highest significance level allowed for the profile t-statistics.
- `delta.t`: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `...`: additional parameters. See documentation on individual methods.

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

- `profile.nls` in package `MASS`,
- For profiling R code, see `Rprof`.

---

Profile the profile log-likelihood function for a fitted model of class "nls".

**Usage**

```r
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
        delta.t = cutoff/5, ...)```

**Arguments**

- `fitted`: the original fitted model object.
- `which`: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
- `maxpts`: maximum number of points to be used for profiling each parameter.
- `alphamax`: highest significance level allowed for the profile t-statistics.
- `delta.t`: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `...`: further arguments passed to or from other methods.
proj

Details

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables

par.vals a matrix of parameter values for each fitted model.
tau the profile t-statistics.

proj

Projections of Models

Description

proj returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for aov models.
Usage

proj(object, ...)

## S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Arguments

object An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.

onedf A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).

unweighted.scale If the fit producing object used weights, this determines if the projections correspond to weighted or unweighted observations.

... Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.

Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
proj(npk.aovE)
```

### prop.test

**Test of Equal or Given Proportions**

**Description**

`prop.test` can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

**Usage**

```r
prop.test(x, n, p = NULL,  
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)
```

**Arguments**

- `x` 
  A vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.

- `n` 
  A vector of counts of trials; ignored if `x` is a matrix or a table.

- `p` 
  A vector of probabilities of success. The length of `p` must be the same as the number of groups specified by `x`, and its elements must be greater than 0 and less than 1.
alternative

a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

conf.level

confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

correct

a logical indicating whether Yates’ continuity correction should be applied where possible.

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to \([-1,1]\) is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is p, or .5 if p is not given. The alternative is that the probability of success is less than, not equal to, or greater than p or 0.5, respectively, as specified by alternative. A confidence interval for the underlying proportion with confidence level as specified by conf.level and clipped to \([0,1]\) is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if p is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by p. The alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

Value

A list with class "htest" containing the following components:

statistic

the value of Pearson’s chi-squared test statistic.

parameter

the degrees of freedom of the approximate chi-squared distribution of the test statistic.

p.value

the p-value of the test.

estimate

a vector with the sample proportions \(x/n\).

conf.int

a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and p is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by conf.level, and is appropriate to the specified alternative hypothesis.

null.value

the value of p if specified by the null, or NULL otherwise.

alternative

a character string describing the alternative.
prop.trend.test

method

da character string indicating the method used, and whether Yates’ continuity
correction was applied.
data.name

da character string giving the names of the data.

References

See Also

binom.test for an exact test of a binomial hypothesis.

Examples

```r
heads <- rbinom(1, size = 100, prob = .5)
prop.test(heads, 100) # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)

## Data from Fleiss (1981), p. 139.
## H0: The null hypothesis is that the four populations from which
## the patients were drawn have the same true proportion of smokers.
## A: The alternative is that this proportion is different in at
## least one of the populations.
smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
prop.test(smokers, patients)
```

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

Usage

```r
prop.trend.test(x, n, score = seq_along(x))
```

Arguments

- **x** Number of events
- **n** Number of trials
- **score** Group score
qqnorm

Value

An object of class "htest" with title, test statistic, p-value, etc.

Note

This really should get integrated with prop.test

Author(s)

Peter Dalgaard

smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
prop.test(smokers, patients)
prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))

qqnorm

| Quantile-Quantile Plots |

Description

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in y. qqline adds a line to a "theoretical", by default normal, quantile-quantile plot which passes through the probs quantiles, by default the first and third quartiles.

qqplot produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to qqnorm, qqplot and qqline.

Usage

qqnorm(y, ...)
## Default S3 method:
 qqnorm(y, ylim, main = "Normal Q-Q Plot",
       xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
       plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
       probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE,
       xlab = deparse1(substitute(x)),
       ylab = deparse1(substitute(y)), ...)
**Arguments**

- **x**  The first sample for `qqplot`.
- **y**  The second or only data sample.
- **xlab, ylab, main**  plot labels. The xlab and ylab refer to the y and x axes respectively if `datax = TRUE`.
- **plot.it**  logical. Should the result be plotted?
- **datax**  logical. Should data values be on the x-axis?
- **distribution**  quantile function for reference theoretical distribution.
- **probs**  numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
- **qtype**  the type of quantile computation used in `quantile`.
- **ylim, ...**  graphical parameters.

**Value**

For `qqnorm` and `qqplot`, a list with components

- **x**  The x coordinates of the points that were/would be plotted
- **y**  The original y vector, i.e., the corresponding y coordinates including NAs.

**References**

**See Also**

`ppoints`, used by `qqnorm` to generate approximations to expected order statistics for a normal distribution.

**Examples**

```r
require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qqline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")
```

```r
## "QQ-Chisquare" : ------------------------------
y <- rchisq(500, df = 3)
## Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(qchisq(ppoints(500), df = 3), y,
    main = expression("Q-Q plot for" ~~ {chi^2}[nu == 3]))
qqline(y, distribution = function(p) qchisq(p, df = 3),
    probs = c(0.1, 0.6), col = 2)
mtext("qqline(*, dist = qchisq(., df=3), prob = c(0.1, 0.6))")
## (Note that the above uses ppoints() with a = 1/2, giving the
## probability points for quantile type 5: so theoretically, using
## qqline(qtype = 5) might be preferable.)
```

### quade.test

#### Quade Test

**Description**

Performs a Quade test with unreplicated blocked data.

**Usage**

```r
quade.test(y, ...)  
```

## Default S3 method:
```r
quade.test(y, groups, blocks, ...)  
```

## S3 method for class 'formula'
```r
quade.test(formula, data, subset, na.action, ...)  
```

**Arguments**

- `y` either a numeric vector of data values, or a data matrix.
- `groups` a vector giving the group for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `blocks` a vector giving the block for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `formula` a formula of the form `a ~ b | c`, where `a`, `b` and `c` give the data values and corresponding groups and blocks, respectively.
- `data` an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...` further arguments to be passed to or from methods.

**Details**

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the groups.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA’s are not allowed in `groups` or `blocks`; if `y` contains NA’s, corresponding blocks are removed.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of Quade’s F statistic.
- **parameter**: a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Quade test".
- **data.name**: a character string giving the names of the data.

```r
## Conover (1999, p. 375f):
## Numbers of five brands of a new hand lotion sold in seven stores
## during one week.
## y <- matrix(c( 5, 4, 7, 10, 12,
##   1, 3, 1, 0, 2,
##   16, 12, 22, 22, 35,
##   5, 4, 3, 5, 4,
##   10, 9, 7, 13, 10,
##   19, 18, 28, 37, 58,
##   10, 7, 6, 8, 7),
## nrow = 7, byrow = TRUE,
## dimnames =
## list(Store = as.character(1:7),
##      Brand = LETTERS[1:5]))
##
y (qTst <- quade.test(y))

## Show equivalence of different versions of test:
utils::str(dy <- as.data.frame(as.table(y)))
qT. <- quade.test(Freq ~ Brand|Store, data = dy)
qT.$data.name <- qTst$data.name
stopifnot(all.equal(qTst, qT., tolerance = 1e-15))
dys <- dy[order(dy[,"Freq"],),]
qTs <- quade.test(Freq ~ Brand|Store, data = dys)
qTs$data.name <- qTst$data.name
stopifnot(all.equal(qTst, qTs, tolerance = 1e-15))
```
The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

```r
quantile(x, ...)    # Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE, names = TRUE, type = 7, digits = 7, ...)
```

**Arguments**
- `x` numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also 'details'). `NA` and `NaN` values are not allowed in numeric vectors unless `na.rm` is `TRUE`.
- `probs` numeric vector of probabilities with values in `[0, 1]`. (Values up to `2e-14` outside that range are accepted and moved to the nearby endpoint.)
- `na.rm` logical; if true, any `NA` and `NaN`’s are removed from `x` before the quantiles are computed.
- `names` logical; if true, the result has a `names` attribute. Set to `FALSE` for speedup with many `probs`.
- `type` an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.
- `digits` used only when `names` is true: the precision to use when formatting the percentages. In R versions up to 4.0.x, this had been set to `max(2,getOption("digits"))`, internally.
- `...` further arguments passed to or from other methods.

**Details**
A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute.

`NA` and `NaN` values in `probs` are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that `sort` and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of `sort` in `base` will be used, not some S4 generic of that name. Also note that that is no check on the ‘correctly’, and so e.g. `quantile` can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see "POSIXt"). Types 1 and 3 can be used for class "Date" and for ordered factors.
The `quantile` function returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in \( x \) at probabilities in \( \text{probs} \). One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by type, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type \( i \) are defined by:

\[
Q_i(p) = (1 - \gamma) x_j + \gamma x_{j+1}
\]

where \( 1 \leq i \leq 9 \), \( \frac{i-m}{n-1} \leq p < \frac{i-m+1}{n} \), \( x_j \) is the \( j \)th order statistic, \( n \) is the sample size, the value of \( \gamma \) is a function of \( j = \lfloor np + m \rfloor \) and \( g = np + m - j \), and \( m \) is a constant determined by the sample quantile type.

**Discontinuous sample quantile types 1, 2, and 3**

For types 1, 2 and 3, \( Q_i(p) \) is a discontinuous function of \( p \), with \( m = 0 \) when \( i = 1 \) and \( i = 2 \), and \( m = -1/2 \) when \( i = 3 \).

- **Type 1** Inverse of empirical distribution function. \( \gamma = 0 \) if \( g = 0 \), and 1 otherwise.

- **Type 2** Similar to type 1 but with averaging at discontinuities. \( \gamma = 0.5 \) if \( g = 0 \), and 1 otherwise (SAS default, see Wicklin(2017)).

- **Type 3** Nearest even order statistic (SAS default till ca. 2010). \( \gamma = 0 \) if \( g = 0 \) and \( j \) is even, and 1 otherwise.

**Continuous sample quantile types 4 through 9**

For types 4 through 9, \( Q_i(p) \) is a continuous function of \( p \), with \( \gamma = g \) and \( m \) given below. The sample quantiles can be obtained equivalently by linear interpolation between the points \((p_k, x_k)\) where \( x_k \) is the \( k \)th order statistic. Specific expressions for \( p_k \) are given below.

- **Type 4** \( m = 0 \). \( p_k = \frac{k}{n} \). That is, linear interpolation of the empirical cdf.

- **Type 5** \( m = 1/2 \). \( p_k = \frac{k-0.5}{n} \). That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

- **Type 6** \( m = p \). \( p_k = \frac{k}{n+1} \). Thus \( p_k = \text{E}[F(x_k)] \). This is used by Minitab and by SPSS.

- **Type 7** \( m = 1 - p \). \( p_k = \frac{k-1}{n-1} \). In this case, \( p_k = \text{mode}[F(x_k)] \). This is used by S.

- **Type 8** \( m = (p + 1)/3 \). \( p_k = \frac{k-1/3}{n+1/3} \). Then \( p_k \approx \text{median}[F(x_k)] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \).

- **Type 9** \( m = p/4 + 3/8 \). \( p_k = \frac{k-3/8}{n+1/8} \). The resulting quantile estimates are approximately unbiased for the expected order statistics if \( x \) is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by \( \text{R} \ < 2.0.0 \). Makkonen argues for type 6, also as already proposed by Weibull in 1939. The Wikipedia page contains further information about availability of these 9 types in software.

**Author(s)**

of the version used in \( \text{R} \geq 2.0.0 \), Ivan Frohne and Rob J Hyndman.

ecdf for empirical distributions of which quantile is an inverse; boxplot.stats and fivenum for computing other versions of quartiles, etc.

Examples

quantile(x <- rnorm(100)) # Extremes & Quartiles by default
quantile(x, probs = c(0.1, 0.5, 1, 2, 5, 10, 50, NA)/100)

### Compare different types
quantAll <- function(x, prob, ...) t(vapply(1:9, function(typ) quantile(x, probs = prob, type = typ, ...), quantile(x, prob, type=1, ...)))
p <- c(0.1, 0.5, 1, 2, 5, 10, 50)/100
signif(quantAll(x, p), 4)

## 0% and 100% are equal to min(), max() for all types:
stopifnot(t(quantAll(x, prob=0:1)) == range(x))

## for complex numbers:
z <- complex(real = x, imaginary = -10*x)
signif(quantAll(z, p), 4)

r2dtable

Random 2-way Tables with Given Marginals

Description

Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage

r2dtable(n, r, c)

Arguments

n a non-negative numeric giving the number of tables to be drawn.

r a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as c.

c a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.
Value

A list of length n containing the generated tables as its components.

References

Examples

```r
## Fisher's Tea Drinker data.
TeaTasting <- matrix(c(3, 1, 1, 3),
nrow = 2,
dimnames = list(Guess = c("Milk", "Tea"),
Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nofCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / nofCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <- sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...
```

read.ftable

Manipulate Flat Contingency Tables

Description

Read, write and coerce 'flat' (contingency) tables, aka ftables.

Usage

```r
read.ftable(file, sep = "", quote = "\",
row.var.names, col.vars, skip = 0)
write.ftable(x, file = "", quote = TRUE, append = FALSE,
digits =getOption("digits"), sep = " ", ...)
## S3 method for class 'ftable'
format(x, quote = TRUE, digits =getOption("digits"),
method = c("non.compact", "row.compact", "col.compact", "compact"),
lsep = " | ",
justify = c("left", "right"),
...)
## S3 method for class 'ftable'
print(x, digits =getOption("digits"), ...)
```
Arguments

file: either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.

sep: the field separator string. Values on each line of the file are separated by this string.

quote: a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.

row.var.names: a character vector with the names of the row variables, in case these cannot be determined automatically.

col.vars: a list giving the names and levels of the column variables, in case these cannot be determined automatically.

skip: the number of lines of the data file to skip before beginning to read data.

x: an object of class "ftable".

append: logical. If TRUE and file is the name of a file (and not a connection or "|cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.

digits: an integer giving the number of significant digits to use for (the cell entries of) x.

method: a string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Can be abbreviated. Available methods are (see the examples):

"non.compact": the default representation of an "ftable" object.

"row.compact": a row-compact version without empty cells below the column labels.

"col.compact": a column-compact version without empty cells to the right of the row labels.

"compact": a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep.

lsep: only for method = "compact", the separation string for row and column labels.

justify: a character vector of length (one or) two, specifying how string justification should happen in format(...), first for the labels, then the table entries.

...: further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().

Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.
Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use \texttt{read.table} to read in the data, and create the contingency table from this using \texttt{xtabs}.

\texttt{write.ftable} writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the \texttt{method} argument, which may be useful, for example, for constructing LaTeX tables.

print(ft22, method="row.compact")
print(ft22, method="col.compact")
print(ft22, method="compact")

## using 'justify' and 'quote' :
\end{verbatim}
rect.hclust

**Draw Rectangles Around Hierarchical Clusters**

**Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

```r
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL, border = 2, cluster = NULL)
```

**Arguments**

- `tree` an object of the type produced by `hclust`.
- `k, h` Scalar. Cut the dendrogram such that either exactly `k` clusters are produced or by cutting at height `h`.
- `which, x` A vector selecting the clusters around which a rectangle should be drawn. `which` selects clusters by number (from left to right in the tree), `x` selects clusters containing the respective horizontal coordinates. Default is `which = 1:k`.
- `border` Vector with border colors for the rectangles.
- `cluster` Optional vector with cluster memberships as returned by `cutree(hclust.obj, k = k)`, can be specified for efficiency if already computed.

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

- `hclust`
- `identify.hclust`

**Examples**

```r
require(graphics)
hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```
relevel

Reorder Levels of Factor

Description
The levels of a factor are re-ordered so that the level specified by ref is first and the others are moved down. This is useful for contr.treatment contrasts which take the first level as the reference.

Usage
relevel(x, ref, ...)

Arguments
x an unordered factor.
ref the reference level, typically a string.
... additional arguments for future methods.

Details
This, as reorder(), is a special case of simply calling factor(x, levels = levels(x)[...]).

Value
A factor of the same length as x.

See Also
factor, contr.treatment, levels, reorder.

Examples
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))

reorder.default

Reorder Levels of a Factor

Description
reorder is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

Usage
reorder(x, ...)

## Default S3 method:
reorder(x, X, FUN = mean, ..., order = is.ordered(x))
Arguments

- **x**: an atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If x is not a factor, its unique values will be used as the implicit levels.

- **X**: a vector of the same length as x, whose subset of values for each unique level of x determines the eventual order of that level.

- **FUN**: a function whose first argument is a vector and returns a scalar, to be applied to each subset of X determined by the levels of x.

- **order**: optional: extra arguments supplied to FUN

Details

This, as `relevel()`, is a special case of simply calling `factor(x, levels = levels(x)[....])`.

Value

A factor or an ordered factor (depending on the value of order), with the order of the levels determined by FUN applied to X grouped by x. The levels are ordered such that the values returned by FUN are in increasing order. Empty levels will be dropped.

Additionally, the values of FUN applied to the subsets of X (in the original order of the levels of x) is returned as the "scores" attribute.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also

`reorder.dendrogram`, `levels`, `relevel`.

Examples

```r
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
        xlab = "Type of spray", ylab = "Insect count",
        main = "InsectSprays data", varwidth = TRUE,
        col = "lightgray")
```

Description

A method for the generic function `reorder`.

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.
Usage

```r
## S3 method for class 'dendrogram'
reorder(x, wts, agglo.FUN = sum, ...)
```

Arguments

- `x`: the (dendrogram) object to be reordered
- `wts`: numeric weights (arbitrary values) for reordering.
- `agglo.FUN`: a function for weights agglomeration, see below.
- `...`: additional arguments

Details

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as $f(w_j)$ where $f$ is `agglo.FUN` and $w_j$ is the weight of the $j$-th sub branch.

Value

A dendrogram where each node has a further attribute `value` with its corresponding weight.

Author(s)

R. Gentleman and M. Maechler

See Also

`reorder`

`rev.dendrogram` which simply reverses the nodes' order; `heatmap`, `cophenetic`.

Examples

```r
require(graphics)
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd reordered <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd reordered, main = "reorder(dd, 10:1)"
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)"
par(op)
```
replications  

**Number of Replications of Terms**

### Description

Returns a vector or a list of the number of replicates for each term in the formula.

### Usage

`replications(formula, data = NULL, na.action)`

### Arguments

- `formula`: a formula or a terms object or a data frame.
- `data`: a data frame used to find the objects in `formula`. Any character vectors in the formula are coerced to factors.
- `na.action`: function for handling missing values. Defaults to a `na.action` attribute of `data`, then a setting of the option `na.action`, or `na.fail` if that is not set.

### Details

If `formula` is a data frame and `data` is missing, `formula` is used for `data` with the formula `~ ..`. A test for balance is `!is.list(replications(formula,data))`. Any character vectors in the formula are coerced to factors.

### Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each term, as a vector, matrix or array as required.

### Author(s)

The design was inspired by the S function of the same name described in Chambers *et al* (1992).

### Typical usage for converting from long to wide format:
# reshape(data, direction = "wide",
# idvar = "___", timevar = "___", # mandatory
# v.names = c(___), # time-varying variables
# varying = list(___), # auto-generated if missing

### Typical usage for converting from wide to long format:
### If names of wide-format variables are in a 'nice' format
# reshape(data, direction = "long",
# varying = c(___), # vector
# sep) # to help guess 'v.names' and 'times'

### To specify long-format variable names explicitly
# reshape(data, direction = "long",

---

### Description

This function reshapes a data frame between 'wide' format (with repeated measurements in separate columns of the same row) and 'long' format (with the repeated measurements in separate rows).

### Usage

```r
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
        idvar = "id", ids = 1:NROW(data),
        times = seq_along(varying[[1]]),
        drop = NULL, direction, new.row.names = NULL,
        sep = ".",
        split = if (sep == "){
            list(regexp = "[A-Za-z][0-9]", include = TRUE)
        } else {
            list(regexp = sep, include = FALSE, fixed = TRUE)
        })
```
# varying = ___, # list / matrix / vector (use with care)
# v.names = ___, # vector of variable names in long format
# timevar, times, # name / values of constructed time variable
# idvar, ids) # name / values of constructed id variable

Arguments

data a data frame

varying names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, when direction = "long", the names can be replaced by indices which are interpreted as referring to names(data). See ‘Details’ for more details and options.

v.names names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.

timevar the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).

idvar Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.

ids the values to use for a newly created idvar variable in long format.

times the values to use for a newly created timevar variable in long format. See ‘Details’.

drop a vector of names of variables to drop before reshaping.

direction character string, partially matched to either "wide" to reshape to wide format, or "long" to reshape to long format.

new.row.names character or NULL: a non-null value will be used for the row names of the result.

sep A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing v.names and times arguments based on the names in varying. If sep == ",", the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format.

split A list with three components, regexp, include, and (optionally) fixed. This allows an extended interface to variable name splitting. See ‘Details’.

Details

Although reshape() can be used in a variety of contexts, the motivating application is data from longitudinal studies, and the arguments of this function are named and described in those terms. A longitudinal study is characterized by repeated measurements of the same variable(s), e.g., height and weight, on each unit being studied (e.g., individual persons) at different time points (which are assumed to be the same for all units). These variables are called time-varying variables. The study may include other variables that are measured only once for each unit and do not vary with time (e.g., gender and race); these are called time-constant variables.

A ‘wide’ format representation of a longitudinal dataset will have one record (row) for each unit, typically with some time-constant variables that occupy single columns, and some time-varying
variables that occupy multiple columns (one column for each time point). A ‘long’ format representation of the same dataset will have multiple records (rows) for each individual, with the time-constant variables being constant across these records and the time-varying variables varying across the records. The ‘long’ format dataset will have two additional variables: a ‘time’ variable identifying which time point each record comes from, and an ‘id’ variable showing which records refer to the same unit.

The type of conversion (long to wide or wide to long) is determined by the direction argument, which is mandatory unless the data argument is the result of a previous call to reshape. In that case, the operation can be reversed simply using reshape(data) (the other arguments are stored as attributes on the data frame).

Conversion from long to wide format with direction = "wide" is the simpler operation, and is mainly useful in the context of multivariate analysis where data is often expected as a wide-format matrix. In this case, the time variable timevar and id variable idvar must be specified. All other variables are assumed to be time-varying, unless the time-varying variables are explicitly specified via the v.names argument. A warning is issued if time-constant variables are not actually constant.

Each time-varying variable is expanded into multiple variables in the wide format. The names of these expanded variables are generated automatically, unless they are specified as the varying argument in the form of a list (or matrix) with one component (or row) for each time-varying variable. If varying is a vector of names, it is implicitly converted into a matrix, with one row for each time-varying variable. Use this option with care if there are multiple time-varying variables, as the ordering (by column, the default in the matrix constructor) may be unintuitive, whereas the explicit list or matrix form is unambiguous.

Conversion from wide to long with direction = "long" is the more common operation as most (univariate) statistical modeling functions expect data in the long format. In the simpler case where there is only one time-varying variable, the corresponding columns in the wide format input can be specified as the varying argument, which can be either a vector of column names or the corresponding column indices. The name of the corresponding variable in the long format output combining these columns can be optionally specified as the v.names argument, and the name of the time variables as the timevar argument. The values to use as the time values corresponding to the different columns in the wide format can be specified as the times argument. If v.names is unspecified, the function will attempt to guess v.names and times from varying (an explicitly specified times argument is unused in that case). The default expects variable names like x.1, x.2, where sep = "." specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use sep = "".

Multiple time-varying variables can be specified in two ways, either with varying as an atomic vector as above, or as a list (or a matrix). The first form is useful (and mandatory) if the automatic variable name splitting as described above is used; this requires the names of all time-varying variables to be suitably formatted in the same manner, and v.names to be unspecified. If varying is a list (with one component for each time-varying variable) or a matrix (one row for each time-varying variable), variable name splitting is not attempted, and v.names and times will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if v.names is given explicitly, even if varying is an atomic vector. In that case, the number of time-varying variables is taken to be the length of v.names, and varying is implicitly converted into a matrix, with one row for each time-varying variable. As in the case of long to wide conversion, the matrix is filled up by column, so careful attention needs to be paid to the order of variable names (or indices) in varying, which is taken to be like x.1, y.1, x.2, y.2 (i.e., variables corresponding to the same time point need to be grouped together).

The split argument should not usually be necessary. The split$regexp component is passed to either strsplit or regexpr, where the latter is used if split$include is TRUE, in which case the
splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

### Value

The reshaped data frame with added attributes to simplify reshaping back to the original form.

### See Also

`stack`, `aperm`, `relist` for reshaping the result of `unlist`. `xtabs` and `as.data.frame.table` for creating contingency tables and converting them back to data frames.

### Examples

```r
summary(Indometh)  # data in long format
## long to wide (direction = "wide") requires idvar and timevar at a minimum
reshape(Indometh, direction = "wide", idvar = "Subject", timevar = "time")

## can also explicitly specify name of combined variable
wide <- reshape(Indometh, direction = "wide", idvar = "Subject",
               timevar = "time", v.names = "conc", sep="_")
wide

## reverse transformation
reshape(wide, direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
                 visit = I(rep(c("Before","After"), 4)),
                 x = rnorm(4), y = runif(4))
reshape(df, timevar = "visit", idvar = "id", direction = "wide")

## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7,]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50),
                 dose1 = c(1,2,1,2),
                 dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
                times = names(state.x77), timevar = "Characteristic",
                varying = list(names(state.x77)), direction = "long")
reshape(long, direction = "wide")
```
residuals

residuals(long, direction = "wide", new.row.names = unique(long$state))

## multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
 time = rep(c(1,1,2,2), 3), score = rnorm(12))
wide <- reshape(df3, idvar = c("school", "class"), direction = "wide")
wide
## transform back
reshape(wide)

---

**residuals**  

**Extract Model Residuals**

**Description**

residuals is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form resid is an alias for residuals. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a residuals method. (Note that the method is for residuals and not resid.)

Methods can make use of naresid methods to compensate for the omission of missing values. The default, nls and smooth.spline methods do.

**Usage**

residuals(object, ...)

resid(object, ...)

**Arguments**

object an object for which the extraction of model residuals is meaningful.

... other arguments.

**Value**

Residuals extracted from the object object.

**References**

**See Also**

coefficients, fitted.values, glm, lm.

influence.measures for standardized (rstandard) and studentized (rstudent) residuals.
**runmed**

**Running Medians – Robust Scatter Plot Smoothing**

**Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

**Usage**

```
runmed(x, k, endrule = c("median", "keep", "constant"),
       algorithm = NULL,
       na.action = c("+Big_alternate", "-Big_alternate", "na.omit", "fail"),
       print.level = 0)
```

**Arguments**

- `x` numeric vector, the ‘dependent’ variable to be smoothed.
- `k` integer width of median window; must be odd. Turlach had a default of \( k < -1 + 2 \times \min((n-1)/2, \text{ceiling}(0.1 \times n)) \). Use \( k = 3 \) for ‘minimal’ robust smoothing eliminating isolated outliers.
- `endrule` character string indicating how the values at the beginning and the end (of the data) should be treated. Can be abbreviated. Possible values are:
  - "keep" keeps the first and last \( k/2 \) values at both ends, where \( k/2 \) is the half-bandwidth \( k/2 = k/2 \), i.e., \( y[j] = x[j] \) for \( j \in \{1, \ldots, k/2; n - k/2 + 1, \ldots, n\} \);
  - "constant" copies \( \text{median}(y[1:k/2]) \) to the first values and analogously for the last ones making the smoothed ends constant;
  - "median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see `smoothEnds`.
- `algorithm` character string (partially matching "Turlach" or "Stuetzle") or the default NULL, specifying which algorithm should be applied. The default choice depends on \( n = \text{length}(x) \) and \( k \) where "Turlach" will be used for larger problems.
- `na.action` character string determining the behavior in the case of NA or NaN in \( x \), (partially matching) one of
  - "+Big_alternate" Here, all the NAs in \( x \) are first replaced by alternating \( \pm B \) where \( B \) is a “Big” number (with \( 2B < M_* \), where \( M_* = .Machine \$ \text{double.xmax} \)). The replacement values are “from left” \( (+B,-B,+B,\ldots) \), i.e. start with "+".
  - "-Big_alternate" almost the same as "+Big_alternate", just starting with \(-B\) ("-Big...").
  - "na.omit" the result is the same as `runmed(x[!is.na(x)], k, ...)`.
  - "fail" the presence of NAs in \( x \) will raise an error.
- `print.level` integer, indicating verboseness of algorithm; should rarely be changed by average users.
Apart from the end values, the result \( y = \text{runmed}(x, k) \) simply has \( y[j] = \text{median}(x[(j-k2):(j+k2)]) \) \( (k = 2k2+1) \), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance \( O(n \log k) \) where \( n = \text{length}(x) \) which is asymptotically optimal.

"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median updating when one observation enters and one leaves the smoothing window. While this performs as \( O(n \times k) \) which is slower asymptotically, it is considerably faster for small \( k \) or \( n \).

Note that, both algorithms (and the \texttt{smoothEnds()} utility) now "work" also when \( x \) contains non-finite entries (\( \pm \text{Inf}, \text{NaN}, \text{NA} \)):

"Turlach" .......

"Stuetzle" currently simply works by applying the underlying math library ("libm") arithmetic for the non-finite numbers; this may optionally change in the future.

Currently \texttt{long vectors} are only supported for \texttt{algorithm = "Stuetzle"}.

\textbf{Value}

vector of smoothed values of the same length as \( x \) with an \texttt{attribute k} containing (the ‘oddified’) \( k \).

\textbf{Author(s)}

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

\textbf{References}

\textbf{See Also}

\texttt{smoothEnds} which implements Tukey’s end point rule and is called by default from \texttt{runmed(*, endrule = "median")}. \texttt{smooth} uses running medians of 3 for its compound smoothers.

\textbf{Examples}

```
require(graphics)
utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

## special: multiple y values for one x
```
### R Code Example

```r
plot(cars, main = "cars' data and runmed(dist, 3)")
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

## nice quadratic with a few outliers
y <- y[c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood implies interpolation
plot(y) # lines(y, lwd = .1, col = "light gray")
lines(lowess(seq(y), y, f = 0.3), col = "brown")
lines(runmed(y, 7), lwd = 2, col = "blue")
lines(runmed(y, 11), lwd = 2, col = "red")

## Lowess is not robust
y <- y[21] <- 6666; x <- seq(y)
col <- c("black", "brown","blue")
plot(y, col = col[1])
lines(lowess(x, y, f = 0.3), col = col[2])
lines(runmed(y, 7), lwd = 2, col = col[3])

## An example with initial NA's - used to fail badly (notably for "Turlach"): 
x15 <- c(rep(NA, 4), c(9, 9, 4, 22, 6, 1, 7, 5, 2, 8, 3))
rS15 <- cbind(Sk.3 = runmed(x15, k = 3, algorithm="S"),
Sk.7 = runmed(x15, k = 7, algorithm="S"),
Sk.11= runmed(x15, k =11, algorithm="S"))
rT15 <- cbind(Tk.3 = runmed(x15, k = 3, algorithm="T", print.level=1),
Tk.7 = runmed(x15, k = 7, algorithm="T", print.level=1),
Tk.9 = runmed(x15, k = 9, algorithm="T", print.level=1),
Tk.11= runmed(x15, k =11, algorithm="T", print.level=1))
cbind(x15, rS15, rT15) # result for k=11 maybe a bit surprising ..
Tv <- rT15[-(1:3),]
stopifnot(3 <= Tv, Tv <= 9, 5 <= Tv[1:10,])
matplot(y = cbind(x15, rT15), type = "b", ylim = c(1,9), pch=1:5, xlab = NA,
main = "runmed(x15, k, algo = "Turlach")")
mtext(paste("x15 <-", deparse(x15)))
points(x15, cex=2)
legend("bottomleft", legend=c("data", paste("k = ", c(3,7,9,11))),
bt='n", col=1:5, lty=1:5, pch=1:5)
```

---

**rWishart**

**Random Wishart Distributed Matrices**

**Description**

Generate $n$ random matrices, distributed according to the Wishart distribution with parameters $\Sigma$ and $df$, $W_p(\Sigma, m)$, $m = df$, $\Sigma = \Sigma$.

**Usage**

```r
rWishart(n, df, Sigma)
```
Arguments

- **n**: integer sample size.
- **df**: numeric parameter, “degrees of freedom”.
- **Sigma**: positive definite \((p \times p)\) “scale” matrix, the matrix parameter of the distribution.

Details

If \(X_1, \ldots, X_m, X_i \in \mathbb{R}^p\) is a sample of \(m\) independent multivariate Gaussians with mean (vector) 0, and covariance matrix \(\Sigma\), the distribution of \(M = X'X\) is \(W_p(\Sigma, m)\).

Consequently, the expectation of \(M\) is

\[
E[M] = m \times \Sigma.
\]

Further, if \(\text{Sigma}\) is scalar \((p = 1)\), the Wishart distribution is a scaled chi-squared \((\chi^2)\) distribution with \(\text{df}\) degrees of freedom, \(W_1(\sigma^2, m) = \sigma^2 \chi^2_m\).

The component wise variance is

\[
\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii} \Sigma_{jj}).
\]

Value

a numeric array, say \(R\), of dimension \(p \times p \times n\), where each \(R[, , i]\) is a positive definite matrix, a realization of the Wishart distribution \(W_p(\Sigma, m)\), \(m = \text{df}, \Sigma = \text{Sigma}\).

Examples

```r
## Artificial
S <- toeplitz((10:1)/10)
set.seed(11)
R <- rWishart(1000, 20, S)
dim(R) # 10 10 1000
mR <- apply(R, 1:2, mean) # ~= E[ Wish(S, 20) ] = 20 * S
stopifnot(all.equal(mR, 20*S, tolerance = .009))

## See Details, the variance is
Va <- 20*(S^2 + tcrossprod(diag(S)))
vR <- apply(R, 1:2, var)
stopifnot(all.equal(vR, Va, tolerance = 1/16))
```
scatter.smooth  

Scatter Plot with Smooth Curve Fitted by Loess

Description

Plot and add a smooth curve computed by loess to a scatter plot.

Usage

scatter.smooth(x, y = NULL, span = 2/3, degree = 1,  
  family = c("symmetric", "gaussian"),  
  xlab = NULL, ylab = NULL,  
  ylim = range(y, pred$y, na.rm = TRUE),  
  evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,  
  family = c("symmetric", "gaussian"), evaluation = 50, ...)

Arguments

x, y  
the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details.

span  
smoothness parameter for loess.

degree  
degree of local polynomial used.

family  
if "gaussian" fitting is by least-squares, and if family = "symmetric" a re-descending M estimator is used. Can be abbreviated.

xlab  
label for x axis.

ylab  
label for y axis.

ylim  
the y limits of the plot.

evaluation  
number of points at which to evaluate the smooth curve.

...  
For scatter.smooth(), graphical parameters, passed to plot() only. For loess.smooth, control parameters passed to loess.control.

lpars  
a list of arguments to be passed to lines().

Details

loess.smooth is an auxiliary function which evaluates the loess smooth at evaluation equally spaced points covering the range of x.

Value

For scatter.smooth, none.

For loess.smooth, a list with two components, x (the grid of evaluation points) and y (the smoothed values at the grid points).

See Also

loess; smoothScatter for scatter plots with smoothed density color representation.
Examples

```r
require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpar =
  list(col = "red", lwd = 3, lty = 3)))
```

screeplot

Screeplots

Description

screeplot.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

Usage

```r
## Default S3 method:
screeplot(x, npcs = min(10, length(x$sdev)),
type = c("barplot", "lines"),
main = deparse1(substitute(x)), ...)
```

Arguments

- `x`: an object containing a `sdev` component, such as that returned by `princomp()` and `prcomp()`.
- `npcs`: the number of components to be plotted.
- `type`: the type of plot. Can be abbreviated.
- `main`, `...`: graphics parameters.

References

See Also

`princomp` and `prcomp`.

Examples

```r
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit, npcs = 24, type = "lines")
```
sd

Standard Deviation

Description
This function computes the standard deviation of the values in x. If na.rm is TRUE then missing values are removed before computation proceeds.

Usage
sd(x, na.rm = FALSE)

Arguments
- x: a numeric vector or an R object but not a factor coercible to numeric by as.double(x).
- na.rm: logical. Should missing values be removed?

Details
Like var this uses denominator \( n - 1 \).

The standard deviation of a length-one or zero-length vector is NA.

See Also
var for its square, and mad, the most robust alternative.

Examples
sd(1:2) ^ 2

se.contrast

Standard Errors for Contrasts in Model Terms

Description
Returns the standard errors for one or more contrasts in an aov object.

Usage
se.contrast(object, ...)  
## S3 method for class 'aov'
se.contrast(object, contrast.obj,  
  coef = contr.helmert(ncol(contrast))[, 1],  
  data = NULL, ...)
Arguments

object A suitable fit, usually from aov.
contrast.obj The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
coef used when contrast.obj is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
data The data frame used to evaluate contrast.obj.
... further arguments passed to or from other methods.

Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use se.contrast than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for aov about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with coef can be found by calling contrasts and indexing the columns by a factor.

Value

A vector giving the standard errors for each contrast.

selfStart

Construct Self-starting Nonlinear Models


Description

Construct self-starting nonlinear models to be used in \texttt{nls}, etc. Via function \texttt{initial} to compute approximate parameter values from data, such models are "self-starting", i.e., do not need a start argument in, e.g., \texttt{nls()}.

Usage

\texttt{selfStart(model, initial, parameters, template)}

Arguments

- \texttt{model}: a function object defining a nonlinear model or a nonlinear \texttt{formula} object of the form \texttt{~ expression}.
- \texttt{initial}: a function object, taking arguments \texttt{mCall}, \texttt{data}, and \texttt{LHS}, and \ldots, representing, respectively, a matched call to the function model, a data frame in which to interpret the variables in \texttt{mCall}, and the expression from the left-hand side of the model formula in the call to \texttt{nls}. This function should return initial values for the parameters in \texttt{model}. The \ldots is used by \texttt{nls()} to pass its control and trace arguments for the cases where \texttt{initial()} itself calls \texttt{nls()} as it does for the ten self-starting nonlinear models in \texttt{R}'s \texttt{stats} package.
- \texttt{parameters}: a character vector specifying the terms on the right hand side of \texttt{model} for which initial estimates should be calculated. Passed as the \texttt{namevec} argument to the \texttt{deriv} function.
- \texttt{template}: an optional prototype for the calling sequence of the returned object, passed as the \texttt{function.arg} argument to the \texttt{deriv} function. By default, a template is generated with the covariates in \texttt{model} coming first and the parameters in \texttt{model} coming last in the calling sequence.

Details

\texttt{nls()} calls \texttt{getInitial} and the initial function for these self-starting models.

This function is generic; methods functions can be written to handle specific classes of objects.

Value

a \texttt{function} object of class "selfStart", for the \texttt{formula} method obtained by applying \texttt{deriv} to the right hand side of the model formula. An \texttt{initial} attribute (defined by the \texttt{initial} argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

Author(s)

José Pinheiro and Douglas Bates

\texttt{nls, getInitial}.

Each of the following are "selfStart" models (with examples) \texttt{SSasymp, SSasympOff, SSasympOrig, SSbiexp, SSfol, SSfpl, SSgompertz, SSlogis, SSmicmen, SSweibull}.

Further, package \texttt{nlme}'s \texttt{nlsList}. 
Examples

```r
## self-starting logistic model

## The "initializer" (finds initial values for parameters from data):
initLogis <- function(mCall, data, LHS) {
  xy <- data.frame(sortedXyData(mCall["input"], LHS, data))
  if(nrow(xy) < 4)
    stop("too few distinct input values to fit a logistic model")
  z <- xy["y"]
  ## transform to proportion, i.e. in (0,1):
  rng <- range(z); dz <- diff(rng)
  z <- (z - rng[1L] + 0.05 * dz)/(1.1 * dz)
  xy["z"] <- log(z/(1 - z)) # logit transformation
  aux <- coef(lm(x ~ z, xy))
  pars <- coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
                  data = xy,
                  start = list(xmid = aux[1L], scal = aux[2L]),
                  algorithm = "plinear"))
  setNames(pars[c(".lin", "xmid", "scal")], nm = mCall[c("Asym", "xmid", "scal")])
}

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
                     initial = initLogis,
                     parameters = c("Asym", "xmid", "scal"))
```

# 'first.order.log.model' is a function object defining a first order
# compartment model
# 'first.order.log.initial' is a function object which calculates initial
# values for the parameters in 'first.order.log.model'

## self-starting first order compartment model
## Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)
## End(Not run)

## Explore the self-starting models already available in R's "stats":
pos.st <- which("package:stats" == search())
mSS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE

# Show the argument list of each self-starting function:
str(fSS, give.attr = FALSE)
```

### setNames

**Set the Names in an Object**

**Description**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.
Usage

setNames(object = nm, nm)

Arguments

object an object for which a names attribute will be meaningful
nm a character vector of names to assign to the object

Value

An object of the same sort as object with the new names assigned.

Author(s)

Douglas M. Bates and Saikat DebRoy

See Also

unname for removing names.

Examples

setNames(1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

## special case of character vector, using default
setNames(nm = c("First", "2nd"))

---

Shapiro-Wilk Normality Test

Description

Performs the Shapiro-Wilk test of normality.

Usage

shapiro.test(x)

Arguments

x a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.
A list with class "htest" containing the following components:

- **statistic**: the value of the Shapiro-Wilk statistic.
- **p.value**: an approximate p-value for the test. This is said in Royston (1995) to be adequate for `p.value < 0.1`.
- **method**: the character string "Shapiro-Wilk normality test".
- **data.name**: a character string giving the name(s) of the data.

Source

The algorithm used is a C translation of the Fortran code described in Royston (1995). The calculation of the p value is exact for \( n = 3 \), otherwise approximations are used, separately for \( 4 \leq n \leq 11 \) and \( n \geq 12 \).

References

See Also

- `qnorm` for producing a normal quantile-quantile plot.

Examples

```r
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

Description

Extract the estimated standard deviation of the errors, the “residual standard deviation” (misnamed also “residual standard error”, e.g., in `summary.lm()`’s output, from a fitted model).

Many classical statistical models have a *scale parameter*, typically the standard deviation of a zero-mean normal (or Gaussian) random variable which is denoted as \( \sigma \). `sigma(.)` extracts the estimated parameter from a fitted model, i.e., \( \hat{\sigma} \).

Usage

```r
sigma(object, ...)
```

### Default S3 method:

```r
sigma(object, use.fallback = TRUE, ...)
```
**Arguments**

- `object` an R object, typically resulting from a model fitting function such as `lm`.
- `use.fallback` logical, passed to `nobs`.
- `...` potentially further arguments passed to and from methods. Passed to `deviance(*, ...) for the default method.

**Details**

The `stats` package provides the S3 generic and a default method. The latter is correct typically for (asymptotically/approximately) generalized gaussian (“least squares”) problems, since it is defined as

\[
sigma.default <- function (object, use.fallback = TRUE, ...) \\
  \sqrt{ \text{deviance}(object, ...) / (NN - PP) }
\]

where \( NN <- \text{nobs}(object, use.fallback = use.fallback) \) and \( PP <- \sum(!\text{is.na(coef(object)))} \) – where in older R versions this was \( \text{length}(\text{coef(object)}) \) which is too large in case of undetermined coefficients, e.g., for rank deficient model fits.

**Value**

typically a number, the estimated standard deviation of the errors (“residual standard deviation”) for Gaussian models, and—less interpretably—the square root of the residual deviance per degree of freedom in more general models. In some generalized linear modelling (glm) contexts, \( \sigma^2 \) (\( \sigma(\cdot)^2 \)) is called “dispersion (parameter)”. Consequently, for well-fitting binomial or Poisson GLMs, \( \sigma \) is around 1.

Very strictly speaking, \( \hat{\sigma} (\text{“\( \sigma \) hat”}) \) is actually \( \sqrt{\sigma^2} \).

For multivariate linear models (class “mlm”), a vector of sigmas is returned, each corresponding to one column of \( Y \).

**Note**

The misnomer “Residual standard error” has been part of too many R (and S) outputs to be easily changed there.

**See Also**

`deviance`, `nobs`, `vcov`.

**Examples**

```r
## -- lm() ----------------------------------
lm1 <- lm(Fertility ~ . , data = swiss)
sigma(lm1) # ~= 7.165 = "Residual standard error" printed from summary(lm1)
stopifnot(all.equal(sigma(lm1), summary(lm1)$sigma, tolerance=1e-15))

## -- nls() --------------------------------
DNase1 <- subset(DNase, Run == 1)
fm.DN1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
sigma(fm.DN1) # =~ 0.01919 as from summary(…)
stopifnot(all.equal(sigma(fm.DN1), summary(fm.DN1)$sigma, tolerance=1e-15))
```
## -- glm() -----------------------------
## -- a) Binomial -- Example from MASS
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20-numdead)
sigma(budworm.lg <- glm(SF ~ sex*ldose, family = binomial))

## -- b) Poisson -- from ?glm :
## Dobson (1990) Page 93: Randomized Controlled Trial :
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
sigma(glm.D93 <- glm(counts ~ outcome + treatment, family = poisson()))
## (currently) *differs* from
## and the *Quasi*poisson's dispersion
sigma(glm.qD93 <- update(glm.D93, family = quasipoisson()))
sigma (glm.qD93)^2 # 1.282285 is close, but not the same
summary(glm.qD93)$dispersion # == 1.2933

## -- Multivariate lm() "mlm" ---------
util:::example("SSD", echo=FALSE)
sigma(mlmfit) # is the same as (but more efficient than)
sqrt(diag(estVar(mlmfit)))

---

**SignRank**  

*Distribution of the Wilcoxon Signed Rank Statistic*

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size \( n \).

**Usage**

```r
designrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)
```

**Arguments**

- \( x, q \)  
  vector of quantiles.
- \( p \)  
  vector of probabilities.
- \( nn \)  
  number of observations. If \( \text{length}(nn) > 1 \), the length is taken to be the number required.
- \( n \)  
  number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
- \( \text{log}, \text{log.p} \)  
  logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \)  
  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

This distribution is obtained as follows. Let \( x \) be a sample of size \( n \) from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values \( x[i] \) for which \( x[i] \) is positive. This statistic takes values between 0 and \( n(n+1)/2 \), and its mean and variance are \( n(n+1)/4 \) and \( n(n+1)(2n+1)/24 \), respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value

dsigrank gives the density, psigrank gives the distribution function, qsgnrank gives the quantile function, and rsigrank generates random deviates.

The length of the result is determined by nn for rsigrank, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than nn are recycled to the length of the result. Only the first elements of the logical arguments are used.

Author(s)

Kurt Hornik; efficiency improvement by Ivo Ugrina.

See Also

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dwilcox for the distribution of two-sample Wilcoxon rank sum statistic.

Examples

```r
require(graphics)
par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
x <- seq(0, n*(n+1)/2, length.out = 501)
plot(x, dsignrank(x, n = n), type = "l",
     main = paste0("dsignrank(x, n = ", n, ")")
}
```

simulate

**Simulate Responses**

Simulate one or more responses from the distribution corresponding to a fitted model object.

Usage

```
simulate(object, nsim = 1, seed = NULL, ...)
```
simulate

Arguments

- **object**: an object representing a fitted model.
- **nsim**: number of response vectors to simulate. Defaults to 1.
- **seed**: an object specifying if and how the random number generator should be initialized ('seeded'). For the "lm" method, either NULL or an integer that will be used in a call to set.seed before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return .Random.seed as the "seed" attribute, see 'Value'.
- ... additional optional arguments.

Details

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package **stats** has a method for "lm" objects which is used for **lm** and **glm** fits. There is a method for fits from glm.nb in package **MASS**, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by **lm** or **glm**(family = "gaussian") assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) simulate component of the family object is used—there is no appropriate simulation method for ‘quasi’ models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights \(w_i\) can be interpreted as meaning that observation \(i\) is an average of \(w_i\) observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function **gamma.shape** in package **MASS**). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is \(IG(\mu_i, \lambda w_i)\) (see [https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution](https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where \(\lambda\) is estimated by the inverse of the dispersion estimate for the fit. The variance is \(\mu_i^3/(\lambda w_i)\) and hence inversely proportional to the prior weights. The simulation is done by function **rinvGauss** from the **SuppDists** package, which must be installed.

Value

Typically, a list of length **nsim** of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument seed is **NULL**, the attribute is the value of .Random.seed before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value as.list(RNGkind()).

See Also

**RNG** about random number generation in **R**, **fitted.values** and **residuals** for related methods; **glm**, **lm** for model fitting.

There are further examples in the ‘simulate.R’ tests file in the sources for package **stats**.
Examples

```r
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
# each column of S3 is a two-column matrix.

x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
yb2 <- factor(1 + yb2, labels = c("failure", "success"))
modb2 <- glm(yb2 ~ x2, family = binomial)
S4 <- simulate(modb2, nsim = 4)
# each column of S4 is a factor
```

smooth

Tukey’s (Running Median) Smoothing

Description

Tukey’s smoothers, 3RS3R, 3RSS, 3R, etc.

Usage

```r
smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = c("Tukey", "copy"), do.ends = FALSE)
```

Arguments

- `x` a vector or time series
- `kind` a character string indicating the kind of smoother required; defaults to "3RS3R".
twiceit logical, indicating if the result should be ‘twiced’. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$, i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance).

drule a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".
do.ends logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = "S".

Details
3 is Tukey’s short notation for running medians of length 3, 3R stands for Repeated 3 until convergence, and S for Splitting of horizontal stretches of length 2 or 3.
Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) Repeated until convergence – which can be bad.

Value
An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

Note
S and S-PLUS use a different (somewhat better) Tukey smoother in smooth(*). Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.
Since R version 1.2, smooth does really implement Tukey’s end-point rule correctly (see argument endrule).
kind = "3RSR" has been the default till R-1.1, but it can have very bad properties, see the examples.
Note that repeated application of smooth(*) does smooth more, for the "3RS*" kinds.

References

See Also
runmed for running medians; lowess and loess; supsmu and smooth.spline.

Examples
```r
require(graphics)
## see also demo(smooth) !

x1 <- c(4, 1, 3, 6, 6, 4, 1, 6, 2, 4, 2) # very artificial
(x3R <- smooth(x1, "3R")) # 2 iterations of "3"
smooth(x3R, kind = "S")

sm.3RS <- function(x, ...) smooth(smooth(x, "3R", ...), "S", ...)

y <- c(1, 1, 19:1)
```
smooth.spline

**Fit a Smoothing Spline**

**Description**

Fits a cubic smoothing spline to the supplied data.

**Usage**

```r
smooth.spline(x, y = NULL, w = NULL, df, spar = NULL, lambda = NULL, 
               cv = FALSE, all.knots = FALSE, nknots = .nknots.smspl, 
               keep.data = TRUE, df.offset = 0, penalty = 1, 
               control.spar = list(), tol = 1e-6 * IQR(x), keep.stuff = FALSE)
```

**Arguments**

- **x**: a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.
- **y**: responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.
- **w**: optional vector of weights of the same length as x; defaults to all 1.
- **df**: the desired equivalent number of degrees of freedom (trace of the smoother matrix). Must be in \((1, n_x)\), \(n_x\) the number of unique x values, see below.
- **spar**: smoothing parameter, typically (but not necessarily) in \((0, 1]\). When spar is specified, the coefficient \(\lambda\) of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the details below. Alternatively lambda may be specified instead of the scale free spar=s.
- **lambda**: if desired, the internal (design-dependent) smoothing parameter \(\lambda\) can be specified instead of spar. This may be desirable for resampling algorithms such as cross validation or the bootstrap.
ordinary leave-one-out (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; is used for smoothing parameter computation only when both spar and df are not specified; it is used however to determine cv.crit in the result. Setting it to NA for speedup skips the evaluation of leverages and any score.

If TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of x[] is used, specifically x[j] where the nknots indices are evenly spaced in 1:n, see also the next argument nknots.

Alternatively, a strictly increasing numeric vector specifying “all the knots” to be used; must be rescaled to [0, 1] already such that it corresponds to the ans $ fit$knots sequence returned, not repeating the boundary knots.

integer or function giving the number of knots to use when all.knots = FALSE. If a function (as by default), the number of knots is nknots(nx). By default for nx > 49 this is less than nx, the number of unique x values, see the Note.

logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.

allows the degrees of freedom to be increased by df.offset in the GCV criterion.

do not used to plug the degrees of freedom in the GCV criterion.

optional list with named components controlling the root finding when the smoothing parameter spar is computed, i.e., missing or NULL, see below.

Note that this is partly experimental and may change with general spar computation improvements!

lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).

upper bound for spar; defaults to +1.5.

the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).

the relative precision used; defaults to 2e-8 (formerly 0.00244).

logical indicating if iterations should be traced.

integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval [low, high].

a tolerance for same-ness or uniqueness of the x values. The values are binned into bins of size tol and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

an experimental logical indicating if the result should keep extras from the internal computations. Should allow to reconstruct the X matrix and more.

Neither x nor y are allowed to containing missing or infinite values.

The x vector should contain at least four distinct values. ‘Distinct’ here is controlled by tol: values which are regarded as the same are replaced by the first of their values and the corresponding y and w are pooled accordingly.

Unless lambda has been specified instead of spar, the computational λ used (as a function of s = spar) is \( \lambda = r + 256^{3s-1} \) where \( r = tr(X'W'X)/tr(\Sigma) \), \( \Sigma \) is the matrix given by \( \Sigma_{ij} = \int B'_i(t)B'_j(t)dt \), \( X \) is given by \( X_{ij} = B_j(x_i) \), W is the diagonal matrix of weights (scaled such that its trace is \( n \), the original number of observations) and \( B_k(\cdot) \) is the \( k \)-th B-spline.
Note that with these definitions, \( f_i = f(x_i) \), and the B-spline basis representation \( f = Xc \) (i.e., \( c \) is the vector of spline coefficients), the penalized log likelihood is \( L = (y - f)'W(y - f) + \lambda c'\Sigma c \), and hence \( c \) is the solution of the (ridge regression) \( (X'WX + \lambda \Sigma)c = X'Wy \).

If \( \text{spar} \) and \( \text{lambda} \) are missing or \( \text{NULL} \), the value of \( \text{df} \) is used to determine the degree of smoothing. If \( \text{df} \) is missing as well, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by \( \text{cv} \)) is used to determine \( \lambda \).

Note that from the above relation, \( \text{spar} \) is \( s = s_0 + 0.0601 \times \log \lambda \), which is intentionally different from the S-PLUS implementation of \texttt{smooth.spline} (where \( \text{spar} \) is proportional to \( \lambda \)). In R’s \((\log \lambda)\) scale, it makes more sense to vary \( \text{spar} \) linearly.

Note however that currently the results may become very unreliable for \( \text{spar} \) values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting \( \text{spar} \) or the controls low and high outside such a safe range, unless you know what you are doing! Similarly, specifying \( \text{lambda} \) instead of \( \text{spar} \) is delicate, notably as the range of “safe” values for \( \text{lambda} \) is not scale-invariant and hence entirely data dependent.

The ‘generalized’ cross-validation method GCV will work correctly when there are duplicated points in \( x \). However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. \( \text{cv} = \text{TRUE} \) is best avoided in that case.

Value

An object of class “\texttt{smooth.spline}” with components

- \( x \) the distinct \( x \) values in increasing order, see the ‘Details’ above.
- \( y \) the fitted values corresponding to \( x \).
- \( w \) the weights used at the unique values of \( x \).
- \( yin \) the \( y \) values used at the unique \( y \) values.
- \( \text{tol} \) the \( \text{tol} \) argument (whose default depends on \( x \)).
- \( \text{data} \) only if \( \text{keep.data} = \text{TRUE} \): itself a \texttt{list} with components \( x \), \( y \) and \( w \) of the same length. These are the original \((x_i, y_i, w_i), i = 1, \ldots, n\), values where \( \text{data}x \) may have repeated values and hence be longer than the above \( x \) component; see details.
- \( \text{lev} \) (when \( \text{cv} \) was not \( \text{NA} \)) leverages, the diagonal values of the smoother matrix.
- \( \text{cv.crit} \) cross-validation score, ‘generalized’ or true, depending on \( \text{cv} \). The CV score is often called “PRESS” (and labeled on \texttt{print()}), for ‘\texttt{PRE}diction \texttt{Sum of Squares}’.
- \( \text{pen.crit} \) the penalized criterion, a non-negative number; simply the (weighted) residual sum of squares \((\text{RSS}), \sum(. \times \text{residuals}(. \times 2))\).
- \( \text{crit} \) the criterion value minimized in the underlying \texttt{Fortran} routine ‘\texttt{sslvrg}’. When \( \text{df} \) has been specified, the criterion is \( 3 + (\text{tr}(S_\lambda) - \text{df})^2 \), where the 3+ is there for numerical (and historical) reasons.
- \( \text{df} \) equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true \( \text{df} \) is between 1 and 2.
- \( \text{spar} \) the value of \( \text{spar} \) computed or given, unless it has been given as \( \text{c}(\text{lambda} = *) \), when it set to \( \text{NA} \) here.
- \( \text{ratio} \) (when \( \text{spar} \) above is not \( \text{NA} \)), the value \( r \), the ratio of two matrix traces.
- \( \lambda \) the value of \( \lambda \) corresponding to \( \text{spar} \), see the details above.
iparms

named integer(3) vector where ..$ipars["iter"] gives number of spar computing iterations used.

auxMat

experimental; when keep.stuff was true, a “flat” numeric vector containing parts of the internal computations.

fit

list for use by predict.smooth.spline, with components

- **knot**: the knot sequence (including the repeated boundary knots), scaled into [0, 1] (via min and range).
- **nk**: number of coefficients or number of ‘proper’ knots plus 2.
- **coef**: coefficients for the spline basis used.
- **min, range**: numbers giving the corresponding quantities of x.

method(class = "smooth.spline") shows a hatvalues() method based on the lev vector above.

**Note**

The number of unique x values, \( nx = n_x \), are determined by the tol argument, equivalently to

\[
x_n \leftarrow \text{length}(x) - \text{sum}(\text{duplicated}(\text{round}((x - \text{mean}(x)) / \text{tol})))
\]

The default all.knots = FALSE and nknots = .nknots.smSpl, entails using only \( O(n_k^{0.2}) \) knots instead of \( n_x \) for \( n_x > 49 \). This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only \( O(n_k) + O(n) \) where \( n_k \) is the number of knots.

In this case where not all unique x values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large df) is used.

**Author(s)**

R implementation by B. D. Ripley and Martin Maechler (spar/lambda, etc).

**Source**

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (originally taken from http://lib.stat.cmu.edu/general/gamfit) which makes use of spline code by Finbarr O’Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

```
smoothEnds

End Points Smoothing (for Running Medians)

Description

Smooth end points of a vector \( y \) using subsequently smaller medians and Tukey’s end point rule at the very end. (of odd span).

Usage

```r
smoothEnds(y, k = 3)
```

Arguments

- **y**: dependent variable to be smoothed (vector).
- **k**: width of largest median window; must be odd.

Details

`smoothEnds` is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window \( k \). The first and last value are computed using Tukey’s end point rule, i.e., \( \text{sm}[1] = \text{median}(y[1], \text{sm}[2], 3 \times \text{sm}[2] - 2 \times \text{sm}[3], \text{na.rm}=\text{TRUE}) \).

In R versions 3.6.0 and earlier, missing values (\( \text{NA} \)) in \( y \) typically lead to an error, whereas now the equivalent of \( \text{median}(*, \text{na.rm}=\text{TRUE}) \) is used.

Value

vector of smoothed values, the same length as \( y \).

require(graphics)

y <- ys <- (-20:20)^2
y[c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, endrule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd = 1.5, lty = 1, col = col3)
eRules <- c("keep", "constant", "median")
legend("topleft", paste("endrule", eRules, sep = " = "),
      col = col3, lwd = 1.5, lty = 1, bty="n")
stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```

```r
## With missing values (for R >= 3.6.1):
yN <- y; yN[c(2,40)] <- NA
rN <- sapply(eRules, function(R) runmed(yN, 7, endrule=R))
matlines(rN, type = "b", pch = 4, lwd = 3, lty = 2,
         col = adjustcolor(c("red", "orange4", "orange1"), 0.5))
yN[c(1, 20:21)] <- NA # additionally
rN. <- sapply(eRules, function(R) runmed(yN, 7, endrule=R))
head(rN., 4); tail(rN.) # more NA's too, still not *so* many:
stopifnot(exprs = {
  !anyNA(rN[,2:3])
  identical(which(is.na(rN[,"keep"])), c(2L, 40L))
  identical(which(is.na(rN.), arr.ind=TRUE, useNames=FALSE),
            cbind(c(1:2, 40L), 1L))
  identical(rN.[38:41, "median"], c(289, 289, 397, 470))
})
```

sortedXyData

Create a sortedXyData Object

Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the `initial` function for a self-starting nonlinear regression model, which will be of the `selfStart` class.

Usage

```r
sortedXyData(x, y, data)
```

Arguments

- **x**: a numeric vector or an expression that will evaluate in `data` to a numeric vector
- **y**: a numeric vector or an expression that will evaluate in `data` to a numeric vector
- **data**: an optional data frame in which to evaluate expressions for `x` and `y`, if they are given as expressions
Value

A `sortedXyData` object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.

Author(s)

José Pinheiro and Douglas Bates

Examples

```r
DNase.2 <- DNase[ DNase$Run == "2", ]
sortedXyData( expression(log(conc)), expression(density), DNase.2 )
```

---

**spec.ar**

Estimate Spectral Density of a Time Series from AR Fit

Description

Fits an AR model to `x` (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

Usage

```r
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail, 
method = "yule-walker", ...)
```

Arguments

- `x` A univariate (not yet: or multivariate) time series or the result of a fit by `ar`.
- `n.freq` The number of points at which to plot.
- `order` The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
- `plot` Plot the periodogram?
- `na.action` NA action function.
- `method` method for `ar` fit.
- `...` Graphical arguments passed to `plot.spec`.

Value

An object of class "spec". The result is returned invisibly if `plot` is true.

Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.
Note

The multivariate case is not yet implemented.

References

See Also

ar, spectrum.

Examples

```r
require(graphics)

spec.ar(lh)

spec.ar(ldeaths)
spec.ar(ldeaths, method = "burg")

spec.ar(log(lynx))
spec.ar(log(lynx), method = "burg", add = TRUE, col = "purple")
spec.ar(log(lynx), method = "mle", add = TRUE, col = "forest green")
spec.ar(log(lynx), method = "ols", add = TRUE, col = "blue")
```

Description

*spec.pgram* calculates the periodogram using a fast Fourier transform, and optionally smoothes the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

Usage

```r
spec.pgram(x, spans = NULL, kernel, taper = 0.1, 
            pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE, 
            plot = TRUE, na.action = na.fail, ...)
```

Arguments

- **x** univariate or multivariate time series.
- **spans** vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
- **kernel** alternatively, a kernel smoother of class "tskernel".
taper specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.

pad proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.

fast logical; if TRUE, pad the series to a highly composite length.

demean logical. If TRUE, subtract the mean of the series.

detrend logical. If TRUE, remove a linear trend from the series. This will also remove the mean.

plot plot the periodogram?

na.action NA action function.

... graphical arguments passed to plot.spec.

Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the fast and not the pad argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

Value

A list object of class "spec" (see spectrum) with the following additional components:

kernel The kernel argument, or the kernel constructed from spans.

df The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with df degrees of freedom.

bandwidth The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).

taper The value of the taper argument.

pad The value of the pad argument.

detrend The value of the detrend argument.

demean The value of the demean argument.

The result is returned invisibly if plot is true.

spec.taper

Taper a Time Series by a Cosine Bell

Description

Apply a cosine-bell taper to a time series.

Usage

spec.taper(x, p = 0.1)

Arguments

x A univariate or multivariate time series
p The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series).
spectrum

Details
The cosine-bell taper is applied to the first and last \( p[i] \) observations of time series \( x[, i] \).

Value
A new time series object.

See Also
spec.pgram, cpgram

spectrum

Spectral Density Estimation

Description
The spectrum function estimates the spectral density of a time series.

Usage
spectrum(x, ..., method = c("pgram", "ar"))

Arguments
x
A univariate or multivariate time series.

method
String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". Can be abbreviated.

...
Further arguments to specific spec methods or plot.spec.

Details
spectrum is a wrapper function which calls the methods spec.pgram and spec.ar.

The spectrum here is defined with scaling \( 1/frequency(x) \), following S-PLUS. This makes the spectral density a density over the range \( (-frequency(x)/2, +frequency(x)/2] \), whereas a more common scaling is \( 2\pi \) and range \( (-0.5, 0.5] \) (e.g., Bloomfield) or 1 and range \( (-\pi, \pi] \).

If available, a confidence interval will be plotted by plot.spec: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

Value
An object of class "spec", which is a list containing at least the following components:

freq
vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.

spec
Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.

coh
NULL for univariate series. For multivariate time series, a matrix containing the squared coherency between different series. Column \( i + (j - 1) * (j - 2)/2 \) of coh contains the squared coherency between columns \( i \) and \( j \) of \( x \), where \( i < j \).
phase: NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.

series: The name of the time series.

snames: For multivariate input, the names of the component series.

method: The method used to calculate the spectrum.

The result is returned invisibly if plot is true.

Note

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

splinefun

Interpolating Splines

Description

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a function performing the interpolation.

Usage

splinefun(x, y = NULL, 
  method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
  ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
  xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)

Arguments

x, y vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords.
  y must be increasing or decreasing for method = "hyman".

m (for splinefunH()): vector of slopes \( m_i \) at the points \((x_i, y_i)\); these together determine the Hermite "spline" which is piecewise cubic, (only) once differentiable continuously.

method specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman". Can be abbreviated.

n if xout is left unspecified, interpolation takes place at \( n \) equally spaced points spanning the interval \([x_{\text{min}}, x_{\text{max}}]\).

xmin, xmax left-hand and right-hand endpoint of the interpolation interval (when xout is unspecified).

xout an optional set of values specifying where interpolation is to take place.

ties handling of tied x values. The string "ordered" or a function (or the name of a function) taking a single vector argument and returning a single number or a length-2 list of both, see approx and its 'Details' section, and the example below.

Details

The inputs can contain missing values which are deleted, so at least one complete \((x, y)\) pair is required. If method = "fmm", the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when method = "natural", and periodic splines when method = "periodic".

The method "monoH.FC" computes a monotone Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by \((x_i, y_i, m_i)\), is monotone (increasing or decreasing) iff the data are.
Method "hyman" computes a monotone cubic spline using Hyman filtering of an method = "fmm" fit for strictly monotonic inputs.

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of \( x \). Extrapolation makes little sense for method = "fmm"; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

**Value**

spline returns a list containing components \( x \) and \( y \) which give the ordinates where interpolation took place and the interpolated values.

splinefun returns a function with formal arguments \( x \) and deriv, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (deriv = 0), or its derivatives (deriv = 1, 2, 3) at the points \( x \), where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

**Warning**

The value returned by splinefun contains references to the code in the current version of \( R \); it is not intended to be saved and loaded into a different \( R \) session. This is safer in \( R \geq 3.0.0 \).

**Author(s)**

R Core Team.

ry <- matrix(unlist(tapply(y, match(x, mx), range, simplify = FALSE)),
    ncol = 2, byrow = TRUE)
segments(mx, ry[, 1], mx, ry[, 2], col = "blue", lwd = 2)

## Another example with sorted x, but ties:
set.seed(8); x <- sort(round(rnorm(30), 1)); y <- round(sin(pi * x) + rnorm(30)/10, 3)
summary(diff(x) == 0) # -> 7 duplicated x-values
str(spline(x, y, n = 201, ties="ordered")) # all '"y' entries are NaN
## The default (ties=mean) is ok, but most efficient to use instead is
sxyo <- spline(x, y, n = 201, ties= list("ordered", mean))
sapply(sxyo, summary)# all fine now
plot(x, y, main = "spline(x,y, ties=list("ordered", mean)) for when x has ties")
```
## An example of monotone interpolation

```r	n <- 20
set.seed(11)
x. <- sort(runif(n)) ; y. <- cumsum(abs(rnorm(n)))
plot(x., y.)
curve(splinefun(x., y.)(x), add = TRUE, col = 2, n = 1001)
curve(splinefun(x., y., method = "monoH.FC")(x), add = TRUE, col = 3, n = 1001)
curve(splinefun(x., y., method = "hyman")(x), add = TRUE, col = 4, n = 1001)
legend("topleft",
paste0("splinefun( ", c("fmm", "monoH.FC", "hyman"), " \" ")"),
col = 2:4, lty = 1, bty = "n")
```

## and one from Fritsch and Carlson (1980), Dougherty et al (1989)

```r
x. <- c(7.09, 8.09, 8.19, 8.7, 9.2, 10, 12, 15, 20)
f <- c(0, 2.76429e-5, 4.37498e-2, 0.169183, 0.469428, 0.943740, 0.998636, 0.999919, 0.999994)
s0 <- splinefun(x., f)
s1 <- splinefun(x., f, method = "monoH.FC")
s2 <- splinefun(x., f, method = "hyman")
plot(x., f, ylim = c(-0.2, 1.2))
curve(s0(x), add = TRUE, col = 2, n = 1001) -> m0
curve(s1(x), add = TRUE, col = 3, n = 1001)
curve(s2(x), add = TRUE, col = 4, n = 1001)
legend("right",
paste0("splinefun( \", c("fmm", "monoH.FC", "hyman"), " \" ")"),
col = 2:4, lty = 1, bty = "n")
```

## they seem identical, but are not quite:

```r
xx <- m0$x
plot(xx, s1(xx) - s2(xx), type = "l", col = 2, lwd = 2,
     main = "Difference monoH.FC - hyman"); abline(h = 0, lty = 3)
x <- xx[xx < 10.2] ## full range: x <- xx .. does not show enough
col <- adjustcolor(2:4, 0.8)
matplot(x, cbind(s0(x, deriv = 2), s1(x, deriv = 2), s2(x, deriv = 2))^2,
        lwd = 2, col = ccol, type = "l", ylab = quote({{f*second}(x)}^2),
        main = expression({{f*second}(x)}^2 ~"for the three 'splines'"))
legend("topright",
paste0("splinefun( \", c("fmm", "monoH.FC", "hyman"), " \" ")"),
lwd = 2, col = ccol, lty = 1:3, bty = "n")
```

## --> "hyman" has slightly smaller integral f'(x)*2 dx than "FC",
## here, and both are 'much worse' than the regular fmm spline.

---

**SSasymp**

**Self-Starting Nls Asymptotic Regression Model**

---

**Description**

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Note that **SSweibull()** generalizes this asymptotic model with an extra parameter.
SSasymp(input, Asym, R0, lrc)

Arguments

input
a numeric vector of values at which to evaluate the model.

Asym
a numeric parameter representing the horizontal asymptote on the right side (very large values of input).

R0
a numeric parameter representing the response when input is zero.

lrc
a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as input. It is the value of the expression \( \text{Asym} + (\text{R0}-\text{Asym}) \times \exp(-\exp(\text{lrc}) \times \text{input}) \). If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSasympOff

Self-Starting Nls Asymptotic Regression Model with an Offset

Description

This selfStart model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters Asym, lrc, and c0.

Usage

SSasympOff(input, Asym, lrc, c0)

Arguments

input  
a numeric vector of values at which to evaluate the model.

Asym  
a numeric parameter representing the horizontal asymptote on the right side (very large values of input).

lrc  
a numeric parameter representing the natural logarithm of the rate constant.

c0  
a numeric parameter representing the input for which the response is zero.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*(1 - exp(-exp(lrc)*(input - c0))). If all of the arguments Asym, lrc, and c0 are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

**SSasympOrig**

**Arguments**

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote.
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.

**Value**

a numeric vector of the same length as input. It is the value of the expression \( \text{Asym} \times (1 - \exp(-\exp(\text{lrc}) \times \text{input})) \). If all of the arguments **Asym** and **lrc** are names of objects, the gradient matrix with respect to these names is attached as an attribute named \text{gradient}.

SSbiexp

Self-Starting Nls Biexponential model

Description

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters A1, lrc1, A2, and lrc2.

Usage

SSbiexp(input, A1, lrc1, A2, lrc2)

Arguments

input | a numeric vector of values at which to evaluate the model.
A1 | a numeric parameter representing the multiplier of the first exponential.
lrc1 | a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
A2 | a numeric parameter representing the multiplier of the second exponential.
lrc2 | a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

a numeric vector of the same length as input. It is the value of the expression A1*exp(-exp(lrc1)*input)+A2*exp(-exp(lrc2)*input). If all of the arguments A1, lrc1, A2, and lrc2 are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

## SSD Matrix and Estimated Variance Matrix in Multivariate Models

### Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

### Usage

```r
# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```
Arguments

- `object`: object of class "mlm", or "SSD" in the case of `estVar`.
- Unused

Value

- `SSD()` returns a list of class "SSD" containing the following components:
  - `SSD`: The residual sums of squares and products matrix
  - `df`: Degrees of freedom
  - `call`: Copied from `object`

`estVar` returns a matrix with the estimated variances and covariances.

See Also

SSfol  
Self-Starting Nls First-order Compartment Model

Description

This `selfStart` model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters $\text{k}_\text{e}$, $\text{k}_\text{a}$, and $\text{Cl}$. 
Usage

\texttt{SSfol(Dose, input, lKe, lKa, lCl)}

Arguments

- \texttt{Dose}: a numeric value representing the initial dose.
- \texttt{input}: a numeric vector at which to evaluate the model.
- \texttt{lKe}: a numeric parameter representing the natural logarithm of the elimination rate constant.
- \texttt{lKa}: a numeric parameter representing the natural logarithm of the absorption rate constant.
- \texttt{lCl}: a numeric parameter representing the natural logarithm of the clearance.

Value

a numeric vector of the same length as \texttt{input}, which is the value of the expression

\[
\frac{Dose \times \exp(lKe+lKa-lCl) \times (\exp(-\exp(lKe) \times input) - \exp(-\exp(lKa) \times input))}{\exp(lKa) - \exp(lKe)}
\]

If all of the arguments \texttt{lKe}, \texttt{lKa}, and \texttt{lCl} are names of objects, the gradient matrix with respect to these names is attached as an attribute named \texttt{gradient}.

Self-Starting Nls Four-Parameter Logistic Model

Description

This `selfStart` model evaluates the four-parameter logistic function and its gradient. It has an initial attribute computing initial estimates of the parameters \(A, B, \text{xmid},\) and \(\text{scal}\) for a given set of data.

Usage

```r
SSfpl(input, A, B, xmid, scal)
```

Arguments

- `input` a numeric vector of values at which to evaluate the model.
- `A` a numeric parameter representing the horizontal asymptote on the left side (very small values of `input`).
- `B` a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- `xmid` a numeric parameter representing the `input` value at the inflection point of the curve. The value of `SSfpl` will be midway between \(A\) and \(B\) at `xmid`.
- `scal` a numeric scale parameter on the `input` axis.

Value

A numeric vector of the same length as `input`. It is the value of the expression \(A+(B-A)/(1+\exp((\text{xmid}-\text{input})/\text{scal}))\). If all of the arguments `A`, `B`, `xmid`, and `scal` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

### SSgompertz

#### Self-Starting Nls Gompertz Growth Model

**Description**

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

**Usage**

```r
SSgompertz(x, Asym, b2, b3)
```

**Arguments**

- `x` : a numeric vector of values at which to evaluate the model.
- `Asym` : a numeric parameter representing the asymptote.
- `b2` : a numeric parameter related to the value of the function at `x = 0`
- `b3` : a numeric parameter related to the scale the `x` axis.

**Value**

a numeric vector of the same length as input. It is the value of the expression `Asym*exp(-b2+b3*x)`. If all of the arguments Asym, b2, and b3 are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSlogis

Self-Starting Nls Logistic Model

Description

This selfStart model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, xmid, and scal. In R 3.4.2 and earlier, that init function failed when min(input) was exactly zero.

Usage

SSlogis(input, Asym, xmid, scal)

Arguments

  input  
a numeric vector of values at which to evaluate the model.

  Asym  
a numeric parameter representing the asymptote.

  xmid  
a numeric parameter representing the x value at the inflection point of the curve. 
The value of SSlogis will be Asym/2 at xmid.

  scal  
a numeric scale parameter on the input axis.

Value

  a numeric vector of the same length as input. It is the value of the expression 
  Asym/(1+exp((xmid-input)/scal)). If all of the arguments Asym, xmid, and scal are names of 
  objects the gradient matrix with respect to these names is attached as an attribute named 
  gradient.

Self-Starting Nls Michaelis-Menten Model

Description
This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters \( V_m \) and \( K \).

Usage
SSmicmen(input, \( V_m \), \( K \))

Arguments
input
a numeric vector of values at which to evaluate the model.
\( V_m \)
a numeric parameter representing the maximum value of the response.
\( K \)
a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.

Value
a numeric vector of the same length as input. It is the value of the expression \( V_m \cdot \text{input}/(K + \text{input}) \). If both the arguments \( V_m \) and \( K \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

**SSweibull**

*Self-Starting Nls Weibull Growth Curve Model*

**Description**

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, Drop, lrc, and pwr for a given set of data.

**Usage**

```r
SSweibull(x, Asym, Drop, lrc, pwr)
```

**Arguments**

- `x` a numeric vector of values at which to evaluate the model.
- `Asym` a numeric parameter representing the horizontal asymptote on the right side (very small values of `x`).
- `Drop` a numeric parameter representing the change from `Asym` to the y intercept.
- `lrc` a numeric parameter representing the natural logarithm of the rate constant.
- `pwr` a numeric parameter representing the power to which `x` is raised.

**Details**

This model is a generalization of the SSasymp model in that it reduces to SSasymp when `pwr` is unity.
Value

a numeric vector of the same length as x. It is the value of the expression
Asym-Drop*exp(-exp(lrc)*x^pwr). If all of the arguments Asym, Drop, lrc, and pwr are names
of objects, the gradient matrix with respect to these names is attached as an attribute named
gradient.

start

Enclose the Terminal Times of Time Series

Description

Extract and encode the times the first and last observations were taken. Provided only for compati-
bility with S version 2.

Usage

start(x, ...)
end(x, ...)

Arguments

x          a univariate or multivariate time-series, or a vector or matrix.
...         extra arguments for future methods.
Details

These are generic functions, which will use the tsp attribute of x if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as c(1995, 7). For a series of frequency f, time n+i/f is presented as c(n, i+1) (even for i = 0 and f = 1).

Warning

The representation used by start and end has no meaning unless the frequency is supplied.

See Also

ts, time, tsp.

stat.anova

GLM Anova Statistics

Description

This is a utility function, used in lm and glm methods for anova(..., test != NULL) and should not be used by the average user.

Usage

stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),
             scale, df.scale, n)

Arguments

table numeric matrix as results from anova.glm(..., test = NULL).
test a character string, partially matching one of "Rao", "LRT", "Chisq", "F" or "Cp".
scale a residual mean square or other scale estimate to be used as the denominator in an F test.
df.scale degrees of freedom corresponding to scale.
n number of observations.

Value

A matrix which is the original table, augmented by a column of test statistics, depending on the test argument.

References

See Also

anova.lm, anova.glm.
**Examples**

```r
#-- Continued from '?glm':
print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
    scale = sum(resid(glm.D93, "pearson")^2)/4,
    df.scale = 4, n = 9)
```

---

**step**  
*Choose a model by AIC in a Stepwise Algorithm*

---

**Description**

Select a formula-based model by AIC.

**Usage**

```r
step(object, scope, scale = 0,
    direction = c("both", "backward", "forward"),
    trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

**Arguments**

- `object`  
  an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.

- `scope`  
  defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.

- `scale`  
  used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. The default value, 0, indicates the scale should be estimated: see `extractAIC`.  

---
**Direction**

The mode of stepwise search can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward". Values can be abbreviated.

**Trace**

If positive, information is printed during the running of step. Larger values may give more detailed information.

**Keep**

A filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.

**Steps**

The maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

**K**

The multiple of the number of degrees of freedom used for the penalty. Only k = 2 gives the genuine AIC: k = \log(n) is sometimes referred to as BIC or SBC.

... any additional arguments to `extractAIC`.

**Details**

Step uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows’ C_p, this is done and the tables are labelled appropriately.

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`. So using . in a `scope` formula means ‘what is already there’, with .^2 indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a `gaussian` family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

**Value**

The stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

**Warning**

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.
Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package `MASS` for a wider range of object classes.

Author(s)

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package `MASS` (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

Examples

```r
## following on from example(lm)
step(lm.D9)

summary(lm1 <- lm(Fertility ~ ., data = swiss))
slm1 <- step(lm1)
summary(slm1)
slm1$anova
```

Description

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), `stepfun(x, y, \ldots)` returns an interpolating 'step' function, say fn. I.e., \(fn(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) right = FALSE, \(fn(x_i) = y_i\) and for right = TRUE, \(fn(x_i) = y_{i-1}\), for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the 'continuity' parameter f. For the default, right = FALSE, \(f = 0\), \(fn\) is a \textit{cadlag} function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their left endpoint. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1 - f)y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(fn\) may no longer be a proper step function, since it can be discontinuous from both sides, unless right = TRUE, \(f = 1\) which is left-continuous (i.e., constant pieces contain their right endpoint).
**stepfun**

**Usage**

```r
going(x, y, f = as.numeric(right), ties = "ordered",
     right = FALSE)
```

```r
is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)
```

```r
## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)
```

```r
## S3 method for class 'stepfun'
summary(object, ...)
```

**Arguments**

- **x**: numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, `x` is as object below.
- **y**: numeric vector one longer than `x`, giving the heights of the function values between the `x` values.
- **f**: a number between 0 and 1, indicating how interpolation outside the given `x` values should happen. See `approxfun`.
- **ties**: Handling of tied `x` values. Either a function or the string "ordered". See `approxfun`.
- **right**: logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- **Fn, object**: an R object inheriting from "stepfun".
- **digits**: number of significant digits to use, see `print`.
- **...**: potentially further arguments (required by the generic).

**Value**

A function of class "stepfun", say `fn`.

There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see `plot.stepfun") stepfun objects.

The **environment** of `fn` contains all the information needed:

- "x", "y": the original arguments
- "n": number of knots (x values)
- "f": continuity parameter
- "yleft", "yright": the function values outside the knots
- "method": (always == "constant", from `approxfun(.)`).

The knots are also available via `knots(fn)`.
Note

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at \texttt{R 3.0.0}). They can usually be re-created by

\[
\text{eval(attr(old_obj, "call"), environment(old_obj))}
\]

since the data used is stored as part of the object's environment.

\texttt{stl}

\textit{Seasonal Decomposition of Time Series by Loess}

Description

Decompose a time series into seasonal, trend and irregular components using \texttt{loess}, acronym STL.
Usage

stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)

Arguments

x univariate time series to be decomposed. This should be an object of class "ts"
    with a frequency greater than one.

s.window either the character string "periodic" or the span (in lags) of the loess win-
    dow for seasonal extraction, which should be odd and at least 7, according to
    Cleveland et al. This has no default.

s.degree degree of locally-fitted polynomial in seasonal extraction. Should be zero or
    one.

t.window the span (in lags) of the loess window for trend extraction, which
    should be odd. If NULL, the default, nextodd(ceiling((1.5*period) /
    (1-(1.5/s.window)))) is taken.

t.degree degree of locally-fitted polynomial in trend extraction. Should be zero or one.

l.window the span (in lags) of the low-pass filter used for each
    subseries. Defaults to the smallest odd integer greater than or equal to
    frequency(x) which is recommended since it prevents competition between
    the trend and seasonal components. If not an odd integer its given value is in-
    creased to the next odd one.

l.degree degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0
    or 1.

s.jump, t.jump, l.jump integers at least one to increase speed of the respective smoother. Linear inter-
    polation happens between every *, jumpth value.

robust logical indicating if robust fitting be used in the loess procedure.

inner integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iter-
    ations suffice.

outer integer; the number of ‘outer’ robustness iterations.

na.action action on missing values.

Details

The seasonal component is found by loess smoothing the seasonal sub-series (the series of all Jan-
uary values, ...); if s.window = "periodic" smoothing is effectively replaced by taking the mean.
The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is
removed from the seasonal component and added to the trend component. This process is iterated
a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, plot.stl.
Value

stl returns an object of class "stl" with components

time.series a multiple time series with columns seasonal, trend and remainder.
weights the final robust weights (all one if fitting is not done robustly).
call the matched call.
win integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
deg integer (length 3) vector with the polynomial degrees for these smoothers.
jump integer (length 3) vector with the 'jumps' (skips) used for these smoothers.
ni number of inner iterations
no number of outer robustness iterations

Note

This is similar to but not identical to the stl function in S-PLUS. The remainder component given by S-PLUS is the sum of the trend and remainder series from this function.

  stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
opt <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars = NULL, labels = NULL,
     main = "stl(mdeaths, s.w = "per")", robust = FALSE / TRUE )")
plot(stmR, set.pars = NULL)
# mark the 'outliers':

stlmethods

Methods for STL Objects

Description

Methods for objects of class stl, typically the result of stl. The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

Usage

## S3 method for class 'stl'
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, ...,
     col.range = "light gray")

Arguments

x stl object.

labels character of length 4 giving the names of the component time-series.

set.pars settings for par(.) when setting up the plot.

main plot main title.

range.bars logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.

... further arguments passed to or from other methods.

col.range colour to be used for the range bars, if plotted. Note this appears after ... and so cannot be abbreviated.

plot.ts and stl, particularly for examples.
**StructTS**

**Fit Structural Time Series**

**Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

\[
\text{StructTS}(x, \text{type} = \text{c("level", "trend", "BSM")}, \text{init} = \text{NULL}, \text{fixed} = \text{NULL}, \text{optim.control} = \text{NULL})
\]

**Arguments**

- **x**: a univariate numeric time series. Missing values are allowed.
- **type**: the class of structural model. If omitted, a BSM is used for a time series with \( \text{frequency}(x) > 1 \), and a local trend model otherwise. Can be abbreviated.
- **init**: initial values of the variance parameters.
- **fixed**: optional numeric vector of the same length as the total number of parameters. If supplied, only \( \text{NA} \) entries in fixed will be varied. Probably most useful for setting variances to zero.
- **optim.control**: List of control parameters for \text{optim}. Method "L-BFGS-B" is used.

**Details**

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by \text{type} = "level". This has an underlying level \( \mu_t \) which evolves by

\[
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
\]

The observations are

\[
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
\]

There are two parameters, \( \sigma_\xi^2 \) and \( \sigma_\epsilon^2 \). It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, \text{type} = "trend", has the same measurement equation, but with a time-varying slope in the dynamics for \( \mu_t \), given by

\[
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
\]

\[
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)
\]

with three variance parameters. It is not uncommon to find \( \sigma_\zeta^2 = 0 \) (which reduces to the local level model) or \( \sigma_\xi^2 = 0 \), which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, \text{type} = "BSM", is a local trend model with an additional seasonal component. Thus the measurement equation is

\[
x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
\]
where \( \gamma_t \) is a seasonal component with dynamics

\[
\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma^2_\omega)
\]

The boundary case \( \sigma^2_\omega = 0 \) corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

**Value**

A list of class "StructTS" with components:

- **coef**: the estimated variances of the components.
- **loglik**: the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to arima nor different types of structural models.
- **loglik0**: the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.
- **data**: the time series \( x \).
- **residuals**: the standardized residuals.
- **fitted**: a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time \( t \) and not at the end of the series).
- **call**: the matched call.
- **series**: the name of the series \( x \).
- **code**: the convergence code returned by optim.
- **model, model0**: Lists representing the Kalman Filter used in the fitting. See KalmanLike. model0 is the initial state of the filter, model its final state.
- **xtsp**: the tsp attributes of \( x \).

**Note**

Optimization of structural models is a lot harder than many of the references admit. For example, the AirPassengers data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include \( \sigma^2_\epsilon \).

**References**

**See Also**

KalmanLike, tsSmooth; stl for different kind of (seasonal) decomposition.
Examples

```r
## see also JohnsonJohnson, Nile and AirPassengers
require(graphics)

trees <- window(treering, start = 0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdia(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1))  # to give appropriate aspect ratio for next plot.
plot(log10(UKgas))
plot(cbind(fitted(fit), resids=resid(fit)), main = "UK gas consumption")

## keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1, 0.001, NA, NA),
         optim.control = list(trace = TRUE))
```

summary.aov

Summarize an Analysis of Variance Model

Description

Summarize an analysis of variance model.

Usage

```r
## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
         expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)
```

Arguments

- `object`: An object of class "aov" or "aovlist".
- `intercept`: logical: should intercept terms be included?
- `split`: an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.
- `expand.split`: logical: should the split apply also to interactions involving the factor?
- `keep.zero.df`: logical: should terms with no degrees of freedom be included?
- `...`: Arguments to be passed to or from other methods, for `summary.aovlist` including those for `summary.aov`.
Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of expand.split = TRUE is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

See Also

aov, summary, model.tables, TukeyHSD

Examples

## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
  y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
  P = ordered(gl(3, 3)),
  N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC , weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
  P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
  expand.split = FALSE)

Description

These functions are all methods for class glm or summary.glm objects.
### S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE, symbolic.cor = FALSE, ...)

### S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3), symbolic.cor = x$symbolic.cor, signif.stars = getOption("show.signif.stars"), ...)

#### Arguments
- **object**: an object of class "glm", usually, a result of a call to glm.
- **x**: an object of class "summary.glm", usually, a result of a call to summary.glm.
- **dispersion**: the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from object (see 'Details').
- **correlation**: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- **digits**: the number of significant digits to use when printing.
- **symbolic.cor**: logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
- **signif.stars**: logical. If TRUE, 'significance stars' are printed for each coefficient.
- **...**: further arguments passed to or from other methods.

#### Details
print.summary.glm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled t ratio if the dispersion is estimated, and z ratio if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the print method. Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

summary can be used with Gaussian glm fits to handle the case of a linear regression with known error variance, something not handled by summary.lm.

#### Value
summary.glm returns an object of class "summary.glm", a list with components
- **call**: the component from object.
family the component from object.
deviance the component from object.
contrasts the component from object.
df.residual the component from object.
null.deviance the component from object.
df.null the component from object.
deviance.resid the deviance residuals: see residuals.glm.
coefficients the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.
aliased named logical vector showing if the original coefficients are aliased.
dispersion either the supplied argument or the inferred/estimated dispersion if the latter is NULL.
df a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones).
cov.unscaled the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.
cov.scaled ditto, scaled by dispersion.
correlation (only if correlation is true.) The estimated correlations of the estimated coefficients.
symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

See Also

glm, summary.

Examples

## For examples see example(glm)
Arguments

object an object of class "lm", usually, a result of a call to lm.
x an object of class "summary.lm", usually, a result of a call to summary.lm.
correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits the number of significant digits to use when printing.
symbolic.cor logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars logical. If TRUE, ‘significance stars’ are printed for each coefficient.
... further arguments passed to or from other methods.

Details

print.summary.lm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if signif.stars is TRUE.
Aliased coefficients are omitted in the returned object but restored by the print method.
Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

Value

The function summary.lm computes and returns a list of summary statistics of the fitted linear model given in object, using the components (list elements) "call" and "terms" from its argument, plus
residuals the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to lm.
coefficients a p × 4 matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
aliased named logical vector showing if the original coefficients are aliased.
sigma the square root of the estimated variance of the random error
\[ \hat{\sigma} = \sqrt{\frac{1}{n-p} \sum w_i R_i^2}, \]
where \(R_i\) is the i-th residual, residuals[i].
df degrees of freedom, a 3-vector \((p, n - p, p^*)\), the first being the number of non-aliased coefficients, the last being the total number of coefficients.
fstatistic (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.
r.squared \(R^2\), the ‘fraction of variance explained by the model’,
\[ R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i(y_i - \bar{y})^2}, \]
where \(\bar{y}\) is the mean of \(y\) if there is an intercept and zero otherwise.
adj.r.squared the above \(R^2\) statistic ‘adjusted’, penalizing for higher \(p\).
cov.unscaled a p × p matrix of (unscaled) covariances of the \(\hat{\beta}_j, j = 1, \ldots, p\).
correlation the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.
symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.
na.action from object, if present there.
See Also

The model fitting function `lm`, `summary`.

Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
coef(sld90) # much more

## model with *aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
    dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```

summary.manova

Summary Method for Multivariate Analysis of Variance

Description

A summary method for class "manova".

Usage

```r
## S3 method for class 'manova'
summary(object,
    test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
    intercept = FALSE, tol = 1e-7, ...)
```

Arguments

- `object`: An object of class "manova" or an aov object with multiple responses.
- `test`: The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- `intercept`: logical. If TRUE, the intercept term is included in the table.
- `tol`: tolerance to be used in deciding if the residuals are rank-deficient: see `qr`.
- `...`: further arguments passed to or from other methods.

Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and
Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance tol is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

- **row.names**: The names of the terms, the row names of the stats table if present.
- **SS**: A named list of sums of squares and product matrices.
- **Eigenvalues**: A matrix of eigenvalues.
- **stats**: A matrix of the statistics, approximate F value, degrees of freedom and P value.

otherwise components **row.names**, **SS** and **Df** (degrees of freedom) for the terms (and not the residuals).

- manova, aov

Examples

```r
## Example on producing plastic film from Krzanowski (1998, p. 381)
tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 6.9, 7.2, 6.9, 6.1, 6.3,
         6.7, 6.6, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4,
           9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 0.8, 5.7, 2.0, 3.9, 1.9, 5.7,
            2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)
Y <- cbind(tear, gloss, opacity)
rate <- gl(2,10, labels = c("Low", "High"))
additive <- gl(2, 5, length = 20, labels = c("Low", "High"))
fit <- manova(Y ~ rate * additive)
summary.aov(fit)  # univariate ANOVA tables
summary(fit, test = "Wilks") # ANOVA table of Wilks' lambda
summary(fit)       # same F statistics as single-df terms
```
Summary method for class "nls".

Usage

## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.nls'
print(x, digits = max(3, getOption("digits") - 3),
symbolic.cor = x$symbolic.cor,
signif.stars = getOption("show.signif.stars"), ...)

Arguments

object    an object of class "nls".
x          an object of class "summary.nls", usually the result of a call to summary.nls.
correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits    the number of significant digits to use when printing.
symbolic.cor logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars logical. If TRUE, 'significance stars' are printed for each coefficient.
...        further arguments passed to or from other methods.

Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

print.summary.nls tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

Value

The function summary.nls computes and returns a list of summary statistics of the fitted model given in object, using the component "formula" from its argument, plus

residuals    the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to nls.
coefficients a p × 4 matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
summary.princomp

sigma the square root of the estimated variance of the random error

\[ \hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2, \]

where \( R_i \) is the \( i \)-th weighted residual.

df degrees of freedom, a 2-vector \((p, n - p)\). (Here and elsewhere \( n \) omits observations with zero weights.)

cov.unscaled a \( p \times p \) matrix of (unscaled) covariances of the parameter estimates.

correlation the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified and there are a non-zero number of residual degrees of freedom.

symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

See Also

The model fitting function \texttt{nls}, \texttt{summary}.

Function \texttt{coef} will extract the matrix of coefficients with standard errors, t-statistics and p-values.

summary.princomp  

Summary method for Principal Components Analysis

Description

The \texttt{summary} method for class "princomp".

Usage

\[
\text{## S3 method for class 'princomp'}
\]

\texttt{summary(object, loadings = FALSE, cutoff = 0.1, \ldots)}

\[
\text{## S3 method for class 'summary.princomp'}
\]

\texttt{print(x, digits = 3, loadings = x$print.loadings,}
\texttt{cutoff = x$cutoff, \ldots)}

Arguments

\texttt{object} an object of class "princomp", as from \texttt{princomp}().

\texttt{loadings} logical. Should loadings be included?

\texttt{cutoff} numeric. Loadings below this cutoff in absolute value are shown as blank in the output.

\texttt{x} an object of class "summary.princomp".

\texttt{digits} the number of significant digits to be used in listing loadings.

\texttt{\ldots} arguments to be passed to or from other methods.

Value

object with additional components cutoff and print.loadings.
# supsmu

## Friedman's SuperSmoother

### Description
Smooth the (x, y) values by Friedman's 'super smoother'.

### Usage

```r
supsmu(x, y, wt =, span = "cv", periodic = FALSE, bass = 0, trace = FALSE)
```

### Arguments
- **x**: x values for smoothing
- **y**: y values for smoothing
- **wt**: case weights, by default all equal
- **span**: the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation.
- **periodic**: if TRUE, the x values are assumed to be in [0, 1] and of period 1.
- **bass**: controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.
- **trace**: logical, if true, prints one line of info "per spar", notably useful for "cv".

### Details

- **supsmu** is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with k/2 data points each side of the predicted point, and values of k as 0.5 × n, 0.2 × n and 0.05 × n, where n is the number of data points. If span is specified, a single smoother with span span × n is used.
- The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.
- The FORTRAN code says: “For small samples (n < 40) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother (span > 0) should be used. Reasonable span values are 0.2 to 0.4.”
- Cases with non-finite values of x, y or wt are dropped, with a warning.

### See Also
- **princomp**

### Examples

```r
summary(pc.cr <- princomp(USArrests, cor = TRUE))
## The signs of the loading columns are arbitrary
print(summary(princomp(USArrests, cor = TRUE),
    loadings = TRUE, cutoff = 0.2), digits = 2)
```
Value

A list with components

\[ x \]  the input values in increasing order with duplicates removed.
\[ y \]  the corresponding y values on the fitted curve.

References

See Also

ppr

Examples

```r
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})
```

---

**symnum**  
Symbolic Number Coding

Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

```r
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
    symbols = if(numeric.x) c(" ", ".", ",", "+", "*", "B")
    else c(".", "!")
    legend = length(symbols) >= 3,
    na = "?", eps = 1e-5, numeric.x = is.numeric(x),
    corr = missing(cutpoints) && numeric.x,
    show.max = if(corr) "1", show.min = NULL,
    abbr.colnames = has.colnames,
    lower.triangular = corr && is.numeric(x) && is.matrix(x),
    diag.lower.tri = corr && !is.null(show.max))
```
Arguments

- **x**: numeric or logical vector or array.
- **cutpoints**: numeric vector whose values \( \text{cutpoints}[j] = c_j \) (after augmentation, see \( \text{corr} \) below) are used for intervals.
- **symbols**: character vector, one shorter than the augmented, see \( \text{corr} \) below) cutpoints. \( \text{symbols}[j] = s_j \) are used as 'code' for the (half open) interval \((c_j, c_{j+1})\).
- **legend**: logical indicating if a "legend" attribute is desired.
- **na**: character or logical. How NAs are coded. If \( \text{na} == \text{FALSE} \), NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.
- **eps**: absolute precision to be used at left and right boundary.
- **numeric.x**: logical indicating if \( x \) should be treated as numbers, otherwise as logical.
- **corr**: logical. If TRUE, \( x \) contains correlations. The cutpoints are augmented by 0 and 1 and \( \text{abs}(x) \) is coded.
- **show.max**: if TRUE, of mode character, the maximal cutpoint is coded especially.
- **show.min**: if TRUE, of mode character, the minimal cutpoint is coded especially.
- **abbr.colnames**: logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and \( x \) has no column names), the column names will all be empty, i.e., ""; otherwise if \( \text{abbr.colnames} \) is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to \( \text{abbreviate}(x, \text{minlength} = \text{abbr.colnames}) \).
- **lower.triangular**: logical. If TRUE and \( x \) is a matrix, only the lower triangular part of the matrix is coded as non-blank.
- **diag.lower.tri**: logical. If \( \text{lower.triangular} \) and this are TRUE, the diagonal part of the matrix is shown.

Value

An atomic character object of class \texttt{noquote} and the same dimensions as \( x \).

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

\[
c_1 s_1 c_2 s_2 \ldots s_n c_{n+1}
\]

where \( c_j = \text{cutpoints}[j] \) and \( s_j = \text{symbols}[j] \).

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

### Examples

```
ii <- setNames(0:8, 0:8)
symnum(ii, cutpoints = 2*(0:4), symbols = c("-", "-", "+", "+")
symnum(ii, cutpoints = 2*(0:4), symbols = c("-", "-", "+", "+"), show.max = TRUE)

symnum(1:12 %% 3 == 0) # --> "|" = TRUE, "." = FALSE for logical

## Pascal's Triangle modulo 2 -- odd and even numbers:
N <- 38
pascal <- t(sapply(0:N, function(n) round(choose(n, 0:N - (N-n)%/%2))))
rownames(pascal) <- rep("", 1+N) # <-- to improve "graphic"
symnum(pascal %% 2, symbols = c(" ", "A"), numeric.x = FALSE)

## Symbolic correlation matrices:
symnum(cor(attitude), diag.lower.tri = FALSE)
symnum(cor(attitude), abbr.colnames = NULL)
symnum(cor(attitude), abbr.colnames = FALSE)
symnum(cor(attitude), abbr.colnames = 2)
symnum(cor(rbind(1, rnorm(25), rnorm(25)*2)))
symnum(cor(matrix(rexp(30, 1), 5, 18))) # <<-- PATTERN ! --
symnum(cm1 <- cor(matrix(rnorm(900), 50, 18))) # < White Noise "BIG" n
symnum(cm2 <- cor(matrix(rnorm(90), 5, 18))) # < White Noise "SMALL" n
symnum(cm1, diag.lower.tri = FALSE)
symnum(cm2, lower.triangular = FALSE)

## NA's:
Cm <- cor(matrix(rnorm(60), 10, 6)); Cm[c(3,6), 2] <- NA
symnum(Cm, show.max = NULL)

## Graphical P-values (aka "significance stars"): 
pval <- rev(sort(c(outer(1:6, 10^-(1:3)))))
symp <- symnum(pval, corr = FALSE,
  cutpoints = c(0, .001,.01,.05, .1, 1),
  symbols = c("***","**","*",".", " "))
noquote(cbind(P.val = format(pval), Signif = symp))
```

### Description

Performs one and two sample t-tests on vectors of data.

### Usage

```
t.test(x, ...)
```

## Default S3 method:
```
t.test(x, y = NULL,
  alternative = c("two.sided", "less", "greater"),
  mu = 0, paired = FALSE, var.equal = FALSE,
  conf.level = 0.95, ...)
```
### S3 method for class 'formula'

t.test(formula, data, subset, na.action, ...)

#### Arguments

- **x**
  - a (non-empty) numeric vector of data values.
- **y**
  - an optional (non-empty) numeric vector of data values.
- **alternative**
  - a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**
  - a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
- **paired**
  - a logical indicating whether you want a paired t-test.
- **var.equal**
  - a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
- **conf.level**
  - confidence level of the interval.
- **formula**
  - a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If `lhs` is of class "Pair" and `rhs` is 1, a paired test is done.
- **data**
  - an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**
  - an optional vector specifying a subset of observations to be used.
- **na.action**
  - a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**
  - further arguments to be passed to or from methods.

#### Details

- `alternative = "greater"` is the alternative that `x` has a larger mean than `y`. For the one-sample case: that the mean is positive.
- If `paired` is `TRUE` then both `x` and `y` must be specified and they must be the same length. Missing values are silently removed (in pairs if `paired` is `TRUE`). If `var.equal` is `TRUE` then the pooled estimate of the variance is used. By default, if `var.equal` is `FALSE` then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.
- If the input data are effectively constant (compared to the larger of the two means) an error is generated.

#### Value

A list with class "htest" containing the following components:

- **statistic**
  - the value of the t-statistic.
- **parameter**
  - the degrees of freedom for the t-statistic.
- **p.value**
  - the p-value for the test.
conf.int  a confidence interval for the mean appropriate to the specified alternative hypothesis.
estimate the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
null.value the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
stderr   the standard error of the mean (difference), used as denominator in the t-statistic formula.
alternative a character string describing the alternative hypothesis.
method   a character string indicating what type of t-test was performed.
data.name a character string giving the name(s) of the data.

See Also

prop.test

Examples

require(graphics)

t.test(1:10, y = c(7:20))  # P = .00001855
t.test(1:10, y = c(7:20, 200))  # P = .1245 -- NOT significant anymore

## Classical example: Student’s sleep data
plot(extra ~ group, data = sleep)
## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))

## Formula interface

## Formula interface to one-sample test
t.test(extra ~ 1, data = sleep)

## Formula interface to paired test
## The sleep data are actually paired, so could have been in wide format:
sleep2 <- reshape(sleep, direction = "wide",
  idvar = "ID", timevar = "group")
t.test(Pair(extra.1, extra.2) ~ 1, data = sleep2)

TDist

The Student t Distribution

Description

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom (and optional non-centrality parameter ncp).
Usage

dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number required.
df  degrees of freedom (> 0, maybe non-integer). df = Inf is allowed.
cp  non-centrality parameter δ; currently except for rt(), only for abs(ncp) <= 37.62. If omitted, use the central t distribution.
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The t distribution with \( df = ν \) degrees of freedom has density

\[
f(x) = \frac{Γ((ν + 1)/2)}{\sqrt{πν}Γ(ν/2)} (1 + x^2/ν)^{-(ν+1)/2}
\]

for all real \( x \). It has mean 0 (for \( ν > 1 \)) and variance \( \frac{ν}{ν-2} \) (for \( ν > 2 \)).

The general non-central t with parameters \( (ν, δ) = (df, ncp) \) is defined as the distribution of \( T_ν(δ) := (U + δ)/\sqrt{V/ν} \) where \( U \) and \( V \) are independent random variables, \( U \sim N(0, 1) \) and \( V \sim \chi^2_ν \) (see Chisquare).

The most used applications are power calculations for t-tests:
Let \( T = \frac{X - µ_0}{S/\sqrt{n}} \) where \( X \) is the mean and \( S \) the sample standard deviation (sd) of \( X_1, X_2, \ldots, X_n \) which are i.i.d. \( N(µ, σ^2) \) Then \( T \) is distributed as non-central t with \( df = n - 1 \) degrees of freedom and non-centrality parameter \( ncp = (µ - µ_0)\sqrt{n}/σ \).

Value

dt gives the density, pt gives the distribution function, qt gives the quantile function, and rt generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for \( rt \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \( ncp = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( ncp \) is omitted. This is to give consistent behaviour in extreme cases with values of \( ncp \) very near zero.

The code for non-zero \( ncp \) is principally intended to be used for moderate values of \( ncp \): it will not be highly accurate, especially in the tails, for large values.
The central $dt$ is computed via an accurate formula provided by Catherine Loader (see the reference in `dbinom`).

For the non-central case of $dt$, C code contributed by Claus Ekstrøm based on the relationship (for $x \neq 0$) to the cumulative distribution.

For the central case of $pt$, a normal approximation in the tails, otherwise via `pbeta`.

For the non-central case of $pt$ based on a C translation of

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central $qt$, a C translation of

altered to take account of

The non-central case is done by inversion.

References

See Also

*Distributions* for other standard distributions, including `df` for the F distribution.

Examples

```r
require(graphics)
1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, length.out = 21)
ncp <- seq(0, 6, length.out = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit,
xlab = "t", ylab = "non-centrality parameter",
zlab = "Pr(T <= t)"
plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
main = "Non-central t - Density", yaxs = "i")
```

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.
Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

Usage

```r
termplot(model, data = NULL, envir = environment(formula(model)),
         partial.resid = FALSE, rug = FALSE,
         terms = NULL, se = FALSE,
         xlabs = NULL, ylabs = NULL, main = NULL,
         col.term = 2, lwd.term = 1.5,
         col.se = "orange", lty.se = 2, lwd.se = 1,
         col.res = "gray", cex = 1, pch = par("pch"),
         col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
         ask = dev.interactive() && nb.fig < n.tms,
         use.factor.levels = TRUE, smooth = NULL, ylim = "common",
         plot = TRUE, transform.x = FALSE, ...)
```

Arguments

- `model` fitted model object
- `data` data frame in which variables in `model` can be found
- `envir` environment in which variables in `model` can be found
- `partial.resid` logical; should partial residuals be plotted?
- `rug` add rugplots (jittered 1-d histograms) to the axes?
- `terms` which terms to plot (default NULL means all terms); a vector passed to `predict(., type = "terms", terms = *)`.
- `se` plot pointwise standard errors?
- `xlabs` vector of labels for the x axes
- `ylabs` vector of labels for the y axes
- `main` logical, or vector of main titles; if TRUE, the model’s call is taken as main title, NULL or FALSE mean no titles.
- `col.term, lwd.term` color and line width for the ‘term curve’, see `lines`.
- `col.se, lty.se, lwd.se` color, line type and line width for the ‘twice-standard-error curve’ when `se = TRUE`.
- `col.res, cex, pch` color, plotting character expansion and type for partial residuals, when `partial.resid = TRUE`, see `points`.
- `ask` logical; if TRUE, the user is asked before each plot, see `par(ask=.)`.
- `use.factor.levels` Should x-axis ticks use factor levels or numbers for factor terms?
smooth

NULL or a function with the same arguments as `panel.smooth` to draw a smooth through the partial residuals for non-factor terms.

`lty.smth, col.smth, span.smth`

Passed to `smooth`.

`ylim`

an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot.

`plot`

if set to FALSE plots are not produced: instead a list is returned containing the data that would have been plotted.

`transform.x`

logical vector; if an element (recycled as necessary) is TRUE, partial residuals for the corresponding term are plotted against transformed values. The model response is then a straight line, allowing a ready comparison against the data or against the curve obtained from `smooth`-`panel.smooth`.

...

other graphical parameters.

Details

The model object must have a `predict` method that accepts `type = "terms"`, e.g., `glm` in the `stats` package, `coxph` and `survreg` in the `survival` package.

For the `partial.resid = TRUE` option model must have a `residuals` method that accepts `type = "partial"`, which `lm` and `glm` do.

The data argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using `na.action=na.exclude` makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The `plot = FALSE` option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

Value

For `plot = FALSE`, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables `x`, `y`, and optionally the pointwise standard errors `se`. For continuous predictors `x` will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

See Also

For (generalized) linear models, `plot.lm` and `predict.glm`.

Examples

```
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2))  ## 2 x 2 plots for same model :
```
The function `terms` is a generic function which can be used to extract `terms` objects from various kinds of R data objects.

**Terms**

**Model Terms**

**Description**

The function `terms` is a generic function which can be used to extract `terms` objects from various kinds of R data objects.

**Usage**

`terms(x, ...)`

**Arguments**

- `x` object used to select a method to dispatch.
- `...` further arguments passed to or from other methods.

**Details**

There are methods for classes "aovlist", and "terms" "formula" (see `terms.formula`): the default method just extracts the terms component of the object, or failing that a "terms" attribute (as used by `model.frame`).

There are `print` and `labels` methods for class "terms": the latter prints the term labels (see `terms.object`).

**Value**

An object of class c("terms", "formula") which contains the `terms` representation of a symbolic model. See `terms.object` for its structure.

**References**

**See Also**

`terms.object`, `terms.formula`, `lm`, `glm`, `formula`. 

```r
termplot(model, main = paste("termplot( ", deparse(model$call)," ...)"))
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

if(requireNamespace("MASS", quietly = TRUE)) {
hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth, 
        terms = "log(dist)", main = "Original")
termplot(hills.lm, transform.x = TRUE,
        partial.resid = TRUE, smooth = panel.smooth, 
        terms = "log(dist)", main = "Transformed")
}
```
Construct a terms Object from a Formula

Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.

Usage

```r
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
     keep.order = FALSE, simplify = FALSE, ..., 
     allowDotAsName = FALSE)
```

Arguments

- `x` : a formula.
- `specials` : which functions in the formula should be marked as special in the terms object? A character vector or NULL.
- `abb` : Not implemented in R.
- `data` : a data frame from which the meaning of the special symbol . can be inferred. It is unused if there is no . in the formula.
- `neg.out` : Not implemented in R.
- `keep.order` : a logical value indicating whether the terms should keep their positions. If FALSE the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
- `simplify` : should the formula be expanded and simplified, the pre-1.7.0 behaviour?
- `...` : further arguments passed to or from other methods.
- `allowDotAsName` : normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.

Details

Not all of the options work in the same way that they do in S and not all are implemented.

Value

A terms.object object is returned. The object itself is the re-ordered (unless keep.order = TRUE) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also

terms, terms.object
Description

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

Value

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

- `factors`: A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing). Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is `numeric(0)`.

- `term.labels`: A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms. Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.

- `variables`: A call to `list` of the variables in the model.

- `intercept`: Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

- `order`: A vector of the same length as `term.labels` indicating the order of interaction for each term.

- `response`: The index of the variable (in variables) of the response (the left hand side of the formula). Zero, if there is no response.

- `offset`: If the model contains `offset` terms there is an `offset` attribute indicating which variable(s) are offsets

- `specials`: If a `specials` argument was given to `terms.formula` there is a `specials` attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the `variables` attribute which contain these special functions.

- `dataClasses`: optional. A named character vector giving the classes (as given by `.MFclass`) of the variables used in a fit.

- `predvars`: optional. An expression to help in computing predictions at new covariate values; see `makepredictcall`.

The object has class `c("terms", "formula")`.

Note

These objects are different from those found in S. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions, the latter from package `survival`.
time

Sampling Times of Time Series

time creates the vector of times at which a time series was sampled.
cycle gives the positions in the cycle of each observation.
frequency returns the number of samples per unit time and deltat the time interval between observations (see ts).

Usage

time(x, ...)  
## Default S3 method:  
time(x, offset = 0, ...)

cycle(x, ...)  
frequency(x, ...)  
deltat(x, ...)

Arguments

x         a univariate or multivariate time-series, or a vector or matrix.
offset    can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.
...         extra arguments for future methods.

Details

These are all generic functions, which will use the tsp attribute of x if it exists. time and cycle have methods for class ts that coerce the result to that class.

toeplitz  

Form Symmetric Toeplitz Matrix

Description

Forms a symmetric Toeplitz matrix given its first row.

Usage

toeplitz(x)

Arguments

x the first row to form the Toeplitz matrix.

Value

The Toeplitz matrix.

Author(s)

A. Trapletti

Examples

x <- 1:5
toeplitz(x)
ts  
Time-Series Objects

Description

The function ts is used to create time-series objects.

as.ts and is.ts coerce an object to a time-series and test whether an object is a time series.

Usage

```r
ts(data = NA, start = 1, end = numeric(), frequency = 1, 
deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
as.ts(x, ...) 
is.ts(x)
```

Arguments

data a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via data.matrix. (See also ‘Details’.)

start the time of the first observation. Either a single number or a vector of two numbers (the second of which is an integer), which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.

data

dend the time of the last observation, specified in the same way as start.

data

deltat the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of frequency or deltat should be provided.

tdata

tdata

tdata

tdata

tdata

tdata

tdata

tdata

tdata

Details

The function ts is used to create time-series objects. These are vectors or matrices with class of "ts" (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., EuStockMarkets[, "DAX"]). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see window). There is a
method for \texttt{t} that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "\texttt{ts}".

Argument \texttt{frequency} indicates the sampling frequency of the time series, with the default value 1 indicating one sample in each unit time interval. For example, one could use a value of 7 for \texttt{frequency} when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) print methods to imply a quarterly and monthly series respectively. As from R 4.0.0, \texttt{frequency} need not be a whole number. For example, \texttt{frequency = 0.2} would imply sampling once every five time units.

\texttt{as.ts} is generic. Its default method will use the \texttt{tsp} attribute of the object if it has one to set the start and end times and frequency.

\texttt{is.ts} tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see \texttt{InternalMethods}.

\section*{References}

\section*{See Also}
\texttt{tsp}, \texttt{frequency}, \texttt{start}, \texttt{end}, \texttt{time}, \texttt{window}; \texttt{print.ts}, the print method for time series objects; \texttt{plot.ts}, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at \url{https://CRAN.R-project.org/view=TimeSeries}.

\section*{Examples}
\begin{verbatim}
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
  # print.ts(.)
  ## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
                 start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z) # as "matrix"
head(z) plot(z)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
\end{verbatim}
Methods for Time Series Objects

Description

Methods for objects of class "ts", typically the result of ts.

Usage

## S3 method for class 'ts'
\text{diff}(x, \text{lag} = 1, \text{differences} = 1, \ldots)

## S3 method for class 'ts'
\text{na.omit}(\text{object}, \ldots)

Arguments

\text{x} \quad \text{an object of class "ts" containing the values to be differenced.}
\text{lag} \quad \text{an integer indicating which lag to use.}
\text{differences} \quad \text{an integer indicating the order of the difference.}
\text{object} \quad \text{a univariate or multivariate time series.}
\text{...} \quad \text{further arguments to be passed to or from methods.}

Details

The \text{na.omit} method omits initial and final segments with missing values in one or more of the series. ‘Internal’ missing values will lead to failure.

Value

For the \text{na.omit} method, a time series without missing values. The class of object will be preserved.

See Also

diff; na.omit, na.fail, na.contiguous.

Plot Multiple Time Series

Description

Plot several time series on a common plot. Unlike \text{plot.ts} the series can have a different time bases, but they should have the same frequency.

Usage

\text{ts.plot}(\ldots, \text{gpars} = \text{list()})
Arguments

\[
\ldots
\]

one or more univariate or multivariate time series.

gpars

list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in \ldots.

Value

None.

Note

Although this can be used for a single time series, \texttt{plot} is easier to use and is preferred.

See Also

plot.ts

Examples

require(graphics)

\[
\texttt{ts.plot(ldeaths, mdeaths, fdeaths,}
\]

\[
\texttt{gpars=list(xlab=\"year\", ylab=\"deaths\", lty=c(1:3)))}
\]

\[
\texttt{ts.union} \quad \textit{Bind Two or More Time Series}
\]

Description

Bind time series which have a common frequency. \texttt{ts.union} pads with NAs to the total time coverage, \texttt{ts.intersect} restricts to the time covered by all the series.

Usage

\[
\texttt{ts.intersect}(\ldots, \texttt{dframe} = \texttt{FALSE})
\]

\[
\texttt{ts.union}(\ldots, \texttt{dframe} = \texttt{FALSE})
\]

Arguments

\[
\ldots
\]

two or more univariate or multivariate time series, or objects which can coerced to time series.

dframe

logical; if TRUE return the result as a data frame.

Details

As a special case, \ldots can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if \texttt{dframe} is \texttt{FALSE}, otherwise a data frame.
tsdiag

Diagnostic Plots for Time-Series Fits

Description

A generic function to plot time-series diagnostics.

Usage

    tsdiag(object, gof.lag, ...)

Arguments

object        a fitted time-series model

    gof.lag        the maximum number of lags for a Portmanteau goodness-of-fit test

...            further arguments to be passed to particular methods

Details

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to gof.lag.

The methods for arima and StructTS objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

Value

None. Diagnostics are plotted.

See Also

    arima, StructTS, Box.test
Examples

```r
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdia(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdia(fit)
```

tsp

Tsp Attribute of Time-Series-like Objects

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hasTsp ensures x has a tsp attribute, by adding one if needed.

Usage

```r
tsp(x)
tsp(x) <- value
hasTsp(x)
```

Arguments

- **x**: a vector or matrix or univariate or multivariate time-series.
- **value**: a numeric vector of length 3 or NULL.

Details

The tsp attribute gives the start time in time units, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute and any "ts" (or "mts") class of x.

Value

An object which differs from x only in the tsp attribute (unless NULL is assigned).

hasTsp adds, if needed, an attribute with a start time and frequency of 1 and end time NROW(x).

tsSmooth

*Use Fixed-Interval Smoothing on Time Series*

**Description**

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

**Usage**

```r
tsSmooth(object, ...)
```

**Arguments**

- `object` a time-series fit. Currently only class `"StructTS"` is supported
- `...` possible arguments for future methods.

**Value**

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

**Author(s)**

B. D. Ripley

**References**

**See Also**

- `KalmanSmooth`, `StructTS`.
- For examples consult `AirPassengers`, `JohnsonJohnson` and `Nile`.

---

Tukey

*The Studentized Range Distribution*

**Description**

Functions of the distribution of the studentized range, $R/s$, where $R$ is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with $df$ degrees of freedom, see `pchisq`.

**Usage**

```r
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```
Arguments

- **q**: vector of quantiles.
- **p**: vector of probabilities.
- **nmeans**: sample size for range (same for each group).
- **df**: degrees of freedom for \( s \) (see below).
- **nranges**: number of groups whose maximum range is considered.
- **log.p**: logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If \( n_g = nranges \) is greater than one, \( R \) is the maximum of \( n_g \) groups of \( nmeans \) observations each.

Value

- `ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.
- The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

Source

`qtukey` is in part adapted from Odeh and Evans (1974).

References

See Also

Distributions for standard distributions, including `pnorm` and `qnorm` for the corresponding functions for the normal distribution.

Examples

```r
if(interactive())
  curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(ptt <- ptukey(0:10, 2, df = 5))
(qtt <- qtukey(.95, 2, df = 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```
TukeyHSD

Compute Tukey Honest Significant Differences

Description
Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)

Arguments
x
A fitted model object, usually an aov fit.

which
A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.

ordered
A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lwr end point is positive.

conf.level
A numeric value between zero and one giving the family-wise confidence level to use.

...
Optional additional arguments. None are used at present.

Details
This is a generic function: the description here applies to the method for fits of class "aov".

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value
A list of class c("multicomp", "TukeyHSD"), with one component for each term requested in which. Each component is a matrix with columns diff giving the difference in the observed means, lwr giving the lower end point of the interval, upr giving the upper end point and p adj giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept xlab, ylab or main arguments and creates its own values for each plot.
The Uniform Distribution

Description

These functions provide information about the uniform distribution on the interval from min to max. dunif gives the density, punif gives the distribution function qunif gives the quantile function and runif generates random deviates.

Usage

dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
min, max lower and upper limits of the distribution. Must be finite.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

If \texttt{min} or \texttt{max} are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

\[
f(x) = \frac{1}{max - min}
\]

for \(min \leq x \leq max\).

For the case of \(u := min == max\), the limit case of \(X \equiv u\) is assumed, although there is no density in that case and \texttt{dunif} will return \texttt{NaN} (the error condition).

\texttt{runif} will not generate either of the extreme values unless \(max = min\) or \(max-min\) is small compared to \(min\), and in particular not for the default arguments.

Value

dunif gives the density, \texttt{punif} gives the distribution function, \texttt{qunif} gives the quantile function, and \texttt{runif} generates random deviates.

The length of the result is determined by \(n\) for \texttt{runif}, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \(n\) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See \texttt{Random.seed} for more information on \texttt{R}'s random number generation algorithms.

References

See Also

\texttt{RNG} about random number generation in \texttt{R}.

\texttt{Distributions} for other standard distributions.

Examples

\begin{verbatim}
  u <- runif(20)

  ## The following relations always hold :
  punif(u) == u
dunif(u) == 1

  var(runif(10000))  # ~ = 1/12 = .08333
\end{verbatim}
uniroot

One Dimensional Root (Zero) Finding

Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval = c(`lower`, `upper`) if `sign(f(x))` does not satisfy the requirements at the interval end points; see the 'Details' section.

Usage

`uniroot(f, interval, ..., lower = min(interval), upper = max(interval), f.lower = f(lower, ...), f.upper = f(upper, ...), extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE, tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)`

Arguments

- `f` the function for which the root is sought.
- `interval` a vector containing the end-points of the interval to be searched for the root.
- `...` additional named or unnamed arguments to be passed to `f`.
- `lower, upper` the lower and upper end points of the interval to be searched.
- `f.lower, f.upper` the same as `f(upper)` and `f(lower)`, respectively. Passing these values from the caller where they are often known is more economical as soon as `f()` contains non-trivial computations.
- `extendInt` character string specifying if the interval c(`lower`, `upper`) should be extended or directly produce an error when `f()` does not have differing signs at the end-points. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated.
- `check.conv` logical indicating whether a convergence warning of the underlying `uniroot` should be caught as an error and if non-convergence in `maxiter` iterations should be an error instead of a warning.
- `tol` the desired accuracy (convergence tolerance).
- `maxiter` the maximum number of iterations.
- `trace` integer number; if positive, tracing information is produced. Higher values giving more details.

Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval `[l, u]` satisfies `f(l) \cdot f(u) \leq 0`. 
If it is known how \( f \) changes sign at the root \( x_0 \), that is, if the function is increasing or decreasing there, \texttt{extendInt} can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define \( S := \pm 1 \), to require \( S = \text{sign}(f(x_0 + \epsilon)) \) at the solution. In that case, the search interval \([l, u]\) possibly is extended to be such that \( S \cdot f(l) \leq 0 \) and \( S \cdot f(u) \geq 0 \).

\texttt{uniroot()} uses Fortran subroutine "zeroin" (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if \( f(x) == 0 \) or the change in \( x \) for one step of the algorithm is less than \( \text{tol} \) (plus an allowance for representation error in \( x \)).

If the algorithm does not converge in \texttt{maxiter} steps, a warning is printed and the current approximation is returned.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

### Value

A list with at least four components: \texttt{root} and \texttt{f.root} give the location of the root and the value of the function evaluated at that point. \texttt{iter} and \texttt{estim.prec} give the number of iterations used and an approximate estimated precision for \texttt{root}. (If the root occurs at one of the endpoints, the estimated precision is \texttt{NA}.)

Further components may be added in future: component \texttt{init.it} was added in \texttt{R 3.1.0}.

### Source

### Examples

```r
require(stats) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2, tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2, tol = 1e-10))
```
uniroot

## Find the smallest value \( x \) for which \( \exp(x) > 0 \) (numerically):
\[
r \leftarrow \text{uniroot}(\text{function}(x) 1e80*\exp(x) - 1e-300, c(-1000, 0), \text{tol} = 1e-15)
\]
\[
\text{str}(r, \text{digits.d} = 15) \quad \# \text{around } -745, \text{depending on the platform.}
\]
\[
\exp(r\$\text{root}) \quad \# = 0, \text{but not for } r\$\text{root} \times 0.999...
\]
\[
\text{minexp} \leftarrow r\$\text{root} \times (1 - 10*\text{Machine}\$\text{double}.esp)
\]
\[
\exp(\text{minexp}) \quad \# \text{typically denormalized}
\]

###--- uniroot() with new interval extension + checking features: ---------------
\[
f1 \leftarrow \text{function}(x) \frac{(121 - x^2)}{(x^2+1)}
\]
\[
f2 \leftarrow \text{function}(x) \exp(-x)*(x - 12)
\]
\[
\text{try(uniroot}(f1, c(0,10))
\]
\[
\text{try(uniroot}(f2, c(0, 2))
\]
\[
\#	ext{--> error: f() .. end points not of opposite sign}
\]
\[
\#	ext{ where as } '\text{extendInt}=\text{yes}' \text{ simply first enlarges the search interval:}
\]
\[
u1 \leftarrow \text{uniroot}(f1, c(0,10), \text{extendInt}=\text{yes}, \text{trace}=1)
\]
\[
u2 \leftarrow \text{uniroot}(f2, c(0,2), \text{extendInt}=\text{yes}, \text{trace}=2)
\]
\[
\text{stopifnot}(\text{all.equal}(u1\$\text{root}, 11, \text{tolerance} = 1e-5),
\]
\[
\text{all.equal}(u2\$\text{root}, 12, \text{tolerance} = 6e-6))
\]

### The *danger* of interval extension:
### No way to find a zero of a positive function, but
### numerically, \( f(-\text{|M|}) \) becomes zero:
\[
u3 \leftarrow \text{uniroot}(\text{exp}, c(0,2), \text{extendInt}=\text{yes}, \text{trace}=\text{TRUE})
\]

### Nonsense example (must give an error):
\[
\text{tools::assertCondition}(\text{uniroot}(\text{function}(x) 1, 0:1, \text{extendInt}=\text{yes}),'\text{error}', \text{verbose}=\text{TRUE})
\]

### Convergence checking:
\[
sinc \leftarrow \text{function}(x) \text{ifelse}(x == 0, 1, \sin(x)/x)
\]
\[
\text{curve}(\text{sinc}, -6,18); \text{abline}(h=0,v=0, \text{lty}=3, \text{col}=\text{adjustcolor}('gray', 0.8))
\]
\[
\text{uniroot}(\text{sinc}, c(0,5), \text{extendInt}=\text{yes}, \text{maxiter}=4) \quad \#\rightarrow '\text{just} a \text{ warning}
\]

### now with \( \text{check.conv}=\text{TRUE} \), must signal a convergence error:
\[
\text{uniroot}(\text{sinc}, c(0,5), \text{extendInt}=\text{yes}, \text{maxiter}=4, \text{check.conv}=\text{TRUE})
\]

### Weibull cumulative hazard (example origin, Ravi Varadhan):
\[
cuhaz \leftarrow \text{function}(t, a, b) \ b \times (t/b)^a
\]
\[
froot \leftarrow \text{function}(x, u, a, b) \ \text{cuhaz}(x, a, b) - u
\]
\[
n \leftarrow 1000
\]
\[
u \leftarrow \text{-log(\text{runif}(n))}
\]
\[
a \leftarrow 1/2
\]
\[
b \leftarrow 1
\]
\[
\#	ext{Find failure times}
\]
\[

\]
update

Update and Re-fit a Model Call

Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

"Extracting the call" in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x$call.

Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.

Usage

update(object, ...)

## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)

Arguments

object, x An existing fit from a model function such as lm, glm and many others.
formula. Changes to the formula – see update.formula for details.
... Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name.
evaluate If true evaluate the new call else return the call.

Value

If evaluate = TRUE the fitted object, otherwise the updated call.

getCall(lm.D90) # "through the origin"
options(oldcon)

update.formula  Model Updating

Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

## S3 method for class 'formula'
update(old, new, ...)

Arguments

old  a model formula to be updated.
new  a formula giving a template which specifies how to update.
...  further arguments passed to or from other methods.

Details

Either or both of old and new can be objects such as length-one character vectors which can be coerced to a formula via as.formula.

The function works by first identifying the left-hand side and right-hand side of the old formula. It then examines the new formula and substitutes the lhs of the old formula for any occurrence of '@' on the left of new, and substitutes the rhs of the old formula for any occurrence of '@' on the right of new. The result is then simplified via terms.formula(simplify = TRUE).

Value

The updated formula is returned. The environment of the result is that of old.
var.test

F Test to Compare Two Variances

Description
Performs an F test to compare the variances of two samples from normal populations.

Usage
var.test(x, ...)    

## Default S3 method:
var.test(x, y, ratio = 1,
  alternative = c("two.sided", "less", "greater"),
  conf.level = 0.95, ...)

## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)

Arguments

x, y numeric vectors of data values, or fitted linear model objects (inherit- ing from class "lm").

ratio the hypothesized ratio of the population variances of x and y.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

conf.level confidence level for the returned confidence interval.

formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

See Also
terms, model.matrix.

Examples
update(y ~ x, . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ .) #> log(y) ~ x
update(. ~ u+v, res ~ .) #> res ~ u + v
Details

The null hypothesis is that the ratio of the variances of the populations from which \( x \) and \( y \) were drawn, or in the data to which the linear models \( x \) and \( y \) were fitted, is equal to \( \text{ratio} \).

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the F test statistic.
- **parameter**: the degrees of the freedom of the F distribution of the test statistic.
- **p.value**: the p-value of the test.
- **conf.int**: a confidence interval for the ratio of the population variances.
- **estimate**: the ratio of the sample variances of \( x \) and \( y \).
- **null.value**: the ratio of population variances under the null.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "F test to compare two variances".
- **data.name**: a character string giving the names of the data.

See Also

- **bartlett.test** for testing homogeneity of variances in more than two samples from normal distributions; **ansari.test** and **mood.test** for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

```r
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y)  # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1))  # The same.
```

---

varimax

**Rotation Methods for Factor Analysis**

Description

These functions 'rotate' loading matrices in factor analysis.

Usage

```r
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

Arguments

- **x**: A loadings matrix, with \( p \) rows and \( k < p \) columns.
- **m**: The power used the target for promax. Values of 2 to 4 are recommended.
- **normalize**: logical. Should Kaiser normalization be performed? If so the rows of \( x \) are re-scaled to unit length before rotation, and scaled back afterwards.
- **eps**: The tolerance for stopping: the relative change in the sum of singular values.
Details

These seek a ‘rotation’ of the factors $x \%*\% T$ that aims to clarify the structure of the loadings matrix. The matrix $T$ is a rotation (possibly with reflection) for varimax, but a general linear transformation for promax, with the variance of the factors being preserved.

Value

A list with components

- loadings: The ‘rotated’ loadings matrix, $x \%*\% \text{rotmat}$, of class "loadings".
- rotmat: The ‘rotation’ matrix.

References

See Also

factanal, Harman74.cor.

Examples

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

vcov

Calculate Variance-Covariance Matrix for a Fitted Model Object

Description

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

Usage

```r
vcov(object, ...)
# S3 method for class 'lm'
vcov(object, complete = TRUE, ...)
# and also for '[summary.]glm' and 'mlm'
# S3 method for class 'aov'
vcov(object, complete = FALSE, ...)

.vcov.aliased(aliased, vc, complete = TRUE)
```
Arguments

object a fitted model object, typically. Sometimes also a summary() object of such a fitted model.

complete for the aov, lm, glm, mlm, and where applicable summary.lm etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and coef(.) contains NAs correspondingly. When complete = TRUE, vcov() is compatible with coef() also in this singular case.

... additional arguments for method functions. For the glm method this can be used to pass a dispersion parameter.

aliased a logical vector typically identical to is.na(coef(.)) indicating which coefficients are ‘aliased’.

vc a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients.

Details

vcov() is a generic function and functions with names beginning in vcov. will be methods for this function. Classes with methods for this function include: lm, mlm, glm, nls, summary.lm, summary.glm, negbin, polr, rlm (in package MASS), multinom (in package nnet) gls, lme (in package nlme), coxph and survreg (in package survival).

(vcov() methods for summary objects allow more efficient and still encapsulated access when both summary(mod) and vcov(mod) are needed.)

.vcov.aliased() is an auxiliary function useful for vcov method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a vcov–matrix vc by NA rows and columns where needed, i.e., when some entries of aliased are true and vc is of smaller dimension than length(aliased).

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the coef method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see alias, then since R version 3.5.0, vcov() (iff complete = TRUE, i.e., by default for lm etc, but not for aov) contains corresponding rows and columns of NAs, wherever coef() has always contained such NAs.

Weibull

The Weibull Distribution

Description

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.
Usage

dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
shape, scale shape and scale parameters, the latter defaulting to 1.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Weibull distribution with shape parameter \( a \) and scale parameter \( \sigma \) has density given by

\[
f(x) = \frac{a}{\sigma} \left(\frac{x}{\sigma}\right)^{a-1} \exp\left(-\left(\frac{x}{\sigma}\right)^a\right)
\]

for \( x > 0 \). The cumulative distribution function is \( F(x) = 1 - \exp\left(-\left(\frac{x}{\sigma}\right)^a\right) \) on \( x > 0 \), the mean is \( E(X) = \sigma \Gamma\left(1 + \frac{1}{a}\right) \), and the \( \text{Var}(X) = \sigma^2 \left(\Gamma\left(1 + \frac{2}{a}\right) - \left(\Gamma\left(1 + \frac{1}{a}\right)\right)^2\right) \).

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.
Invalid arguments will result in return value NaN, with a warning.
The length of the result is determined by \( n \) for rweibull, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[-pweibull(t, a, b, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})\]

which is just \( H(t) = (t/b)^a \).

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

References

See Also

*Distributions* for other standard distributions, including the *Exponential* which is a special case of the Weibull distribution.

Examples

```r
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
         -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

**weighted.mean**

*Weighted Arithmetic Mean*

Description

Compute a weighted mean.

Usage

```r
weighted.mean(x, w, ...)
```

### Default S3 method:

```r
weighted.mean(x, w, ..., na.rm = FALSE)
```

Arguments

- `x` an object containing the values whose weighted mean is to be computed.
- `w` a numerical vector of weights the same length as `x` giving the weights to use for elements of `x`.
- `...` arguments to be passed to or from methods.
- `na.rm` a logical value indicating whether NA values in `x` should be stripped before the computation proceeds.

Details

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[`, multiplication, division and `sum` have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights are normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in `w` are not handled specially and so give a missing value as the result. However, zero weights are handled specially and the corresponding `x` values are omitted from the sum.

Value

For the default method, a length-one numeric vector.
weighted.residuals

See Also

mean

Examples

```r
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

**weighted.residuals**

Compute Weighted Residuals

**Description**

Computed weighted residuals from a linear model fit.

**Usage**

`weighted.residuals(obj, drop0 = TRUE)`

**Arguments**

- `obj` R object, typically of class `lm` or `glm`.
- `drop0` logical. If TRUE, drop all cases with `weights == 0`.

**Details**

Weighted residuals are based on the deviance residuals, which for a `lm` fit are the raw residuals $R_i$ multiplied by $\sqrt{w_i}$, where $w_i$ are the weights as specified in `lm`'s call.

Dropping cases with weights zero is compatible with `influence` and related functions.

**Value**

Numeric vector of length $n'$, where $n'$ is the number of of non-0 weights (drop0 = TRUE) or the number of observations, otherwise.

**See Also**

`residuals`, `lm.influence`, etc.

```r
## following on from example(lm)
all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```
weights

Extract Model Weights

Description

weights is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of napredict methods to compensate for the omission of missing values. The default methods does so.

Usage

weights(object, ...)

Arguments

object
an object for which the extraction of model weights is meaningful.

... other arguments passed to methods.

Value

Weights extracted from the object object: the default method looks for component "weights" and if not NULL calls napredict on it.

References

See Also

weights.glm

wilcox.test

Wilcoxon Rank Sum and Signed Rank Tests

Description

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as 'Mann-Whitney' test.

Usage

wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
    alternative = c("two.sided", "less", "greater"),
    mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
    conf.int = FALSE, conf.level = 0.95,
tol.root = 1e-4, digits.rank = Inf, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action, ...)

Arguments

- **x**: numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.
- **y**: an optional numeric vector of data values: as with x non-finite values will be omitted.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**: a number specifying an optional parameter used to form the null hypothesis. See 'Details'.
- **paired**: a logical indicating whether you want a paired test.
- **exact**: a logical indicating whether an exact p-value should be computed.
- **correct**: a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
- **conf.int**: a logical indicating whether a confidence interval should be computed.
- **conf.level**: confidence level of the interval.
- **tol.root**: (when conf.int is true:) a positive numeric tolerance, used in uniroot(*, tol=tol.root) calls.
- **digits.rank**: a number; if finite, rank(signif(r, digits.rank)) will be used to compute ranks for the test statistic instead of (the default) rank(r).
- **formula**: a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If lhs is of class "Pair" and rhs is 1, a paired test is done
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
- **...**: further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and paired is TRUE, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of x - y (in the paired two sample case) is symmetric about mu is performed.

Otherwise, if both x and y are given and paired is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of mu and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).
By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

For stability reasons, it may be advisable to use rounded data or to set `digits.rank = 7`, say, such that determination of ties does not depend on very small numeric differences (see the example).

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters $x - y$ is computed. (The pseudomedian of a distribution $F$ is the median of the distribution of $(u + v)/2$, where $u$ and $v$ are independent, each with distribution $F$. If $F$ is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does not estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from $x$ and a sample from $y$.

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but not the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

When $x$ (and $y$ if applicable) are valid, the function now always returns, also in the `conf.int = TRUE` case when a confidence interval cannot be computed, in which case the interval boundaries and sometimes the estimate now contain `NaN`.

**Value**

A list with class "htest" containing the following components:

- `statistic` the value of the test statistic with a name describing it.
- `parameter` the parameter(s) for the exact distribution of the test statistic.
- `p.value` the p-value for the test.
- `null.value` the location parameter $\mu$.
- `alternative` a character string describing the alternative hypothesis.
- `method` the type of test applied.
- `data.name` a character string giving the names of the data.
- `conf.int` a confidence interval for the location parameter. (Only present if argument `conf.int = TRUE`.)
- `estimate` an estimate of the location parameter. (Only present if argument `conf.int = TRUE`.)

**Warning**

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

**Note**

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by $m(m + 1)/2$ for a first sample of size $m$. (It seems Wilcoxon’s original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)
R’s value can also be computed as the number of all pairs \( (x[i], y[j]) \) for which \( y[j] \) is not greater than \( x[i] \), the most common definition of the Mann-Whitney test.

---

Wilcoxon Distribution of the Wilcoxon Rank Sum Statistic

### Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size m and n, respectively.

### Usage

```r
?wilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
?rwilcox(nn, m, n)
```

### Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `nn` number of observations. If length(nn) > 1, the length is taken to be the number required.
- `m, n` numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

### Details

This distribution is obtained as follows. Let x and y be two random, independent samples of size m and n. Then the Wilcoxon rank sum statistic is the number of all pairs (x[i], y[j]) for which y[j] is not greater than x[i]. This statistic takes values between 0 and m * n, and its mean and variance are m * n / 2 and m * n * (m + n + 1) / 12, respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.
Value

dwilcox gives the density, pwilcox gives the distribution function, qwilcox gives the quantile function, and rwilcox generates random deviates.

The length of the result is determined by nn for rwilcox, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than nn are recycled to the length of the result. Only the first elements of the logical arguments are used.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see wilcox.test for details.

Author(s)

Kurt Hornik

Source

These ("d","p","q") are calculated via recursion, based on cwilcox(k, m, n), the number of choices with statistic k from samples of size m and n, which is itself calculated recursively and the results cached. Then dwilcox and pwilcox sum appropriate values of cwilcox, and qwilcox is based on inversion.

rwilcox generates a random permutation of ranks and evaluates the statistic. Note that it is based on the same C code as sample(), and hence is determined by .Random.seed, notably from RNGkind(sample.kind = ..) which changed with R version 3.6.0.

See Also

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dsignrank for the distribution of the one-sample Wilcoxon signed rank statistic.

Examples

```R
require(graphics)
x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)")
plot(x, Fx, type = "s", col = "blue",

\end{verbatim}

---

**Description**

`window` is a generic function which extracts the subset of the object \texttt{x} observed between the times \texttt{start} and \texttt{end}. If a frequency is specified, the series is then re-sampled at the new frequency.

**Usage**

```r
window(x, ...)  
## S3 method for class 'ts'
window(x, ...)  
## Default S3 method: 
window(x, start = NULL, end = NULL, 
      frequency = NULL, deltat = NULL, extend = FALSE, ts.eps = getOption("ts.eps"), ...)  
```

**Arguments**

- \texttt{x}  
a time-series (or other object if not replacing values).
- \texttt{start}  
the start time of the period of interest.
- \texttt{end}  
the end time of the period of interest.
- \texttt{frequency, deltat}  
the new frequency can be specified by either (or both if they are consistent).
- \texttt{extend}  
logical. If true, the start and end values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
- \texttt{ts.eps}  
time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than \texttt{ts.eps}.
- \texttt{...}  
further arguments passed to or from other methods.
- \texttt{value}  
replacement values.
Details

The start and end times can be specified as for ts. If there is no observation at the new start or end, the immediately following (start) or preceding (end) observation time is used.

The replacement function has a method for ts objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. window.default will return a vector or matrix with an appropriate tsp attribute.

window.ts differs from window.default only in ensuring the result is a ts object.

If extend = TRUE the series will be padded with NAs if needed.

References

See Also

time, ts.

Examples

```r
window(presidents, 1960, c(1969,4)) # values in the 1960's
window(presidents, deltat = 1) # All Qtr1s
window(presidents, start = c(1945,3), deltat = 1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres
```

xtabs

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

```r
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE, na.action, addNA = FALSE, exclude = if(laddNA) c(NA, NaN), drop.unused.levels = FALSE)

## S3 method for class 'xtabs'
print(x, na.print = "", ...)```
xtabs

Arguments

formula  a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.

data  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset  an optional vector specifying a subset of observations to be used.

sparse  logical specifying if the result should be a sparse matrix, i.e., inheriting from sparseMatrix. Only works for two factors (since there are no higher-order sparse array classes yet).

na.action  a function which indicates what should happen when the data contain NAs. If unspecified, and addNA is true, this is set to na.pass. When it is na.omit and formula has a left hand side (with counts), sum(*, na.rm = TRUE) is used instead of sum(*) for the counts.

addNA  logical indicating if NAs should get a separate level and be counted, using addNA(*, ifany=TRUE) and setting the default for na.action to na.pass.

exclude  a vector of values to be excluded when forming the set of levels of the classifying factors.

drop.unused.levels  a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

x  an object of class "xtabs".

na.print  character string (or NULL) indicating how NA are printed. The default ("") does not show NAs clearly, and na.print = "NA" maybe advisable instead.

...  further arguments passed to or from other methods.

Details

There is a summary method for contingency table objects created by table or xtabs(*, sparse = FALSE), which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).

If a left hand side is given in formula, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in formula which are factors, exclude must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when na.action = na.pass, sometimes zeroes (0) were returned instead of NAs.

Note that when addNA is false as by default, and na.action is not specified (or set to NULL), in effect na.action =getOption("na.action", default=na.omit) is used; see also the examples.
Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a "call" attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package `Matrix`.

See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package `Matrix`.

Examples

```r
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ... 
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))
## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))
## with NA's
DN <- DF; DN[cbind(6:9, c(1:2,4,1))] <- NA
DN # 'Freq' is missing only for (Rejected, Female, B)
tools::assertError(# 'na.fail' should fail :
  xtabs(Freq ~ Gender + Admit, DN, na.action=na.fail), verbose=TRUE)
op <- options(na.action = "na.fail") # the "factory" default
(xtabs(Freq ~ Gender + Admit, DN) -> xtd)
noC <- function(O) attrs(O, "call")
ident_noC <- function(x,y) identical(noC(x), noC(y))
stopifnot(exprs = {
  ident_noC(xtd, xtabs(Freq ~ Gender + Admit, DN, na.action = na.omit))
  ident_noC(xtd, xtabs(Freq ~ Gender + Admit, DN, na.action = NULL))
})
xtabs(Freq ~ Gender + Admit, DN, na.action = na.pass)
## The Female:Rejected combination has NA 'Freq' (and NA prints 'invisibly' as "")
(xtNA <- xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE)) # ==> count NAs
## show NA's better via na.print = "." :
print(xtNA, na.print = "NA")

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
```
```
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----
if(require("Matrix")) withAutoprint({
  ## similar to "nlme"s 'ergoStool':
  d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
                       Subj = gl(9, 4, 36*4))
  xtabs(~ Type + Subj, data = d.ergo) # 4 replicates each
  set.seed(15) # a subset of cases:
  xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE)

  ## Hypothetical two-level setup:
  inner <- factor(sample(letters[1:25], 100, replace = TRUE))
  inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
  fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
  xtabs(~ inner + outer, fr, sparse = TRUE)
})
```
Chapter 11

The stats4 package

stats4-package Statistical Functions using S4 Classes

Description

Statistical Functions using S4 classes.

Details

This package contains functions and classes for statistics using the S version 4 class system. The methods currently support maximum likelihood (function mle() returning class "mle"), including methods for logLik for use with AIC.

Author(s)

R Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

coeff-methods Methods for Function coef in Package stats4

Description

Extract the coefficient vector from "mle" objects.

Methods

signature(object = "ANY") Generic function: see coef.
signature(object = "mle") Extract the full coefficient vector (including any fixed coefficients) from the fit.
signature(object = "summary.mle") Extract the coefficient vector and standard errors from the summary of the fit.
Methods

signature(object = "ANY") Generic function: see confint.
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

logLik-methods

Methods

signature(object = "ANY") Generic function: see logLik.
signature(object = "mle") Extract log-likelihood from the fit.

Note

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with BIC.

mle

Maximum Likelihood Estimation

Description

Estimate parameters by the method of maximum likelihood.

Usage

mle(minuslogl, start,
    optim = stats::optim,
    method = if(!useLim) "BFGS" else "L-BFGS-B",
    fixed = list(), nobs, lower, upper, ...)
Arguments

minuslog1  Function to calculate negative log-likelihood.
start    Named list of vectors or single vector. Initial values for optimizer. By default taken from the default arguments of minuslog1
optim    Optimizer function. (Experimental)
method   Optimization method to use. See optim.
fixed    Named list of vectors or single vector. Parameter values to keep fixed during optimization.
nobs     optional integer: the number of observations, to be used for e.g. computing BIC.
lower, upper Named lists of vectors or single vectors. Bounds for optim, if relevant.
...      Further arguments to pass to optim.

Details

The optim optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum. By default, optim from the stats package is used; other optimizers need to be plug-compatible, both with respect to arguments and return values.

The function minuslog1 should take one or several arguments, each of which can be a vector. The optimizer optimizes a function which takes a single vector argument, containing the concatenation of the arguments to minuslog1, removing any values that should be held fixed. This function internally unpacks the argument vector, inserts the fixed values and calls minuslog1.

The vector arguments start, fixed, upper, and lower, can be given in both packed and unpacked form, either as a single vector or as a list of vectors. In the latter case, you only need to specify those list elements that are actually affected. For vector arguments, including those inside lists, use a default marker for those values that you don’t want to set: NA for fixed and start, and +Inf, -Inf for upper, and lower.

Value

An object of class mle-class.

Note

Notice that the mll argument should calculate -log L (not -2 log L). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

## End(Not run)

options(od)
mle-class

Class "mle" for Results of Maximum Likelihood Estimation

Description

This class encapsulates results of a generic maximum likelihood procedure.

Objects from the Class

Objects can be created by calls of the form \texttt{new("mle", \ldots)}, but most often as the result of a call to \texttt{mle}.

Slots

call: Object of class "language". The call to \texttt{mle}.

coeff: Object of class "numeric". Estimated parameters.

cfullcoef: Object of class "numeric". Full parameter set of fixed and estimated parameters.

fixed: Object of class "numeric". Fixed parameter values (\texttt{NA} for non-fixed parameters).

vcov: Object of class "matrix". Approximate variance-covariance matrix.

min: Object of class "numeric". Minimum value of objective function.

details: a "list", as returned from \texttt{optim}.

minuslogl: Object of class "function". The negative loglikelihood function.

nobs: "integer" of length one. The number of observations (often \texttt{NA}, when not set in call explicitly).

method: Object of class "character". The optimization method used.

Methods

\textbf{confint} signature(object = "mle"): Confidence intervals from likelihood profiles.

\textbf{logLik} signature(object = "mle"): Extract maximized log-likelihood.

\textbf{profile} signature(fitted = "mle"): Likelihood profile generation.

\textbf{nobs} signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.

\textbf{show} signature(object = "mle"): Display object briefly.

\textbf{summary} signature(object = "mle"): Generate object summary.

\textbf{update} signature(object = "mle"): Update fit.

\textbf{vcov} signature(object = "mle"): Extract variance-covariance matrix.
plot-methods

Methods for Function plot in Package stats4

Description
Plot profile likelihoods for "mle" objects.

Usage
## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)

Arguments
x an object of class "profile.mle"
levels levels, on the scale of the absolute value of a t statistic, at which to interpolate
intervals. Usually conf is used instead of giving levels explicitly.
conf a numeric vector of confidence levels for profile-based confidence intervals on
the parameters.
nseg an integer value giving the number of segments to use in the spline interpolation
of the profile t curves.
absVal a logical value indicating whether or not the plots should be on the scale of the
absolute value of the profile t. Defaults to TRUE.
...
other arguments to the plot function can be passed here.

Methods
signature(x = "ANY", y = "ANY") Generic function: see plot.
signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

profile-methods

Methods for Function profile in Package stats4

Description
Profile likelihood for "mle" objects.

Usage
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
        zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
        trace = FALSE, ...)

profile.mle-class

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fitted</td>
<td>Object to be profiled</td>
</tr>
<tr>
<td>which</td>
<td>Optionally select subset of parameters to profile.</td>
</tr>
<tr>
<td>maxsteps</td>
<td>Maximum number of steps to bracket zmax.</td>
</tr>
<tr>
<td>alpha</td>
<td>Significance level corresponding to zmax, based on a Scheffe-style multiple testing interval. Ignored if zmax is specified.</td>
</tr>
<tr>
<td>zmax</td>
<td>Cutoff for the profiled value of the signed root-likelihood.</td>
</tr>
<tr>
<td>del</td>
<td>Initial stepsize on root-likelihood scale.</td>
</tr>
<tr>
<td>trace</td>
<td>Logical. Print intermediate results.</td>
</tr>
<tr>
<td>...</td>
<td>Currently unused.</td>
</tr>
</tbody>
</table>

Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

signature(fitted = "ANY") Generic function: see profile.

signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle" object.

profile.mle-class Class "profile.mle"; Profiling information for "mle" object

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form new("profile.mle", ...), but most often by invoking profile on an "mle" object.

Slots

profile: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called z being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by par.vals.

summary: Object of class "summary.mle". Summary of object being profiled.
Methods

**confint** signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

**plot** signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

mle, mle-class, summary.mle-class

Description

Show objects of classes mle and summary.mle

Methods

signature(object = "mle") Print simple summary of mle object. Just the coefficients and the call.

signature(object = "summary.mle") Shows call, table of coefficients and standard errors, and \(-2 \log L\).

Description

Summarize objects

Methods

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of \(-2 \log L\).
summary.mle-class  

Class "summary.mle", Summary of "mle" Objects

Description

Extract of "mle" object

Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

Slots

call: Object of class "language" The call that generated the "mle" object.

coef: Object of class "matrix". Estimated coefficients and standard errors

m2logL: Object of class "numeric". Minus twice the log likelihood.

Methods

show signature(object = "summary.mle"): Pretty-prints object

c coef signature(object = "summary.mle"): Extracts the contents of the coef slot

See Also

`summary`, `mle`, `mle-class`

update-methods  

Methods for Function `update` in Package `stats4`

Description

Update "mle" objects.

Usage

```r
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

Arguments

- `object`: An existing fit.
- `...`: Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate`: If true evaluate the new call else return the call.
Methods

signature(object = "ANY") Generic function: see update.

signature(object = "mle") Update a fit.

Examples

x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 8, 5, 4, 8)
l1 <- function(ymax = 15, xhalf = 6)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(l1)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))

Description

Extract the approximate variance-covariance matrix from "mle" objects.

Methods

signature(object = "ANY") Generic function: see vcov.

signature(object = "mle") Extract the estimated variance-covariance matrix for the estimated parameters (if any).
Chapter 12

The tcltk package

---

tcltk-package

Tcl/Tk Interface

Description

Interface and language bindings to Tcl/Tk GUI elements.

Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See TkWidgets for a list of supported widgets, TkWidgetcmds for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use ls("package:tcltk").

Note that Tk will not be initialized if there is no DISPLAY variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on tcltk in a session that does not actually use it (e.g., during installation).

tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion()

### Arguments

- **objv**: a named vector of Tcl objects
- **win**: a window structure
- **x**: an object
- **i**: character or (unquoted) name
- **drop**: logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one
- **value**: For tclvalue assignments, a character string. For tclObj assignments, an object of class tclObj
- **ID**: a window ID
- **parent**: a window which becomes the parent of the resulting window
- **path**: path to a directory containing Tcl packages
- **package**: a Tcl package name
- **warn**: logical. Warn if not found?
- **...**: Additional arguments. See below.
- **init**: initialization value

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level .Tcl sends a command as a text string to the Tcl interpreter and returns the result as an object of class tclObj (see below). A newer variant .Tcl.args converts an R argument list of tag = value pairs to the Tcl -option value style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value tag = NULL can be used. Most values are just converted to character mode and inserted in the
command string, but window objects are passed using their ID string, and callbacks are passed via
the result of \texttt{.Tcl.callback}. Tags are converted to option flags simply by prepending a `-'
\texttt{Tcl.args.objv} serves a similar purpose as \texttt{Tcl.args} but produces a list of \texttt{tclobj}
objects suitable for passing to \texttt{Tcl.objv}. The names of the list are converted to Tcl option style internally
by \texttt{Tcl.objv}.

Callbacks can be either \textit{atomic callbacks} handled by \texttt{Tcl.callback} or expressions. An expression
is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it
is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break
expression is translated directly to the Tcl counterpart. \texttt{Tcl.callback} converts \texttt{R} functions and
unevaluated calls to Tcl command strings. The argument must be either a function closure or an
object of mode "call" followed by an environment. The return value in the first case is of the form \texttt{R_call 0x408b94d4}
in which the hexadecimal number is the memory address of the function. In the second case it will be of the form \texttt{R_call_lang 0x8a95904 0x819bf0d0}. For expressions, a
sequence of similar items is generated, separated by semicolons. \texttt{Tcl.args} takes special precautions
to ensure that functions or calls will continue to exist at the specified address by assigning the
callback into the relevant window environment (see below).

Tk windows are represented as objects of class \texttt{tkwin} which are lists containing a ID field and an
env field which is an \texttt{R} environments, enclosed in the global environment. The value of the ID
field is identical to the Tk window name. The env environment contains a parent variable and a
num.subwin variable. If the window obtains sub-windows and callbacks, they are added as variables
to the environment. \texttt{TkRoot} is the top window with ID "."; this window is not displayed in order
to avoid ill effects of closing it via window manager controls. The parent variable is undefined for
\texttt{TkRoot}.

\texttt{Tk.ID} extracts the ID of a window, \texttt{Tk.newwin} creates a new window environment with a given
ID and \texttt{Tk.subwin} creates a new window which is a sub-window of a given parent window.
\texttt{tkdestroy} destroys a window and also removes the reference to a window from its parent.
\texttt{is.tkwin} can be used to test whether a given object is a window environment.

\texttt{tclVar} creates a new Tcl variable and initializes it to \texttt{init}. An \texttt{R} object of class \texttt{tclVar}
is created to represent it. Using \texttt{as.character} on the object returns the Tcl variable name. Accessing the Tcl
variable from \texttt{R} is done using the \texttt{tclvalue} function, which can also occur on the left-hand side of
assignments. If \texttt{tclvalue} is passed an argument which is not a \texttt{tclVar} object, then it will assume
that it is a character string explicitly naming global Tcl variable. Tcl variables created by \texttt{tclVar}
are uniquely named and automatically unset by the garbage collector when the representing object
is no longer in use.

\texttt{tclArray} creates a new Tcl array and initializes it to the empty array. An \texttt{R} object of class \texttt{tclArray}
and inheriting from class \texttt{tclVar} is created to represent it. You can access elements of the Tcl
array using indexing with [[ or $, which also allow replacement forms. Notice that Tcl arrays are
associative by nature and hence unordered; indexing with a numeric index \texttt{i} refers to the element
with the name \texttt{as.character(i)}. Multiple indices are pasted together separated by commas to
form a single name. You can query the length and the set of names in an array using methods for
\texttt{length} and \texttt{names}, respectively; these cannot meaningfully be set so assignment forms exist only
to print an error message.

It is possible to access Tcl's `dual-ported` objects directly, thus avoiding parsing and deparsing of
their string representation. This works by using objects of class \texttt{tclobj}. The string representation
of such objects can be extracted (but not set) using \texttt{tclvalue} and conversion to vectors of mode
"character", "double", "integer", "logical", and "raw" is performed using the standard co-
ercion functions as \texttt{character}, etc. Conversely, such vectors can be converted using as \texttt{tclobj}.
There is an ambiguity as to what should happen for length one vectors, controlled by the \texttt{drop}
argument; there are cases where the distinction matters to Tcl, although mostly it treats them equi-

It is possible to access Tcl's `dual-ported` objects directly, thus avoiding parsing and deparsing of
their string representation. This works by using objects of class \texttt{tclobj}. The string representation
of such objects can be extracted (but not set) using \texttt{tclvalue} and conversion to vectors of mode
"character", "double", "integer", "logical", and "raw" is performed using the standard co-
ercion functions as \texttt{character}, etc. Conversely, such vectors can be converted using as \texttt{tclobj}.
There is an ambiguity as to what should happen for length one vectors, controlled by the \texttt{drop}
argument; there are cases where the distinction matters to Tcl, although mostly it treats them equi-

Notice that \texttt{tclvalue} and \texttt{as.character} differ on an object whose string representation
TclInterface has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of tclread, tkgetOpenFile, and similar functions. The as.raw method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a tclVar object is extracted using tclObj(x) which also allows an assignment form, in which the right hand side of the assignment is automatically converted using as.tclObj. There is a print method for tclObj objects; it prints <Tcl> followed by the string representation of the object. Notice that as.character on a tclVar object is the name of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with tclRequire; it may be necessary to add the directory where they are found to the Tcl search path with addTclPath. The return value is a class "tclObj" object if it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R character vector, use

```
strsplit(tclvalue('auto_path'), " ")[[1]]
```

The Tcl version (including patchlevel) is returned as a character string (such as "8.6.3").

**Note**

Strings containing unbalanced braces are currently not handled well in many circumstances.

**See Also**

TkWidgets, TkCommands, TkWidgetcmds.
capabilities("tc1tk") to see if Tcl/Tk support was compiled into this build of R.

**Examples**

tclVersion()

```
.Tcl("format \"%s\n\" \"Hello, World!\"\")
f <- function() cat("HI!\n")
## IGNORE_RDIFF_BEGIN
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address
## IGNORE_RDIFF_END

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))
```

## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
top <- tktopplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all.names = TRUE)

## End(Not run)

```
## IGNORE_RDIFF_BEGIN
ls(envir = .TkRoot$env, all.names = TRUE) # .Tcl.args put a callback ref in here
## IGNORE_RDIFF_END
```
tclServiceMode  Allow Tcl events to be serviced or not

Description
This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

Usage
tclServiceMode(on = NULL)

Arguments
- on: (logical) Whether event servicing is turned on.

Details
If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

Value
The value of the Tcl service mode before the call.

Examples
## see demo(tkcanvas) for an example
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()

---

TkCommands  Tk non-widget commands

Description
These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.
Usage

tcl(...)  
tktitle(x)

  tktitle(x) <- value

tkbell(...)  
tkbind(...)  
tkbindtags(...)  
tkfocuss(...)  
tklower(...)

tclclose(...)            
tclputs(...)             
tclread(...)             
```

**Arguments**

- `x`  A window object
- `value`  For `tktitle` assignments, a character string.
- `...`  Handled via `.Tcl.args`

**Details**

tcl provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.

tktitle and its assignment form provides an alternate interface to Tk’s `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`. 
tkpager

Page file using Tk text widget

Description

This plugs into file.show, showing files in separate windows.

Usage

```r
tkpager(file, header, title, delete.file)
```

Arguments

- `file` character vector containing the names of the files to be displayed
- `header` headers to use for each file
- `title` common title to use for the window(s). Pasted together with the header to form actual window title.
- `delete.file` logical. Should file(s) be deleted after display?

Note

The "\b_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

See Also

`file.show`
**tkProgressBar**

**Progress Bars via Tk**

**Description**

Put up a Tk progress bar widget.

**Usage**

```r
tkProgressBar(title = "R progress bar", label = "", min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

**Arguments**

- `title, label` character strings, giving the window title and the label on the dialog box respectively.
- `min, max` (finite) numeric values for the extremes of the progress bar.
- `initial, value` initial or new value for the progress bar.
- `width` the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb, con` an object of class "tkProgressBar".
- `...` for consistency with the generic.

**Details**

tkProgressBar will display a widget containing a label and progress bar.

setTkProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R’s copy of BWidget’s progressbar.

**Value**

For tkProgressBar an object of class "tkProgressBar".

For getTkProgressBar and setTkProgressBar, a length-one numeric vector giving the previous value (invisibly for setTkProgressBar).

**See Also**

txtProgressBar
Examples

pb <- tkProgressBar("test progress bar", "Some information in \%", 0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d\% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)

tkStartGUI

Tcl/Tk GUI startup

Description

Starts up the Tcl/Tk GUI

Usage

tkStartGUI()

Details

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by help()) to be the Tk pager.

Note

tkStartGUI() saves its evaluation environment as .GUIenv. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named Term, Menu, and Toolbar, and the various submenus and callback functions can be seen with ls(envir = .GUIenv).

tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>The widget this applies to</td>
</tr>
<tr>
<td>...</td>
<td>Handled via .Tcl.args</td>
</tr>
</tbody>
</table>

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like .a.b selection clear are converted to function names like tkselection.clear and the widget is given as the first argument.

</tr>
<tr>
<td>...</td>
<td>Handled via .Tcl.args.</td>
</tr>
</tbody>
</table>

Details

These functions create Tk widgets. tkwidget creates a widget of a given type, the others simply call tkwidget with the respective type argument.

The functions starting ttk are for the themed widget set for Tk 8.5 or later. A tutorial can be found at https://tkdocs.com/.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

TclInterface, TkCommands, TkWidgetcmds

Examples

```r
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

# Create top-level window
tt <- tktoplevel()

# Add a label and a button
label.widget <- ttklabel(tt, text = "Hello, World!")
button.widget <- ttkbutton(tt, text = "Push",
                           command = function()cat("OW!\n"))

# Pack the widgets
tkpack(label.widget, button.widget)  # geometry manager
  # see Tk-commands

## Push the button and then...

tkdestroy(tt)
```
## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
    # make use of themed widgets
    # list themes
    themes <- as.character(tcl("ttk::style", "theme", "names"))
    themes
    # select a theme -- for pre-XP windows
    # tcl("ttk::style", "theme", "use", "winnative")
    tcl("ttk::style", "theme", "use", themes[1])
} else {
    # use Tk 8.0 widgets
}

## End(Not run)

---

**tk_choose.dir**

*Choose a Folder Interactively*

### Description
Use a Tk widget to choose a directory interactively.

### Usage
```
tk_choose.dir(default = "", caption = "Select directory")
```

### Arguments
- **default**: which directory to show initially.
- **caption**: the caption on the selection dialog.

### Value
A length-one character vector, character NA if 'Cancel' was selected.

### See Also
- `tk_choose.files`

### Examples
```
if (interactive()) tk_choose.dir(getwd(), "Choose a suitable folder")
```
tk_choose.files Choose a List of Files Interactively

Description
Use a Tk file dialog to choose a list of zero or more files interactively.

Usage
tk_choose.files(default = "", caption = "Select files",
multi = TRUE, filters = NULL, index = 1)

Arguments
default which filename to show initially.
caption the caption on the file selection dialog.
multi whether to allow multiple files to be selected.
filters two-column character matrix of filename filters.
index unused.

Details
Unlike file.choose, tk_choose.files will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas file.choose would signal an error.

The format of filters can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. The format may change before release.

Value
A character vector giving zero or more file paths.

Note
A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

See Also
file.choose, tk_choose.dir

Examples
Filters <- matrix(c("R code", ".R", "R code", ".s",
"Text", ".txt", "All files", "*")
4, 2, byrow = TRUE)
Filters
if(interactive()) tk_choose.files(filter = Filters)
**tk_messageBox**

**Tk Message Box**

**Description**
An implementation of a generic message box using Tk.

**Usage**
```
 tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
                  "retrycancel", "abortretryignore"),
               message, caption = "", default = "", ...)
```

**Arguments**
- `type` character. The type of dialog box. It will have the buttons implied by its name. Can be abbreviated.
- `message` character. The information field of the dialog box.
- `caption` the caption on the widget displayed.
- `default` character. The name of the button to be used as the default.
- `...` additional named arguments to be passed to the Tk function of this name. An example is `icon = "warning"`.

**Value**
A character string giving the name of the button pressed.

**See Also**
- `tkmessageBox` for a ‘raw’ interface.

**tk_select.list**

**Select Items from a List**

**Description**
Select item(s) from a character vector using a Tk listbox.

**Usage**
```
 tk_select.list(choices, preselect = NULL, multiple = FALSE,
                title = NULL)
```

**Arguments**
- `choices` a character vector of items.
- `preselect` a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- `multiple` logical: can more than one item be selected?
- `title` optional character string for window title, or NULL for no title.
Details

This is a version of `select.list` implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

`select.list` (a text version except on Windows and the macOS GUI), `menu` (whose `graphics = TRUE` mode uses this on most Unix-alikes).
Chapter 13

The tools package

tools-package  Tools for Package Development

Description
Tools for package development, administration and documentation.

Details
This package contains tools for manipulating R packages and their documentation. For a complete list of functions, use library(help = "tools").

Author(s)
Kurt Hornik and Friedrich Leisch
Maintainer: R Core Team <R-core@r-project.org>

.print.via.format  Printing Utilities

Description
/print.via.format is a “prototype” print() method, useful, at least as a start, by a simple

\[
\text{print.<myS3class>} \leftarrow \text{/print.via.format}
\]

Usage
/print.via.format(x, ...)

Arguments
x  object to be printed.
...  optional further arguments, passed to format.
Value

x, invisibly (by invisible()), as print methods should.

See Also

The print generic; its default method print.default (used for many basic implicit classes such as "numeric", "character" and arrays of them, lists etc).

Examples

## The function is simply defined as
function (x, ...) {
  writelines(format(x, ...))
  invisible(x)
}

## is used for simple print methods in R, and as prototype for new methods.
assertCondition

### Asserting Error Conditions

#### Description
When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

#### Usage
- `assertError(expr, classes = "error", verbose = FALSE)`
- `assertWarning(expr, classes = "warning", verbose = FALSE)`
- `assertCondition(expr, ..., .exprString = , verbose = FALSE)`

#### Arguments
- **expr**: an unevaluated 
- **classes, ...**: character strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.
- **.exprString**: The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If `assertCondition()` is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version.
- **verbose**: If TRUE, a message is printed when the condition is satisfied.

#### Details
- `assertCondition()` uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.
- `assertError()` is a convenience function for asserting errors; it calls `assertCondition()`.
- `assertWarning()` asserts that a warning will be signalled, but not an error, whereas `assertCondition(expr, "warning")` will be satisfied even if an error follows the warning. See the examples.

#### Value
If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See `conditionMessage` for the interpretation of these objects. Note that all conditions signalled during the evaluation are returned, whether or not they were among the requirements.

#### Author(s)
John Chambers and Martin Maechler
bibstyle

See Also

stop, warning, signalCondition, tryCatch.

Examples

```r
assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition(""-1") # ok, any condition would satisfy this

try(assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
assertCondition(sqrt("abc"), "error") # ok
try(assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4,3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
assertCondition(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt(2 ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"), "error")
```

```r
bibstyle

Select or Define a Bibliography Style

Description

This function defines and registers styles for rendering bibentry objects into ‘Rd’ format, for later conversion to text, HTML, etc.

Usage

bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
```
Arguments

- **style**: A character string naming the style.
- **envir** (optional): An environment holding the functions to implement the style.
- **...**: Named arguments to add to the environment.
- **.init**: Whether to initialize the environment from the default style "JSS".
- **.default**: Whether to set the specified style as the default style.
- **all**: Whether to return the names of all registered styles.

Details

Rendering of **bibentry** objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the ‘jss.bst’ style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `...`. (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by **bibentry** as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`'ed entry from the **bibentry** vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original **bibentry** vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named ".index" to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn’t use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

Value

- **bibstyle** returns the environment which has been selected or created.
- **getBibstyle** returns the name of the default style, or all style names.

refs <-

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs), fmtPrefix = function(paper) paste0("[", paper$.index, "]"), .init = TRUE)
print(refs, .bibstyle = "unsorted")

buildVignette

Build One Vignette

Description

Run Sweave (or other custom weave function), texi2pdf, and/or Stangle (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

Usage

buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE, quiet = TRUE, clean = TRUE, keep = character(), engine = NULL, buildPkg = NULL, encoding, ...)

Arguments

file character; the vignette source file.
dir character; the working directory in which the intermediate and output files will be produced.
weave logical; should weave be run?
l latex logical; should texi2pdf be run if weaving produces a \'.tex\' file?
tangle logical; should tangle be run?
quiet logical; run in quiet mode?
clean logical; whether to remove some newly created, often intermediate, files. See details below.
buildVignettes

keep
   a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.

engine
   NULL or character; name of vignette engine to use. Overrides any \VignetteEngine{\} markup in the vignette.

buildPkg
   NULL or a character vector; optional packages in which to find the vignette engine.

encoding
   the encoding to assume for the file. If not specified, it will be read if possible from the file’s contents. Note that if the vignette is part of a package, buildVignettes reads the package’s encoding from the ‘DESCRIPTION’ file but this function does not.

... Additional arguments passed to weave and tangle.

Details

This function determines the vignette engine for the vignette (default utils::Sweave), then weaves and/or tangles the vignette using that engine. Finally, if clean is TRUE, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in keep) will be deleted. If clean is NA, and weave is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If buildPkg is specified, those packages will be loaded before the vignette is processed and will be used as the default packages in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using \VignetteEngine{utils::Sweave} to specify the Sweave engine in the utils package) will override it. In contrast, if the engine argument is given, it will override the vignette source.

Value

A character vector naming the files that have been produced.

Author(s)

Henrik Bengtsson and Duncan Murdoch

See Also

buildVignettes for building all vignettes in a package.
Arguments

package a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory ‘doc’.

dir a character string specifying the path to a package’s root source directory. If given, vignette source files are by default looked for in subdirectory ‘vignettes’.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

quiet logical. Weave and run texi2pdf in quiet mode.

clean Remove all files generated by the build, even if there were copies there before.

tangle logical. Do tangling as well as weaving.

ser_elibs For use from R CMD check.

subdirs a character vector of subdirectories of dir in which to look for vignettes. The first which exists is used. Defaults to “doc” if package is supplied, otherwise “vignettes”.

output logical indicating if the output filenames for each vignette should be returned (in component outputs).

source logical indicating if the tangled output filenames for each vignette should be returned (in component sources).

check logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines.

Details

buildVignettes is used by R CMD build and R CMD check to (re-)build vignette outputs from their sources.

As from R 3.4.1, both of these functions ignore files that are listed in the ‘.Rbuildignore’ file in dir.

Value

buildVignettes is called for its side effect of creating the outputs of all vignettes, and if tangle = TRUE, extracting the R code.

pkgVignettes returns an object of class “pkgVignettes” if a vignette directory is found, otherwise NULL.

Examples

```r
gVigns <- pkgVignettes("grid")
str(gVigns)
```
Description

`charset_to_Unicode` is a matrix of Unicode code points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

`charset_to_Unicode`

`Adobe_glyphs`

Details

`charset_to_Unicode` is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by `libiconv`: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file `'R_HOME/share/encodings/Adobe_glyphlist'`.

Examples

```r
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.hexmode(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

checkFF

Check Foreign Function Calls

Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "NativeSymbolInfo" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.
Usage

checkFF(package, dir, file, lib.loc = NULL,
registration = FALSE, check_DUP = FALSE,
verbose = getOption("verbose"))

Arguments

package a character string naming an installed package. If given, the installed R code of the package is checked.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘R’ (for R code). Only used if package is not given.
file the name of a file containing R code to be checked. Used if neither package nor dir are given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
registration a logical. If TRUE, checks the registration information on the call (if available).
check_DUP a logical. If TRUE, .C and .Fortran calls with DUP = FALSE are reported.
verbose a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a useDynLib directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first useDynLib directive.

This checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the ‘DESCRIPTION’ file).

Value

An object of class "checkFF".

There are format and print methods to display the information contained in such objects.

See Also

.C, .Fortran; Foreign.

Examples

# order is pretty much random
checkFF(package = "stats", verbose = TRUE)
checkMD5sums

Check and Create MD5 Checksum Files

Description

checkMD5sums checks the files against a file 'MD5'.

Usage

checkMD5sums(package, dir)

Arguments

package the name of an installed package
dir the path to the top-level directory of an installed package.

Details

The file 'MD5' which is created is in a format which can be checked by md5sum -c MD5 if a suitable command-line version of md5sum is available. (For Windows, one is supplied in the bundle at https://cran.r-project.org/bin/windows/Rtools/.)

If dir is missing, an installed package of name package is searched for.

The private function tools:::.installMD5sums is used to create MD5 files in the Windows build.

Value

checkMD5sums returns a logical, NA if there is no 'MD5' file to be checked.

See Also

md5sum

checkPoFiles

Check Translation Files for Inconsistent Format Strings

Description

These functions compare formats embedded in English messages with translated strings to check for consistency. checkPoFile checks one file, while checkPoFiles checks all files for a specified language.

Usage

checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
checkPoFiles

Arguments

f
a character string giving a single filepath.

strictPlural
whether to compare formats of singular and plural forms in a strict way.

language
a character string giving a language code.

dir
a path to a directory in which to check files.

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R sprintf and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C’s sprintf() function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the strictPlural argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When checkPoFiles calls checkPoFile, the strictPlural argument is set to TRUE for files with names starting ‘R-’, and to FALSE otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign "\uFF05"). Such signs will not be recognized as format specifiers, and are likely to be errors.

Value

Both functions return an object of S3 class “check_po_files”. A print method is defined for this class to display a report on the differences.

Author(s)

Duncan Murdoch

References

See the GNU gettext manual for the ‘.po’ file format:

update_pkg_po() which calls checkPoFile(); xgettext, sprintf.
checkRd

Examples

```r
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")

## End(Not run)
```

---

checkRd  

Check an Rd Object

Description

Check an help file or the output of the `parse_Rd` function.

Usage

```r
checkRd(Rd, defines = .Platform$OS.type, stages = "render", 
unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

Arguments

- **Rd**: a filename or Rd object to use as input.
- **defines**: string(s) to use in `#ifdef` tests.
- **stages**: at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
- **unknownOK**: unrecognized macros are treated as errors if `FALSE`, otherwise warnings.
- **listOK**: unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if `FALSE`, otherwise warnings.
- **...**: additional parameters to pass to `parse_Rd` when `Rd` is a filename. One that is often useful is `encoding`.
- **def_enc**: logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?

Details

checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from `prepare_Rd` have level 0. These include

- All text must be in a section
- Only one tag name section is allowed: the first will be used
- Section name is unrecognized and will be dropped
- Dropping empty section name
checkRd itself can show

- Tag tag name not recognized
- \tablular format must be simple text
- Unrecognized \tablular format: ...
- Only n columns allowed in this table
- Must have a tag name
- Only one tag name is allowed
- Tag tag name must not be empty
- \docType must be plain text
- Tag \method is only valid in \usage
- Tag \dontrun is only valid in \examples
- Tag tag name is invalid in a block name block
- Title of \section must be non-empty plain text
- \title content must be plain text
- Empty section tag name
- Non-ASCII contents without declared encoding
- Non-ASCII contents in second part of \enc
- Tag \ldots is not valid in a code block
- Apparent non-ASCII contents without declared encoding
- Apparent non-ASCII contents in second part of \enc
- Unnecessary braces at ...
- \method not valid outside a code block

and variations with \method replaced by \S3method or \S4method.

Note that both prepare_Rd and checkRd have tests for an empty section: that in checkRd is stricter (essentially that nothing is output).

**Value**

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a print method which only prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in R CMD check.)

Possible fatal errors are those from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from prepare_Rd (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections).

**Author(s)**

Duncan Murdoch, Brian Ripley

**See Also**

parse_Rd, Rd2HTML.
checkRdaFiles

Report on Details of Saved Images or Re-saves them

Description

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `.rda` or `RData`, hence the name of the function.

Usage

```r
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
              compression_level, version = NULL)
```

Arguments

- **paths**: A character vector of paths to `save` files. If this specifies a single directory, it is taken to refer to all `.rda` and `RData` files in that directory.
- **compress, compression_level**: Type and level of compression: see `save`. Values of compressor can be abbreviated.
- **version**: The format to be used when re-saving: see `save`.

Details

- `compress = "auto"` asks `R` to choose the compression and ignores `compression_level`. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

  For back-compatibility, `version = NULL` is interpreted to mean version 2: however version-3 files will only be saved as version 3.

Value

- For `checkRdaFiles`, a data frame with rows names `paths` and columns
  - **size**: numeric: file size in bytes, NA if the file does not exist.
  - **ASCII**: logical: true for `save(ASCII = TRUE)`, NA if the format is not that of an R save file.
  - **compress**: character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R).
  - **version**: integer: positive with the version(s) of the `save()`, see there on which versions have been default in which versions of R, and NA for non-Rda files.
Examples

```r
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad, ]
## End(Not run)
```

checkTnF

Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of `T` or `F`, and gathers the expression containing these. This is useful as in R `T` and `F` are just variables which are set to the logicals `TRUE` and `FALSE` by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use `TRUE` and `FALSE` for the logicals.

Usage

```r
checkTnF(package, dir, file, lib.loc = NULL)
```

Arguments

- `package`: a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.
- `dir`: a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked.
- `file`: the name of a file containing R code to be checked. Used if neither package nor `dir` are given.
- `lib.loc`: a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. The specified library trees are used to search for `package`.

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of `T` or `F` were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a `print` method for nicely displaying the information contained in such objects.
checkVignettes  

**Check Package Vignettes**

### Description

Check all vignettes of a package by running **Sweave** (or other custom weave function) and/or **Stangle** (or other custom tangle function) on them. All R source code files found after the tangling step are **source**d to check whether all code can be executed without errors.

### Usage

```r
checkVignettes(package, dir, lib.loc = NULL, 
tangle = TRUE, weave = TRUE, latex = FALSE, 
workdir = c("tmp", "src", "cur"), 
keepfiles = FALSE)
```

### Arguments

- **package**: a character string naming an installed package. If given, vignette source files are looked for in subdirectory ‘doc’.
- **dir**: a character string specifying the path to a package’s root source directory. If given, vignette source files are looked for in subdirectory ‘vignettes’.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- **tangle**: Perform a tangle and **source** the extracted code?
- **weave**: Perform a weave?
- **latex**: logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes directory, run the intermediate ‘.tex’ outputs from weaving through **texi2pdf**.
- **workdir**: Directory used as working directory while checking the vignettes. If “tmp” then a temporary directory is created, this is the default. If “src” then the directory containing the vignettes itself is used, if “cur” then the current working directory of R is used.
- **keepfiles**: Delete files in the temporary directory? This option is ignored when workdir != “tmp”.

### Details

This function first uses **pkgVignettes** to find the package vignettes, and in particular their vignette engines (see **vignetteEngine**).

If tangle is true, it then runs **Stangle** (or other custom tangle function provided by the engine) to produce (one or more) R code files from each vignette, then **source**s each code file in turn.

If weave is true, the vignettes are run through **Sweave** (or other custom weave function provided by the engine). If latex is also true and there is no ‘Makefile’ in the vignettes directory, **texi2pdf** is run on the intermediate ‘.tex’ files from weaving for those vignettes which did not give errors in the previous steps.
check_packages_in_dir

Check Source Packages and Their Reverse Dependencies

Description

Check source packages in a given directory, optionally with their reverse dependencies.

Usage

check_packages_in_dir(dir, check_args = character(), check_args_db = list(), reverse = NULL, check_env = character(), xvfb = FALSE, Ncpus =getOption("Ncpus", 1L), clean = TRUE, ...)

summarize_check_packages_in_dir_results(dir, all = TRUE, full = FALSE, ...)
summarize_check_packages_in_dir_timings(dir, all = FALSE, full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE, which = c("Depends", "Imports", "LinkingTo"))

check_packages_in_dir_changes(dir, old, outputs = FALSE, sources = FALSE, ...)
check_packages_in_dir_details(dir, logs = NULL, drop_ok = TRUE, ...)

Arguments

dir a character string giving the path to the directory with the source `.tar.gz` files to be checked.

check_args a character vector with arguments to be passed to `R CMD check`, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.

check_args_db a named list of character vectors with arguments to be passed to `R CMD check`, with names the respective package names.

reverse a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (a subset of getOption("repos"), the default), the types of reverse dependencies (default: c("Depends", "Imports", "LinkingTo")), with shorthands "most" and "all"
check_packages_in_dir allows to conveniently check source package '*.tar.gz' files in the given directory dir, along with their reverse dependencies as controlled by reverse.

The "which" component of reverse can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of reverse (which is recycled as needed).

If needed, the source '*.tar.gz' files of the reverse dependencies to be checked as well are downloaded into dir (and removed at the end if clean is true). Next, all packages (additionally) needed for checking are installed to the 'Library' subdirectory of dir. Then, all '*.tar.gz' files are checked using the given arguments and environment variables, with outputs and messages to files in the 'Outputs' subdirectory of dir. The '*.Rcheck' directories with the check results of the reverse dependencies are renamed by prefixing their base names with 'rdepends_'.

Results and timings can conveniently be summarized using summarize_check_packages_in_dir_results and summarize_check_packages_in_dir_timings, respectively.

Installation and checking is performed in parallel if Ncpus is greater than one: this will use mclapply on Unix and parLapply on Windows.
check_packages_in_dir returns an object inheriting from class "check_packages_in_dir" which has \texttt{print} and \texttt{summary} methods.

check_packages_in_dir_changes allows to analyze the effect of changing (some of) the sources. With \texttt{dir} and \texttt{old} the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options \texttt{outputs} and \texttt{sources}. The changes object returned can be subscripted according to change in severity from the old to the new results by using one of "==", "!=" or "<", "<=" or ">=" as row index.

check_packages_in_dir_details analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables \texttt{Check}, \texttt{Status} and \texttt{Output}, respectively).

Environment variable \_R\_CHECK\_ELAPSED\_TIMEOUT\_ can be used to set a limit on the elapsed time of each check run. See the ‘R Internals’ manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a check run.

\textbf{Note}

This functionality is still experimental: interfaces may change in future versions.

\textbf{Examples}

```r
## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
    reverse = list(repos = getOption("repos")["CRAN"],
        which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
    check_args = c("--as-cran", ""),
    reverse = list(repos = getOption("repos")["CRAN"]))
## End(Not run)
```

codoc \hspace{1cm} \textit{Check Code/Documentation Consistency}

\textbf{Description}

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.
**codoc**

**Usage**

```r
codoc(package, dir, lib.loc = NULL, use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

**Arguments**

- **package**: a character string naming an installed package.
- **dir**: a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘**man**’ with R documentation sources (in Rd format) and ‘**R**’ with R code. Only used if package is not given.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- **use.values**: if FALSE, do not use function default values when comparing code and docs. Otherwise, compare all default values if TRUE, and only the ones documented in the usage otherwise (default).
- **verbose**: a logical. If TRUE, additional diagnostics are printed.

**Details**

The purpose of codoc is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument use.values. Synopsis sections are used if present; their occurrence is reported if verbose is true.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by prompt are recognized by codocData and used provided that the documentation object is for a single data frame (i.e., only has one alias). codocClasses analogously handles slot names for classes in documentation objects obtained by editing shells created by promptClass.

Help files named ‘**pkgname-defunct.Rd**’ for the appropriate **pkgname** are checked more loosely, as they may have undocumented arguments.

**Value**

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches.
(which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

Note

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

---

**compactPDF**

*Compact PDF Files*

**Description**

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

**Usage**

```r
compactPDF(paths, qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")), gs_cmd = Sys.getenv("R_GSCMD", ""), gs_quality = Sys.getenv("GS_QUALITY", "none"), gs_extras = character())
```

```r
## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
```

**Arguments**

- **paths**
  A character vector of paths to PDF files, or a length-one character vector naming a directory, when all `.pdf` files in that directory will be used.

- **qpdf**
  Character string giving the path to the qpdf command. If empty, qpdf will not be used.

- **gs_cmd**
  Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to `gswin32c.exe` or `gswin64c.exe`. If "" (the default), the function will try to find a platform-specific path to GhostScript where required.

- **gs_quality**
  A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi). Can be abbreviated.

- **gs_extras**
  An optional character vector of further options to be passed to GhostScript.

- **x**
  An object of class "compactPDF".

- **ratio, diff**
  Limits for reporting: files are only reported whose sizes are reduced both by a factor of ratio and by diff bytes.

- **...**
  Further arguments to be passed to or from other methods.
Details

This by default makes use of qpdf, available from http://qpdf.sourceforge.net/ (including as a Windows binary) and included with the CRAN macOS distribution of R. If gs_cmd is non-empty and gs_quality != "none", GhostScript will used first, then qpdf if it is available. If gs_quality != "none" and gs_cmd is "", an attempt will be made to find a GhostScript executable.

qpdf and/or gs_cmd are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX’s pdflatex. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when gs_quality != "none" and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

Value

An object of class c("compactPDF", "data.frame"). This has two columns, the old and new sizes in bytes for the files that were changed.

There are format and print methods: the latter passes ... to the format method, so will accept ratio and diff arguments.

Note

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some vignettes in CRAN packages.

See Also

resaveRdaFiles.

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.
Usage

CRAN_package_db()
CRAN_check_results(flavors = NULL)
CRAN_check_details(flavors = NULL)
CRAN_check_issues()
summarize_CRAN_check_status(packages,
                           results = NULL,
                           details = NULL,
                           issues = NULL)

Arguments

packages a character vector of package names.
flavors a character vector of CRAN check flavor names, or NULL (default), corresponding to all available flavors.
results the return value of CRAN_check_results() (default), or a subset of this.
details the return value of CRAN_check_details() (default), or a subset of this.
issues the return value of CRAN_check_issues() (default), or a subset of this.

Details

CRAN_package_db() returns a character data frame with most ‘DESCRIPTION’ metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by utils::available.packages().

CRAN_check_results() returns a data frame with the basic CRAN package check results including timings, with columns Package, Flavor and Status giving the package name, check flavor, and overall check status, respectively.

CRAN_check_details() returns a data frame inheriting from class ”check_details” (which has useful print and format methods) with details on the check results, providing check name, status and output for every non-OK check (via columns Check, Status and Output, respectively). Packages with all-OK checks are indicated via a Check wildcard name and OK Status.

CRAN_check_issues() returns a character frame with additional check issues (including the memory-access check results made available from https://www.stats.ox.ac.uk/pub/bdr/memtests/ and the without-long-double check results from https://www.stats.ox.ac.uk/pub/bdr/noLD/), as a character frame with variables Package, Version, kind (an identifier for the issue) and href (a URL with information on the issue).

CRAN_memtest_notes() is now deprecated, with its functionality integrated into that of CRAN_check_issues().

Value

See ‘Details’. Note that the results are collated on CRAN: currently this is done in a locale which sorts aAbB . . . .

Which CRAN?

The main functions access a CRAN mirror specified by the environment variable R_CRAN_WEB, defaulting to one specified in the ‘repositories’ file (see setRepositories): if that specifies
@CRAN@ (the default) then https://CRAN.R-project.org is used. (Note that options("repos") is not consulted.)

Note that these access parts of CRAN under ‘web/contrib’ and ‘web/packages’ so if you have specified a mirror of just ‘src/contrib’ for installing packages you will need to set R_CRAN_WEB to point to a full mirror.

Examples

```r
## This can be rather slow, especially with a non-local CRAN mirror
## and would fail (slowly) without Internet access in that case.
set.seed(11)  # but the packages chosen will change as soon as CRAN does.
pdb <- CRAN_package_db()
dim(pdb)
## DESCRIPTION fields included:
colnames(pdb)
## Summarize publication dates:
summary(as.Date(pdb$Published))
## Summarize numbers of packages according to maintainer:
summary(lengths(split(pdb$Package, pdb$Maintainer)))
## Packages with 'LASSO' in their Description:
pdb$Package[grepl("LASSO", pdb$Description)]
```

```r
results <- CRAN_check_results()
## Available variables:
names(results)
## Tabulate overall check status according to flavor:
with(results, table(Flavor, Status))
```

```r
details <- CRAN_check_details()
## Available variables:
names(details)
## Tabulate checks according to their status:
tab <- with(details, table(Check, Status))
## Inspect some installation problems:
bad <- subset(details,
  ((Check == "whether package can be installed") &
  (Status != "OK")))
## Show a random sample of up to 6
head(bad[sample(seq_len(NROW(bad)), NROW(bad)), ])
```

```r
issues <- CRAN_check_issues()
head(issues)
## Show counts of issues according to kind:
table(issues[, "kind"])
```

```r
## Summarize CRAN check status for 10 randomly-selected packages
## (reusing the information already read in):
pos <- sample(seq_len(NROW(pdb)), 10L)
summarize_CRAN_check_status(pdb[pos, "Package"],
  results, details, issues)
```
Description

Match delimited substrings in a character vector, with proper nesting.

Usage

delimMatch(x, delim = c("\", ")", syntax = "Rd")

Arguments

x a character vector.
delim a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
syntax currently, always the string "Rd" indicating Rd syntax (i.e., ‘%’ starts a comment extending till the end of the line, and ‘\’ escapes). Future versions might know about other syntax, perhaps via ’syntax tables’ allowing to flexibly specify comment, escape, and quote characters.

Value

An integer vector of the same length as x giving the starting position (in characters) of the first match, or −1 if there is none, with attribute ”match.length” giving the length (in characters) of the matched text (or −1 for no match).

See Also

regexpr for ‘simple’ pattern matching.

Examples

x <- c("\value{foo}", "function(bar)"

delimMatch(x)
delimMatch(x, c("\", ")")

dependsOnPkgs Find Reverse Dependencies

description

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

Usage

dependsOnPkgs(pkgs,
dependencies = "strong",
recursive = TRUE, lib.loc = NULL,
installed =
utils::installed.packages(lib.loc, fields = "Enhances"))
Arguments

pkgs a character vector of package names.
dependencies a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector.
recursive logical: should reverse dependencies of reverse dependencies (and so on) be included?
lib.loc a character vector of R library trees, or NULL for all known trees (see .libPaths).
installed a result of calling installed.packages.

Value

A character vector of package names, which does not include any from pkgs.

See Also

package_dependencies() to get the regular ("forward") dependencies of a package.

Examples

## there are few dependencies in a vanilla R installation:
## lattice may not be installed
dependsOnPkgs("lattice")

encoded_text_to_latex

Translate non-ASCII Text to LaTeX Escapes

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

encoded_text_to_latex(x,

encoding = c("latin1", "latin2", "latin9",
"UTF-8", "utf8"))

Arguments

x a character vector.
encoding the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX’s inputenc package.
**Details**

Non-ASCII characters in `x` are replaced by an appropriate LaTeX escape sequence, or ‘?’ if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to ‘\-‘.

**Value**

A character vector of the same length as `x`.

**See Also**

`iconv`

**Examples**

```r
x <- "fa\xE7ile"
encoded_text_to_latex(x, "latin1")

## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- rawToChar(as.raw(160:255), multiple = TRUE)
(x <- matrix(x, ncol = 16, byrow = TRUE))
xx <- x
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-encoding.tex", "w")
header <- c("\documentclass{article}",
"\usepackage[T1]{fontenc}",
"\usepackage{Rd}",
"\begin{document}"
"\HeaderA{test}{}{test}",
"\begin{Details}\relax",
"\Tabular{cccccccccccccccc}{")
trailer <- c("\}", "\end{Details}", "\end{document}"
writeLines(header, con)
writeLines(paste(xx, "\", sep = ""), con)
writeLines(trailer, con)
close(con)
## and some UTF_8 chars
x <- intToUtf8(as.integer(
  c(160:383,0x0192,0x02C6,0x02C7,0x02CA,0x02D8,
    0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
    0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
  multiple = TRUE)
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\", sep = ""), con)
writeLines(trailer, con)
close(con)

## End(Not run)
```
Description

Utilities for listing files, and manipulating file paths.

Usage

```r
file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
                      full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
                     full.names = TRUE, OS_subdirs = .OS_type())
```

Arguments

- `x` character vector giving file paths.
- `compression` logical: should compression extension `.gz`, `.bz2` or `.xz` be removed first?
- `dir` a character string with the path name to a directory.
- `exts` a character vector of possible file extensions (excluding the leading dot).
- `all.files` a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.
- `full.names` a logical indicating whether the full paths of the files found are returned (default), or just the file names.
- `type` a character string giving the 'type' of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).
- `OS_subdirs` a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of `.Platform$OS.type`, is used.

Details

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, x must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.
list_files_with_type returns the paths of the files in dir of the given 'type', as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of OS_subdirs. Note that by default, full paths are returned, and that only visible files are used.

See Also

file.path, file.info, list.files

Examples

dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))

---

find_gs_cmd

Find a GhostScript Executable

Description

Find a GhostScript executable in a cross-platform way.

Usage

find_gs_cmd(gs_cmd = "")

Arguments

gs_cmd

The name, full or partial path of a GhostScript executable.

Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called gs. The name (and possibly path) of the command is taken first from argument gs_cmd then from the environment variable R_GSCMD and default gs. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument gs_cmd then from the environment variables R_GSCMD and GSC. If neither of those produces a suitable command name, gswin64c and gswin32c are tried in turn. In all cases the command is looked for on the system PATH.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.
Examples

## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

## End(Not run)

getVignetteInfo

Get Information on Installed Vignettes

Description

This function gets information on installed vignettes.

Usage

gETCHiv{getVignetteInfo}(package = NULL, lib.loc = NULL, all = TRUE)

Arguments

- package: Which package to look in, or NULL for all packages.
- lib.loc: Which library to look in.
- all: Whether to search all installed packages, or just attached packages.

Value

A matrix with columns

- Package: the name of the package
- Dir: the directory where the package is installed
- Topic: the name of the vignette
- File: the base filename of the source of the vignette
- Title: the title of the vignette
- R: the tangled R source from the vignette
- PDF: the PDF or HTML file for display

Note

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

See Also

pkgVignettes is a similar function that can work on an uninstalled package.

Examples

gETCHiv{getVignetteInfo}("grid")
Generate a Standard HTML Header for R Help

Description

This function generates the standard HTML header used on R help pages.

Usage

```r
HTMLheader(title = "R", logo = TRUE, up = NULL,
            top = file.path(Rhome, "doc/html/index.html"),
            Rhome = ",
            css = file.path(Rhome, "doc/html/R.css"),
            headerTitle = paste("R:\", title),
            outputEncoding = "UTF-8")
```

Arguments

- `title`: The title to display and use in the HTML headers. Should have had any HTML escaping already done.
- `logo`: Whether to display the R logo after the title.
- `up`: Which page (if any) to link to on the “up” button.
- `top`: Which page (if any) to link to on the “top” button.
- `Rhome`: A relative path to the R home directory. See the ‘Details’.
- `css`: The relative URL for the Cascading Style Sheet.
- `headerTitle`: The title used in the headers.
- `outputEncoding`: The declared encoding for the whole page.

Details

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘../..’) to it should be used.

Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

Examples

```r
cat(HTMLheader("This is a sample header"), sep="\n")
```
**HTMLLinks**

Collect HTML Links from Package Documentation

**Description**

Compute relative file paths for URLs to other package’s installed HTML documentation.

**Usage**

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

**Arguments**

- `pkgDir` the top-level directory of an installed package. The default indicates no package.
- `lib.loc` character vector describing the location of R library trees to scan: the default indicates `.libPaths()`.
- `level` Which level(s) to include.

**Details**

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

**Value**

A named character vector of file paths, relative to the ‘html’ directory of an installed package. So these are of the form ‘"../../somepkg/html/sometopic.html"’.

**Author(s)**

**loadRdMacros**

Load User-defined Rd Help System Macros

**Description**

Loads macros from an `.Rd` file, or from several `.Rd` files contained in a package.

**Usage**

```
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros)
```
Arguments

file A file in Rd format containing macro definitions.

macros TRUE or a previous set of macro definitions, in the format expected by the parse_Rd macros argument.

pkgdir The base directory of a source package or an installed package.

Details

The files parsed by this function should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The macros argument may be a filename of a base set of macros, or the result of a previous call to loadRdMacros or loadPkgRdMacros in the same session. These results should be assumed to be valid only within the current session.

The loadPkgRdMacros function first looks for an "RdMacros" entry in the package ‘DESCRIPTION’ file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for ‘.Rd’ files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have emptyenv() as its parent.

parse_Rd

Examples

f <- tempfile()
writeLines(paste0("\\newcommand{\logo}{\\if{html}{\figure{Rlogo.svg}{options: width=100}}
", "\\if{latex}{\figure{Rlogo.pdf}{options: width=0.5in}}}"),
   f)

m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
**makevars**

*User and Site Compilation Variables*

**Description**

Determine the location of the user and site specific ‘Makevars’ files for customizing package compilation.

**Usage**

```r
makevars_user()
makevars_site()
```

**Details**

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of ‘src’), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with ‘-f’ to custom Make invocations.

**Value**

A character string with the path to the user or site specific ‘Makevars’ file, or an empty character vector if there is no such file.

**See Also**

Section ‘Customizing package compilation’ in the ‘R Installation and Administration’ manual.

**Examples**

```r
makevars_user()
makevars_site()
```
md5sum

Arguments

srcdir The R source directory.
outDir The directory into which to place the prepared package.
append The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0.

Details

This extracts the translations in a current R source distribution and packages them as a source package called translations which can be distributed on CRAN and installed by update.packages. This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions 3.x.* for a single x.

md5sum

Compute MD5 Checksums

Description

Compute the 32-byte MD5 hashes of one or more files.

Usage

md5sum(files)

Arguments

files character. The paths of file(s) whose contents are to be hashed.

Details

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently modified.

Value

A character vector of the same length as files, with names equal to files (possibly expanded). The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

Source

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of glibc.

---

package_dependencies

Computations on the Dependency Hierarchy of Packages

Description

Find (recursively) dependencies or reverse dependencies of packages.

Usage

package_dependencies(packages = NULL, db = NULL, which = "strong",
recursive = FALSE, reverse = FALSE,
verbose = getOption("verbose"))

Arguments

packages
  a character vector of package names.

db
  character matrix as from available.packages() (with the default NULL the
  results of this call) or data frame variants thereof. Alternatively, a pack-
  age database like the one available from https://cran.r-project.org/web/
  packages/packages.rds.

which
  a character vector listing the types of dependencies, a subset of c("Depends",
  "Imports", "LinkingTo", "Suggests", "Enhances"). Character string
  "all" is shorthand for that vector, character string "most" for the same vec-
  tor without "Enhances", character string "strong" (default) for the first three
  elements of that vector.

recursive
  a logical indicating whether (reverse) dependencies of (reverse) dependencies
  (and so on) should be included, or a character vector like which indicating
  the type of (reverse) dependencies to be added recursively.

reverse
  logical: if FALSE (default), regular dependencies are calculated, otherwise re-
  verse dependencies.

verbose
  logical indicating if output should monitor the package search cycles.

Value

Named list with one element for each package in argument packages, each consists of a character
vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

dependsOnPkgs.
package_native_routine_registration_skeleton

Write Skeleton for Adding Native Routine Registration to a Package

Description

Write a skeleton for adding native routine registration to a package.

Usage

package_native_routine_registration_skeleton(dir, con = stdout(),
                                           align = TRUE, character_only = TRUE, include_declarations = TRUE)

Arguments

dir              Top-level directory of a package.
con              Connection on which to write the skeleton: can be specified as a file path.
align            Logical: should the registration tables be lined up in three columns each?
character_only   Logical: should only .NAME arguments specified by character strings (and not as
                 names of R objects nor expressions) be extracted?
include_declarations    Logical: should the output include declarations (also known as 'prototypes') for
                         the registered routines?
Details

Registration is described in section ‘Registering native routines’ of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to .C, .Fortran, .Call and .External and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as -1: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code. For .Call and .External calls they will often suffice, but for .C and .Fortran calls the void * arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in ‘init.c’).

The default value of character_only is appropriate when working on a package without any existing registration: character_only = FALSE can be used to suggest updates for a package which has been extended since registration. For the default value, if .NAME values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols via additional arguments in a useDynLib directive will probably most easily be updated to use registration with character_only = FALSE.

If an entry point is used with different numbers of arguments in the package’s R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only .External calls can have a variable number of arguments, which should be declared as -1.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as .Call(...) will be silently ignored.

Value

None: the output is written to the connection con.

Extracting C/C++ prototypes

There are several tools available to extract function declarations from C or C++ code.

For C code one can use cproto (https://invisible-island.net/cproto/cproto.html; Windows executables are available), for example

    cproto -I/path/to/R/include -e *.c

ctags (commonly distributed with the OS) covers C and C++, using something like

    ctags -x *.c

To list all function usages. (The ‘Exuberant’ version allows a lot more control.)
**Extracting Fortran prototypes**

*extract* Fortran 9.2 and later can extract C prototypes for Fortran subroutines with a special flag:

```
gfortran -c -fc-prototypes-external file.f
```

although ironically not for functions declared `bind(C)`.

**Note**

This only examines the ‘R’ directory: it will not find e.g. `.Call` calls used directly in examples, tests etc. Static code analysis is used to find the `.C` etc calls: it *will* find those in parts of the R code ‘commented out’ by inclusion in `if(FALSE) { ... }`. On the other hand, it will fail to find the entry points in constructs like

```
.Call(if(int) "rle_i" else "rle_d", i, force)
```

and does not know the value of variables in calls like

```
.Call (cfun, ...)  
.Call(..., PACKAGE="sparseLTSEigen")
```

(but if character_only is false, will extract the first as "cfun`). Calls which have not been fully resolved will be noted via comments in the output file. Call to entry points in other packages will be ignored if they have an explicit (character string) PACKAGE argument.

**See Also**

package.skeleton.

**Examples**

```r
## Not run:  
## with a completed splines/DESCRIPTION file,  
tools::package_native_routine_registration_skeleton('splines',,,FALSE)  
## produces  
#include <R.h>
#include <Rinternals.h>
#include <stdlib.h> // for NULL
#include <R_ext/Rdynload.h>

/* FIXME:  
Check these declarations against the C/Fortran source code.  */
/
/* .Call calls */
extern SEXP spline_basis(SEXP, SEXP, SEXP, SEXP);
extern SEXP spline_value(SEXP, SEXP, SEXP, SEXP, SEXP);
static const R_CallMethodDef CallEntries[] = {
```
parseLatex

Experimental Functions to Work with LaTeX Code

Description

The parseLatex function parses LaTeX source, producing a structured object; deparseLatex reverses the process. The latexToUtf8 function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

Usage

parseLatex(text, filename = deparse1(substitute(text)),
    verbose = FALSE,
    verbatim = c("verbatim", "verbatim*",
                 "Sinput", "Soutput"))
deparseLatex(x, dropBraces = FALSE)
llatexToUtf8(x)

Arguments

text A character vector containing LaTeX source code.
filename A filename to use in syntax error messages.
verbose If TRUE, print debug error messages.
verbatim A character vector containing the names of LaTeX environments holding verbatim text.
x A "LaTeX" object.
dropBraces Drop unnecessary braces when displaying a "LaTeX" object.

Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the \verb macro (with single character delimiters), and environments whose names are listed in the verbatim argument.
parse_Rd

Value

The parseLatex() function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.

The deparseLatex() function returns a single element character vector, possibly containing embedded newlines. The latexToUtf8() function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch

Examples

latex <- parseLatex("fa\c{c}ile")
deparseLatex(latexToUtf8(latex))

parse_Rd Parse an Rd File

Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
         macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
         permissive = FALSE)

## S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
## S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)

Arguments

file A filename or text-mode connection. At present filenames work best.
srcfile NULL, or a "srcfile" object. See the 'Details' section.
encoding Encoding to be assumed for input strings.
verbose Logical indicating whether detailed parsing information should be printed.
fragment Logical indicating whether file represents a complete Rd file, or a fragment.
warningCalls Logical: should parser warnings include the call?
macros Filename or environment from which to load additional macros, or a logical value. See the Details below.
permissive Logical indicating that unrecognized macros should be treated as text with no warning.
x An object of class Rd.
deparse If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object.
... Further arguments to be passed to or from other methods.
Details

This function parses ‘Rd’ files according to the specification given in https://developer.r-project.org/parseRd.pdf.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘\newcommand’ or ‘\renewcommand’. An environment may also be given: it would be produced by loadRdMacros, loadPkgRdMacros, or by a previous call to parse_Rd. If a logical value is given, only the default built-in macros will be used; FALSE indicates that no "macros" attribute will be returned with the result.

The permissive argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a bibentry. With permissive = TRUE, this will be passed through as plain text. Since parse_Rd doesn’t know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

Value

parse_Rd returns an object of class "Rd". The internal format of this object is subject to change. The as.character() and print() methods defined for the class return character vectors and print them, respectively.

Unless macros = FALSE, the object will have an attribute named "macros", which is an environment containing the macros defined in file, in a format that can be used for further parse_Rd calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

Rd2HTML for the converters that use the output of parse_Rd().

------------------

pskill

Kill a Process

Description

pskill sends a signal to a process, usually to terminate it.
Usage

pskill(pid, signal = SIGTERM)

SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2

Arguments

pid  positive integers: one or more process IDs as returned by Sys.getpid.
signal integer, most often one of the symbolic constants.

Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a kill system call to send a signal to a process, most often to terminate it. Function pskill provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, Ctrl-C sends SIGINT, Ctrl-\ sends SIGQUIT and Ctrl-Z sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The SIG* objects contain the appropriate integer values for the current platform (or NA_INTEGER_ if the signal is not defined).

Only SIGINT and SIGKILL will be defined on Windows, and pskill will always use the Windows system call TerminateProcess.

Value

A logical vector of the same length as pid, TRUE (for success) or FALSE, invisibly.

See Also

Package parallel has several means to launch child processes which record the process IDs.

psnice

Examples

## Not run:
pskill(c(237, 245), SIGKILL)

## End(Not run)
psnice

Get or Set the Priority (Niceness) of a Process

**Description**

Get or set the ‘niceness’ of the current process, or one or more other processes.

**Usage**

```r
psnice(pid = Sys.getpid(), value = NA_integer_)
```

**Arguments**

- `pid`: positive integers: the process IDs of one of more processes: defaults to the R session process.
- `value`: The niceness to be set, or `NA` for an enquiry.

**Details**

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and `/usr/bin/renice -n`) specifies an increment in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

**Value**

An integer vector of previous niceness values, `NA` if unknown for any reason.

**See Also**

Various functions in package `parallel` create child processes whose priority may need to be changed. `pskill`.
QC Checks for R Code and/or Documentation

Description

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

Usage

checkDocFiles (package, dir, lib.loc = NULL, chkInternal = FALSE)
checkDocStyle (package, dir, lib.loc = NULL)
checkReplaceFuns (package, dir, lib.loc = NULL)
checkS3methods (package, dir, lib.loc = NULL)
checkRdContents (package, dir, lib.loc = NULL, chkInternal = FALSE)

langElts
nonS3methods (package)

Arguments

package  a character string naming an installed package.
dir  a character string specifying the path to a package's root source (or installed in some cases) directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if package is not given.
lib.loc  a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
chkInternal  logical indicating if Rd files marked with keyword internal should be checked as well.

Details

checkDocFiles checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

checkDocStyle investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd \method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by checkDocStyle.)

checkReplaceFuns checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named value.

checkS3methods checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for
the method. As an exception, the first argument of a formula method may be called `formula` even if this is not the name used by the generic. The rules when ... is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see `InternalMethods`), and S3 group generics (see `Math`). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the base package and (currently) the packages `graphics`, `stats`, and `utils` added in R 1.9.0 by splitting the former base, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.

`checkRdContents()` checks Rd content, e.g., whether arguments of functions in the usage section have non empty descriptions.

`nonS3methods(package)` returns a `character` vector with the names of the functions in package which ‘look’ like S3 methods, but are not. Using `package = NULL` returns all known examples.

`langElt()` is a character vector of names of “language elements” of R. These are implemented as “very primitive” functions (no argument list; `print()`ing as `.Primitive("<name>")`).

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the base package), after possibly detaching an already loaded version of the package.

Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are `print` methods for nicely displaying the information contained in such objects.

---

**Rcmd**

<table>
<thead>
<tr>
<th>R CMD Interface</th>
</tr>
</thead>
</table>

**Description**

Invoke R CMD tools from within R.

**Usage**

`Rcmd(args, ...)`

**Arguments**

- **args**
  - a character vector of arguments to R CMD.
- **...**
  - arguments to be passed to `system2`.

**Details**

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via `system2`.

**Value**

See section “Value” in `system2`.  

Rd2HTML  

Rd Converters

Description

These functions take the output of `parse_Rd()`, an Rd object, and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

Usage

```r
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
  Links = NULL, Links2 = NULL,
  stages = "render", outputEncoding = "UTF-8",
  dynamic = FALSE, no_links = FALSE, fragment = FALSE,
  stylesheet = "R.css", ...)
```

```r
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
  stages = "render", outputEncoding = "",
  fragment = FALSE, options, ...)
```

```r
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
  stages = "render", outputEncoding = "UTF-8",
  fragment = FALSE, ..., writeEncoding = TRUE)
```

```r
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
  stages = "render", outputEncoding = "UTF-8",
  commentDontrun = TRUE, commentDonttest = FALSE, ...)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rd</td>
<td>a filename or Rd object to use as input.</td>
</tr>
<tr>
<td>out</td>
<td>a filename or connection object to which to write the output. The default out = &quot;&quot; is equivalent to out = stdout().</td>
</tr>
<tr>
<td>package</td>
<td>the package to list in the output.</td>
</tr>
<tr>
<td>defines</td>
<td>string(s) to use in #ifdef tests.</td>
</tr>
<tr>
<td>stages</td>
<td>at which stage (&quot;build&quot;, &quot;install&quot;, or &quot;render&quot;) should \Sexpr macros be executed? See the notes below.</td>
</tr>
<tr>
<td>outputEncoding</td>
<td>see the ‘Encodings’ section below.</td>
</tr>
<tr>
<td>dynamic</td>
<td>logical: set links for render-time resolution by dynamic help system.</td>
</tr>
<tr>
<td>no_links</td>
<td>logical: suppress hyperlinks to other help topics. Used by R CMD Rdconv.</td>
</tr>
<tr>
<td>fragment</td>
<td>logical: should fragments of Rd files be accepted? See the notes below.</td>
</tr>
<tr>
<td>stylesheet</td>
<td>character: a URL for a stylesheet to be used in the header of the HTML output page.</td>
</tr>
<tr>
<td>Links, Links2</td>
<td>NULL or a named (by topics) character vector of links, as returned by findHTMLlinks.</td>
</tr>
<tr>
<td>options</td>
<td>An optional named list of options to pass to Rd2txt_options.</td>
</tr>
<tr>
<td>...</td>
<td>additional parameters to pass to parse_Rd when Rd is a filename.</td>
</tr>
</tbody>
</table>
writeEncoding should \inputencoding lines be written in the file for non-ASCII encodings?
commentDontrun should \dontrun sections be commented out?
commentDonttest should \donttest sections be commented out?

Details

These functions convert help documents: Rd2HTML produces HTML, Rd2txt produces plain text, Rd2latex produces LaTeX. Rd2ex extracts the examples in the format used by example and 

Each of the functions accepts a filename for an Rd file, and will use parse_Rd to parse it before applying the conversions or checks.

The difference between arguments Link and Link2 is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Before R 3.6.0, the default for Rd2latex was outputEncoding = "ASCII", including using the second option of \enc markup, because LaTeX versions did not provide enough coverage of UTF-8 glyphs for a long time.

Rd2txt will format text paragraphs to a width determined by width, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

Rd2txt will use directional quotes (see sQuote) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by Rd2txt are controlled by the options argument, documented with the Rd2txt_options function. Changes made using options are temporary, those made with Rd2txt_options are persistent.

When fragment = TRUE, the Rd file will be rendered with no processing of \Sexpr elements or conditional defines using #ifdef or #ifndef. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For Rd2latex, the output name is given an attribute "latexEncoding" giving the encoding of the file in a form suitable for use with the LaTeX `inputenc` package.

Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the 'encoding' section for there to be any hope of correct rendering.

For output, the outputEncoding argument will be used: outputEncoding = "" will choose the native encoding for the current system.

If the text cannot be converted to the outputEncoding, byte substitution will be used (see iconv): Rd2latex and Rd2ex give a warning.
Note

The \Sexpr{} macro is a new addition to Rd files. It includes R code that will be executed at one of three times: build time (when a package's source code is built into a tarball), install time (when the package is installed or built into a binary package), and render time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2021-11-11 at 06:33:13,
2. installed on 2021-11-11 at 06:33:13, and
3. rendered on 2021-11-11 at 06:37:38.

Examples

```r
## Not run:
## Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")
outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools",
                 stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools",
                 stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

## End(Not run)
```

---

**Rd2txt_options**

_Set Formatting Options for Text Help_

**Description**

This function sets various options for displaying text help.

**Usage**

Rd2txt_options(...)
Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

Details

This function persistently sets various formatting options for the \texttt{Rd2txt} function which is used in displaying text format help. Currently defined options are:

- \texttt{width} (default 80): The width of the output page.
- \texttt{minIndent} (default 10): The minimum indent to use in a list.
- \texttt{extraIndent} (default 4): The extra indent to use in each level of nested lists.
- \texttt{sectionIndent} (default 5): The indent level for a section.
- \texttt{sectionExtra} (default 2): The extra indentation for each nested section level.
- \texttt{itemBullet} (default "* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.
- \texttt{enumFormat} : A function to format item numbers in enumerated lists.
- \texttt{showURLs} (default \texttt{FALSE}): Whether to show URLs when expanding \texttt{\href} tags.
- \texttt{code_quote} (default \texttt{TRUE}): Whether to render \texttt{"code} and similar with single quotes.
- \texttt{underline_titles} (default \texttt{TRUE}): Whether to render section titles with underlines (via backspacing).

Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

Author(s)

Duncan Murdoch

Examples

```r
# The \texttt{itemBullet} is locale-specific
saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()
Rd2txt_options(saveOpts)
Rd2txt_options()
```
Rdiff

Difference R Output Files

Description

Given two R output files, compute differences ignoring headers, footers and some other differences.

Usage

Rdiff(from, to, useDiff = FALSE, forEx = FALSE, nullPointers = TRUE, Log = FALSE)

Arguments

from, to filepaths to be compared
useDiff should diff always be used to compare results?
forEx logical: extra pruning for ‘-Ex.Rout’ files to exclude the header.
nullPointers logical: should the displayed addresses of pointers be set to 0x00000000 before comparison?
Log logical: should the returned value include a log of differences found?

Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see sQuote) and on Windows, Windows’ so-called ‘smart quotes’, are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., <environment: 0x12345678>) are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b-like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag ‘-w’ is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

Mainly for use in examples, text from marker ‘> ## IGNORE_RDIFF_BEGIN’ up to (but not including) ‘> ## IGNORE_RDIFF_END’ is ignored.

Value

If Log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, 0L if and only if no differences were found.

The shell script run as R CMD Rdiff.
Rdindex

Rdindex

1865

Generate Index from Rd Files

Description
Print a 2-column index table with names and titles from given R documentation files to a given
output file or connection. The titles are nicely formatted between two column positions (typically
25 and 72, respectively).
Usage
Rdindex(RdFiles, outFile = "", type = NULL,
width = 0.9 * getOption("width"), indent = NULL)
Arguments
RdFiles

a character vector specifying the Rd files to be used for creating the index, either
by giving the paths to the files, or the path to a single directory with the sources
of a package.

outFile

a connection, or a character string naming the output file to print to. "" (the
default) indicates output to the console.

type

a character string giving the documentation type of the Rd files to be included in
the index, or NULL (the default). The type of an Rd file is typically specified via
the \docType tag; if type is "data", Rd files whose only keyword is datasets
are included as well.

width

a positive integer giving the target column for wrapping lines in the output.

indent

a positive integer specifying the indentation of the second column. Must not be
greater than width/2, and defaults to width/3.

Details
If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

RdTextFilter

Select Text in an Rd File

Description
This function blanks out all non-text in an Rd file, for spell checking or other uses.
Usage
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
drop = character(), keep = character(),
macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))


**Arguments**

- **ifile**: An input file specified as a filename or connection, or an "Rd" object from `parse_Rd`.
- **encoding**: An encoding name to pass to `parse_Rd`.
- **keepSpacing**: Whether to try to leave the text in the same lines and columns as in the original file.
- **drop**: Additional sections of the Rd to drop.
- **keep**: Sections of the Rd file to keep.
- **macros**: Macro definitions to assume when parsing. See `parse_Rd`.

**Details**

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as `aspell` can check only the text and report the position in the original file. (If `keepSpacing` is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags `\S3method`, `\S4method`, `\command`, `\docType`, `\email`, `\encoding`, `\file`, `\keyword`, `\link`, `\linkS4class`, `\method`, `\pkg`, and `\var` are skipped. Additional tags can be skipped by listing them in the `drop` argument; listing tags in the `keep` argument will stop them from being skipped. It is also possible to keep any of the `c("RCODE", "COMMENT", "VERB")` tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

**Note**

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

**Author(s)**

Duncan Murdoch

**See Also**

`aspell`, for which this is an acceptable filter.
Rdutils

Rd Utilities

Description
Utilities for computing on the information in Rd objects.

Usage
Rd_db(package, dir, lib.loc = NULL, stages = "build")

Arguments
package
a character string naming an installed package.
dir
a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
stages
if dir is specified and the database is being built from source, which stages of \Sexpr processing should be processed?

Details
Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running parse_Rd on the Rd source files in the package and processing platform conditionals and some \Sexpr macros.

See Also
parse_Rd

Examples

## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::.Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1:5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(db, tools:::.Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
**read.00Index**  
*Read 00Index-style Files*

**Description**

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

```r
read.00Index(file)
```

**Arguments**

- `file`  
  the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, `file` can be a `connection`, which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

**See Also**

- `formatDL` for the inverse operation of creating a 00Index-style file from items and their descriptions.

**showNonASCII**  
*Pick Out Non-ASCII Characters*

**Description**

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

**Usage**

```r
showNonASCII(x)
showNonASCIIfile(file)
```

**Arguments**

- `x`  
  a character vector.
- `file`  
  path to a file.
startDynamicHelp

Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

Usage

startDynamicHelp(start = TRUE)

Arguments

start logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running.

Details

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If options("help.ports") is set to a vector of non-zero integer values, startDynamicHelp will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable R_DISABLE_HTTPD to a non-empty value or options("help.ports") to 0.

startDynamicHelp is called by functions that need to use the server, so would rarely be called directly by a user.

Note that options(help_type = "html") must be set to actually make use of HTML help, although it might be the default for an R installation.
If the server cannot be started or is disabled, \texttt{help.start} will be unavailable and requests for HTML help will give text help (with a warning). The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.

**Value**

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

**See Also**

\texttt{help.start} and \texttt{help(help_type = "html")} will attempt to start the HTTP server if required \texttt{Rd2HTML} is used to render the package help pages.

---

**SweaveTeXFilter**

*Strip R Code out of Sweave File*

**Description**

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

**Usage**

\texttt{SweaveTeXFilter(ifile, encoding = "unknown")}

**Arguments**

- **ifile**: Input file or connection.
- **encoding**: Text encoding to pass to \texttt{readLines}.

**Details**

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

**Author(s)**

Duncan Murdoch

**See Also**

\texttt{aspell}, for which this is used with \texttt{filter = "Sweave"}. 
testInstalledPackage  Test Installed Packages

Description
These functions allow an installed package to be tested, or all base and recommended packages.

Usage
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".", types = c("examples", "tests", "vignettes"),
srcdir = NULL, Ropts = ",", ...)
testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
scope = c("both", "base", "recommended"),
types = c("examples", "tests", "vignettes"),
srcdir = NULL, Ropts = ",", ...)
testInstalledBasic(scope = c("basic", "devel", "both", "internet"))

Arguments
pkg name of an installed package.
lib.loc library path(s) in which to look for the package. See library.
outDir the directory into which to write the output files: this should already exist.
types type(s) of tests to be done.
errorsAreFatal logical: should testing terminate at the first error?
srcdir Optional directory to look for .save files.
Ropts Additional options such as ‘-d valgrind’ to be passed to R CMD BATCH when running examples or tests.
... additional arguments use when preparing the files to be run, e.g. commentDontrun and commentDonttest.
scope Which set(s) should be tested? Can be abbreviated.

Details
These tests depend on having the package example files installed (which is the default). If package-
specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default,
but will be if R CMD INSTALL --install-tests was used. Finally, the R code in any vignettes can
be extracted and tested.

Package tests are run in a ‘pkg-tests’ subdirectory of ‘outDir’, and leave their output there.
testInstalledBasic runs the basic tests, if installed. This should be run with LC_COLLATE=C set:
the function tries to set this by it may not work on all OSes. For non-English locales it may be
desirable to set environment variables LANGUAGE to ‘en’ and LC_TIME to ‘C’ to reduce the number
differences from reference results.

Except on Windows, if the environment variable TEST_MC_CORES is set to an integer greater than
one, testInstalledPackages will run the package tests in parallel using its value as the maximum
number of parallel processes.
The package-specific tests for the base and recommended packages are not normally installed, but make install-tests is provided to do so (as well as the basic tests).

Value

Invisibly 0L for success, 1L for failure.

texi2dvi  Compile LaTeX Files

Description

Run latex/pdflatex, makeindex and bibtex until all cross-references are resolved to create a dvi or a PDF file.

Usage

texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE, 
          texi2dvi = getOption("texi2dvi"), 
          texinputs = NULL, index = TRUE)

texi2pdf(file, clean = FALSE, quiet = TRUE, 
          texi2dvi = getOption("texi2dvi"), 
          texinputs = NULL, index = TRUE)

Arguments

file character string. Name of the LaTeX source file.

pdf logical. If TRUE, a PDF file is produced instead of the default dvi file (texi2dvi command line option ‘--pdf’).

clean logical. If TRUE, all auxiliary files created during the conversion are removed.

quiet logical. No output unless an error occurs.

texi2dvi character string (or NULL). Script or program used to compile a TeX file to dvi or PDF. The default (selected by "" or "texi2dvi" or NULL) is to look for a program or script named ‘texi2dvi’ on the path and otherwise emulate the script with system2 calls (which can be selected by the value "emulation"). See also ‘Details’.

texinputs NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.

index logical: should indices be prepared?

Details

texi2pdf is a wrapper for the common case of texi2dvi(pdf = TRUE).

Despite the name, this is used in R to compile LaTeX files, specifically those generated from vignettes and by the Rd2pdf script (used for package reference manuals). It ensures that the ‘R_HOME/share/texmf’ directory is in the TEXINPUTS path, so R style files such as ‘Sweave’ and ‘Rd’ will be found. The TeX search path used is first the existing TEXINPUTS setting (or the current directory if unset), then elements of argument texinputs, then ‘R_HOME/share/texmf’ and finally the default path. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.
The default option for `texi2dvi` is set from environment variable `R_TEXI2DVICMD`, and the default for that is set from environment variable `TEXI2DVI` or if that is unset, from a value chosen when `R` is configured.

A shell script `texi2dvi` is part of GNU’s `texinfo`. Several issues have been seen with released versions, so if yours does not work correctly try `R_TEXI2DVICMD=emulation`.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the ‘hyperref’ LaTeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.

**Value**

Invisible `NULL`. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if `clean = FALSE`).

**Note**

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this `R` wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (`texi2dvi` 5.0 and later; `texify.exe` from MiKTeX), option `--max-iterations=20` is used to avoid infinite retries.

The emulation mode supports `quiet = TRUE` from `R` 3.2.3 only. Currently `clean = TRUE` only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables `LATEX`, `PDFLATEX`, `MAKEINDEX` and `BIBTEX` for the full paths to the corresponding commands.

**Author(s)**

Originally Achim Zeileis but largely rewritten by R-core.

```
## S3 method for class 'packageIQR'
toHTML(x, ...)

## S3 method for class 'news_db'
toHTML(x, ...)
```

**Description**

This generic function generates a complete HTML page from an object.

**Usage**

```
toHTML(x, ...)
## S3 method for class 'packageIQR'
toHTML(x, ...)
## S3 method for class 'news_db'
toHTML(x, ...)
```
Arguments

x  An object to display.
...
Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to HTMLheader.

Value

A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

See Also

HTMLheader

Examples

cat(toHTML(demo(package = "base")), sep = "\n")

deprecated

Tools-deprecated

Description

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

Usage

package.dependencies(x, check = FALSE, depLevel = c("Depends", "Imports", "Suggests"))

gDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

installFoundDepends(depPkgList, ...)

vignetteDepends(vignette, recursive = TRUE, reduce = TRUE, local = TRUE, lib.loc = NULL)

Arguments

x  A matrix of package descriptions as returned by available.packages.
check  If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.
depLevel  Whether to look for Depends or Suggests level dependencies. Can be abbreviated.
depMtrx  a dependency matrix as from package.dependencies().
pkg the name of the package
instPkgs a matrix specifying all packages installed on the local system, as from installed.packages
recursive whether or not to include indirect dependencies.
local whether or not to search only locally
reduce whether or not to collapse all sets of dependencies to a minimal value
lib.loc what libraries to use when looking for installed packages. NULL indicates all library directories in the current .libPaths(). Note that lib.loc is not used in getDepList() and deprecated there.

depPkgList A Found element from a pkgDependsList object
... Arguments to pass on to install.packages

vignette the path to the vignette source

Deprecated, Defunct

---

toRd Generic Function to Convert Object to a Fragment of Rd Code

Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

Usage

toRd(obj, ...)  
# S3 method for class 'bibentry'  
toRd(obj, style = NULL, ...)

Arguments

obj The object to be rendered.
style The style to be used in converting a bibentry object.
... Additional arguments used by methods.

Details

See bibstyle for a discussion of styles. The default style = NULL value gives the default style.

Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts obj to mode character, then escapes any Rd markup within it. The bibentry method converts an object of that class to markup appropriate for use in a bibliography.
toTitleCase  

Convert Titles to Title Case

Description

Convert a character vector to title case, especially package titles.

Usage

toTitleCase(text)

Arguments

text  

a character vector.

Details

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

Value

A character vector of the same length as text, without names.

undoc  

Find Undocumented Objects

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

undoc(package, dir, lib.loc = NULL)

Arguments

package  
a character string naming an installed package.

dir  
a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively.

lib.loc  
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
**Details**

This function is useful for package maintainers mostly. In principle, all user-level R objects should be documented.

The base package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments .ArgsEnv and .GenericArgsEnv in the base package that are used for various purposes: undoc("base") checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

**Value**

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a print method for nicely displaying the information contained in such objects.

**See Also**

codoc, QC

**Examples**

```r
undoc("tools")  # Undocumented objects in 'tools'
```

---

**update_PACKAGES**

Update Existing PACKAGES Files

**Description**

Update an existing repository by reading the PACKAGES file, retaining entries which are still valid, removing entries which are no longer valid, and only processing built package tarballs which do not match existing entries.

update_PACKAGES can be much faster than write_PACKAGES for small-moderate changes to large repository indexes, particularly in non-strict mode (see Details).

**Usage**

```r
update_PACKAGES(dir = ".", fields = NULL, type = c("source", "mac.binary", "win.binary"), verbose.level = as.integer(dryrun), latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz", strict = TRUE, dryrun = FALSE)
```

**Arguments**

- `dir` See write_PACKAGES
- `fields` See write_PACKAGES
- `type` See write_PACKAGES
- `verbose.level` (0, 1, 2) What level of informative messages which should be displayed throughout the process. Defaults to 0 if dryrun is FALSE (the default) and 1 otherwise. See details for more information.
- `latestOnly` See write_PACKAGES
addFiles  See write_PACKAGES
rds_compress  See write_PACKAGES
strict  logical. Should 'strict mode' be used when checking existing PACKAGES entries. See details. Defaults to TRUE.
dryrun  logical. Should the updates to existing PACKAGES files be computed but NOT applied. Defaults to FALSE.

Details

Throughout this section, package tarball is defined to mean any archive file in dir whose name can be interpreted as <package>_<version>_<ext> - with _<ext> the appropriate extension for built packages of type type - (or that is pointed to by the File field of an existing PACKAGES entry). Novel package tarballs are those which do not match an existing PACKAGES file entry.

update_PACKAGES calls directly down to write_PACKAGES with a warning (and thus all package tarballs will be processed), if any of the following conditions hold:

- type is win.binary and strict is TRUE (no MD5 checksums are included in win.binary PACKAGES files)
- No PACKAGES file exists under dir
- A PACKAGES file exists under dir but is empty
- fields is not NULL and one or more specified fields are not present in the existing PACKAGES file

update_PACKAGES avoids (re)processing package tarballs in cases where a PACKAGES file entry already exists and appears to remain valid. The logic for detecting still-valid entries is as follows:

Any package tarball which was last modified more recently than the existing PACKAGES file is considered novel; existing PACKAGES entries appearing to correspond to such tarballs are always considered stale and replaced by newly generated ones. Similarly, all PACKAGES entries that do not correspond to any package tarball found in dir are considered invalid and are excluded from the resulting updated PACKAGES files.

When strict is TRUE, PACKAGES entries that match a package tarball (by package name and version) are confirmed via MD5 checksum; only those that pass are retained as valid. All novel package tarballs are fully processed by the standard machinery underlying write_PACKAGES and the resulting entries are added. Finally, if latestOnly is TRUE, package-version pruning is performed across the entries.

When strict is FALSE, package tarballs are assumed to encode correct metadata in their filenames. PACKAGES entries which appear to match a package tarball are retained as valid (No MD5 checksum testing occurs). If latestOnly is TRUE, package-version pruning is performed across the full set of retained entries and novel package tarballs before the processing of the novel tarballs, at significant computational and time savings in some situations. After the optional pruning, any relevant novel package tarballs are processed via the standard machinery and added to the set of retained entries.

In both cases, after the above process concludes, entries are sorted alphabetically by the string concatenation of Package and Version. This should match the entry order write_PACKAGES outputs.

The fields within the entries are ordered as follows: canonical fields - i.e., those appearing as columns when available.packages is called on a CRAN mirror - appear first in their canonical order, followed by any non-canonical fields.

After entry and field reordering, the final database of PACKAGES entries is written to all three PACKAGES files, overwriting the existing versions.
When verbose.level is 0, no extra messages are displayed to the user. When it is 1, detailed information about what is happening is conveyed via messages, but underlying machinery from `write_PACKAGES` is invoked with verbose = FALSE. Behavior when verbose.level is 2 is identical to verbose.level 1 with the exception that underlying machinery from `write_PACKAGE` is invoked with verbose = TRUE, which will individually list every processed tarball.

**Note**

While both strict and non-strict modes can offer speedups when updating small percentages of large repositories, non-strict mode is much faster and is recommended in situations where the assumption it makes about tarballs' filenames encoding accurate information is safe.

**Note**

Users should expect significantly smaller speedups over `write_PACKAGES` in the type == "win.binary" case on at least some operating systems. This is due to `write_PACKAGES` being significantly faster in this context, rather than `update_PACKAGES` being slower.

**Author(s)**

Gabriel Becker (adapted from previous, related work by him in the `switchr` package which is copyright Genentech, Inc.)

**See Also**

`write_PACKAGES`

**Examples**

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
data(Package1)
write_PACKAGES("c:/myFolder/myRepository") # on Windows
data(Package2)
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
type = "win.binary") # on Linux
data(Package3)
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
type = "win.binary") # on Linux

## End(Not run)
```
Arguments

pkgdir  The path to the package directory.

pkg  The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file.

version  The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file.

mergeOpts  a string, by default empty, of options to msgmerge in addition to "--update". Since R 4.2.0, "--no-wrap" is used when called from file.path(R.home("po"), "Makefile").

copyright, bugs  optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files.

Details

This performs a series of steps to prepare or update messages in the package.

• If the package sources do not already have a ‘po’ directory, one is created.

• xgettext2pot is called to create/update a file ‘po/R-pkgname.pot’ containing the translatable messages in the package.

• All existing files in directory po with names ‘R-lang.po’ are updated from ‘R-pkgname.pot’, checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.

• In a UTF-8 locale, a ‘translation’ ‘R-en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

• The remaining steps are done only if file ‘po/pkgname.pot’ already exists. The ‘src/*.c,cc,cpp,m,mm’ files in the package are examined to create a file ‘po/pkgname.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.

• All existing files in directory po with names ‘lang.po’ are updated from ‘pkgname.pot’, checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.

• In a UTF-8 locale, a ‘translation’ ‘en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/pkgname.pot’ in the package sources and run this function again.

pkg = "base" is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

System requirements

This function requires the following tools from the GNU gettext-tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

userdir  

R User Directories

Description
Directories for storing R-related user-specific data, configuration and cache files.

Usage
R_user_dir(package, which = c("data", "config", "cache"))

Arguments
package  a character string giving the name of an R package
which  a character string indicating the kind of file(s) of interest. Can be abbreviated.

Details
For desktop environments using X Windows, the freedesktop.org project (formerly X Desktop Group, XDG) developed the XDG Base Directory Specification (https://specifications.freedesktop.org/basedir-spec) for standardizing the location where certain files should be placed. CRAN package rappdirs provides these general locations with appropriate values for all platforms for which R is available.

R_user_dir specializes the general mechanism to R package specific locations for user files, by providing package specific subdirectories inside a ‘R’ subdirectory inside the “base” directories appropriate for user-specific data, configuration and cache files (see the examples), with the intent that packages will not interfere if they work within their respective subdirectories.

The locations of these base directories can be customized via the specific environment variables R_USER_DATA_DIR, R_USER_CONFIG_DIR and R_USER_CACHE_DIR. If these are not set, the general XDG-style environment variables XDG_DATA_HOME, XDG_CONFIG_HOME and XDG_CACHE_HOME are used if set, and otherwise, defaults appropriate for the R platform in use are employed.

Examples
## IGNORE_RDIFF_BEGIN
R_user_dir("FOO", "cache")
## IGNORE_RDIFF_END

vignetteEngine  Set or Get a Vignette Processing Engine

Description
Vignettes are normally processed by Sweave, but package writers may choose to use a different engine (e.g., one provided by the knitr, noweb or R.rsp packages). This function is used by those packages to register their engines, and internally by R to retrieve them.
Usage

vignetteEngine(name, weave, tangle, pattern = NULL, package = NULL, aspell = list())

Arguments

name the name of the engine.
weave a function to convert vignette source files to PDF/HTML or intermediate LaTeX output.
tangle a function to convert vignette source files to R code.
pattern a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern.
package the package registering the engine. By default, this is the package calling vignetteEngine.
aspell a list with element names filter and/or control giving the respective arguments to be used when spell checking the text in the vignette source file with aspell.

Details

If weave is missing, vignetteEngine will return the currently registered engine matching name and package.

If weave is NULL, the specified engine will be deleted.

Other settings define a new engine. The weave and tangle functions must be defined with argument lists compatible with function(file,...). Currently the ... arguments may include logical argument quiet and character argument encoding; others may be added in future. These are described in the documentation for Sweave and Stangle.

The weave and tangle functions should return the filename of the output file that has been produced. Currently the weave function, when operating on a file named '<name><pattern>' must produce a file named '<name>[.](tex|pdf|html)'. The '.tex' files will be processed by pdflatex to produce '.pdf' output for display to the user; the others will be displayed as produced. The tangle function must produce a file named '<name>[.[rRsS]]' containing the executable R code from the vignette. The tangle function may support a split = TRUE argument, and then it should produce files named '<name>.*[.[rRsS]]'.

The pattern argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to NULL, the default pattern "[.]\([rRsS]\)\(nw|tex\)\)$" is used.

Value

If the engine is being deleted, NULL. Otherwise a list containing components

name The name of the engine
package The name of its package
pattern The pattern for vignette input files
weave The weave function
tangle The tangle function

Examples

str(vignetteEngine("Sweave"))

describe vignetteInfo

Basic Information about a Vignette

Description

Provide basic information including package and dependency of a vignette from its source file.

Usage

vignetteInfo(file)

Arguments

file file name of the vignette.

Value

a list with components, each a possibly empty character:

file the basename of the file.
title the vignette title.
depends the package dependencies.
keywords keywords if provided.
engine the vignette engine such as "Sweave", "knitr", etc.

Note

vignetteInfo(file)$depends is a substitute for the deprecated vignetteDepends() functionality.

package_dependencies

Examples

gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vi <- vignetteInfo(gridEx)
str(vi)
**write_PACKAGES**  
*Generate PACKAGES Files*

**Description**

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

**Usage**

```r
write_PACKAGES(dir = ".", fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
               latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
               validate = FALSE)
```

**Arguments**

- **dir**  
  Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to.

- **fields**  
  a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default).

  The default corresponds to the fields needed by `available.packages`: "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if `addFiles = TRUE` and the path to the subdirectory in field "Path" if subdirectories are used.

- **type**  
  Type of packages: currently source `.tar.{gz,bz2,xz}` archives, and macOS or Windows binary (`.tgz` or `.zip`, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.

- **verbose**  
  logical. Should packages be listed as they are processed?

- **unpacked**  
  a logical indicating whether the package contents are available in unpacked form or not (default).

- **subdirs**  
  either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed).

- **latestOnly**  
  logical: if multiple versions of a package are available should only the latest version be included?

- **addFiles**  
  logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.

- **rds_compress**  
  The type of compression to be used for ‘PACKAGES.rds’: see `saveRDS`. The default is the one found to give maximal compression, and is as used on CRAN.

- **validate**  
  a logical indicating whether ‘DESCRIPTION’ files should be validated, and the corresponding packages skipped in case this finds problems.
write_PACKAGES scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files, where the first two represent the information in DCF format, and the third serializes it via saveRDS.

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when `foo_1.0` depends on `R >= 2.15.0` but `foo_0.9` is available which depends on `R >= 2.11.0`.

Support for repositories with subdirectories and hence for `subdirs != FALSE` depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) via a "File" field in the 'PACKAGES' files can be used by download.packages. If the file names are not of the standard form, use `addFiles = TRUE`.

type = "win.binary" uses `unz` connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory `dir`, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by available.packages processing the downloaded file(s). For large repositories it is likely to be beneficial to use `rds_compress = "xz"`.

Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

Note

Processing `.tar.gz` archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

Author(s)

Uwe Ligges and R-core.

See Also

See `read.dcf` and `write.dcf` for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files. See `update_PACKAGES` for efficiently updating existing 'PACKAGES' and 'PACKAGES.gz' files.

Examples

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository")  # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
               type = "win.binary")  # on Linux

## End(Not run)
```
xgettext  

Extract Translatable Messages from R Files in a Package

Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a source package, extract the unique arguments passed to stop, warning, message, gettext and gettextf, or to ngettext.

Usage

xgettext(dir, verbose = FALSE, asCall = TRUE)

xngettext(dir, verbose = FALSE)

xgettext2pot(dir, potFile, name = “R”, version, bugs)

Arguments

dir  
the directory of a source package, i.e., with a ‘./R’ sub directory.

verbose  
logical: should each file be listed as it is processed?

asCall  
logical: if TRUE each argument is converted to string and returned whole, otherwise the string literals within each argument are extracted (recursively). See Examples.

potFile  
name of po template file to be produced. Defaults to ‘R-pkgname.pot’ where pkgname is the basename of ‘dir’.

name, version, bugs
as recorded in the template file: version defaults the version number of the currently running R, and bugs to “bugs.r-project.org”.

Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to gettext, gettextf, stop, warning, and message, as it is by the internal code that passes strings for translation.

We look to see if the matched functions were called with domain = NA. If so, when asCall is true, the whole call is omitted. Note that a call might contain a nested call to gettext (or warning, etc.) whose strings would be visible if asCall is false.

xgettext2pot calls xgettext and then xngettext, and writes a PO template file (to potFile) for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for ngettext calls (and the rules are not stated in the Gettext manual, but msgfmt complains if there is duplication between the sets.).

If applied to the base package, this also looks in the ‘.R’ files in ‘R_HOME/share/R’.

Value

For xgettext, a list of objects of class "xgettext" (which has a print method), one per source file that contains potentially translatable strings.

For xngettext, a list of objects of class "xngettext", which are themselves lists of length-2 character vectors.
See Also

update_pkg_po() which calls xgettext2pot().

Examples

## Not run: ## in a source-directory build (not typical!) of R;
## otherwise, download and unpack the R sources, and replace
## R.home() by "<my_path_to_source_R>" :
xgettext(file.path(R.home(), "src", "library", "splines"))

## Create source package-like <tmp>/R/foo.R and get text from it:
tmpPkg <- tempdir()
tmpRDir <- file.path(tmpPkg, "R")
dir.create(tmpRDir, showWarnings = FALSE)
fnChar <- paste(sep = "\n",
  "foo <- function(x) {",
  " if (x < -1) stop('too small'),",
  " # messages unduplicated (not so for ngettext),",
  " if (x < -.5) stop('too small'),",
  " if (x < 0) {",
  " warning('",
  " 'sqrt(x) is', sqrt(as.complex(x))",",
  " ', which may be too small'),",
  " )",
  " },
  " }",
  " # calls with domain=NA are skipped",
  " if (x == 0) cat(gettext('x is 0!
', domain=NA))",
  " # gettext strings may be ignored due to 'outer' domain=NA",
  " if (x > 10) stop('x is ', gettextf("%.2f", x), domain=NA",
  " x",
  " )")
writeLines(fnChar, con = file.path(tmpRDir, "foo.R"))

## [[1]] : suppressing (tmpfile) name to make example Rdiff-able
xgettext(tmpPkg, asCall=TRUE )[[1]] # default; shows ' sqrt(as.complex(x)) '
xgettext(tmpPkg, asCall=FALSE)[[1]] # doesn't; but then '%.2f'

**adist**  
*Approximate String Distances*

**Description**

Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another.

**Usage**

```
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,  
partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
```
Arguments

x a character vector. Long vectors are not supported.
y a character vector, or NULL (default) indicating taking x as y.
costs a numeric vector or list with names partially matching 'insertions', 'deletions' and 'substitutions' giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations.
counts a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the "counts" attribute of the return value.
fixed a logical. If TRUE (default), the x elements are used as string literals. Otherwise, they are taken as regular expressions and partial = TRUE is implied (corresponding to the approximate string distance used by agrep with fixed = FALSE).
partial a logical indicating whether the transformed x elements must exactly match the complete y elements, or only substrings of these. The latter corresponds to the approximate string distance used by agrep (by default).
ignore.case a logical. If TRUE, case is ignored for computing the distances.
useBytes a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character.

details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for partial = FALSE, currently using a dynamic programming algorithm (see, e.g., https://en.wikipedia.org/wiki/Levenshtein_distance) with space and time complexity $O(mn)$, where $m$ and $n$ are the lengths of $s$ and $t$, respectively. Additionally computing the transformation sequence and counts is $O(\max(m,n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of t with minimal distance to the pattern s (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., https://en.wikipedia.org/wiki/Approximate_string_matching. This distance is computed for partial = TRUE using 'tre' by Ville Laurikari (https://github.com/laurikari/tre) and corresponds to the distance used by agrep. In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between s and t can be different from the distance between t and s.

value

A matrix with the approximate string distances of the elements of x and y, with rows and columns corresponding to x and y, respectively.

If counts is TRUE, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of x, the elements of y, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if partial = FALSE, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements 'M', 'I', 'D' and 'S' indicating a match, insertion, deletion and substitution, respectively. If partial = TRUE, the offsets (positions of the first and last element)
of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets − 1 in case of no match).

See Also

agrep for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

```r
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

Description

Gives an audible or visual signal to the user.

Usage

```r
alarm()
```

Details

alarm() works by sending a "\a" character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see flush.console).

Value

No useful value is returned.

Examples

alarm()
Description

`apropos()` returns a character vector giving the names of objects in the search list matching (as a regular expression) what.

`find()` returns where objects of a given name can be found.

Usage

```r
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

Arguments

- `what`: character string. For `simple.words = FALSE` the name of an object; otherwise a regular expression to match object names against.
- `where`, `numeric`: a logical indicating whether positions in the search list should also be returned
- `ignore.case`: logical indicating if the search should be case-insensitive, `TRUE` by default.
- `mode`: character; if not "any", only objects whose `mode` equals `mode` are searched.
- `simple.words`: logical; if `TRUE`, the what argument is only searched as a whole word.

Details

If `mode !="any"` only those objects which are of mode `mode` are considered.

`find` is a different user interface for a similar task to `apropos`. By default (`simple.words == TRUE`), only whole names are matched. Unlike `apropos`, matching is always case-sensitive.

Unlike the default behaviour of `ls`, names which begin with a `'.'` are included (and these are often ‘internal’ objects — as from R 3.4.0 most such are excluded).

Value

For `apropos`, a character vector sorted by name. For `where = TRUE` this has names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names or (for `numeric = TRUE`) a numerical vector of positions on the search path with names the names of the corresponding environments.

Author(s)

Originally, Kurt Hornik and Martin Maechler (May 1997).

See Also

`glob2rx` to convert wildcard patterns to regular expressions.

`objects` for listing objects from one place, `help.search` for searching the help system, `search` for the search path.
Examples

require(stats)

## Not run: apropos("lm")
apropos("GLM")  # several
apropos("GLM", ignore.case = FALSE)  # not one
apropos("lq")

cor <- 1:pi
find("cor")  #> ".GlobalEnv"  "package:stats"
find("cor", numeric = TRUE)  # numbers with these names
find("cor", numeric = TRUE, mode = "function")  # only the second one
rm(cor)

## Not run: apropos ".", mode="list")  # a long list

# need a DOUBLE backslash '\\' (in case you don't see it anymore)
apropos("\\(")

# everything % not diff-able
length(apropos("."))

# those starting with 'pr'
apropos("pr")

# the 1-letter things
apropos(".$")
# the 1-2-letter things
apropos("..$")
# the 2-to-4 letter things
apropos(".(2,4)$")

# the 8-and-more letter things
apropos("^.(8)$")
table(nchar(apropos("^.(8)$")))

---

aregexec

*Approximate String Match Positions*

Description

Determine positions of approximate string matches.

Usage

aregexec(pattern, text, max.distance = 0.1, costs = NULL,
ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)

Arguments

pattern  
a non-empty character string or a character string containing a regular expression
(for fixed = FALSE) to be matched. Coerced by as.character to a string if possible.
text character vector where matches are sought. Coerced by `as.character` to a character vector if possible.

max.distance maximum distance allowed for a match. See `agrep`.

costs cost of transformations. See `agrep`.

ignore.case a logical. If TRUE, case is ignored for computing the distances.

fixed If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.

useBytes a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.

Details

`aregexec` provides a different interface to approximate string matching than `agrep` (along the lines of the interfaces to exact string matching provided by `regexec` and `grep`).

Note that by default, `agrep` performs literal matches, whereas `aregexec` performs regular expression matches.

See `agrep` and `adist` for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as "bytes".

Value

A list of the same length as `text`, each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute "match.length" an integer vector giving the lengths of the matches (or −1 for no match).

See Also

`regmatches` for extracting the matched substrings.

Examples

```r
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

---

**arrangeWindows**

Rearrange Windows on MS Windows

Description

This function allows you to tile or cascade windows, or to minimize or restore them (on Windows, i.e. when `(.Platform$OS.type == "windows")`). This may include windows not “belonging” to R.
Usage

arrangeWindows(action, windows, preserve = TRUE, outer = FALSE)

Arguments

- **action**: a character string, the action to perform on the windows. The choices are `c("vertical", "horizontal", "cascade", "minimize", "restore")` with default "vertical"; see the 'Details' for the interpretation. Abbreviations may be used.
- **windows**: a list of window handles, by default produced by `getWindowsHandles()`. If `windows` is unspecified, it is set to the result of `getWindowsHandles()` (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the `getWindowsHandles` man page for a discussion of the optional arguments to that function.
- **preserve**: If TRUE, when tiling preserve the outer boundary of the collection of windows; otherwise make them as large as will fit.
- **outer**: This argument is only used in MDI mode. If TRUE, tile the windows on the system desktop. Otherwise, tile them within the MDI frame.

Details

The actions are as follows:

- "vertical" Tile vertically.
- "horizontal" Tile horizontally.
- "cascade" Cascade the windows.
- "minimize" Minimize all of the windows.
- "restore" Restore all of the windows to normal size (not minimized, not maximized).

The tiling and cascading are done by the standard Windows API functions, but unlike those functions, they will apply to all of the windows in the `windows` list.

By default, `windows` is set to the result of `getWindowsHandles()` (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the `getWindowsHandles` man page for a discussion of the optional arguments to that function.

When `action = "restore"` is used with `windows` unspecified, `minimized = TRUE` is added to the argument list of `getWindowsHandles` so that minimized windows will be restored.

In MDI mode, by default tiling and cascading will happen within the R GUI frame. However, if `outer = TRUE`, tiling is done on the system desktop. This will generally not give desirable results if any R child windows are included within windows.

Value

This function is called for the side effect of arranging the windows. The list of window handles is returned invisibly.

Note

This is only available on Windows.

Author(s)

Duncan Murdoch
askYesNo

Ask a Yes/No Question

Description

askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.

Usage

askYesNo(msg, default = TRUE, 
  prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))), 
  ...)

Arguments

msg
  The prompt message for the user.

default
  The default response.

prompts
  Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call.

...
  Additional parameters, ignored by the default function.

Details

askYesNo will accept case-independent partial matches to the prompts. If no response is given the value of default will be returned; if a non-empty string that doesn’t match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for prompts, it will be called as fn(msg = msg, default = default, prompts = prompts, ...). On Windows, the GUI uses the unexported utils:::askYesNoWinDialog function for this purpose.

If strings (or a string such as "Y/N/C") are given as prompts, the choices will be mapped to lowercase for the non-default choices, and left as-is for the default choice.

Value

TRUE for yes, FALSE for no, and NA for cancel.

See Also

getWindowsHandles

Examples

## Not run: ## Only available on Windows:
arrangeWindows("v")
# This default is useful only in SDI mode: it will tile any Firefox window
# along with the R windows
.arrangeWindowsDefaults <- list(c("R", "all"), pattern = c("", "Firefox"))

   askYesNo("Do you want to use askYesNo?")

aspell Spell Check Interface

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

aspell(files, filter, control = list(), encoding = "unknown",
program = NULL, dictionaries = character())

Arguments

files a character vector with the names of files to be checked.
filter an optional filter for processing the files before spell checking, given as either a function (with formals ifile and encoding), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See Details for available filters. If missing or NULL, no filtering is performed.
control a list or character vector of control options for the spell checker.
encoding the encoding of the files. Recycled as needed.
program a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.
dictionaries a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted.

Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See http://aspell.net, https://hunspell.github.io/ and https://www.cs.hmc.edu/~geoff/ispell.html, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "Rd" (corresponding to RdTextFilter), "Sweave" (corresponding to SweaveTeXFilter), "R", "pot", "dcf" and "md".
Filter "R" is for R code and extracts the message string constants in calls to message, warning, stop, packageStartupMessage, gettext, gettextf, and ngettext (the unnamed string constants for the first five, and fmt and msg1/msg2 string constants, respectively, for the latter two).

Filter "pot" is for message string catalog '.pot' files. Both have an argument ignore allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using "[^\t][^\t]*[^\t[:punct:]]" ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument keep (a character vector with the respective field names). By default, 'Title' and 'Description' fields are kept.

Filter "md" is for files in Markdown format ('.md' and '.Rmd' files), and needs packages commonmark and xml2 to be available.

The print method for the objects returned by aspell has an indent argument controlling the indentation of the positions of possibly misspelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension '.rds' obtained by serializing character vectors of word lists using saveRDS. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker's personal dictionary (option '-p'): hence, the default personal dictionary is not used in this case.

Value
A data frame inheriting from aspell (which has a useful print method) with the information about possibly misspelled words.

References

aspell-utils for utilities for spell checking packages.

Examples

## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Swx", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
aspell-utils  Spell Check Utilities

Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

Usage

aspell_package_Rd_files(dir, drop = c("\author", "\references"),
control = list(), program = NULL,
dictionaries = character())
aspell_package_vignettes(dir,
control = list(), program = NULL,
dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
aspell_write_personal_dictionary_file(x, out, language = "en",
program = NULL)

Arguments

dir  a character string specifying the path to a package’s root directory.
drop a character vector naming additional Rd sections to drop when selecting text via
RdTextFilter.
control a list or character vector of control options for the spell checker.
program a character string giving the name (if on the system path) or full path of the
spell check program to be used, or NULL (default). By default, the system path
is searched for aspell, hunspell and ispell (in that order), and the first one
found is used.
dictionaries a character vector of names or file paths of additional R level dictionaries to use.
See aspell.
ignore a character vector with regular expressions to be replaced by blanks when filter-
ing the message strings.
x a character vector, or the result of a call to aspell().
out a character string naming the personal dictionary file to write to.
language a character string indicating a language as used by Aspell.

Details

Functions aspell_package_Rd_files, aspell_package_vignettes,
aspell_package_R_files and aspell_package_C_files perform spell checking on the
Rd files, vignettes, R files, and C-level messages of the package with root directory dir. They
determine the respective files, apply the appropriate filters, and run the spell checker.
See aspell for details on filters.
The C-level message string are obtained from the 'po/PACKAGE.pot' message catalog file, with
PACKAGING the basename of dir. See the section on 'C-level messages' in 'Writing R Extensions' for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands \Sexpr, \citep, \code, \pkg, \proglang and \samp. Further commands can be skipped by adding --add-tex-command options to the control argument. E.g., to skip both option and parameter of \mycmd, add --add-tex-command='mycmd op'.

Suitable values for control, program, dictionaries, drop and ignore can also be specified using a package defaults file which should go as 'defaults.R' into the '.aspell' subdirectory of dir, and provides defaults via assignments of suitable named lists, e.g.,

```r
vignettes <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to Rd_files, R_files and C_files for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options '--master=en_US' and '--add-extra-dicts=en_GB' to Aspell and control options '-d en_US,en_GB' to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function aspell_write_personal_dictionary_file to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., '.rds' files obtained by serializing character vectors of such words using \saveRDS. For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the '.aspell' subdirectory.

aspell

### available.packages

List Available Packages at CRAN-like Repositories

**Description**

available.packages returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

**Usage**

```r
available.packages(contriburl = contrib.url(repos, type), method,
fields = NULL, type = getOption("pkgType"),
filters = NULL, repos = getOption("repos"),
ignore_repo_cache = FALSE, max_repo_cache_age,
quiet = TRUE, ...)
```
Arguments

contriburl  URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD.

method  download method, see download.file.

type  character string, indicate which type of packages: see install.packages. If type = "both" this will use the source repository.

fields  a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

filters  a character vector or list or NULL (default). See ‘Details’.

type  character vector, the base URL(s) of the repositories to use.

ignore_repo_cache  logical. If true, the repository cache is never used (see ‘Details’).

max_repo_cache_age  any cached values older than this in seconds will be ignored. See ‘Details’.

quiet  logical, passed to download.file(); change only if you know what you are doing.

...  allow additional arguments to be passed from callers (which might be arguments to future versions of this function). Currently these are all passed to download.file().

Details

The list of packages is either copied from a local mirror (specified by a ‘file:///’ URI) or downloaded. If downloaded and ignore_repo_cache is false (the default), the list is cached for the R session in a per-repository file in tempdir() with a name like

repos_http%3a%2f%2fcran.r-project.org%2fsrch%2fcontrib.rds

The cached values are renewed when found to be too old, with the age limit controlled via argument max_repo_cache_age. This defaults to the current value of the environment variable R_AVAILABLE_PACKAGES_CACHE_CONTROL_MAX_AGE, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument filters can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as install.packages: this value corresponds to getOption("available_packages_filters") and to c("R_version", "OS_type", "subarch", "duplicates") if that is unset or set to NULL.

The built-in filters are

"R_version" Exclude packages whose R version requirements are not met.

"OS_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and vice versa.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in contriburl) with the latest version if that is in more than one repository.
"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., https://en.wikipedia.org/wiki/FOSS) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be known to be FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied before the default "duplicates" filter, so cannot be used with add = TRUE.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by available.packages, and return a matrix consisting of a subset of the rows of the argument.

The special 'filter' add = TRUE appends the other elements of the filter list to the default filters.

Value

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including install.packages.

See Also

install.packages, download.packages, contrib.url.

The 'R Installation and Administration' manual for how to set up a repository.

Examples

## Not run:
## Count package licenses
db <- available.packages(filters = "duplicates")
table(db[,"License"])

## Use custom filter function to only keep recommended packages
## which do not require compilation
available.packages(filters = list(
  add = TRUE,
  function (db) db[db[,"Priority"] %in% "recommended" &
  db[,"NeedsCompilation"] == "no", ]
))

## Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters = c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))
## Give priority to released versions on CRAN, rather than development
## versions on R-Forge etc.
```r
options(available_packages_filters =
c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))
```
## End(Not run)

### Description

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

### Usage

```r
R CMD BATCH [options] infile [outfile]
```

### Arguments

- **infile**: the name of a file with R code to be executed.
- **options**: a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If `infile` starts with a `'-`', use `--` as the final option. The default options are `--restore --save --no-readline`.
  (Without `--no-readline` on Windows.)
- **outfile**: the name of a file to which to write output. If not given, the name used is that of `infile`, with a possible `.R` extension stripped, and `.Rout` appended.

### Details

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option `--no-echo`.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression `proc.time()` will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option `--no-timing`.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after the default options (see the description of the `options` argument) and before any options given on the command line.

### Note

On Unix-alikes only: Unlike Splus BATCH, this does not run the R process in the background. In most shells,

```r
R CMD BATCH [options] infile [outfile] &
```

will do so.
bibentry

Bibliography Entries

Description

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

Usage

bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
    key = NULL, ..., other = list(),
    mheader = NULL, mfooter = NULL)

## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)

## S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL,
    citation.bibtex.max = getOption("citation.bibtex.max", 1),
    bibtex = length(x) <= citation.bibtex.max,
    sort = FALSE, macros = NULL, ...)

## S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)

## S3 method for class 'citation'
print(x, style = "citation", ...)

## S3 method for class 'citation'
format(x, style = "citation", ...)

Arguments

bibtype a character string with a BibTeX entry type. See Entry Types for details.
textVersion a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if format(x, style = "text") works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a textVersion should be provided.
header a character string with optional header text.
footer a character string with optional footer text.
key a character string giving the citation key for the entry.
... for bibentry: arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. Arguments with empty values are dropped. See Entry Fields for details.

For the print() method, extra arguments to pass to the renderer which typically includes the format() method.

For the citation class methods, arguments passed to the next method, i.e., the corresponding bibentry one.
other  a list of arguments as in ... (useful in particular for fields named the same as formals of bibentry).
mheader  a character string with optional “outer” header text.
mfooter  a character string with optional “outer” footer text.
x  an object inheriting from class “bibentry”.
style  an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see Details.
decreasing  logical, passed to order indicating the sort direction.
.bibstyle  a character string naming a bibliography style.
citation.bibtex.max  (deprecated, use bibtex = T|F instead!) a number, say m, indicating that the bibtex code should be given in addition to the formatted tex when there are not more than m entries. The default is taken as getOption("citation.bibtex.max", 1) which is 1 typically. For example, to see no bibtex at all, you can change the default by options(citation.bibtex.max = 0).
bibtex  logical indicating if bibtex code should be given additionally; currently applies only to style = "citation". The default depends on on the number of (bib) entries and getOption("citation.bibtex.max").
sort  logical indicating if bibentries should be sorted, using bibstyle(.bibstyle)$sortKeys(x).
macros  a character string or an object with already loaded Rd macros, see Details.
drop  logical used as x[..., drop=drop] inside the sort() method.

Details

The bibentry objects created by bibentry can represent an arbitrary positive number of references. One can use c() to combine bibentry objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use bibentry to directly create a multiple reference object by “vectorizing” the given arguments, i.e., use character vectors instead of character strings.

The print method for bibentry objects provides a choice between seven different styles: plain text (style "text"), BibTeX ("Bibtex"), a mixture of plain text and BibTeX as traditionally used for citations ("citation"), HTML ("html"), LaTeX ("latex"), R code ("R"), and a simple copy of the textVersion elements (style "textVersion"). The "text", "html" and "latex" styles make use of the .bibstyle argument using the bibstyle function. In addition, one can use the macros argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via loadRdMacros, or an object with macros already loaded.

When printing bibentry objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

The print method is based on a format method which provides the same styles, and for formatting as R code a choice between giving a character vector with one bibentry() call for each bibentry (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with c() if there is more than one bibentry. This can be contro-
to 1) determines for up to how many citation bibentries text style is shown together with bibtex, automatically.

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are NULL).

There is also a toBibtex method for direct conversion to BibTeX.

Value

bibentry produces an object of class "bibentry".

Entry Types

bibentry creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

Article: An article from a journal or magazine.
InBook: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.
InCollection: A part of a book having its own title.
InProceedings: An article in a conference proceedings.
Misc: Use this type when nothing else fits.
Proceedings: The proceedings of a conference.
TechReport: A report published by a school or other institution, usually numbered within a series.
Unpublished: A document having an author and title, but not formally published.

Entry Fields

The ... argument of bibentry can be any number of BibTeX fields, including

address: The address of the publisher or other type of institution.
author: The name(s) of the author(s), either as a person object, or as a character string which
as.person correctly coerces to such.
booktitle: Title of a book, part of which is being cited.
chapter: A chapter (or section or whatever) number.
editor: Name(s) of editor(s), same format as author.
institution: The publishing institution of a technical report.
journal: A journal name.
note: Any additional information that can help the reader. The first word should be capitalized.
number: The number of a journal, magazine, technical report, or of a work in a series.
pages: One or more page numbers or range of numbers.
publisher: The publisher’s name.
school: The name of the school where a thesis was written.
series: The name of a series or set of books.
title: The work’s title.
url: A URL for the reference. (If the URL is an expanded DOI, we recommend to use the ‘doi’ field with the unexpanded DOI instead.)
volume: The volume of a journal or multi-volume book.
year: The year of publication.

    year = "1997",
  )
)`
browseEnv

Description

The browseEnv function opens a browser with list of objects currently in sys.frame() environment.

Usage

browseEnv(envir = .GlobalEnv, pattern,
           excludepatt = "^last\.warning",
           html = .Platform$GUI != "AQUA",
           expanded = TRUE, properties = NULL,
           main = NULL, debugMe = FALSE)

Arguments

envir an environment the objects of which are to be browsed.
pattern a regular expression for object subselection is passed to the internal ls() call.
excludepatt a regular expression for dropping objects with matching names.
html is used to display the workspace on a HTML page in your favorite browser. The default except when running from R.app on macOS.
expanded whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if html is set to FALSE.
browseURL

properties a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used.

main a title string to be used in the browser; when NULL (as per default) a title is constructed.

debugeMe logical switch; if true, some diagnostic output is produced.

Details

Very experimental code: displays a static HTML page on all platforms except R.app on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the tkWidget package (from https://www.bioconductor.org).

}

browseURL

Load URL into an HTML Browser

Description

Load a given URL into an HTML browser.

Usage

browseURL(url, browser = getOption("browser"),
          encodeIfNeeded = FALSE)
Arguments

url a non-empty character string giving the URL to be loaded. Some platforms also accept file paths.

browser a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser. Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.

encodeIfNeeded Should the URL be encoded by URLencode before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for `file://` URLs on some systems and for `http://` URLs passed to some CGI applications. Fortunately, most URLs do not need encoding.

Details

On Unix-alikes: The default browser is set by option "browser", in turn set by the environment variable $R_BROWSER which is by default set in file `R_HOME/etc/Renviron` to a choice made manually or automatically when R was configured. (See Startup for where to override that default value.) To suppress showing URLs altogether, use the value "false".

On many platforms it is best to set option "browser" to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use open and on many other Unix-alikes use xdg-open.

If browser supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla and Opera), Galeon, KDE konqueror (via kfmclient) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode url if necessary (see URLencode).

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

On Windows: The default browser is set by option "browser", in turn set by the environment variable $R_BROWSER if that is set, otherwise to NULL. To suppress showing URLs altogether, use the value "false".

Some browsers have required : be replaced by \ in file paths: others do not accept that. All seem to accept \ as a path separator even though the RFC1738 standard requires /.

To suppress showing URLs altogether, set browser = "false".

URL schemes

Which URL schemes are accepted is platform-specific: expect 'http://', 'https://' and 'ftp://' to work, but 'mailto:' may or may not (and if it does may not use the user's preferred email client).

For the 'file:///' scheme the format accepted (if any) can depend on both browser and OS.
Examples

```r
## Not run:
## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")

browseURL("https://www.r-project.org")

## On Windows-only, something like
browseURL("file://d:/R/R-2.5.1/doc/html/index.html",
          browser = "C:/Program Files/Mozilla Firefox/firefox.exe")

## End(Not run)
```

browseVignettes

List Vignettes in an HTML Browser

Description

List available vignettes in an HTML browser with links to PDF, LaTeX/noWeb source, and (tangled) 
R code (if available).

Usage

```r
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)
```

## S3 method for class 'browseVignettes'
print(x, ...)

Arguments

- **package**: a character vector with the names of packages to search through, or NULL in 
  which "all" packages (as defined by argument `all`) are searched.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value 
  of NULL corresponds to all libraries currently known.
- **all**: logical; if TRUE search all available packages in the library trees specified by 
  `lib.loc`, and if FALSE, search only attached packages.
- **x**: Object of class `browseVignettes`.
- **...**: Further arguments, ignored by the print method.

Details

Function `browseVignettes` returns an object of the same class; the print method displays it as an 
HTML page in a browser (using `browseURL`).

See Also

`browseURL`, `vignette`
## List vignettes from all *attached* packages

`browseVignettes(all = FALSE)`

## List vignettes from a specific package

`browseVignettes("grid")`

---

### Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

### Usage

```r
bug.report(subject = "", address, 
           file = "R.bug.report", package = NULL, lib.loc = NULL, 
           ...)```

### Arguments

- **subject**
  
  Subject of the email.

- **address**
  
  Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).

- **file**
  
  Filename to use (if needed) for setting up the email.

- **package**
  
  Optional character vector naming a single package which is the subject of the bug report.

- **lib.loc**
  
  A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known.

- **...**
  
  Additional named arguments such as `method` and `ccaddress` to pass to `create.post`.

### Details

If `package` is NULL or a base package, this opens the R bugs tracker at https://bugs.r-project.org/.

If `package` is specified, it is assumed that the bug report is about that package, and parts of its ‘DESCRIPTION’ file are added to the standard information. If the package has a non-empty `BugReports` field in the ‘DESCRIPTION’ file specifying the URL of a webpage, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`. If there is any other form of `BugReports` field or a `Contact` field, this is examined as it may provide a preferred email address.

### Value

Nothing useful.
When is there a bug?

If \( R \) executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really \( R \)‘s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an \( R \) error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start \( R \) until the problem happens. Always include the version of \( R \), machine, and operating system that you are using; type `version` in \( R \) to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how \( R \) is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[]` method that had a bug causing \( R \)‘s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.
Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function bug.report(). For reports on R this will open the Web page at https://bugs.r-project.org/: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on contributed packages should not be sent to the R bug tracker: rather make use of the package argument.

capture.output  Send Output to a Character String or File

Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to sink similarly to how with is related to attach.

Usage

capture.output(..., file = NULL, append = FALSE,
    type = c("output", "message"), split = FALSE)

Arguments

...  Expressions to be evaluated.
file  A file name or a connection, or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit.
append  logical. If file a file name or unopened connection, append or overwrite?
type, split are passed to sink(), see there.

Details

It works via sink(<file connection>) and hence the R code in dots must not interfere with the connection (e.g., by calling closeAllConnections()).

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for file = NULL all output will be lost.

Messages sent to stderr() (including those from message, warning and stop) are captured by type = "message". Note that this can be “unsafe” and should only be used with care.
changedFiles

Detect which Files Have Changed

Description

fileSnapshot takes a snapshot of a selection of files, recording summary information about each. changedFiles compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

Usage

fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL, md5sum = FALSE, digest = NULL, full.names = length(path) > 1, ...)

changedFiles(before, after, path = before$path, timestamp = before$timestamp, check.file.info = c("size", "isdir", "mode", "mtime"), md5sum = before$md5sum, digest = before$digest, full.names = before$full.names, ...)

## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)

## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
Arguments

- **path**: character vector; the path(s) to record.
- **file.info**: logical; whether to record `file.info` values for each file.
- **timestamp**: character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.
- **md5sum**: logical; whether MD5 summaries of each file should be taken as part of the snapshot.
- **digest**: a function or NULL; a function with header `function(filename)` which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.
- **full.names**: logical; whether full names (as in `list.files`) should be recorded. Must be TRUE if `length(path) > 1`.
- **...**: additional parameters to pass to `list.files` to control the set of files in the snapshots.
- **before, after**: objects produced by `fileSnapshot`; two snapshots to compare. If `after` is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in `before` as defaults.
- **check.file.info**: character vector; which columns from `file.info` should be compared.
- **x**: the object to print.
- **verbose**: logical; whether to list all data when printing.

Details

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info, md5sum, and digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file_test` function is used to compare the age of all files common to both before and after to it. This test may be unreliable: it compares the current modification time of the after files to the `timestamp`; that may not be the same as the modification time when the after snapshot was taken. It may also give incorrect results if the clock on the file system holding the `timestamp` differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

Value

`fileSnapshot` returns an object of class "fileSnapshot". This is a list containing the fields

- **info**: a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data
- **path**: the normalized path from the call
timestamp, file.info, md5sum, digest, full.names
a record of the other arguments from the call
args other arguments passed via ... to list.files.

changedFiles produces an object of class "changedFiles". This is a list containing
added, deleted, changed, unchanged
character vectors of filenames from the before and after snapshots, with obvious meanings
changes a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test.

print methods are defined for each of these types. The print method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing all of the TRUE values.

Author(s)
Duncan Murdoch, using suggestions from Karl Millar and others.

file.info, file_test, md5sum.

Examples
# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes

charClass

Character Classification

Description
An interface to the (C99) wide character classification functions in use.

Usage
charClass(x, class)
Arguments

- **x**: Either a UTF-8-encoded length-1 character vector or an integer vector of Unicode points (or a vector coercible to integer).
- **class**: A character string, one of those given in the ‘Details’ section.

Details

The classification into character classes is platform-dependent. The classes are determined by internal tables on Windows and (optionally but by default) on macOS and AIX.

The character classes are interpreted as follows:

- "alnum": Alphabetic or numeric.
- "alpha": Alphabetic.
- "blank": Space or tab.
- "cntrl": Control characters.
- "digit": Digits 0-9.
- "graph": Graphical characters (printable characters except whitespace).
- "lower": Lower-case alphabetic.
- "print": Printable characters.
- "punct": Punctuation characters. Some platforms treat all non-alphanumeric graphical characters as punctuation.
- "space": Whitespace, including tabs, form and line feeds and carriage returns. Some OSes include non-breaking spaces, some exclude them.
- "upper": Upper-case alphabetic.
- "xdigit": Hexadecimal character, one of 0-9A-fa-f.

Alphabetic characters contain all lower- and upper-case ones and some others (for example, those in 'title case').

Whether a character is printable is used to decide whether to escape it when printing – see the help for `print.default`.

If `x` is a character string, it should either be ASCII or declared as UTF-8 – see `Encoding`.

`charClass` was added in R 4.1.0. A less direct way to examine character classes which also worked in earlier versions is to use something like `grepl("[:print:]", intToUtf8(x))` – however, the regular-expression code might not use the same classification functions as printing and on macOS used not to.

Value

A logical vector of the length the number of characters or integers in `x`.

Note

Non-ASCII digits are excluded by the C99 standard from the class "digit": most platforms will have them as alphabetic.

It is an assumption that the system's wide character classification functions are coded in Unicode points, but this is known to be true for all recent platforms.

In principle the classification could depend on the locale even on one platform, but that seems no longer to be seen.
choose.dir

See Also
Character classes are used in regular expressions.
The OS’s man pages for iswctype and wctype.

Examples
x <- c(48:70, 32, 0xa0) # Last is non-breaking space
cl <- c("alnum", "alpha", "blank", "digit", "graph", "punct", "upper", "xdigit")
X <- lapply(cl, function(y) charClass(x,y)); names(X) <- cl
X <- as.data.frame(X); row.names(X) <- sQuote(intToUtf8(x, multiple = TRUE))
X

charClass("ABC123", "alpha")
## Some accented capital Greek characters
(x <- "\u0386\u0388\u0389")
charClass(x, "upper")

## How many printable characters are there? (Around 280,000 in Unicode 13.)
## There are 2^21-1 possible Unicode points (most not yet assigned).
pr <- charClass(1:0x1fffff, "print")
table(pr)

choose.dir

Choose a Folder Interactively on MS Windows

Description
Use a Windows shell folder widget to choose a folder interactively.

Usage
choose.dir(default = "", caption = "Select folder")

Arguments
default which folder to show initially.
caption the caption on the selection dialog.

Details
This brings up the Windows shell folder selection widget. With the default default = "", ‘My Computer’ (or similar) is initially selected.
To workaround a bug, on Vista and later only folders under ‘Computer’ are accessible via the widget.

Value
A length-one character vector, character NA if ‘Cancel’ was selected.

Note
This is only available on Windows.
choose.files

See Also

choose.files (on Windows) and file.choose (on all platforms).

Examples

if (interactive() && .Platform$OS.type == "windows")
  choose.dir(getwd(), "Choose a suitable folder")

choose.files (Choose a List of Files Interactively on MS Windows)

Description

Use a Windows file dialog to choose a list of zero or more files interactively.

Usage

choose.files(default = "", caption = "Select files",
  multi = TRUE, filters = Filters,
  index = nrow(Filters))

Filters

Arguments

default which filename to show initially
caption the caption on the file selection dialog
multi whether to allow multiple files to be selected
filters a matrix of filename filters (see Details)
index which row of filters to use by default

Details

Unlike file.choose, choose.files will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas file.choose would signal an error. choose.dir chooses a directory.

Windows file dialog boxes include a list of ‘filters’, which allow the file selection to be limited to files of specific types. The filters argument to choose.files allows the list of filters to be set. It should be an n by 2 character matrix. The first column gives, for each filter, the description the user will see, while the second column gives the mask(s) to select those files. If more than one mask is used, separate them by semicolons, with no spaces. The index argument chooses which filter will be used initially.

Filters is a matrix giving the descriptions and masks for the file types that R knows about. It is large but this function is not intended to select thousands of files, when the limit might be reached.
chooseBioCmirror

Value

A character vector giving zero or more file paths.

Note

This is only available on Windows.

See Also

file.choose, choose.dir.
Sys.glob or list.files to select multiple files by pattern.

Examples

if (interactive() && .Platform$OS.type == "windows")
  choose.files(filters = Filters[c("zip", "All"),])

chooseBioCmirror Select a Bioconductor Mirror

Description

Interact with the user to choose a Bioconductor mirror.

Usage

chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL,
  local.only = FALSE)

Arguments

  graphics Logical. If true, use a graphical list: on Windows or the macOS GUI use a list
  box, and on a Unix-alike use a Tk widget if package tcltk and an X server are
  available. Otherwise use a text menu.

  ind Optional numeric value giving which entry to select.

  local.only Logical, try to get most recent list from the Bioconductor master or use file on
  local disk only.

Details

This sets the option "BioC_mirror": it is used before a call to setRepositories. The out-
of-the-box default for that option is NULL, which currently corresponds to the mirror https:
//bioconductor.org.

The ‘Bioconductor (World-wide)’ mirror is a network of mirrors providing reliable world-wide
access; other mirrors may provide faster access on a geographically local scale.

ind chooses a row in ‘R_HOME/doc/BioC_mirrors.csv’, by number.

Value

None: this function is invoked for its side effect of updating options("BioC_mirror").
chooseCRANmirror

Select a CRAN Mirror

Description
Interact with the user to choose a CRAN mirror.

Usage
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL,
local.only = FALSE)
gerCRANmirrors(all = FALSE, local.only = FALSE)

Arguments
- graphics Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package {tcltk} and an X server are available. Otherwise use a text menu.
- ind Optional numeric value giving which entry to select.
- all Logical, get all known mirrors or only the ones flagged as OK.
- local.only Logical, try to get most recent list from the CRAN master or use file on local disk only.

Details
A list of mirrors is stored in file '\texttt{R_HOME/doc/CRAN\_mirrors.csv}', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function is called by a Windows GUI menu item and by \texttt{contrib.url} if it finds the initial dummy value of \texttt{options("repos")}.

HTTPS mirrors with mirroring over \texttt{ssh} will be offered in preference to other mirrors (which are listed in a sub-menu).

\texttt{ind} chooses a row in the list of current mirrors, by number. It is best used with \texttt{local.only = TRUE} and row numbers in '\texttt{R_HOME/doc/CRAN\_mirrors.csv}'.

Value
None for \texttt{chooseCRANmirror()}, this function is invoked for its side effect of updating \texttt{options("repos")}.

\texttt{getCRANmirrors()} returns a data frame with mirror information.

See Also
\texttt{setRepositories, chooseBioCmirror, contrib.url}.
Description

How to cite R and R packages in publications.

Usage

```r
citation(package = "base", lib.loc = NULL, auto = NULL)
readCitationFile(file, meta = NULL)
```

Arguments

- `package` a character string with the name of a single package. An error occurs if more than one package name is given.
- `lib.loc` a character vector with path names of R libraries, or the directory containing the source for package, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- `auto` a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or NULL (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class "packageDescription" with package metadata (see below).
- `file` a file name.
- `meta` a list of package metadata as obtained by `packageDescription`, or NULL (the default).

Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package (using `readCitationFile` with `meta` equal to `packageDescription(package, lib.loc)`) or auto-generates citation information from the ‘DESCRIPTION’ file.

In R >= 2.14.0, one can use a ‘Authors@R’ field in ‘DESCRIPTION’ to provide (R code giving) a `person` object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by `citation()` shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals.
and computations. Function readCitationFile() is used by citation() to extract the information in ‘CITATION’ files. The file is source()ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class "bibentry") are collected.

Traditionally, the ‘CITATION’ file contained zero or more calls to citHeader, then one or more calls to citEntry, and finally zero or more calls to citFooter, where in fact citHeader and citFooter are simply wrappers to paste, with their ... argument passed on to paste as is. The "bibentry" class makes for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write ‘CITATION’ files using the unified bibentry interface.

One can include an auto-generated package citation in the ‘CITATION’ file via citation(auto = meta).

readCitationFile makes use of the Encoding element (if any) of meta to determine the encoding of the file.

**Value**

An object of class "citation", inheriting from class "bibentry"; see there, notably for the print and format methods.

**See Also**

bibentry

**Examples**

```r
## the basic R reference
citation()
```

```r
## references for a package -- might not have these installed
if(nchar(system.file(package = "lattice"))) citation("lattice")
if(nchar(system.file(package = "foreign"))) citation("foreign")
```

```r
## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)
```

```r
## A citation with more than one bibentry:
cm <- tryCatch(citation("mgcv"),
               error = function(e) {
                 warning("Recommended package 'mgcv' is not installed properly")
                 stop(e$message) })
cm # short entries (2-3 lines each)
print(cm, bibtex = TRUE) # each showing its bibtex code
```
Description

Cite a bibentry object in text. The cite() function uses the cite() function from the default bibstyle if present, or citeNatbib() if not. citeNatbib() uses a style similar to that used by the LaTeX package natbib.

Usage

cite(keys, bib, ...)  
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,  
              mode = c("authoryear", "numbers", "super"),  
              abbreviate = TRUE, longnamesfirst = TRUE,  
              bibpunct = c("(", ",", ";", ",", ",", ",", ",")

Arguments

keys A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.
bib A "bibentry" object containing the list of documents in which to find the keys.
... Additional arguments to pass to the cite() function for the default style.
textual Produce a "textual" style of citation, i.e. what \citet would produce in LaTeX.
before Optional text to display before the citation.
after Optional text to display after the citation.
mode The "mode" of citation.
abbreviate Whether to abbreviate long author lists.
longnamesfirst If abbreviate == TRUE, whether to leave the first citation long.
bibpunct A vector of punctuation to use in the citation, as used in natbib. See the Details section.
previous A list of keys that have been previously cited, to be used when abbreviate == TRUE and longnamesfirst == TRUE

Details

Argument names are chosen based on the documentation for the LaTeX natbib package. See that documentation for the interpretation of the bibpunct entries.

The entries in bibpunct are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the "mode": "n" for numbers, "s" for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if mode is specified, it overrides the mode specification in bibpunct[4]. Partial matching is used for mode.

The defaults for citeNatbib have been chosen to match the JSS style, and by default these are used in cite. See bibstyle for how to set a different default style.
Value

A single element character string is returned, containing the citation.

    bibpunct = c("[", ",", ",", "n", ",", ",")
)
cite("R, boot-package", refs, textual = TRUE)
refs
## restore the old style
tools::bibstyle(savestyle, .default = TRUE)

citEntry  |  Bibliography Entries (Older Interface)

**Description**

Functionality for specifying bibliographic information in enhanced BibTeX style.

**Usage**

citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)  
citFooter(...)

**Arguments**

- **entry**: a character string with a BibTeX entry type. See section **Entry Types** in `bibentry` for details.
- **textVersion**: a character string with a text representation of the reference.
- **header**: a character string with optional header text.
- **footer**: a character string with optional footer text.
- **...**: for `citEntry`, arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. See section **Entry Fields** in `bibentry` for details.

For `citHeader` and `citFooter`, character strings.

**Value**

citEntry produces an object of class "bibentry".

**See Also**

citation for more information about citing R and R packages and ‘CITATION’ files; bibentry for the newer functionality for representing and manipulating bibliographic information.
clipboard

Read/Write to/from the Clipboard in MS Windows

Description
Transfer text between a character vector and the Windows clipboard in MS Windows (only).

Usage
```r
getClipboardFormats(numeric = FALSE)
readClipboard(format = 1, raw = FALSE)
writeClipboard(str, format = 1)
```

Arguments
- `numeric`: logical: should the result be in human-readable form (the default) or raw numbers?
- `format`: an integer giving the desired format.
- `raw`: should the value be returned as a raw vector rather than as a character vector?
- `str`: a character vector or a raw vector.

Details
The Windows clipboard offers data in a number of formats: see e.g. https://docs.microsoft.com/en-gb/windows/desktop/dataxchg/clipboard-formats.
The standard formats include

<table>
<thead>
<tr>
<th>Format Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CF_TEXT</td>
<td>Text in the machine’s locale</td>
</tr>
<tr>
<td>CF_BITMAP</td>
<td>Metafile picture</td>
</tr>
<tr>
<td>CF_METAFILEPICT</td>
<td>Metafile picture</td>
</tr>
<tr>
<td>CF_SYLK</td>
<td>Symbolic link</td>
</tr>
<tr>
<td>CF_DIF</td>
<td>Data Interchange Format</td>
</tr>
<tr>
<td>CF_TIFF</td>
<td>Tagged-Image File Format</td>
</tr>
<tr>
<td>CF_OEMTEXT</td>
<td>Text in the OEM codepage</td>
</tr>
<tr>
<td>CF_DIB</td>
<td>Device-Independent Bitmap</td>
</tr>
<tr>
<td>CF_PALETTE</td>
<td></td>
</tr>
<tr>
<td>CF_PENDATA</td>
<td>10</td>
</tr>
<tr>
<td>CF_RIFF</td>
<td>11 Audio data</td>
</tr>
<tr>
<td>CF_WAVE</td>
<td>12 Audio data</td>
</tr>
<tr>
<td>CF_UNICODETEXT</td>
<td>Text in Unicode (UCS-2)</td>
</tr>
<tr>
<td>CF_ENHMETAFILE</td>
<td>Enhanced metafile</td>
</tr>
<tr>
<td>CF_HDROP</td>
<td>15 Drag-and-drop data</td>
</tr>
<tr>
<td>CF_LOCALE</td>
<td>Locale for the text on the clipboard</td>
</tr>
<tr>
<td>CF_MAX</td>
<td>17 Shell-oriented formats</td>
</tr>
</tbody>
</table>

Applications normally make data available in one or more of these and possibly additional private formats. Use `raw = TRUE` to read binary formats, `raw = FALSE` (the default) for text formats. The current codepage is used to convert text to Unicode text, and information on that is contained in the `CF_LOCALE` format. (Take care if you are running R in a different locale from Windows.)
The `writeClipboard` function will write a character vector as text or Unicode text with standard CR-LF line terminators. It will copy a raw vector directly to the clipboard without any changes.

**Value**

For `getClipboardFormats`, a character or integer vector of available formats, in numeric order. If non human-readable character representation is known, the number is returned.

For `readClipboard`, a character vector by default, a raw vector if `raw` is `TRUE`, or `NULL`, if the format is unavailable.

For `writeClipboard` an invisible logical indicating success or failure.

**Note**

This is only available on Windows.

**See Also**

- `file` which can be used to set up a connection to a clipboard.

---

**close.socket**

*Close a Socket*

**Description**

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

**Usage**

```r
close.socket(socket, ...)```

**Arguments**

- `socket`: a socket object
- `...`: further arguments passed to or from other methods.

**Value**

logical indicating success or failure

**Author(s)**

Thomas Lumley

**See Also**

- `make.socket`, `read.socket`

Compiling in support for sockets was optional prior to R 3.3.0: see `capabilities("sockets")` to see if it is available.
combn

Generate All Combinations of n Elements, Taken m at a Time

Description

Generate all combinations of the elements of x taken m at a time. If x is a positive integer, returns all combinations of the elements of seq(x) taken m at a time. If argument FUN is not NULL, applies a function given by the argument to each point. If simplify is FALSE, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the FUN function, if specified.

Usage

combn(x, m, FUN = NULL, simplify = TRUE, ...)

Arguments

x vector source for combinations, or integer n for x <- seq_len(n).
m number of elements to choose.
FUN function to be applied to each combination; default NULL means the identity, i.e., to return the combination (vector of length m).
simplify logical indicating if the result should be simplified to an array (typically a matrix); if FALSE, the function returns a list. Note that when simplify = TRUE as by default, the dimension of the result is simply determined from FUN(1st combination) (for efficiency reasons). This will badly fail if FUN(u) is not of constant length.

... optionally, further arguments to FUN.

Details

Factors x are accepted.

Value

A list or array, see the simplify argument above. In the latter case, the identity dim(combn(n, m)) == c(m, choose(n, m)) holds.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package combinat and documentation by Vince Carey <stvjc@channing.harvard.edu>: small changes by the R core team, notably to return an array in all cases of simplify = TRUE, e.g., for combn(5,5).

References

See Also

choose for fast computation of the number of combinations. expand.grid for creating a data frame from all combinations of factors or vectors.
Examples

```r
combn(letters[1:4], 2)  # minimum value in each combination
(m <- combn(10, 5, min))
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m), is.array(m), # 1-dimensional
          c(2,3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                        dim(cc) == c(m, choose(n, m)),
                        identical(cc, combn(n, m, identity)) || m == 1)
```

Description

Compare two package version numbers to see which is later.

Usage

```r
compareVersion(a, b)
```

Arguments

a, b  
Character strings representing package version numbers.

Details

R package version numbers are of the form x.y-z for integers x, y and z, with components after x optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function strcmp).

See Also

`package_version`, `library`, `packageStatus`.

Examples

```r
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```
Description

Compile given source files so that they can subsequently be collected into a shared object using `R CMD SHLIB` or an executable program using `R CMD LINK`. Not available on Windows.

Usage

```
R CMD COMPILE [options] srcfiles
```

Arguments

- **srcfiles**: A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions `.c`, `.cc` (or `.cpp`), `.m`, `.mm` (or `.M`), `.f` and `.f90` or `.f95`, respectively.
- **options**: A list of compile-relevant settings, or for obtaining information about usage and version of the utility.

Details

`R CMD SHLIB` can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to `R CMD SHLIB` is more reliable.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `.o` file is present.

Note

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

`LINK`, `SHLIB`, `dyn.load`; the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).
contrib.url

Find Appropriate Paths in CRAN-like Repositories

Description

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

Usage

contrib.url(repos, type = getOption("pkgType"))

Arguments

repos character vector, the base URL(s) of the repositories to use.

Details

If type = "both" this will use the source repository.

Value

A character vector of the same length as repos.

See Also

setRepositories to set options("repos"), the most common value used for argument repos.

available.packages, download.packages, install.packages.

The ‘R Installation and Administration’ manual for how to set up a repository.

count.fields

Count the Number of Fields per Line

Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

Usage

count.fields(file, sep = "", quote = "\"", skip = 0,
blank.lines.skip = TRUE, comment.char = "#")
Arguments

- **file**: a character string naming an ASCII data file, or a `connection`, which will be opened if necessary, and if so closed at the end of the function call.
- **sep**: the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.
- **quote**: the set of quoting characters
- **skip**: the number of lines of the data file to skip before beginning to read data.
- **blank.lines.skip**: logical: if TRUE blank lines in the input are ignored.
- **comment.char**: character: a character vector of length one containing a single character or an empty string.

Details

This used to be used by `read.table` and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see `scan`.

Consistent with `scan`, `count.fields` allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as `NA`, and the ending line will include the count of all fields from the beginning of the record.

Value

A vector with the numbers of fields found.

See Also

- `read.table`

Examples

```r
fil <- tempfile()
cat("NAME", "1:John", "2:Paul", file = fil, sep = "\n")
count.fields(fil, sep = "\n")
unlink(fil)
```

create.post  Ancillary Function for Preparing Emails and Postings

Description

An ancillary function used by `bug.report` and `help.request` to prepare emails for submission to package maintainers or to R mailing lists.

Usage

```r
create.post(instructions = character(), description = "post", subject = "", method = getOption("mailer"), address = "the relevant mailing list", ccaddress = getOption("ccaddress", ""), filename = "R.post", info = character())
```
create.post

Arguments

instructions  Character vector of instructions to put at the top of the template email.
description   Character string: a description to be incorporated into messages.
subject       Subject of the email. Optional except for the "mailx" method.
method        Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See ‘Details’.
adress        Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
ccaddress     Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.
filename      Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).
info          Character vector of information to include in the template email below the 'please do not edit the information below' line.

Details

What this does depends on the method. The function first creates a template email body.

none  A file editor (see file.edit) is opened with instructions and the template email. When this returns, the completed email is in file file ready to be read/pasted into an email program.

mailto  This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.
         This works where default mailers are set up (usual on macOS and Windows, and where xdg-open is available and configured on other Unix-alikes: if that fails it tries the browser set by R_BROWSER).
         This is the ‘factory-fresh’ default method.

mailx  (Unix-alikes only.) A file editor (see file.edit) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as mailx, to the address (and optionally, the Cc: address) given.

gnudoit  An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the gnudoit program to be available. Currently subject is ignored.

ess  The body of the template email is sent to stdout.

Value

Invisible NULL.

See Also

bug.report, help.request.
**data**

**Data Sets**

**Description**

Loads specified data sets, or list the available data sets.

**Usage**

```r
data(..., list = character(), package = NULL, lib.loc = NULL, verbose = getOption("verbose"), envir = .GlobalEnv, overwrite = TRUE)
```

**Arguments**

- `...`: literal character strings or names.
- `list`: a character vector.
- `package`: a character vector giving the package(s) to look in for data sets, or NULL. By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory.
- `lib.loc`: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
- `verbose`: a logical. If TRUE, additional diagnostics are printed.
- `envir`: the environment where the data should be loaded.
- `overwrite`: logical: should existing objects of the same name in `envir` be replaced?

**Details**

Currently, four formats of data files are supported:

1. files ending `.R` or `r` are `source()`d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the `utils` package is attached, in case it had been run via `utils::data`.)
2. files ending `.RData` or `.rda` are `load()`ed.
3. files ending `.tab`, `.txt` or `.TXT` are read using `read.table(...)`, `header = TRUE, as.is=FALSE`, and hence result in a data frame.
4. files ending `.csv` or `.CSV` are read using `read.table(...)`, `header = TRUE, sep = ";", as.is=FALSE`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `.txt`, `.tab` or `.csv` can be compressed, with or without further extension `.gz`, `.b2` or `.xz`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`.R` or `r`, and `.RData` or `.rda files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.
If no data sets are specified, `data` lists the available data sets. It looks for a new-style data index in the 'Meta' or, if this is not found, an old-style '00Index' file in the 'data' directory of each specified package, and uses these files to prepare a listing. If there is a 'data' area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class "packageIQR". The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1` which tells us that dataset `beaver1` can be retrieved by the call `data(beaver)`.

If `lib.loc` and `package` are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the 'data' directory (if any) of the current working directory.

If `lib.loc = NULL` but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the 'data' directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

**Value**

A character vector of all data sets specified (whether found or not), or information about all available data sets in an object of class "packageIQR" if none were specified.

**Good practice**

There is no requirement for `data(foo)` to create an object named `foo` (nor to create one object), although it much reduces confusion if this convention is followed (and it is enforced if datasets are lazy-loaded).

`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use: that need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of `data` within a function without an `envir` argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by `data(..., envir = environment())`. However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘R/sysdata.rda’ in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees `mytable` as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by `::`, e.g., `survival::survexp.us`.
Warning

This function creates objects in the \texttt{envir} environment (by default the user’s workspace) replacing any which already existed. \texttt{data(“foo”)} can silently create objects other than \texttt{foo}: there have been instances in published packages where it created/replaced \texttt{.Random.seed} and hence change the seed for the session.

Note

One can take advantage of the search order and the fact that a \texttt{.R} file will change directory. If raw data are stored in \texttt{’mydata.txt’} then one can set up \texttt{’mydata.R’} to read \texttt{’mydata.txt’} and pre-process it, e.g., using \texttt{transform()}. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the \texttt{.R} file can effectively contain a metadata specification for the plaintext formats.

In older versions of \texttt{R}, up to 3.6.x, both \texttt{package = ”base”} and \texttt{package = ”stats”} were using \texttt{package = ”datasets”}, (with a warning), as before 2004, (most of) the datasets in \texttt{datasets} were either in \texttt{base} or \texttt{stats}. For these packages, the result is now empty as they contain no data sets.

See Also

\texttt{help} for obtaining documentation on data sets, \texttt{save} for creating the second (\texttt{.rda}) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ for considerations in preparing the ‘data’ directory of a package.

Examples

\begin{verbatim}
require(utils)
data()                  # list all available data sets
try(data(package = "rpart"), silent = TRUE) # list the data sets in the rpart package
data(USArrests, "VADeaths")   # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)    
## End(Not run)
help(USArrests)            # give information on data set 'USArrests'
\end{verbatim}

\begin{description}
\item[dataentry] \textit{Spreadsheet Interface for Entering Data}
\end{description}

Description

A spreadsheet-like editor for entering or editing data.

Usage

\begin{verbatim}
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
\end{verbatim}
Arguments

... A list of variables: currently these should be numeric or character vectors or list containing such vectors.
Modes The modes to be used for the variables.
Names The names to be used for the variables.
data A list of numeric and/or character vectors.
modes A list of length up to that of data giving the modes of (some of) the variables. list() is allowed.

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. The functions de, de.ncols, de.setup and de.restore are designed to help achieve these side effects. If the user passes in a matrix, X say, then the matrix is broken into columns before dataentry is called. Then on return the columns are collected and glued back together and the result assigned to the variable X. If you don’t want this behaviour use dataentry directly.

The primitive function is dataentry. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the dataentry window are returned as vectors in a list when the spreadsheet is closed. de.ncols counts the number of columns which are supplied as arguments to data.entry. It attempts to count columns in lists, matrices and vectors. de.setup sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by de.restore.

Value

de and dataentry return the edited value of their arguments. data.entry invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

Resources

The data entry window responds to X resources of class R_dataentry. Resources foreground, background and geometry are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).
Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including -.es) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.) Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. You can specify fixed column widths by setting option de.cellwidth to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

vi, edit: edit uses dataentry to edit data frames.

Examples

# call data entry with variables x and y
## Not run: data.entry(x, y)

ddebugcall## Debug a Call

ddebugcall(call, once = FALSE)
undebugcall(call)
**Arguments**

- call: An R expression calling a function. The called function will be debugged. See Details.
- once: logical; if TRUE, debugging only occurs once, as via debugonce. Defaults to FALSE

**Details**

dbgcall debugs the non-generic function, S3 method or S4 method that would be called by evaluating call. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see isS3stdGeneric).

**Value**

dbgcall invisibly returns the debugged call expression.

**Note**

Non-standard evaluation is used to retrieve the call (via substitute). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

**See Also**

- debug for the primary debugging interface

**Examples**

```r
## Not run:
## Evaluate call after setting debugging
##
## f <- factor(1:10)
## res <- eval(debugcall(summary(f)))
##
## End(Not run)
```

---

**debugger**

**Post-Mortem Debugging**

**Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

dump.frames(dumpto = "last.dump", to.file = FALSE,
            include.GlobalEnv = FALSE)

debugger(dump = last.dump)
Arguments

dumpto a character string. The name of the object or file to dump to.
to.file logical. Should the dump be to an R object or to a file?
include.GlobalEnv logical indicating if a copy of the .GlobalEnv environment should be included in addition to the sys.frames(). Will be particularly useful when used in a batch job.
dump an R dump object created by dump.frames.

Details

To use post-mortem debugging, set the option error to be a call to dump.frames. By default this dumps to an R object last.dump in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to save). The dumped object contain the call stack, the active environments and the last error message as returned by geterrmessage.

When dumping to file, dumpto gives the name of the dumped object and the file name has ‘.rda’ appended.

A dump object of class "dump.frames" can be examined by calling debugger. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the browser called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any ... argument.

If dump.frames is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

Value

Invisible NULL.

Note

Functions such as sys.parent and environment applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report "recursive default argument reference" when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

References

See Also

browser for the actions available at the Browse prompt.

options for setting error options; recover is an interactive debugger working similarly to debugger but directly after the error occurs.
Examples

### Not run:
```r
options(error = quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f() # will generate a dump on file "testdump.rda"
options(error = NULL)
```

### possibly in another R session
```r
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]> Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0
```

### A possible setting for non-interactive sessions
```r
options(error = quote({dump.frames(to.file = TRUE); q(status = 1)}))
```

### End(Not run)

demo

**Demonstrations of R Functionality**

demo is a user-friendly interface to running some demonstration R scripts. `demo()` gives the list of available topics.

**Usage**

```r
demo(topic, package = NULL, lib.loc = NULL,
```
character.only = FALSE, verbose = getOption("verbose"),
echo = TRUE, ask = getOption("demo.ask"),
encoding = getOption("encoding"))

Arguments

topic     the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.
package   a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.
lib.loc   a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
character.only logical; if TRUE, use topic as character string.
verbose   a logical. If TRUE, additional diagnostics are printed.
echo      a logical. If TRUE, show the R input when sourcing.
ask       a logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive, the user is asked to press RETURN to start.
encoding  See source. If the package has a declared encoding, that takes preference.

Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR".

See Also

source and devAskNewPage which are called by demo.

Examples

demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)
## End(Not run)

## Find the location of a demo

```r
system.file("demo", "lm.glm.R", package = "stats")
```

### DLL.version

**DLL Version Information on MS Windows**

**Description**

On MS Windows only, return the version of the package and the version of R used to build the DLL, if available.

**Usage**

```r
DLL.version(path)
```

**Arguments**

- `path`: character vector of length one giving the complete path to the DLL.

**Value**

- If the DLL does not exist, `NULL`.
- A character vector of length two, giving the DLL version and the version of R used to build the DLL. If the information is not available, the corresponding string is empty.

**Note**

This is only available on Windows.

**Examples**

```r
if(.Platform$OS.type == "windows") withAutoprint({
  DLL.version(file.path(R.home("bin"), "R.dll"))
  DLL.version(file.path(R.home(), "library/stats/libs", .Platform$r_arch, "stats.dll"))
})
```

### download.file

**Download File from the Internet**

**Description**

This function can be used to download a file from the Internet.

**Usage**

```r
download.file(url, destfile, method, quiet = FALSE, mode = "w", cacheOK = TRUE, extra =getOption("download.file.extra"), headers = NULL, ...)
```
Arguments

url  a character string (or longer vector e.g., for the "libcurl" method) naming the URL of a resource to be downloaded.
destfile a character string (or vector, see the url argument) with the file path where the downloaded file is to be saved. Tilde-expansion is performed.
method Method to be used for downloading files. Current download methods are "internal", "wininet" (Windows only) "libcurl", "wget" and "curl", and there is a value "auto": see 'Details' and 'Note'. The method can also be set through the option "download.file.method": see options().
quiet If TRUE, suppress status messages (if any), and the progress bar.
mode character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl". See also 'Details', notably about using "wb" for Windows.
cacheOK logical. Is a server-side cached value acceptable?
extra character vector of additional command-line arguments for the "wget" and "curl" methods.
headers named character vector of HTTP headers to use in HTTP requests. It is ignored for non-HTTP URLs. The User-Agent header, coming from the HTTPUserAgent option (see options) is used as the first header, automatically.

Details

The function download.file can be used to download a single file as described by ur1 from the internet and store it in destfile.

The ur1 must start with a scheme such as 'http://', 'https://' or 'file://'. Which methods support which schemes varies by R version, but method = "auto" will try to find a method which supports the scheme.

For method = "auto" (the default) the "internal" method is used for 'file:///' URLs, and "libcurl" for all others.

Support for method "libcurl" was optional on Windows prior to R 4.2.0: use capabilities("libcurl") to see if it is supported on an earlier version. It uses an external library of that name (https://curl.se/libcurl/) against which R can be compiled.

When method "libcurl" is used, it provides (non-blocking) access to 'https://' and (usually) 'ftps://' URLs. There is support for simultaneous downloads, so ur1 and destfile can be character vectors of the same length greater than one (but the method has to be specified explicitly and not via "auto"). For a single URL and quiet = FALSE a progress bar is shown in interactive use.

For methods "wget" and "curl" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

cacheOK = FALSE is useful for 'http://' and 'https://' URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by available.packages.

The "libcurl" and "wget" methods follow 'http://' and 'https://' redirections to any scheme they support. (For method "curl" use argument extra = "-L". To disable redirection in wget, use extra = "--max-redirect=0".) The "wininet" method supports some redirections but not all. (For method "libcurl", messages will quote the endpoint of redirections.)
Support for 'http://' URLs in the "internal" method and 'ftp://' URLs in the "internal" and "wininet" methods was deprecated in R 4.1.1 and removed in R 4.2.0.

See url for how ‘file://’ URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see URLencode), but it seems the "wininet" method does.

The remaining details apply to the "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option timeout which defaults to 60 seconds. This is often insufficient for downloads of large files (50MB or more) and so should be increased when download.file is used in packages to do so. Note that the user can set the default timeout by the environment variable R_DEFAULT_INTERNET_TIMEOUT in recent versions of R, so to ensure that this is not decreased packages should use something like

```r
options(timeout = max(300, getOption("timeout")))
```

(It is unrealistic to require download times of less than 1s/MB.)

The level of detail provided during transfer can be set by the quiet argument and the internet.info option: the details depend on the platform and scheme. For the "internal" method setting option internet.info to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer platform-specifically:

**On Windows** If the file length is known, the full width of the bar is the known length. Otherwise the initial width represents 100 Kbytes and is doubled whenever the current width is exceeded. (In non-interactive use this uses a text version. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.)

**On a unix-alike** If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

The choice of binary transfer (mode = "wb" or "ab") is important on Windows, since unlike Unix-alikes it does distinguish between text and binary files and for text transfers changes \n line endings to \r\n (aka 'CRLF').

On Windows, if mode is not supplied (missing()) and url ends in one of .gz, .bz2, .xz, .tgz, .zip, .jar, .rda, .rds or .RData, mode = "wb" is set so that a binary transfer is done to help unwary users.

Code written to download binary files must use mode = "wb" (or "ab"), but the problems incurred by a text transfer will only be seen on Windows.

**Value**

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

What happens to the destination file(s) in the case of error depends on the method and R version. Currently the "internal", "wininet" and "libcurl" methods will remove the file if there the URL is unavailable except when mode specifies appending when the file should be unchanged.
Setting Proxies

For the Windows-only method "wininet", the 'Internet Options' of the system are used to choose proxies and so on; these are set in the Control Panel and are those used for system browsers.

For the "libcurl" and "curl" methods, proxies can be set via the environment variables http_proxy or ftp_proxy. See https://curl.se/libcurl/c/libcurl-tutorial.html for further details.

Secure URLs

Methods which access 'https://' and 'ftps://' URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see https://curl.se/docs/sslcerts.html.

This is an issue for method = "libcurl" on Windows, where the OS does not provide a suitable CA certificate bundle, so by default on Windows certificates are not verified. To turn verification on, set environment variable CURL_CA_BUNDLE to the path to a certificate bundle file, usually named 'ca-bundle.crt' or 'curl-ca-bundle.crt'. (This is normally done for a binary installation of R, which installs 'R_HOME/etc/curl-ca-bundle.crt' and sets CURL_CA_BUNDLE to point to it if that environment variable is not already set.) For an updated certificate bundle, see https://curl.se/docs/sslcerts.html. Currently one can download a copy from https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt and set CURL_CA_BUNDLE to the full path to the downloaded file.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

FTP sites

'ftp:' URLs are accessed using the FTP protocol which has a number of variants. One distinction is between 'active' and '(extended) passive' modes: which is used is chosen by the client. The "libcurl" methods uses passive mode, and that is almost universally used by browsers.

Good practice

Setting the method should be left to the end user. Neither of the wget nor curl commands is widely available: you can check if one is available via Sys.which, and should do so in a package or script.

If you use download.file in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error.

The supported methods do change: method libcurl was introduced in R 3.2.0 and was optional on Windows until R 4.2.0 – use capabilities("libcurl") in a program to see if it is available.

Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Methods "wget" and "curl" are mainly for historical compatibility but provide may provide capabilities not supported by the "libcurl" or "wininet" methods.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.
wget (https://www.gnu.org/software/wget/) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from Cygwin, gnuwin32 and elsewhere.

curl (https://curl.se/) is installed on macOS and commonly on Unix-alikes. Windows binaries are available at that URL.

See Also

options to set the HTTPUserAgent, timeout and internet.info options used by some of the methods.

url for a finer-grained way to read data from URLs.

url.show, available.packages, download.packages for applications.

Contributed packages RCurl and curl provide more comprehensive facilities to download from URLs.

download.packages Download Packages from CRAN-like Repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

Usage

download.packages(pkgs, destdir, available = NULL, repos = getOption("repos"), contriburl = contrib.url(repos, type), method, type = getOption("pkgType"), ...)

Arguments

pkgs character vector of the names of packages whose latest available versions should be downloaded from the repositories.
destdir directory where downloaded packages are to be stored.
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.
repos character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "https://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".
contriburl URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the `contrib` section on a CD. Overrides argument repos.
method Download method, see download.file.
type character string, indicate which type of packages: see install.packages and 'Details'.
... additional arguments to be passed to download.file and available.packages.
1950

edit

Details
download.packages takes a list of package names and a destination directory, downloads the
newest versions and saves them in destdir. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file:",
then the packages are not downloaded but used directly. Both "file:" and "file:///" are allowed
as prefixes to a file path. Use the latter only for URLs: see url for their interpretation. (Other forms
of ‘file://’ URLs are not supported.)
For download.packages, type = "both" looks at source packages only.
Value
A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are
given.
See Also
available.packages, contrib.url.
The main use is by install.packages.
See download.file for how to handle proxies and other options to monitor file transfers.
The ‘R Installation and Administration’ manual for how to set up a repository.

edit

Invoke a Text Editor

Description
Invoke a text editor on an R object.
Usage
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
editor = getOption("editor"), ...)
vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
Arguments
name

a named object that you want to edit. If name is missing then the file specified
by file is opened for editing.

file

a string naming the file to write the edited version to.

title

a display name for the object being edited.


`edit` usually a character string naming (or giving the path to) the text editor you want to use. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used. On Windows it defaults to "internal", the script editor. On the macOS GUI the argument is ignored and the document editor is always used.

`editor` can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

... further arguments to be passed to or from methods.

**Details**

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of `name` is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes `file` to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()` with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.

**Note**

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

**See Also**

`edit.data.frame`, `data.entry`, `fix`.

**Examples**

```r
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```
edit.data.frame  Edit Data Frames and Matrices

Description

Use data editor on data frame or matrix contents.

Usage

## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
     edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)

Arguments

name | A data frame or (numeric, logical or character) matrix.
factor.mode | How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.
edit.row.names | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names.

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to character unless numeric (in the sense of is.numeric), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged, and from the edited output if edit.row.names = TRUE and there are no duplicates. (If the row.names column is incomplete, it is extended by entries like row223.) In all other cases the row names are replaced by seq(length = n rows).
For a matrix, colnames will be added (of the form colX) if needed. The rownames will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged (otherwise NULL), and from the edited output if edit.row.names = TRUE. (If the row.names column is incomplete, it is extended by entries like row223.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.

Note

fix(dataframe) works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of edit.

At present the data editor is limited to 65535 rows.

Author(s)

Peter Dalgaard

See Also

data.entry, edit

Examples

## Not run:
edit(InsectSprays)
edit(InsectSprays, factor.mode = "numeric")

## End(Not run)
Arguments

- **topic**: name or literal character string: the online help topic the examples of which should be run.
- **package**: a character vector giving the package names to look into for the topic, or NULL (the default), when all packages on the search path are used.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **character.only**: a logical indicating whether topic can be assumed to be a character string.
- **give.lines**: logical: if true, the lines of the example source code are returned as a character vector.
- **local**: logical: if TRUE evaluate locally, if FALSE evaluate in the workspace.
- **echo**: logical; if TRUE, show the R input when sourcing.
- **verbose**: logical; if TRUE, show even more when running example code.
- **setRNG**: logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. setRNG = TRUE sets the same state as R CMD check does for running a package’s examples. This is currently equivalent to setRNG = (RNGkind("default", "default", "default"); set.seed(1)).
- **ask**: logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.
- **prompt.prefix**: character; prefixes the prompt to be used if echo = TRUE.
- **run.dontrun**: logical indicating that \dontrun should be ignored.
- **run.donttest**: logical indicating that \donttest should be ignored.

Details

If lib.loc is not specified, the packages are searched for amongst those already loaded, then in the libraries given by .libPaths(). If lib.loc is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If local = TRUE objects are not created in the workspace and so not available for examination after example completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the manual Writing R Extensions, the author of the help page can markup parts of the examples for exception rules

dontrun encloses code that should not be run.
donshow encloses code that is invisible on help pages, but will be run both by the package checking tools, and the example() function. This was previously testonly, and that form is still accepted.
donttest encloses code that typically should be run, but not during package checking. The default run.donttest = interactive() leads example() use in other help page examples to skip \donttest sections appropriately.
**Value**

The value of the last evaluated expression, unless `give.lines` is true, where a character vector is returned.

**Author(s)**

Martin Maechler and others

**See Also**

demo

**Examples**

```r
example(InsectSprays)
## force use of the standard package 'stats':
eexample("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:
r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2

## Exploring examples code:
## How large are the examples of "lm...()" functions?
 lmex <- sapply(apropos("^lm", mode = "function"),
               example, character.only = TRUE, give.lines = TRUE)
 sapply(lmex, length)
```

---

**Description**

Edit one or more files in a text editor.

**Usage**

```r
file.edit(..., title = file, editor = getOption("editor"),
       fileEncoding = "")
```
Arguments

one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see `path.expand`.

title
the title to use in the editor; defaults to the filename.

editor
the text editor to be used, usually as a character string naming (or giving the path to) the text editor you want to use. See `Details`.

fileEncoding
the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for `file`.

Details

The behaviour of this function is very system-dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for `editor` is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of `editor`. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used.

editor can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

On Windows, UTF-8-encoded paths not valid in the current locale can be used.

See Also

`files`, `file.show`, `edit`, `fix`.

Examples

```r
## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")
## End(Not run)
```

Description

Utility for shell-style file tests.

Usage

`file_test(op, x, y)`
Arguments

op a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory), "-d" (existence and directory), "-L" or "-h" (existence and symbolic link), "-x" (executable as a file or searchable as a directory), "-w" (writable) and "-r" (readable). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist.

x, y character vectors giving file paths.

Details

'Existence' here means being on the file system and accessible by the stat system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see file.access.

See Also

file.exists which only tests for existence (test -e on some systems) but not for not being a directory.

file.path, file.info

Examples

dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))

findLineNum  Find the Location of a Line of Source Code, or Set a Breakpoint There

Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with keep.source = TRUE.

Usage

findLineNum(srcfile, line, nameonly = TRUE, envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE, envir = parent.frame(), lastenv, verbose = TRUE, tracer, print = FALSE, clear = FALSE, ...)
Arguments

srcfile The name of the file containing the source code.
line The line number within the file. See Details for an alternate way to specify this.
nameonly If TRUE (the default), we require only a match to basename(srcfile), not to
the full path.
envir Where do we start looking for function objects?
lastenv Where do we stop? See the Details.
verbose Should we print information on where breakpoints were set?
tracer An optional tracer function to pass to trace. By default, a call to browser is
inserted.
print The print argument to pass to trace.
clear If TRUE, call untrace rather than trace.
... Additional arguments to pass to trace.

Details

The findLineNum function searches through all objects in environment envir, its parent, grandparent,
etc., all the way back to lastenv.

lastenv defaults to the global environment if envir is not specified, and to the root environment
emptyenv() if envir is specified. (The first default tends to be quite fast, and will usually find all
user code other than S4 methods; the second one is quite slow, as it will typically search all attached
system libraries.)

For convenience, envir may be specified indirectly: if it is not an environment, it will be replaced
with environment(envir).

setBreakpoint is a simple wrapper function for trace and untrace. It will set or clear breakpoints
at the locations found by findLineNum.

The srcfile is normally a filename entered as a character string, but it may be a "srcfile" object,
or it may include a suffix like "filename.R#nn", in which case the number nn will be used as a
default value for line.

As described in the description of the where argument on the man page for trace, the R package
system uses a complicated scheme that may include more than one copy of a function in a package.
The user will typically see the public one on the search path, while code in the package will see
a private one in the package namespace. If you set envir to the environment of a function in the
package, by default findLineNum will find both versions, and setBreakpoint will set the break-
point in both. (This can be controlled using lastenv; e.g., envir = environment(foo), lastenv
= globalenv() will find only the private copy, as the search is stopped before seeing the public
copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic func-
tion, which may be in the base or other package, so it is usually necessary to have lastenv =
emptyenv() in order to find them. In some cases transformations are done by R when storing them
and findLineNum may not be able to find the original code. Many special cases, e.g. methods on
primitive generics, are not yet supported.

Value

findLineNum returns a list of objects containing location information. A print method is defined
for them.

setBreakpoint has no useful return value; it is called for the side effect of calling trace or
untrace.
fix

trace

Examples

## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)

---

fix          Fix an Object

Description

fix invokes edit on x and then assigns the new (edited) version of x in the user’s workspace.

Usage

fix(x, ...)

Arguments

x the name of an R object, as a name or a character string.

... arguments to pass to editor: see edit.

Details

The name supplied as x need not exist as an R object, in which case a function with no arguments
and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under edit.
See edit.data.frame for changes that can occur when editing a data frame or matrix.

See Also

edit, edit.data.frame
Examples

```r
## Not run:
## Assume 'my.fun' is a user defined function:
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)
```

flush.console

**Flush Output to a Console**

Description

This does nothing except on console-based versions of R. On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

```r
flush.console()
```

format

**Format Unordered and Ordered Lists**

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

```r
formatUL(x, label = "x", offset = 0,
         width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 * getOption("width"))
```

Arguments

- `x` a character vector of list items.
- `label` a character string used for labelling the items.
- `offset` a non-negative integer giving the offset (indentation) of the list.
- `width` a positive integer giving the target column for wrapping lines in the output.
- `type` a character string specifying the 'type' of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.
getAnywhere

start

a positive integer specifying the starting number of the first item in an ordered list.

Value

A character vector with the formatted entries.

See Also

formatDL for formatting description lists.

Examples

## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
  "Pour in wet ingredients.",
  "Mix for 10 minutes.",
  "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))

getAnywhere

Retrieve an R Object, Including from a Namespace

Description

These functions locate all objects with name matching their argument, whether visible on the search
path, registered as an S3 method or in a namespace but not exported. getAnywhere() returns the
objects and argsAnywhere() returns the arguments of any objects that are functions.

Usage

getAnywhere(x)
argsAnywhere(x)

Arguments

  x

  a character string or name.

Details

These functions look at all loaded namespaces, whether or not they are associated with a package
on the search list.
They do not search literally “anywhere”: for example, local evaluation frames and namespaces that
are not loaded will not be searched.
Where functions are found as registered S3 methods, an attempt is made to find which namespace
registered them. This may not be correct, especially if namespaces have been unloaded.
**Usage**

```r
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))
assignInNamespace(x, value, ns, pos = -1, 
                   envir = as.environment(pos))
assignInMyNamespace(x, value)
fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```
**Arguments**

- **x**
  - an object name (given as a character string).
- **value**
  - an R object.
- **ns**
  - a namespace, or character string giving the namespace.
- **pos**
  - where to look for the object: see `get`.
- **envir**
  - an alternative way to specify an environment to look in.
- ... arguments to pass to the editor: see `edit`.

**Details**

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for `get`: `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes `edit` on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

**Value**

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

**Warning**

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

**Note**

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used only for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

**See Also**

`get`, `fix`, `getS3method`
getParseData

Get Detailed Parse Information from Object

Description
If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage
getParseData(x, includeText = NA)
getParseText(parseData, id)

Arguments
x an expression returned from parse, or a function or other object with source reference information
includeText logical; whether to include the text of parsed items in the result
parseData a data frame returned from getParseData
id a vector of item identifiers whose text is to be retrieved

Details
In version 3.0.0, the R parser was modified to include code written by Romain Francois in his parser package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the srcref record associated with source references in the parsed code, and retrieved by the getParseData function.

Value
For getParseData:
If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

- line1 integer. The line number where the item starts. This is the parsed line number called "parse" in getSrcLocation, which ignores #line directives.
- col1 integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in getSrcLocation.
- line2 integer. The line number where the item ends.

Examples
getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats:::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")

## End(Not run)
The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the srcfile record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For getParseText:
A character vector of the same length as id containing the associated text items. If they are not included in parseData, they will be retrieved from the original file.

Note

There are a number of differences in the results returned by getParseData relative to those in the original parser code:

- Fewer columns are kept.
- The internal token number is not returned.
- col1 starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by getParseData.
- #line directives are identified, but other comment markup (e.g., roxygen comments) are not.

parse, srcref

Examples

fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "+"")
  sum <- d$parent[plus]
getS3method

Get an S3 Method

Description

Get a method for an S3 generic, possibly from a namespace or the generic’s registry.

Usage

getS3method(f, class, optional = FALSE, envir = parent.frame())

Arguments

- **f**: a character string giving the name of the generic.
- **class**: a character string giving the name of the class.
- **optional**: logical: should failure to find the generic or a method be allowed?
- **envir**: the environment in which the method and its generic are searched first.

Details

S3 methods may be hidden in namespaces, and will not then be found by `get`: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic \( f \) is called from: `getS3method` returns the method found if \( f \) were called from the same environment.

Value

The function found, or NULL if no function is found and optional = TRUE.

See Also

- `methods`, `get`, `getAnywhere`

Examples

```r
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```
getWindowsHandle

Get a Windows Handle

Description
Get the Windows handle of a window or of the R process in MS Windows.

Usage
getWindowsHandle(which = "Console")

Arguments
which a string (see below), or the number of a graphics device window (which must a windows one).

Details
getWindowsHandle gets the Windows handle. Possible choices for which are:

- "Console" The console window handle.
- "Frame" The MDI frame window handle.
- "Process" The process pseudo-handle.
- A device number The window handle of a graphics device

These values are not normally useful to users, but may be used by developers making add-ons to R. NULL is returned for the Frame handle if not running in MDI mode, for the Console handle when running Rterm, for any unrecognized string for which, or for a graphics device with no corresponding window.
Other windows (help browsers, etc.) are not accessible through this function.

Value
An external pointer holding the Windows handle, or NULL.

Note
This is only available on Windows.

See Also
getIdentification, getWindowsHandles

Examples
if(.Platform$OS.type == "windows")
  print( getWindowsHandle() )
getWindowsHandles  Get handles of Windows in the MS Windows RGui

Description

This function gets the Windows handles of visible top level windows or windows within the R MDI frame (when using the Rgui).

Usage

getWindowsHandles(which = "R", pattern = "", minimized = FALSE)

Arguments

which
A vector of strings "R" or "all" (possibly with repetitions). See the Details section.

pattern
A vector of patterns that the titles of the windows must match.

minimized
A logical vector indicating whether minimized windows should be considered.

Details

This function will search for Windows handles, for passing to external GUIs or to the arrangeWindows function. Each of the arguments may be a vector of values. These will be treated as follows:

- The arguments will all be recycled to the same length.
- The corresponding elements of each argument will be applied in separate searches.
- The final result will be the union of the windows identified in each of the searches.

If an element of which is "R", only windows belonging to the current R process will be returned. In MDI mode, those will be the child windows within the R GUI (Rgui) frame. In SDI mode, all windows belonging to the process will be included.

If the element is "all", then top level windows will be returned.

The elements of pattern will be used to make a subset of windows whose title text matches (according to grep) the pattern.

If minimized = FALSE, minimized windows will be ignored.

Value

A list of external pointers containing the window handles.

Note

This is only available on Windows.

Duncan Murdoch
glob2rx

Description

Change wildcard aka globbing patterns into the corresponding regular expressions (regexp).

Usage

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

Arguments

pattern character vector
trim.head logical specifying if leading "^.*" should be trimmed from the result.
trim.tail logical specifying if trailing ".*$" should be trimmed from the result.

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. ? is mapped to . (match a single character), * to .* (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even ., [ and ] can be used in pattern, but glob2rx() may not work correctly with arbitrary characters in pattern.

Value

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

regexp about regular expression, sub, etc about substitutions using regexps.
Examples

```r
stopifnot(glob2rx("abc.*") == "^abc\",".",
glob2rx("a?b.*") == "^a.b\",".",
glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\..*$",
glob2rx("*.doc") == "^.*\\.doc$",
glob2rx("*.doc", trim.head = TRUE) == "\\.doc$",
glob2rx("*.t*") == "^.*\\.t",
glob2rx("*.t??") == "^.*\\.t..*$",
glob2rx("*\[") == "^.*\["
)
```

globalVariables

### Declarations Used in Checking a Package

#### Description

For **globalVariables**, the names supplied are of functions or other objects that should be regarded as defined globally when the **check** tool is applied to this package. The call to **globalVariables** will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to **codetools**. (This case is handled automatically by **setRefClass()** and friends, using the supplied field and method names.)

For **suppressForeignCheck**, the names supplied are of variables used as `.NAME` in foreign function calls which should not be checked by **checkFF(registration = TRUE)**. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a **dontCheck** function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

#### Usage

```r
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

#### Arguments

- **names**
  - The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.

- **package**
  - The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.

  When the call to **globalVariables** or **suppressForeignCheck** comes in the package’s source file, the argument is normally omitted, as in the example below.

- **add**
  - Should the contents of **names** be added to the current global variables or replace it?
Details

The lists of declared global variables and native symbol objects are stored in a metadata object in the package's namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package `tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

Value

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in check and/or in codetools, so in this version the information is stored at the package level.

Author(s)

John Chambers and Duncan Murdoch

See Also

dontCheck.

Examples

```r
## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)
```
**hasName**  
*Check for Name*

**Description**

hasName is a convenient way to test for one or more names in an R object.

**Usage**

```r
hasName(x, name)
```

**Arguments**

- `x`: Any object.
- `name`: One or more character values to look for.

**Details**

`hasName(x, name)` is defined to be equivalent to `name %in% names(x)`, though it will evaluate slightly more quickly. It is intended to replace the common idiom `!is.null(x$name)`. The latter can be unreliable due to partial name matching; see the example below.

**Value**

A logical vector of the same length as `name` containing `TRUE` if the corresponding entry is in `names(x)`.

**See Also**

`%in%`, `exists`

**Examples**

```r
x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a)  # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")
```

---

**head**  
*Return the First or Last Parts of an Object*

**Description**

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.
Usage

head(x, ...)  
## Default S3 method:  
head(x, n = 6L, ...)

## S3 method for class 'matrix'  
head(x, n = 6L, ...) # is exported as head.matrix()  
## NB: The methods for 'data.frame' and 'array' are identical to the 'matrix' one

## S3 method for class 'ftable'  
head(x, n = 6L, ...)

## S3 method for class 'function'  
head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:  
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)

## S3 method for class 'matrix'  
tail(x, n = 6L, keepnums = TRUE, addrownums, ...) # exported as tail.matrix()  
## NB: The methods for 'data.frame', 'array', and 'table'  
## are identical to the 'matrix' one

## S3 method for class 'ftable'  
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)

## S3 method for class 'function'  
tail(x, n = 6L, ...)

Arguments

x          an object
n          an integer vector of length up to dim(x) (or 1, for non-dimensioned objects).  

Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of n[i] includes the first/last n[i] indices in that dimension, while a negative value excludes the last/first abs(n[i]), including all remaining indices. NA or non-specified values (when length(n) < length(dim(x))) select all indices in that dimension. Must contain at least one non-missing value.

keepnums   in each dimension, if no names in that dimension are present, create them using the indices included in that dimension. Ignored if dim(x) is NULL or its length 1.

addrownums deprecated - keepnums should be used instead. Taken as the value of keepnums if it is explicitly set when keepnums is not.

...        arguments to be passed to or from other methods.

Details

For vector/array based objects, head() (tail()) returns a subset of the same dimensionality as x, usually of the same class. For historical reasons, by default they select the first (last) 6 indices in the first dimension ("rows") or along the length of a non-dimensioned vector, and the full extent (all indices) in any remaining dimensions. head.matrix() and tail.matrix() are exported.
The default and array/matrix methods for head() and tail() are quite general. They will work as is for any class which has a dim() method, a length() method (only required if dim() returns NULL), and a [ method (that accepts the drop argument and can subset in all dimensions in the dimensioned case).

For functions, the lines of the deparsed function are returned as character strings.

When \( x \) is an array/matrix of dimensionality two and more, tail() will add dimnames similar to how they would appear in a full printing of \( x \) for all dimensions \( k \) where \( n[k] \) is specified and non-missing and \( \text{dimnames}(x)[[k]] \) (or dimnames(\( x \)) itself) is NULL. Specifically, the form of the added dimnames will vary for different dimensions as follows:

- \( k=1 \) (rows): "\([n,]\)" (right justified with whitespace padding)
- \( k=2 \) (columns): "\([,n]\)" (with no whitespace padding)
- \( k>2 \) (higher dims): "\(n\)", i.e., the indices as character values

Setting keepnums = FALSE suppresses this behaviour.

As data.frame subsetting (‘indexing’) keeps attributes, so do the head() and tail() methods for data frames.

**Value**

An object (usually) like \( x \) but generally smaller. Hence, for arrays, the result corresponds to \( x[,\ldots,\text{drop}=\text{FALSE}] \). For ftable objects \( x \), a transformed \text{format}(\( x \)).

**Note**

For array inputs the output of tail when keepnums is TRUE, any dimnames vectors added for dimensions \( >2 \) are the original numeric indices in that dimension as character vectors. This means that, e.g., for 3-dimensional array arr, tail(arr, c(2,2,-1))[,2] and tail(arr, c(2,2,-1))[,,"2"] may both be valid but have completely different meanings.

**Author(s)**

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet. Multi-dimension support added by Gabriel Becker.

**Examples**

```r
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

head(iris3)
head(iris3, c(6L, 2L))
head(iris3, c(6L, -1L, 2L))

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
## the bottom-right "corner" :
tail(freeny.x, n = c(4, 2))
tail(freeny.y)
```
tail(iris3)
tail(iris3, c(6L, 2L))
tail(iris3, c(6L, -1L, 2L))

## iris with dimnames stripped
a3d <- iris3; dimnames(a3d) <- NULL
tail(a3d, c(6, -1, 2)) # keepnums = TRUE is default here!
tail(a3d, c(6, -1, 2), keepnums = FALSE)

## data frame w/ a (non-standard) attribute:
treeS <- structure(trees, foo = "bar")
(n <- nrow(treeS))
stopifnot(exprs = {
  # attribute is kept
  identical(htS <- head(treeS), treeS[1:6, ])
  identical(attr(htS, "foo"), "bar")
  identical(tS <- tail(treeS), treeS[(n-5):n, ])
  ## BUT if I use "useAttrib(.)", this is *not* ok, when n is of length 2:
  ## --- because [i,j]-indexing of data frames *also* drops "other" attributes ..
  identical(tail(treeS, 3:2), treeS[(n-2):n, 2:3])
})
tail(library) # last lines of function

head(stats::ftable(Titanic))

## 1d-array (with named dim) :
a1 <- array(1:7, 7); names(dim(a1)) <- "O2"
stopifnot(exprs = {
  identical(tail(a1, 10), a1)
  identical(head(a1, 10), a1)
  identical(head(a1, 1), a1[1, drop=FALSE]) # was a1[1] in R <= 3.6.x
  identical(tail(a1, 2), a1[6:7])
  identical(tail(a1, 1), a1[7, drop=FALSE]) # was a1[7] in R <= 3.6.x
})

---

help

Documentation

**Description**

help is the primary interface to the help systems.

**Usage**

```r
help(topic, package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      help_type = getOption("help_type"))
```

**Arguments**

- **topic**
  - usually, a name or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.
If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a reserved word (if syntactically valid) or character string. See ‘Details’ for what happens if this is omitted.

package

a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples).

lib.loc

a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).

verbose

logical; if TRUE, the file name is reported.

try.all.packages

logical; see Note.

help_type

character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.

Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by browseURL.

(On Unix-alikes, where possible an existing browser window is re-used: the macOS GUI uses its own browser window.)

If for some reason HTML help is unavailable (see startDynamicHelp), plain text help will be used instead.

- For help only, typeset as PDF – see the section on ‘Offline help’.

On Unix-alikes: The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

On Windows: The default for the type of help is selected when R is installed – the ‘factory-fresh’ default is HTML help.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting options(useFancyQuotes = FALSE).

topic is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If lib.loc only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by backticks) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next). The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

If multiple help files matching topic are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be
an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

## Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file `Rhelp.cfg` somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some environment variables are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration’ manual).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

### Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are **not** searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither `packages` nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

## References

## See Also

`?` for shortcuts to help topics.

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the help objects they contain; `data()` for listing available data sets; `methods()`.

Use `prompt()` to get a prototype for writing help pages of your own package.

## Examples

```r
help()
help(help)  # the same
help(lapply)
```
help("for")  # or ?"for", but quotes/backticks are needed

try(# requires working TeX installation:
   help(dgamma, help_type = "pdf")
   ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
   system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
)

help(package = "splines")  # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE))  # reports not found (an error)
help("bs", try.all.packages = TRUE)  # reports can be found
   # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))

---

**help.request** Send a Post to R-help

**Description**

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

**Usage**

```
help.request(subject = "",
              address = "r-help@R-project.org",
              file = "R.help.request", ...)
```

**Arguments**

- **subject**: subject of the email. Please do not use single quotes ('') in the subject! Post separate help requests for multiple queries.
- **address**: recipient’s email address.
- **file**: filename to use (if needed) for setting up the email.
- **...**: additional named arguments such as `method` and `ccaddress` to pass to `create.post`.

**Details**

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see [https://www.r-project.org/posting-guide.html](https://www.r-project.org/posting-guide.html)).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response if given.
help.search

• checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
• asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to `create.post`.

Value

Nothing useful.

Author(s)

Heather Turner, based on the then current code and help page of `bug.report()`.

See Also

The posting guide (https://www.r-project.org/posting-guide.html), also `sessionInfo()` from which you may add to the help request.

`create.post`.

---

help.search

Search the Help System

Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

Usage

```r
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db =getOption("help.db"),
            verbose =getOption("verbose"),
            rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
            types =getOption("help.search.types"))

??pattern
field??pattern
```
Arguments

pattern a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored.

fields a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched.

apropos a character string to be matched in the help page topics and title.

keyword a character string to be matched in the help page 'keywords'. ‘Keywords’ are really categories: the standard categories are listed in file ‘R.home("doc")/KEYWORDS’ (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE.

whatis a character string to be matched in the help page topics.

ignore.case a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.

package a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

help.db a character string giving the file path to a previously built and saved help database, or NULL.

verbose logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for verbose = 1 and a package-by-package list for verbose >= 2.

rebuild a logical indicating whether the help database should be rebuilt. This will be done automatically if lib.loc or the search path is changed, or if package is used and a value is not found.

agrep if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via agrep is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via grep. If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument max.distance in the documentation for agrep.

use_UTF8 logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in agrep to be Perl regexps.

types a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.

field a single value of fields to search.

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database via hsearch_db.
The arguments `apropos` and `whatis` play a role similar to the Unix commands with the same names. Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session. Note that currently the aliases in the matching help files are not displayed. As with `?`, in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

For help files, `\keyword` entries which are not among the standard keywords as listed in file `KEYWORDS` in the R documentation directory are taken as concepts. For standard keyword entries different from `internal`, the corresponding descriptions from file `KEYWORDS` are additionally taken as concepts. All `\concept` entries used as concepts.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the \VignetteKeyword entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

See Also

`hsearch_db` for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

`help; help.start` for starting the hypertext (currently HTML) version of R’s online documentation, which offers a similar search mechanism.

`RSiteSearch` to access an on-line search of R resources.

`apropos` uses regexps and has nice examples.

Examples

```r
help.search("linear models")  # In case you forgot how to fit linear models
help.search("non-existent topic")

??utils::help  # All the topics matching "help" in the utils package

help.search("print")  # All help pages with topics or title matching 'print'
help.search(apropos = "print")  # The same

help.search(keyword = "hplot")  # All help pages documenting high-level plots.
file.show(file.path(R.home("doc"), "KEYWORDS"))  # show all keywords
```
help.start

## Help pages with documented topics starting with 'try'.

```r
help.search("\btry\", fields = "alias")
```

---

**help.start**

**Hypertext Documentation**

### Description

Start the hypertext (currently HTML) version of R’s online documentation.

### Usage

```r
help.start(update = FALSE, gui = "irrelevant",
            browser = getOption("browser"), remote = NULL)
```

### Arguments

- **update**
  - logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if `remote` is non-NULL.)
- **gui**
  - just for compatibility with S-PLUS.
- **browser**
  - the name of the program to be used as hypertext browser. It should be in the `PATH`, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used.
- **remote**
  - A character string giving a valid URL for the `R_HOME` directory on a remote location.

### Details

Unless `remote` is specified this requires the HTTP server to be available (it will be started if possible: see `startDynamicHelp`).

One of the links on the index page is the HTML package index, `R.home("docs")/html/packages.html`, which can be remade by `make.packages.html()`. For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if `.libPaths` has changed or any of the directories has been changed). This can be slow, and using `update = TRUE` will ensure that the packages list is updated before launching the index page.

Argument `remote` can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

### See Also

- `help()` for on- and off-line help in other formats.
- `browseURL` for how the help file is displayed.
- `RSiteSearch` to access an on-line search of R resources.
Examples

```r
help.start()
## Not run:
if(.Platform$OS.type == "unix") # includes Mac
## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))
## End(Not run)
```

### hsearch-utils

**Help Search Utilities**

**Description**

Utilities for searching the help system.

**Usage**

```r
hsearch_db(package = NULL, lib.loc = NULL,
            types = getOption("help.search.types"),
            verbose = getOption("verbose"),
            rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
```

**Arguments**

- **package**: a character vector with the names of packages to search through, or `NULL` in which case all available packages in the library trees specified by `lib.loc` are searched.
- **lib.loc**: a character vector describing the location of R library trees to search through, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- **types**: a character vector listing the types of documentation to search. See `help.search` for details.
- **verbose**: a logical controlling the verbosity of building the help search database. See `help.search` for details.
- **rebuild**: a logical indicating whether the help search database should be rebuilt. See `help.search` for details.
- **use_UTF8**: logical: should results be given in UTF-8 encoding?
- **db**: a help search database as obtained by calls to `hsearch_db()`.

**Details**

`hsearch_db()` builds and caches the help search database for subsequent use by `help.search`. (In fact, re-builds only when forced (`rebuild = TRUE`) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to.
Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in help.search for how searchable entries are interpreted according to help type. hsearch_db_concepts() and hsearch_db_keywords() extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

Examples

db <- hsearch_db()

## Total numbers of documentation objects, aliases, keywords and
## concepts (using the current format):
sapply(db, NROW)

## Can also be obtained from print method:
db

## 10 most frequent concepts:
head(hsearch_db_concepts(), 10)

## 10 most frequent keywords:
head(hsearch_db_keywords(), 10)

---

**INSTALL**

*Install Add-on Packages*

**Description**

Utility for installing add-on packages.

**Usage**

R CMD INSTALL [options] [-l lib] pkgs

**Arguments**

- **pkgs**: a space-separated list with the path names of the packages to be installed. See ‘Details’.
- **lib**: the path name of the R library tree to install to. Also accepted in the form ‘--library=lib’. Paths including spaces should be quoted, using the conventions for the shell in use.
- **options**: a space-separated list of options through which in particular the process for building the help files can be controlled. Use R CMD INSTALL --help for the full current list of options.

**Details**

This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as R CMD INSTALL pkgs without explicitly specifying lib, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree lib, use R CMD INSTALL -l lib pkgs. This prepends lib to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).
Both lib and the elements of pkgs may be absolute or relative path names of directories. pkgs may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpackaged by the internal untar function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to ‘tar.exe’ has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by ‘--preclean’ or after by ‘--clean’: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a ‘configure’ script that can be passed arguments or variables via the option ‘--configure-args’ and ‘--configure-vars’, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables LIBS and CPPFLAGS to specify these locations (and set these via ‘--configure-vars’), see section ‘Configuration variables’ in ‘R Installation and Administration’ for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option ‘--no-configure’.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for install.packages.

Option ‘--build’ can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by utils::tar unless environment variable R_INSTALL_TAR is set.

By default a package is installed with static HTML help pages if and only if R was: use options ‘--html’ and ‘--no-html’ to override this.

Packages are not by default installed keeping the source formatting (see the keep.source argument to source): this can be enabled by the option ‘--with-keep.source’ or by setting environment variable R_KEEP_PKG_SOURCE to yes.

Specifying the ‘--install-tests’ option copies the contents of the ‘tests’ directory into the package installation. If the R_ALWAYS_INSTALL_TESTS environment variable is set to a true value, the tests will be installed even if ‘--install-tests’ is omitted.

Use R CMD INSTALL --help for concise usage information, including all the available options.

Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use ‘--no-multiarch’. To install just the compiled code for another sub-architecture, use ‘--libs-only’.
There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag ‘--force-biarch’ (and packages can specify this via a ‘Biarch: yes’ field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

**Staged installation**

The default way to install source packages changed in R 3.6.0, so packages are first installed to a temporary location and then (if successful) moved to the destination library directory. Some older packages were written in ways that assume direct installation to the destination library.

Staged installation can currently be overridden by having a line ‘StagedInstall: no’ in the package’s DESCRIPTION file, via flag ‘--no-staged-install’ or by setting environment variable R_INSTALL_STAGED to a false value (e.g. ‘false’ or ‘no’).

Staged installation requires either ‘--pkglock’ or ‘--lock’, one of which is used by default.

**Note**

The options do not have to precede ‘pkgs’ on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see `tempdir`, usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

**See Also**

`REMOVE`, `.libPaths` for information on using several library trees; `install.packages` for R-level installation of packages; `update.packages` for automatic update of packages using the Internet or a local repository.

---

install.packages

### Install Packages from Repositories or Local Files

#### Description

Download and install packages from CRAN-like repositories or from local files.

#### Usage

```
install.packages(pkgs, lib, repos = getOption("repos"),
method, available = NULL, destdir = NULL,
dependencies = NA, type = getOption("pkgType"),
configure.args = getOption("configure.args"),
configure.vars = getOption("configure.vars"),
```
install.packages

install.packages(clean = FALSE, Ncpus =getOption("Ncpus", 1L),
verbose = getOption("verbose"),
libs_only = FALSE, INSTALL_opts, quiet = FALSE,
keep_outputs = FALSE, ...)

Arguments

pkgs character vector of the names of packages whose current versions should be downloaded from the repositories.
If repos = NULL, a character vector of file paths,
on windows, file paths of `.zip` files containing binary builds of packages.
(http:// and file:// URLs are also accepted and the files will be downloaded and installed from local copies.) Source directories or file paths or URLs of archives may be specified with type = "source", but some packages need suitable tools installed (see the 'Details' section).
On Unix-alikes, these file paths can be source directories or archives or binary package archive files (as created by R CMD build --binary). (http:// and file:// URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for macOS these can be `.tgz` files containing binary package archives. Tilde-expansion will be done on file paths.
If this is missing, a listbox of available packages is presented where possible in an interactive R session.

lib character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of .libPaths().

repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org". For more details on supported URL schemes see url.
Can be NULL to install from local files, directories or URLs: this will be inferred by extension from pkgs if of length one.

ccontriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD, or only have binary packages. Overrides argument repos. Incompatible with type = "both".

method download method, see download.file. Unused if a non-NULL available is supplied.

available a matrix as returned by available.packages listing packages available at the repositories, or NULL when the function makes an internal call to available.packages. Incompatible with type = "both".

destdir directory where downloaded packages are stored. If it is NULL (the default) a subdirectory downloaded_packages of the session temporary directory will be used (and the files will be deleted at the end of the session).

dependencies logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances").
Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.
install.packages

The default, NA, means c("Depends", "Imports", "LinkingTo").
TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests")
for pkgs and c("Depends", "Imports", "LinkingTo") for added dependen-
cies: this installs all the packages needed to run pkgs, their examples, tests and
vignettes (if the package author specified them correctly).

In all of these, "LinkingTo" is omitted for binary packages.

type character, indicating the type of package to download and install. Will be
"source" except on Windows and some macOS builds: see the section on 'Bi-
nary packages' for those.

configure.args (Used only for source installs.) A character vector or a named list. If a character
vector with no names is supplied, the elements are concatenated into a single
string (separated by a space) and used as the value for the '--configure-args' flag in the call to R CMD INSTALL. If the character vector has names these are
assumed to identify values for '--configure-args' for individual packages.
This allows one to specify settings for an entire collection of packages which
will be used if any of those packages are to be installed. (These settings can
therefore be re-used and act as default settings.)
A named list can be used also to the same effect, and that allows multi-element
character strings for each package which are concatenated to a single string to
be used as the value for '--configure-args'.

configure.vars (Used only for source installs.) Analogous to configure.args for flag
'--configure-vars', which is used to set environment variables for the
configure run.

clean a logical value indicating whether to add the '--clean' flag to the call to R CMD
INSTALL. This is sometimes used to perform additional operations at the end of
the package installation in addition to removing intermediate files.

Ncpus the number of parallel processes to use for a parallel install of more than one
source package. Values greater than one are supported if the make command
specified by Sys.getenv("MAKE", "make") accepts argument -k -j Ncpus.

verbose a logical indicating if some "progress report" should be given.

libs_only a logical value: should the '--libs-only' option be used to install only addi-
tional sub-architectures for source installs? (See also INSTALL_opts.) This can
also be used on Windows to install just the DLL(s) from a binary package, e.g. to
add 64-bit DLLs to a 32-bit install.

INSTALL_opts an optional character vector of additional option(s) to be passed to R CMD
INSTALL for a source package install. E.g., c("--html", "--no-multiarch", "--no-test-load").
Can also be a named list of character vectors to be used as additional options,
with names the respective package names.

quiet logical: if true, reduce the amount of output. This is not passed to
available.packages() in case that is called, on purpose.

keep_outputs a logical: if true, keep the outputs from installing source packages in the current
working directory, with the names of the output files the package names with
'.out' appended. Alternatively, a character string giving the directory in which
to save the outputs. Ignored when installing from local files.

Arguments to be passed to download.file, available.packages, or to the
functions for binary installs on macOS and Windows (which accept an argument
"lock": see the section on 'Locking').
install.packages

Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in .libPaths(), with a message if there is more than one.) If lib is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of Sys.getenv("R_LIBS_USER")) and install there.

Detection of a writable directory is problematic on Windows: see the ‘Note’ section.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in lib are on the default library path for installs (set by environment variable R_LIBS).

You are advised to run update.packages before install.packages to ensure that any already installed dependencies have their latest versions.

Value

Invisible NULL.

Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as source packages, but binary packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of type are (currently) "source", "mac.binary", and "win.binary": the appropriate binary type where supported can also be selected as "binary".

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

options(install.packages.check.source = "no")

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means ‘use binary if available and current, otherwise try source’. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by getOption("install.packages.compile.from.source"). type = "both" will be silently changed to "binary" if either contriburl or available is specified.

Using packages with type = "source" always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise,

on Windows you will need to have installed the Rtools collection as described in the ‘R for Windows FAQ’ and you must have the PATH environment variable set up as required by Rtools.

For a 32/64-bit installation of R on Windows, a small minority of packages with compiled code need either INSTALL_opts = "--force-biarch" or INSTALL_opts = "--merge-multiarch" for a source installation. (It is safe to always set the latter when installing from a repository or tarballs, although it will be a little slower.)

When installing a package on Windows, install.packages will abort the install if it detects that the package is already installed and is currently in use. In some circumstances (e.g.,
multiple instances of R running at the same time and sharing a library) it will not detect a problem, but the installation may fail as Windows locks files in use.

**On Unix-alikes**, when the package contains C/C++/Fortran code that needs compilation, on macOS you need to have installed the ‘Command-line tools for Xcode’ (see the ‘R Installation and Administration’ manual) and if needed by the package a Fortran compiler, and have them in your path.

**Locking**

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is ‘locked’ by creating a directory ‘00LOCK’ within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option ‘--pkglock’ which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when \( Ncpus > 1 \). Finally locking (and restoration on error) can be suppressed by ‘--no-lock’.

For a macOS binary install, no locking is done by default. Setting argument lock to TRUE (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs. For Windows binary install, per-directory locking is used by default (lock defaults to the value of `getOption("install.lock", TRUE)`). If the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed; this inhibits any further installs to the library directory (or for --pkglock, of the package) until the lock directory is removed manually.

**Parallel installs**

Parallel installs are attempted if \( \text{pkgs} \) has length greater than one and \( Ncpus > 1 \). It makes use of a parallel make, so the make specified (default make) when R was built must be capable of supporting make \(-j n\): GNU make, dmake and pmake do, but Solaris make and older FreeBSD make do not: if necessary environment variable MAKE can be set for the current session to select a suitable make.

`install.packages` needs to be able to compute all the dependencies of \( \text{pkgs} \) from \( \text{available} \), including if one element of \( \text{pkgs} \) depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, \( \text{available} \) needs to cover both CRAN and Bioconductor packages.

**Timeouts**

A limit on the elapsed time for each call to \( \text{R CMD INSTALL} \) (so for source installs) can be set via environment variable \_R_INSTALL_PACKAGES_ELAPSED_TIMEOUT_: in seconds (or in minutes or hours with optional suffix ‘m’ or ‘h’, suffix ‘s’ being allowed for the default seconds) with \( 0 \) meaning no limit.

For non-parallel installs this is implemented via the timeout argument of `system2`: for parallel installs via the OS’s `timeout` command. (The one tested is from GNU `coreutils`, commonly available on Linux but not other Unix-alikes. If no such command is available the timeout request is ignored, with a warning.) For parallel installs a ‘Error 124’ message from make indicates that timeout occurred.

Timeouts during installation might leave lock directories behind and not restore previous versions.
**Version requirements on source installs**

If you are not running an up-to-date version of R you may see a message like

```
package 'RODBC' is not available (for R version 3.5.3)
```

One possibility is that the package is not available in any of the selected repositories; another is that it is available but only for current or recent versions of R. For CRAN packages take a look at the package’s CRAN page (e.g., [https://cran.r-project.org/package=RODBC](https://cran.r-project.org/package=RODBC)). If that indicates in the ‘Depends’ field a dependence on a later version of R you will need to look in the ‘Old sources’ section and select the URL of a version of comparable age to your R. Then you can supply that URL as the first argument of `install.packages()`: you may need to first manually install its dependencies.

For other repositories, using `available.packages(filters = "OS_type")[pkgname, ]` will show if the package is available for any R version (for your OS).

**Note**

**On Unix-alikes:** Some binary distributions of R have INSTALL in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called with `type = "source"` on such a system.

Some binary Linux distributions of R can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of R which should bring in all those tools as dependencies.

**On Windows:** `install.packages` tries to detect if you have write permission on the library directories specified, but Windows reports unreliably. If there is only one library directory (the default), R tries to find out by creating a test directory, but even this need not be the whole story: you may have permission to write in a library directory but lack permission to write binary files (such as `.dll` files) there. See the ‘R for Windows FAQ’ for workarounds.

**See Also**

`update.packages`, `available.packages`, `download.packages`, `installed.packages`, `contrib.url`.

See `download.file` for how to handle proxies and other options to monitor file transfers.

`untar` for manually unpacking source package tarballs.

`INSTALL`, `REMOVE`, `remove.packages`, `library`, `.packages`, `read.dcf`

The ‘R Installation and Administration’ manual for how to set up a repository.

**Examples**

```r
## Not run:
## A Linux example for Fedora’s layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
    configure.args = c(RNetCDF = "--with-netcdf=include=/usr/include/udunits2"))
```

## End(Not run)
installed.packages  Find Installed Packages

Description

Find (or retrieve) details of all packages installed in the specified libraries.

Usage

installed.packages(lib.loc = NULL, priority = NULL, 
                    noCache = FALSE, fields = NULL, 
                    subarch = .Platform$r_arch, ...)

Arguments

lib.loc character vector describing the location of R library trees to search through, or 
            NULL for all known trees (see .libPaths).

priority character vector or NULL (default). If non-null, used to select packages; "high"
            is equivalent to c("base", "recommended"). To select all packages without an
            assigned priority use priority = "NA".

noCache Do not use cached information, nor cache it.

fields a character vector giving the fields to extract from each package’s DESCRIPTION
            file in addition to the default ones, or NULL (default). Unavailable fields result in
            NA values.

subarch character string or NULL. If non-null and non-empty, used to select packages
            which are installed for that sub-architecture.

... allows unused arguments to be passed down from other functions.

Details

installed.packages scans the ‘DESCRIPTION’ files of each package found along lib.loc and
returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified fields argument, 
and updated only if the top-level library directory has been altered, for example by installing or
removing a package. If the cached information becomes confused, it can be avoided by specifying
noCache = TRUE.

Value

A matrix with one row per package, row names the package names and column names (cur-
"Suggests", "Enhances", "OS_type", "License" and "Built" (the R version the package was
built under). Additional columns can be specified using the fields argument.
isS3method

**Note**

This needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

It will be slow when thousands of packages are installed, so do not use it to find out if a named package is installed (use `find.package` or `system.file`) nor to find out if a package is usable (call `requireNamespace` or `require` and check the return value) nor to find details of a small number of packages (use `packageDescription`).

**See Also**

`update.packages`, `install.packages`, `INSTALL`, `REMOVE`.

**Examples**

```r
## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table( plic[, "License"] )
```

---

**isS3method**

*Is 'method' the Name of an S3 Method?*

**Description**

Checks if `method` is the name of a valid/registered S3 method. Alternatively, when `f` and `class` are specified, it is checked if `f` is the name of an S3 generic function and `paste(f, class, sep=".")` is a valid S3 method.

**Usage**

`isS3method(method, f, class, envir = parent.frame())`

**Arguments**

- `method` a character string, typically of the form "<fn>.<class>". If omitted, `f` and `class` have to be specified instead.
- `f` optional character string, typically specifying an S3 generic function. Used, when `method` is not specified.
- `class` optional character string, typically specifying an S3 class name. Used, when `method` is not specified.
- `envir` the `environment` in which the method and its generic are searched first, as in `getS3method()`.

**Value**

`logical` TRUE or FALSE
isS3stdGeneric

Check if a Function Acts as an S3 Generic

Description

Determines whether \( f \) acts as a standard S3-style generic function.

Usage

\[ \text{isS3stdGeneric}(f) \]

Arguments

\( f \)  

a function object

Details

A closure is considered a standard S3 generic if the first expression in its body calls \( \text{UseMethod} \). Functions which perform operations before calling \( \text{UseMethod} \) will not be considered “standard” S3 generics.

If \( f \) is currently being traced, i.e., inheriting from class "traceable", the definition of the original untraced version of the function is used instead.

Value

If \( f \) is an S3 generic, a logical containing TRUE with the name of the S3 generic (the string passed to \( \text{UseMethod} \)). Otherwise, FALSE (unnamed).
Description

Front-end for creating executable programs on unix-alikes, i.e., not on Windows.

Usage

`R CMD LINK [options] linkcmd`

Arguments

linkcmd  a list of commands to link together suitable object files (include library objects) to create the executable program.

options  further options to control the linking, or for obtaining information about usage and version.

Details

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of `libtool` installed at `R_HOME/bin`.

R CMD LINK --help gives usage information.

Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

`COMPILE`.

Examples

```
## Not run: ## examples of front-ends linked against R.
## First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo.o `R CMD config --ldflags`

## if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo.o ForFoo.o `R CMD config --ldflags` $FLIBS

## And for a C++ front-end
CXX=`R CMD config CXX`
R CMD COMPILIE foo.cc
R CMD LINK $CXX -o foo.o `R CMD config --ldflags`

## End(Not run)
```
localeToCharset  Select a Suitable Encoding Name from a Locale Name

Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

localeToCharset(locale = Sys.getlocale("LC_CTYPE"))

Arguments

locale character string naming a locale.

Details

The operation differs by OS.

On Windows, a locale is specified like "English_United Kingdom.1252". The final component gives the codepage, and this defines the encoding.

On Unix-alikes: Locale names are normally like es_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.

See Also

Sys.getlocale, iconv.

Examples

localeToCharset()
**ls.str**  

**List Objects and their Structure**

**Description**

ls.str and lsf.str are variations of `ls` applying `str()` to each matched name: see section Value.

**Usage**

```r
ls.str(pos = -1, name, envir, all.names = FALSE,  
      pattern, mode = "any")

lsf.str(pos = -1, envir, ...)
```

```r
## S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ...,
     digits = max(1,getOption("str")$digits))
```

**Arguments**

- `pos` integer indicating search path position, or -1 for the current environment.
- `name` optional name indicating search path position, see `ls`.
- `envir` environment to use, see `ls`.
- `all.names` logical indicating if names which begin with a . are omitted; see `ls`.
- `pattern` a regular expression passed to `ls`. Only names matching pattern are considered.
- `max.level` maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.
- `give.attr` logical; if TRUE (default), show attributes as sub structures.
- `mode` character specifying the mode of objects to consider. Passed to `exists` and `get`.
- `x` an object of class "ls_str".
- `...` further arguments to pass. `lsf.str` passes them to `ls.str` which passes them on to `ls`. The (non-exported) print method `print.ls_str` passes them to `str`.
- `digits` the number of significant digits to use for printing.

**Value**

`ls.str` and `lsf.str` return an object of class "ls_str", basically the character vector of matching names (functions only for `lsf.str`), similarly to `ls`, with a `print()` method that calls `str()` on each object.

**Author(s)**

Martin Maechler

**See Also**

`str`, `summary`, `args`.
Examples

require(stats)

lsf.str() #-- how do the functions look like which I am using?
ls.str(mode = "list") #-- what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name?
lsf.str(pos = length(search()), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]: tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2))," *: *"), `[
`, 1))
stopifnot(nms == c("aa", "r","x","y"))

Description
Show the name and email address of the maintainer of a package.

Usage
maintainer(pkg)

Arguments
pkg Character string. The name of a single package.

Details
Accesses the package description to return the name and email address of the maintainer.
Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the bug.report function.

Value
A character string giving the name and email address of the maintainer of the package, or NA if no such package is installed.

Author(s)
David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

Examples

maintainer("MASS")

make.packages.html

Update HTML Package List

Description

Re-create the HTML list of packages.

Usage

make.packages.html(lib.loc = .libPaths(), temp = FALSE,
    verbose = TRUE, docdir = R.home("doc"))

Arguments

lib.loc character vector. List of libraries to be included.

temp logical: should the package indices be created in a temporary location for use
    by the HTTP server?

verbose logical. If true, print out a message.

docdir If temp is false, directory in whose ‘html’ directory the ‘packages.html’ file is
    to be created/updated.

Details

This creates the ‘packages.html’ file, either a temporary copy for use by help.start, or the copy
in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For temp = TRUE there is some caching of information, so the file will only be re-created if lib.loc
or any of the directories it lists have been changed.

Value

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable
permissions.

See Also

help.start
make.socket

Create a Socket Connection

Description
With server = FALSE attempts to open a client socket to the specified port and host. With server = TRUE the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use on.exit to ensure that a socket is closed, as you only get 64 of them.

Usage
make.socket(host = "localhost", port, fail = TRUE, server = FALSE)

Arguments
- host: name of remote host
- port: port to connect to/listen on
- fail: failure to connect is an error?
- server: a server socket?

Value
An object of class "socket", a list with components:
- socket: socket number. This is for internal use. On a Unix-alike it is a file descriptor.
- port: port number of the connection.
- host: name of remote computer.

Warning
I don’t know if the connecting host name returned when server = TRUE can be trusted. I suspect not.

Author(s)
Thomas Lumley

References
Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins “Practical UNIX Programming”.

Examples
### Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.
### End(Not run)
menu

Description

menu presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select ‘0’.

Usage

menu(choices, graphics = FALSE, title = NULL)

Arguments

choices a character vector of choices
graphics a logical indicating whether a graphics menu should be used if available.
title a character string to be used as the title of the menu. NULL is also accepted.

Details

If graphics = TRUE and a windowing system is available (Windows, macOS or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use menu in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if title is NULL or "".

Value

The number corresponding to the selected item, or 0 if no choice was made.

References

See Also

select.list, which is used to implement the graphical menu, and allows multiple selections.

Examples

## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
cat("Nothing done
”), letters, LETTERS)
## End(Not run)

---

**methods**

[List Methods for S3 Generic Functions or Classes]

### Description

List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

### Usage

```r
methods(generic.function, class)
.S3methods(generic.function, class, envir=parent.frame())
```

### Arguments

- **generic.function**
  - a generic function, or a character string naming a generic function.
- **class**
  - a symbol or character string naming a class: only used if `generic.function` is not supplied.
- **envir**
  - the environment in which to look for the definition of the generic function, when the generic function is passed as a character string.
- **x**
  - typically the result of `methods(..)`, an R object of S3 class "MethodsFunction", see "Value" below.
- **byclass**
  - an optional `logical` allowing to override the "byclass" attribute determining how the result is printed, see "Details".
- **...**
  - potentially further arguments passed to and from methods; unused currently.

### Details

`methods()` finds S3 and S4 methods associated with either the `generic.function` or `class` argument. Methods are found in all packages on the current `search()` path. `.S3methods()` finds only S3 methods, `.S4methods()` finds only S4 methods.

When invoked with the `generic.function` argument, the "byclass" attribute (see Details) is FALSE, and the print method by default displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a ".", as
The S3 method name is followed by an asterisk * if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as generic.class-method; S4 allows for multiple dispatch, so there may be several classes in the signature generic,A,B-method.

When invoked with the class argument, "byclass" is TRUE, and the print method by default displays the names of the generic functions associated with the class, generic.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as generic.class. For S3 functions not exported from the namespace, see getAnywhere or getS3method. For S4 methods, see getMethod.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut ? with the name of the generic and tab completion, ?"generic<tab>" to select the method for which help is desired.

The S3 functions listed are those which are named like methods and may not actually be methods (known exceptions are discarded in the code).

Value
An object of class "MethodsFunction", a character vector of method names with "byclass" and "info" attributes. The "byclass" attribute is a logical indicating if the results were obtained with argument class defined. The "info" attribute is a data frame with columns:

- generic character vector of the names of the generic.
- visible logical(), is the method exported from the namespace of the package in which it is defined?
- isS4 logical(), true when the method is an S4 method.
- from a factor, the location or package name where the method was found.

Note
The original methods function was written by Martin Maechler.

References

See Also
S3Methods, class, getS3method.

For S4, getMethod, showMethods, Introduction or Methods_Details.

Examples
methods(class = "MethodsFunction") # format and print
require(stats)

methods(summary)
methods(class = "aov") # S3 class
## The same, with more details and more difficult to read:
print(methods(class = "aov"), byclass=FALSE)
methods("[""") # uses C-internal dispatching
methods("$")
**mirrorAdmin**

**Managing Repository Mirrors**

**Description**

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

**Usage**

```r
mirror2html(mirrors = NULL, file = "mirrors.html", head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

**Arguments**

- **mirrors** A data frame, by default the CRAN list of mirrors is used.
- **file** A connection or a character string.
- **head** Name of optional header file.
- **foot** Name of optional footer file.
- **method** Download method, see `download.file`.

**Details**

`mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

`checkCRAN` performs a sanity checks on all CRAN mirrors.
modifyList

Recursively Modify Elements of a List

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

modifyList(x, val, keep.null = FALSE)

Arguments

x
A named list, possibly empty.

val
A named list with components to replace corresponding components in x.

keep.null
If TRUE, NULL elements in val become NULL elements in x. Otherwise, the corresponding element, if present, is deleted from x.

Value

A modified version of x, with the modifications determined as follows (here, list elements are identified by their names). Elements in val which are missing from x are added to x. For elements that are common to both but are not both lists themselves, the component in x is replaced (or possibly deleted, depending on the value of keep.null) by the one in val. For common elements that are in both lists, x[[name]] is replaced by modifyList(x[[name]], val[[name]])..

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

Examples

foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)

news

Build and Query R or Package News Information

Description

Build and query the news data base for R or add-on packages.
Usage

news(query, package = "R", lib.loc = NULL, format = NULL, 
reader = NULL, db = NULL)

## S3 method for class 'news_db'
print(x, doBrowse = interactive(), 
    browser = getOption("browser"), ...)

Arguments

query an expression for selecting news entries
package a character string giving the name of an installed add-on package, or "R" or
"R-3" or "R-2".
lib.loc a character vector of directory names of R libraries, or NULL. The default value
of NULL corresponds to all libraries currently known.
format Not yet used.
reader Not yet used.
db, x a news db obtained from news().
doBrowse logical specifying that the news should be opened in the browser (by browseURL,
accessible as via help.start) instead of printed to the console.

... potentially further arguments passed to print().

Details

If package is "R" (default), a news db is built with the news since the 4.0.0 release of R (corre-
sponding to R’s top-level ‘NEWS’ file). For “R-3” or “R-2”, news for R 3.x.y or R 2.x.y respectively.
Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read
its news in structured form from files ‘inst/NEWS.Rd’, ‘NEWS.md’ (since R version 3.6.0, needs
packages commonmark and xml2 to be available), ‘NEWS’ or ‘inst/NEWS’ (in that order).

File ‘inst/NEWS.Rd’ should be an Rd file given the entries as Rd \itemize lists, grouped according
to version using section elements with names starting with a suitable prefix (e.g. “Changes in
version”) followed by a space and the version number, and optionally followed by a space and a
parenthesized ISO 8601 (%Y-%m-%d, see strftime) format date, and possibly further grouped
according to categories using \subsection elements named as the categories. At the very end of
\section(.,.) the date may also be specified as (%Y-%m-%d, <note>), i.e., including parentheses.

File ‘NEWS.md’ should contain the news in Markdown (following the CommonMark (https://
commonmark.org/) specification), with the primary heading level giving the version number after
a prefix followed by a space, and optionally followed by a space and a parenthesized ISO 8601
format date. Where available, secondary heading are taken to indicate categories. To accommodate
for common practice, news entries are only split down to the category level.

The plain text ‘NEWS’ files in add-on packages use a variety of different formats; the default news
reader should be capable to extract individual news entries from a majority of packages from the
standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header “Changes in version” at the
  beginning of a line, followed by a version number, optionally followed by an ISO 8601 format
date, possibly parenthesized.
Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.

Entries are written as itemize-type lists, using one of ‘o’, ‘*’, ‘-’ or ‘+’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package tools provides an (internal) utility function news2Rd to convert plain text ‘NEWS’ files to Rd. For ‘NEWS’ files in a format which can successfully be handled by the default reader, package maintainers can use tools:::news2Rd(dir, "NEWS.Rd"), possibly with additional argument codify = TRUE, with dir a character string specifying the path to a package’s root directory. Upon success, the ‘NEWS.Rd’ file can further be improved and then be moved to the ‘inst’ subdirectory of the package source directory.

The news db built is a character data frame inheriting from "news_db" with variables Version, Category, Date and Text, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using query, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, query should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, Version and Date are coerced to numeric_version and Date objects, respectively, so that the comparison operators for these classes can be employed.

A data frame inheriting from class "news_db", with attributes "package" (and "subset" if the query lead to proper subsetting).

Examples

```r
## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 4.0.0.
db4 <- news(Version == "4.0.0" & grepl("^BUG", Category) & grepl("PR#", Text),
  db = db)
nrow(db4)

## print db4 to show in an HTML browser.

## News from a date range ('Matrix' is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet = TRUE)) && nzchar(iM)) {
  dM <- news(package="Matrix")
  stopifnot(identical(dM, news(db=dM)))
  dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
  stopifnot(paste0("1.1-", 2:4) %in% dM2014[,"Version"])
}

## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)

## Entries with version >= 4.0.0
table(news(Version >= "4.0.0", db = db)$Version)
```
## do the same for R 3.x.y, more slowly

db3 <- news(package = "R-3")
sort(table(db3[, "Category"]), decreasing = TRUE)
## Entries with version >= 3.6.0
table(news(Version >= "3.6.0", db = db3)$Version)

---

### nsl

**Look up the IP Address by Hostname (on Unix-alikes)**

#### Description

Interface to the system gethostbyname, currently available only on unix-alikes, i.e., not on Windows.

#### Usage

nsl(hostname)

##### Arguments

- **hostname**
  
  the name of the host.

#### Details

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’.

This function is not available on Windows.

#### Value

The IP address, as a character string, or NULL if the call fails.

#### Examples

if(.Platform$OS.type == "unix") # includes Mac
print( nsl("www.r-project.org") )

---

### object.size

**Report the Space Allocated for an Object**

#### Description

Provides an estimate of the memory that is being used to store an R object.
object.size

Usage

object.size(x)

## S3 method for class 'object_size'
format(x, units = "b", standard = "auto", digits = 1L, ...)

## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", standard = "auto",
digits = 1L, ...)

Arguments

x

an R object.

quote

logical, indicating whether or not the result should be printed with surrounding quotes.

units

the units to be used in formatting and printing the size. Allowed values for the different standards are

standard = "SI": "B", "kB", "MB", "GB", "TB", "PB", "EB", "ZB" and "YB".

For all standards, unit = "auto" is also allowed. If standard = "auto", any of the "legacy" and IEC units are allowed. See 'Formatting and printing object sizes' for details.

standard

the byte-size unit standard to be used. A character string, possibly abbreviated from "legacy", "IEC", "SI" and "auto". See 'Formatting and printing object sizes' for details.

digits

the number of digits after the decimal point, passed to round.

...

arguments to be passed to or from other methods.

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a EXTPTRSXP points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Sizes of objects using a compact internal representation may be over-estimated.

Value

An object of class "object.size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.
Formatting and printing object sizes

Object sizes can be formatted using byte-size units from R’s legacy standard, the IEC standard, or the SI standard. As illustrated by below tables, the legacy and IEC standards use binary units (multiples of 1024), whereas the SI standard uses decimal units (multiples of 1000).

For methods format and print, argument standard specifies which standard to use and argument units specifies which byte-size unit to use. units = "auto" chooses the largest units in which the result is one or more (before rounding). Byte sizes are rounded to digits decimal places. standard = "auto" chooses the standard based on units, if possible, otherwise, the legacy standard is used.

Summary of R’s legacy and IEC units:

<table>
<thead>
<tr>
<th>object size</th>
<th>legacy</th>
<th>IEC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 bytes</td>
<td>1 B</td>
</tr>

package.skeleton

Create a Skeleton for a New Source Package

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

Usage

package.skeleton(name = "anRpackage", list,
       environment = .GlobalEnv,
       path = ".", force = FALSE,
       code_files = character(), encoding = "unknown")

Arguments

name character string: the package name and directory name for your package. Must be a valid package name.
list character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See ‘Details’.
environment an environment where objects are looked for. See ‘Details’.
path path to put the package directory in.
force If FALSE will not overwrite an existing directory.
code_files  a character vector with the paths to R code files to build the package around. See 'Details'.

encoding  optionally a character string with an encoding for an optional Encoding: line in 'DESCRIPTION' when non-ASCII characters will be used; typically one of "latin1", "latin2", or "UTF-8"; see the WRE manual.

Details

The arguments list, environment, and code_files provide alternative ways to initialize the package. If code_files is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise list defaults to the objects in environment (including those whose names start with .), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the prompt, promptClass, and promptMethods functions. If an object from another package is intended to be imported and re-exported without changes, the promptImport function should be used after package.skeleton to generate a simple help file linking to the original one.

The package sources are placed in subdirectory name of path. If code_files is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in code_files should have suffix ".R" and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by ‘_’, invalid names are preceded by ‘zz’, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by make.unique(sep = "_"). This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

Functions with names starting with a dot are placed in file ‘R/name~internal.R’.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

Value

Used for its side-effects.

References

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a source package you need to install it: see the ‘R Installation and Administration’ manual, INSTALL and install.packages.

Examples

```r
require(stats)
## two functions and two "data sets":
f <- function(x, y) x+y
g <- function(x, y) x-y
```
packageDescription

Description

Parses and returns the ‘DESCRIPTION’ file of a package as a "packageDescription".
Utility functions return (transformed) parts of that.

Usage

packageDescription(pkg, lib.loc = NULL, fields = NULL, drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
packageDate(pkg, lib.loc = NULL, date.fields = c("Date", "Packaged", "Date/Publication", "Built"),
            tryFormats = c("%Y-%m-%d", "%Y/%m/%d", "%D", "%m/%d/%y"),
            desc = packageDescription(pkg, lib.loc=lib.loc, fields=date.fields))
asDateBuilt(built)

Arguments

pkg a character string with the package name.
lib.loc a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value
         of \texttt{NULL} corresponds to all libraries currently known. If the default is used, the
         loaded packages and namespaces are searched before the libraries.
fields a character vector giving the tags of fields to return (if other fields occur in the
        file they are ignored).
drop If \texttt{TRUE} and the length of \texttt{fields} is 1, then a single character string with
        the value of the respective field is returned instead of an object of class
        "packageDescription".
encoding If there is an \texttt{Encoding} field, to what encoding should re-encoding be attempted?
        If \texttt{NA}, no re-encoding. The other values are as used by \texttt{iconv}, so the default
        "" indicates the encoding of the current locale.
date.fields character vector of field tags to be tried. The first for which \texttt{as.Date(.)} is not
        \texttt{NA} will be returned. (Partly experimental, see \texttt{Note}.)
tryFormats date formats to try, see \texttt{as.Date.character()}. 
desc optionally, a named \texttt{list} with components named from date.fields; where
        the default is fine, a complete packageDescription() maybe specified as well.
built for \texttt{asDateBuilt()}, a \texttt{character} string as from packageDescription(*, fields="Built").
Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An attached environment named to look like a package (e.g., package:utils2) will be ignored.

packageVersion() is a convenience shortcut, allowing things like if (packageVersion("MASS") < "7.3") { do.things }.

For packageDate(), if desc is valid, both pkg and lib.loc are not made use of.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, packageDescription returns an object of class “packageDescription”, which is a named list with the values of the (given) fields as elements and the tags as names, unless drop = TRUE.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if fields is not null, and NA otherwise.

packageVersion() returns a (length-one) object of class "package_version".

packageDate() will return a “Date” object from as.Date() or NA.

asDateBuilt(built) returns a “Date” object or signals an error if built is invalid.

Note

The default behavior of packageDate(), notably for date.fields, is somewhat experimental and may change. Using date.fields = <string> single

  message("you need to update 'MASS'")

pu <- packageDate("utils")
str(pu)
stopifnot(identical(pu, packageDate(desc = packageDescription("utils"))),
          identical(pu, packageDate("stats"))) # as "utils" and "stats" are
          # both 'base R' and "Built" at same time
packageName

Find Package Associated with an Environment

Description

Many environments are associated with a package; this function attempts to determine that package.

Usage

packageName(env = parent.frame())

Arguments

tenv

The environment whose name we seek.

Details

Environment env would be associated with a package if topenv(env) is the namespace environment for that package. Thus when env is the environment associated with functions inside a package, or local functions defined within them, packageName will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. packageName will return NULL in these cases.

Value

A length one character vector containing the name of the package, or NULL if there is no name.

See Also

getPackageName is a more elaborate function that can construct a name if none is found.

Examples

packageName()
packageName(environment(mean))

packageStatus

Package Management Tools

Description

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.
Usage

packageStatus(lib.loc = NULL, repositories = NULL, method, 
    type = getOption("pkgType"), ...)

## S3 method for class 'packageStatus'
summary(object, ...)

## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
    repositories = levels(object$avail$Repository), ...)

## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)

Arguments

lib.loc a character vector describing the location of R library trees to search through, or
    NULL. The default value of NULL corresponds to all libraries currently known.
repositories a character vector of URLs describing the location of R package repositories
    on the Internet or on the local machine. If specified as NULL, derive appropriate
    URLs from option "repos".
method Download method, see download.file.
type type of package distribution: see install.packages.
object an object of class "packageStatus" as returned by packageStatus.
ask if TRUE, the user is prompted which packages should be upgraded and which
    not.
... for packageStatus: arguments to be passed to available.packages and
    installed.packages.
for the upgrade method, arguments to be passed to install.packages for other methods: currently not used.

Details

The URLs in repositories should be full paths to the appropriate contrib sections of the repositories. The default is contrib.url(getOption("repos")).

There are print and summary methods for the "packageStatus" objects: the print method gives a brief tabular summary and the summary method prints the results.

The update method updates the "packageStatus" object. The upgrade method is similar to update.packages: it offers to install the current versions of those packages which are not currently up-to-date.

Value

An object of class "packageStatus". This is a list with two components

inst a data frame with columns as the matrix returned by installed.packages plus
    "Status", a factor with levels c("ok", "upgrade", "unavailable"). Only the
    newest version of each package is reported, in the first repository in which it
    appears.
avail

a data frame with columns as the matrix returned by `available.packages` plus "Status", a factor with levels c("installed", "not installed").

For the summary method the result is also of class "summary.packageStatus" with additional components

Libs a list with one element for each library
Repos a list with one element for each repository

with the elements being lists of character vectors of package name for each status.

See Also

`installed.packages`, `available.packages`

Examples

```r
## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)
## End(Not run)
```

-----------------------------------------------------------------

page

Invoke a Pager on an R Object

Description

Displays a representation of the object named by `x` in a pager via `file.show`.

Usage

```r
page(x, method = c("dput", "print"), ...)
```

Arguments

- `x` An R object, or a character string naming an object.
- `method` The default method is to dump the object via `dput`. An alternative is to use `print` and capture the output to be shown in the pager. Can be abbreviated.
- `...` additional arguments for `dput`, `print` or `file.show` (such as `title`).

Details

If `x` is a length-one character vector, it is used as the name of an object to look up in the environment from which `page` is called. All other objects are displayed directly.

A default value of `title` is passed to `file.show` if one is not supplied in ....
See Also

`file.show`, `edit`, `fix`.

To go to a new page when graphing, see `frame`.

Examples

```r
## Not run: ## four ways to look at the code of 'page'
page(page) # as an object
page("page") # a character string
v <- "page"; page(v) # a length-one character vector
page(utils::page) # a call

## End(Not run)
```

person

## S3 method for class 'person'
format(x,
include = c("given", "family", "email", "role", "comment"),
braces = list(given = "", family = ", email = c("<", ">"),
role = c("[", "]"), comment = c("("", ")")),
collapse = list(given = " ", family = ", email = " ",
role = ", ", comment = " ",
...,
style = c("text", "R")
)

Arguments

given a character vector with the given names, or a list thereof.
family a character string with the family name, or a list thereof.
middle a character string with the collapsed middle name(s). Deprecated, see Details.
email a character string (or vector) giving an e-mail address (each), or a list thereof.
role a character vector specifying the role(s) of the person (see Details), or a list thereof.
comment a character string (or vector) providing comments, or a list thereof.
first a character string giving the first name. Deprecated, see Details.
last   a character string giving the last name. Deprecated, see Details.
x     a character string for the as.person default method; an object of class "person" otherwise.
include  a character vector giving the fields to be included when formatting.
braces   a list of characters (see Details).
collapse a list of characters (see Details).
...     currently not used.
style    a character string specifying the print style, with "R" yielding formatting as R code.

Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to person() with list arguments, or by first creating objects representing single persons and combining these via c().

The format() method collapses information about persons into character vectors (one string for each person): the fields in include are selected, each collapsed to a string using the respective element of collapse and subsequently “embraced” using the respective element of braces, and finally collapsed into one string separated by white space. If braces and/or collapse do not specify characters for all fields, the defaults shown in the usage are imputed. If collapse is FALSE or NA the corresponding field is not collapsed but only the first element is used. The print() method calls the format() method and prints the result, the toBibtex() method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using $) or by position (using []). as.person() is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., https://en.wikipedia.org/wiki/Personal_name. The current implementation (starting from R 2.12.0) of the "person" class uses the notions of given (including middle names) and family names, as specified by given and family respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments first, middle and last are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments. For persons which are not natural persons (e.g., institutions, companies, etc.) it is appropriate to use given (but not family) for the name, e.g., person("R Core Team", role = "aut").

The new scheme also adds the possibility of specifying roles based on a subset of the MARC Code List for Relators (https://www.loc.gov/marc/relators/relaterm.html). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.
"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.
"cph" (Copyright holder) Use for all copyright holders. This is a legal concept so should use the legal name of an institution or corporate body.
"cre" (Creator) Use for the package maintainer.
"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

"ctr" (Contractor) Use for authors who have been contracted to write (parts of) the package and hence do not own intellectual property.

"dtc" (Data contributor) Use for persons who contributed data sets for the package.

"fnd" (Funder) Use for persons or organizations that furnished financial support for the development of the package.

"rev" (Reviewer) Use for persons or organizations responsible for reviewing (parts of) the package.

"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

"trl" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator personList() for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the personList mechanism.

The comment field can be used for “arbitrary” additional information about persons. Elements named "ORCID" will be taken to give ORCID identifiers (see https://orcid.org/ for more information), and be displayed as the corresponding URIs by the print() and format() methods (see Examples below).

Value

person() and as.person() return objects of class "person".

PkgUtils

Utilities for Building and Checking Add-on Packages

Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

Usage

R CMD check [options] pkgdirs
R CMD build [options] pkgdirs

Arguments

pkgdirs a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension '.tar.gz', '.tgz', '.tar.bz2' or '.tar.xz'.
options further options to control the processing, or for obtaining information about usage and version of the utility.

Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.
R CMD build builds R source tarballs. The name(s) of the packages are taken from the 'DESCRIPTION' files and not from the directory names. This works entirely on a copy of the supplied source directories.
Use R CMD foo --help to obtain usage information on utility foo.
The defaults for some of the options to R CMD build can be set by environment variables _R_BUILD_RESAVE_DATA_ and _R_BUILD_COMPACT_VIGNETTES_; see 'Writing R Extensions'. Many of the checks in R CMD check can be turned off or on by environment variables: see Chapter 'Tools' of the 'R Internals' manual.
By default R CMD build uses the "internal" option to tar to prepare the tarball. An external tar
program can be specified by the R_BUILD_TAR environment variable. This may be substantially
faster for very large packages, and can be needed for packages with long path names (over 100
bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.
R CMD check by default unpacks tarballs by the internal untar function: if needed an external tar
command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can
handle the type of compression used on the tarball. (This is sometimes needed for tarballs contain-
ing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR
to 'tar .exe' has been needed to overcome permissions issues on some Windows systems.)

Note

Only on Windows: They make use of a temporary directory specified by the environment variable
TMPDIR and defaulting to ‘c:/TEMP’. Do ensure that if set forward slashes are used.

tensions’ (see on Unix-alikes the ‘doc/manual’ subdirectory of the R source tree, on Windows, see
the Manuals sub-menu of the Help menu on the console).

process.events

Trigger Event Handling

Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated
by the OS. These are processed automatically by R at intervals during computations, but in some
cases it may be desirable to trigger immediate event handling. The process.events function does
that.

Usage

process.events()

Details

This is a simple wrapper for the C API function R_ProcessEvents. As such, it is possible that it
will not return if the user has signalled to interrupt the calculation.

Value

NULL is returned invisibly.

Author(s)

Duncan Murdoch

R_ProcessEvents function.
Produce Prototype of an R Documentation File

Description
Facilitate the constructing of files documenting R objects.

Usage
prompt(object, filename = NULL, name = NULL, ...)

## Default S3 method:
prompt(object, filename = NULL, name = NULL,
   force.function = FALSE, ...)

## S3 method for class 'data.frame'
prompt(object, filename = NULL, name = NULL, ...)

promptImport(object, filename = NULL, name = NULL,
   importedFrom = NULL, importPage = name, ...)

Arguments
object
  an R object, typically a function for the default method. Can be missing when
  name is specified.
filename
  usually, a connection or a character string giving the name of the file to which
  the documentation shell should be written. The default corresponds to a file
  whose name is name followed by "\.Rd". Can also be NA (see below).
name
  a character string specifying the name of the object.
force.function
  a logical. If TRUE, treat object as function in any case.
...
  further arguments passed to or from other methods.
importedFrom
  a character string naming the package from which object was imported. De-
 faults to the environment of object if object is a function.
importPage
  a character string naming the help page in the package from which object was
  imported.

Details
Unless filename is NA, a documentation shell for object is written to the file specified by
filename, and a message about this is given. For function objects, this shell contains the proper
function and argument names. R documentation files thus created still need to be edited and moved
into the ‘man’ subdirectory of the package containing the object to be documented.

If filename is NA, a list-style representation of the documentation shell is created and returned.
Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the
list-style representation.

When prompt is used in for loops or scripts, the explicit name specification will be useful.
The importPage argument for promptImport needs to give the base of the name of the help file of
the original help page. For example, the approx function is documented in ‘approxfun.Rd’ in the
stats package, so if it were imported and re-exported it should have importPage = “approxfun”.
Objects that are imported from other packages are not normally documented unless re-exported.
Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling prompt on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use promptData to create documentation skeletons for data sets.

Note

The documentation file produced by prompt.data.frame does not have the same format as many of the data frame documentation files in the base package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for prompt.data.frame

See Also

promptData, help and the chapter on ‘Writing R documentation’ in ‘Writing R Extensions’ (see the ‘doc/manual’ subdirectory of the R source tree).

For creation of many help pages (for a package), see package.skeleton.

To prompt the user for input, see readline.

Examples

```r
require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")
prompt(women) # data.frame
unlink("women.Rd")
prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")
```

```r
## Not run:
## Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)
```
promptData  Generate Outline Documentation for a Data Set

Description

Generates a shell of documentation for a data set.

Usage

promptData(object, filename = NULL, name = NULL)

Arguments

object  
an R object to be documented as a data set.

filename  
usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).

name  
a character string specifying the name of the object.

Details

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Currently, only data frames are handled explicitly by the code.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

prompt

Examples

promptData(sunspots)
unlink("sunspots.Rd")
promptPackage

Generate a Shell for Documentation of a Package

Description

Generates a shell of documentation for an installed or source package.

Usage

promptPackage(package, lib.loc = NULL, filename = NULL,
name = NULL, final = FALSE)

Arguments

package  a character string with the name of an installed or source package to be documented.
lib.loc   a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. For a source package this should specify the parent directory of the package’s sources.
filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).
name      a character string specifying the name of the help topic, typically of the form ‘<pkg>-package’.
final     a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.

Details

Unless filename is NA, a documentation shell for package is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If final is TRUE, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but final = TRUE is certainly less work).

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Examples

```r
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

Description

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an `R` object or a data set) can be displayed by either `help("name")` or `?name`.

Usage

`?topic`

`type?topic`

Arguments

- **topic**
  - Usually, a `name` or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls `pkg:::topic` and `pkg:::topic` are treated specially, and look for help on `topic` in package `pkg`.

- **type**
  - the special type of documentation to use for this topic; for example, if the type is `class`, documentation is provided for the class with name `topic`. See the Section ‘S4 Method Documentation’ for the uses of `type` to get help on formal methods, including `methods?function` and `method?call`.

Details

This is a shortcut to `help` and uses its default type of help.

Some topics need to be quoted (by `backticks`) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow `reserved` words (including `if`, `else for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

S4 Method Documentation

Authors of formal (`S4`) methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f-methods`.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated.
See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with doc_type supplied as method; in this case also, the topic argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using selectMethod (see the documentation for `getMethod`). A limitation is that methods in packages (as opposed to regular functions) will only be found if the package exporting them is on the search list, even if it is specified explicitly using the `?package::generic()` notation.

**References**

**See Also**

`help ??` for finding help pages on a vague topic.

**Examples**

```r
?lapply
?"for"   # but quotes/backticks are needed
?`+`

?women   # information about data set "women"
```

```r
## Not run:
require(methods)
## define a S4 generic function and some methods
combo <- function(x, y) c(x, y)
setGeneric("combo")
setMethod("combo", c("numeric", "numeric"), function(x, y) x+y)

## assume we have written some documentation
## for combo, and its methods ....

?combo   # produces the function documentation
methods?combo # looks for the overall methods documentation
method?combo("numeric", "numeric") # documentation for the method above

?combo(1:10, rnorm(10)) # ... the same method, selected according to
# the arguments (one integer, the other numeric)

?combo(1:10, letters) # documentation for the default method
```

## End(Not run)
Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

Usage

```r
rc.settings(ops, ns, args, dots, func, ipck, S3, data, help, argdb, fuzzy, quotes, files)
rc.status()
rc.getOption(name)
rc.options(...)
.DollarNames(x, pattern)
## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'
.DollarNames(x, pattern = "")
```

Arguments

- `ops`, `ns`, `args`, `dots`, `func`, `ipck`, `S3`, `data`, `help`, `argdb`, `fuzzy`, `quotes`, `files` logical, turning some optional completion features on and off.
  - `ops`: Activates completion after the `$` and `@` operators.
  - `ns`: Controls namespace related completions.
  - `args`: Enables completion of function arguments.
  - `dots`: If disabled, drops `...` from list of function arguments. Relevant only if `args` is enabled.
  - `func`: Enables detection of functions. If enabled, a customizable extension ("(" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.
  - `S3`: When `args = TRUE`, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).
  - `ipck`: Enables completion of installed package names inside `library` and `require`.
data: Enables completion of data sets (including those already visible) inside data.

help: Enables completion of help requests starting with a question mark, by looking inside help index files.

argdb: When args = TRUE, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to args. While this gives results that are technically correct, the use of the ... argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting argdb = TRUE enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function .addFunctionInfo (see below).

fuzzy: Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change.

quotes: Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by ?), help completion is invoked. Setting this to FALSE relegates completion to the underlying completion front-end, which may do its own processing (for example, readline on Unix-alikes will do filename completion).

files: Deprecated. Use quotes instead.

All settings are turned on by default except ipck, func, and fuzzy. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

name, ... user-settable options. Currently valid names are

function.suffix: default "(
funarg.suffix: default " = 
package.suffix default ": :"

Usage is similar to that of options.

x An R object for which valid names after "$" are computed and returned.

pattern A regular expression. Only matching names are returned.

Details

There are several types of completion, some of which can be disabled using rc.settings. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., TRUE). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

Completion after extractors $ and @: When the ops setting is turned on, completion after $ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of [, $, etc do not inhibit evaluation).

Valid completions after the $ extractor are determined by the generic function .DollarNames. Some basic methods are provided, and more can be written for custom classes.
Completion inside namespaces: When the ns setting is turned on, completion inside namespaces is attempted when a token is preceded by the :: or ::: operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., foopkg:: becomes a valid completion of foo if "foopkg" is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if MASS is not loaded, MAS will not complete to MASS:::. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on MASS:::fr will load MASS if it is not already loaded.

Completion for help items: When the help setting is turned on, completion on help topics is attempted when a token is preceded by ?. Prefixes (such as class, method) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the args setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that ... is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an in-line function call. Our compromise is to consider arguments of all currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like print and plot), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the S3 setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete seq([TAB] and seq(from = 1, [TAB]) will both list only the arguments of seq (or any of its methods), whereas trying to complete seq(length[TAB] will list both the length.out argument and the length( function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

Special functions: For a few special functions (library, data, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The ipck setting, which controls whether library and require will complete on installed packages, is disabled by default because the first call to installed.packages is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to installed.packages is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.
Value

If rc.settings is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns NULL invisibly.

rc.status returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to rc.status itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

- **comps**: The possible completions generated by the last call to .completeToken, as a character vector.
- **token**: The token that was (or, is to be) completed, as set by the last call to .assignToken (possibly inside a call to .guessTokenFromLine).
- **linebuffer**: The full line, as set by the last call to .assignLinebuffer.
- **start**: The start position of the token in the line buffer, as set by the last call to .assignStart.
- **end**: The end position of the token in the line buffer, as set by the last call to .assignEnd.
- **fileName**: Logical, indicating whether the cursor is currently inside quotes.
- **fguess**: The name of the function the cursor is currently inside.
- **isFirstArg**: Logical. If cursor is inside a function, is it the first argument?

In addition, the components settings and options give the current values of settings and options respectively.

rc.getOption and rc.options behave much likegetOption and options respectively.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```r
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
.assignEnd(end)

.completeToken()
.retrieveCompletions()
.getFileComp()

.guessTokenFromLine()
.win32consoleCompletion(linebuffer, cursorPosition, check.repeat = TRUE, minlength = -1)

.addFunctionInfo(...)
```
The first four functions set up a completion attempt by specifying the token to be completed (text), and indicating where (start and end, which should be integers) the token is placed within the complete line typed so far (line).

Potential completions of the token are generated by .completeToken, and the completions can be retrieved as an R character vector using .retrieveCompletions. It is possible for the user to specify a replacement for this function by setting rc.options("custom.completer"); if not NULL, this function is called to compute potential completions. This facility is meant to help in situations where completing as R code is not appropriate. See source code for more details.

If the cursor is inside quotes, completion may be suppressed. The function .getFileComp can be used after a call to .completeToken to determine if this is the case (returns TRUE), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The .guessTokenFromLine function is provided for use with backends that do not already break a line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The .win32consoleCompletion is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the linebuffer and cursor position as arguments, and returns a list with three components, addition, possible and comps. If there is an unambiguous extension at the current position, addition contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in possible, or as a single string in comps. possible consists of lines formatted using the current width option, so that printing them on the console one line at a time will be a reasonable way to list them. comps is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The minlength argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If check.repeat is TRUE, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function .addFunctionInfo can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the argdb setting is TRUE, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set ops = FALSE. Otherwise, trying to complete foo@ba will evaluate foo, trying to complete foo[i, 1:10]$ba will evaluate foo[i, 1:10], etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this will affect promises and lazy loaded symbols.

Author(s)

read.DIF

Data Input from Spreadsheet

Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

Usage

read.DIF(file, header = FALSE,
          dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
          row.names, col.names, as.is = !stringsAsFactors,
          na.strings = "NA", colClasses = NA, nrows = -1,
          skip = 0, check.names = TRUE, blank.lines.skip = TRUE,
          stringsAsFactors = FALSE,
          transpose = FALSE, fileEncoding = "")

Arguments

file the name of the file which the data are to be read from, or a connection, or a complete URL.
The name "clipboard" may also be used on Windows, in which case read.DIF("clipboard") will look for a DIF format entry in the Windows clipboard.

header a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.

dec the character used in the file for decimal points.

numerals string indicating how to convert numbers whose conversion to double precision would lose accuracy, see type.convert.

row.names a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.
If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.
Using row.names = NULL forces row numbering.

col.names a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using type.convert as in read.table.
Note: to suppress all conversions including those of numeric columns, set colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

`na.strings` a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

`colClasses` character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.

Possible values are NA (when `type.convert` is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package `methods`) for conversion from "character" to the specified formal class.

Note that `colClasses` is specified per column (not per variable) and so includes the column of row names (if any).

`nrows` the maximum number of rows to read in. Negative values are ignored.

`skip` the number of lines of the data file to skip before beginning to read data.

`check.names` logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.

`blank.lines.skip` logical: if TRUE blank lines in the input are ignored.

`stringsAsFactors` logical: should character vectors be converted to factors?

`transpose` logical, indicating if the row and column interpretation should be transposed. Microsoft’s Excel has been known to produce (non-standard conforming) DIF files which would need transpose = TRUE to be read correctly.

`fileEncoding` character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the ‘Encoding’ section of the help for `file`, the ‘R Data Import/Export’ manual and ‘Note’.

Value

A data frame (`data.frame`) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header` = TRUE results in a 0-row data frame.

Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

Author(s)

R Core; transpose option by Christoph Buser, ETH Zurich
References

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also https://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

See Also

The R Data Import/Export manual. scan, type.convert, read.fwf for reading fixed width formatted input; read.table; data.frame.

Examples

## read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))

read.fortran Read Fixed-Format Data in a Fortran-like Style

Description

Read fixed-format data files using Fortran-style format specifications.

Usage

read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)

Arguments

file File or connection to read from.
format Character vector or list of vectors. See ‘Details’ below.
... Other arguments for read.fwf.
as.is Keep characters as characters?
colClasses Variable classes to override defaults. See read.table for details.

Details

The format for a field is one of the following forms: rFl. d, rDl. d, rXl, rAl, rIl, where l is the number of columns, d is the number of decimal places, and r is the number of repeats. F and D are numeric formats, A is character, I is integer, and X indicates columns to be skipped. The repeat code r and decimal place code d are always optional. The length code l is required except for X formats when r is present.

For a single-line record, format should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (X) columns are not passed to read.fwf, so colClasses, col.names, and similar arguments passed to read.fwf should not reference these columns.
Value
A data frame

Note
read.fortran does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying \( d > 0 \) in the \( F \) or \( D \) format will shift the decimal \( d \) places to the left, even if it is explicitly specified in the input file.

read.fwf, read.table, read.csv

Examples
```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1","F2.0","I2"))
read.fortran(ff, c("2F1.0","2X","2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1","A2"), c("3I2","2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

### read.fwf

#### Description
Read a table of fixed width formatted data into a `data.frame`.

#### Usage
```
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names = col.names, n = -1,
         buffersize = 2000, fileEncoding = "", ...)  
```

#### Arguments
- **file**: the name of the file which the data are to be read from. Alternatively, `file` can be a `connection`, which will be opened if necessary, and if so closed at the end of the function call.
- **widths**: integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.
- **header**: a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by `sep`. 

sep character; the separator used internally; should be a character that does not occur in the file (except in the header).

skip number of initial lines to skip; see \texttt{read.table}.

row.names see \texttt{read.table}.

col.names see \texttt{read.table}.

n the maximum number of records (lines) to be read, defaulting to no limit.

buffersize Maximum number of lines to read at one time

fileEncoding character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for \texttt{file}, the ‘R Data Import/Export’ manual and ‘Note’.

... further arguments to be passed to \texttt{read.table}. Useful such arguments include \texttt{as.is}, \texttt{na.strings}, \texttt{colClasses} and \texttt{strip.white}.

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in \texttt{file} are replaced by \texttt{NA}.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by \texttt{read.table} and so should not be included in a \texttt{col.names} or \texttt{colClasses} argument (nor in the header line, if present).

Reducing the \texttt{buffersize} argument may reduce memory use when reading large files with long lines. Increasing \texttt{buffersize} may result in faster processing when enough memory is available.

Note that \texttt{read.fwf} (not \texttt{read.table}) reads the supplied file, so the latter’s argument \texttt{encoding} will not be useful.

Value

A \texttt{data.frame} as produced by \texttt{read.table} which is called internally.

Author(s)

Brian Ripley for R version: originally in \texttt{Perl} by Kurt Hornik.

See Also

\texttt{scan} and \texttt{read.table}.

\texttt{read.fortran} for another style of fixed-format files.

Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3)) #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0,2,3)) #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0,2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```
read.socket

Read from or Write to a Socket

Description

read.socket reads a string from the specified socket, write.socket writes to the specified socket. There is very little error checking done by either.

Usage

read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)

Arguments

socket a socket object.
maxlen maximum length (in bytes) of string to read.
loop wait for ever if there is nothing to read?
string string to write to socket.

Value

read.socket returns the string read as a length-one character vector.
write.socket returns the number of bytes written.

Author(s)

Thomas Lumley

Examples

finger <- function(user, host = "localhost", port = 79, print = TRUE)
{
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, "\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
read.table

Data Input

Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

Usage

read.table(file, header = FALSE, sep = "", quote = """, dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"), row.names, col.names, as.is = !stringsAsFactors, na.strings = "NA", colClasses = NA, nrows = -1, skip = 0, check.names = TRUE, fill = !blank.lines.skip, strip.white = FALSE, blank.lines.skip = TRUE, comment.char = "#", allowEscapes = FALSE, flush = FALSE, stringsAsFactors = FALSE, fileEncoding = ",", encoding = "unknown", text, skipNul = FALSE)

read.csv(file, header = TRUE, sep = ",", quote = """, dec = ".", fill = TRUE, comment.char = "", ...) read.csv2(file, header = TRUE, sep = ";", quote = """, dec = ",", fill = TRUE, comment.char = "", ...) read.delim(file, header = TRUE, sep = "\t", quote = """, dec = ",", fill = TRUE, comment.char = "", ...) read.delim2(file, header = TRUE, sep = "\t", quote = """, dec = ",", fill = TRUE, comment.char = "", ...)  

Arguments

file

the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an absolute path, the file name is relative to the current working directory, getwd(). Tilde-expansion is performed where supported. This can be a compressed file (see file).

Alternatively, file can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If stdin() is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on stdin() will be cleared before return.)

file can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for url.)
header
a logical value indicating whether the file contains the names of the variables as
its first line. If missing, the value is determined from the file format: header is
set to TRUE if and only if the first row contains one fewer field than the number
of columns.

sep
the field separator character. Values on each line of the file are separated by
this character. If sep = "" (the default for read.table) the separator is ‘white
space’, that is one or more spaces, tabs, newlines or carriage returns.

quote
the set of quoting characters. To disable quoting altogether, use quote = "". See
scan for the behaviour on quotes embedded in quotes. Quoting is only consid-
ered for columns read as character, which is all of them unless colClasses is
specified.

dec
the character used in the file for decimal points.

numerals
string indicating how to convert numbers whose conversion to double precision
would lose accuracy, see type.convert. Can be abbreviated. (Applies also to
complex-number inputs.)

row.names
a vector of row names. This can be a vector giving the actual row names, or a
single number giving the column of the table which contains the row names, or
character string giving the name of the table column containing the row names.
If there is a header and the first row contains one fewer field than the number of
columns, the first column in the input is used for the row names. Otherwise if
row.names is missing, the rows are numbered.

Using row.names = NULL forces row numbering. Missing or NULL row.names
generate row names that are considered to be ‘automatic’ (and not preserved by
as.matrix).

col.names
a vector of optional names for the variables. The default is to use "V" followed
by the column number.

as.is
controls conversion of character variables (insofar as they are not converted
to logical, numeric or complex) to factors, if not otherwise specified by
colClasses. Its value is either a vector of logicals (values are recycled if neces-
sary), or a vector of numeric or character indices which specify which columns
should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set
colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the
column of row names (if any) and any columns to be skipped.

na.strings
a character vector of strings which are to be interpreted as NA values. Blank
fields are also considered to be missing values in logical, integer, numeric and
complex fields. Note that the test happens after white space is stripped from
the input, so na.strings values may need their own white space stripped in
advance.

colClasses
character. A vector of classes to be assumed for the columns. If unnamed,
recycled as necessary. If named, names are matched with unspecified values
being taken to be NA.

Possible values are NA (the default, when type.convert is used), "NULL" (when
the column is skipped), one of the atomic vector classes (logical, integer, nu-
meric, complex, character, raw), or "factor", "Date" or "POSIXct". Other-
wise there needs to be an as method (from package methods) for conversion
from "character" to the specified formal class.

Note that colClasses is specified per column (not per variable) and so includes
the column of row names (if any).
\texttt{nrows} integer: the maximum number of rows to read in. Negative and other invalid values are ignored.

\texttt{skip} integer: the number of lines of the data file to skip before beginning to read data.

\texttt{check.names} logical. If \texttt{TRUE} then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by \texttt{make.names}) so that they are, and also to ensure that there are no duplicates.

\texttt{fill} logical. If \texttt{TRUE} then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.

\texttt{strip.white} logical. Used only when \texttt{sep} has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See \texttt{scan} for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.

\texttt{blank.lines.skip} logical: if \texttt{TRUE} blank lines in the input are ignored.

\texttt{comment.char} character: a character vector of length one containing a single character or an empty string. Use “” to turn off the interpretation of comments altogether.

\texttt{allowEscapes} logical. Should C-style escapes such as ‘\n’ be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see \texttt{scan}.

\texttt{flush} logical: if \texttt{TRUE}, \texttt{scan} will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.

\texttt{stringsAsFactors} logical: should character vectors be converted to factors? Note that this is overridden by \texttt{as.is} and \texttt{colClasses}, both of which allow finer control.

\texttt{fileEncoding} character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for \texttt{file}, the ‘R Data Import/Export’ manual and ‘Note’.

\texttt{encoding} encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see \texttt{Encoding}): it is not used to re-encode the input, but allows \texttt{R} to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’.

\texttt{text} character string: if \texttt{file} is not supplied and this is, then data are read from the value of \texttt{text} via a text connection. Notice that a literal string can be used to include (small) data sets within \texttt{R} code.

\texttt{skipNul} logical: should nulls be skipped?

\texttt{...} Further arguments to be passed to \texttt{read.table}.

\textbf{Details}

This function is the principal means of reading tabular data into \texttt{R}.

Unless \texttt{colClasses} is specified, all columns are read as character columns and then converted using \texttt{type.convert} to logical, integer, numeric, complex or (depending on \texttt{as.is}) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.
If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of `col.names` if it is specified and is longer. This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary (as in the ‘Examples’).

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading ‘comma separated value’ files (‘.csv’) or (read.csv2) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded nuls are unsupported: skipping them (with `skipNu1 = TRUE`) may work.

**Value**

A data frame (`data.frame`) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if `encoding` is "latin1" or "UTF-8".

**CSV files**

See the help on `write.csv` for the various conventions for `.csv` files. The commonest form of CSV file with row names needs to be read with `read.csv(...)`, `row.names = 1)` to use the names in the first column of the file as row names.

**Memory usage**

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if `colClasses` is specified as one of the six atomic vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read *data frames* which may have columns of very different classes. Use `scan` instead for matrices.
Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the `encoding` argument to declare that. If the input is in some other encoding, then it may be translated on input. The `fileEncoding` argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

References

The ‘R Data Import/Export’ manual.

`scan`, `type.convert`, `read.fwf` for reading fixed width formatted input; `write.table`; `data.frame`.

`count.fields` can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

Examples

```r
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
##
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)
read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE, col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
c 2
3 4
")
```
**Description**

On Windows, read values of keys in the Windows Registry, and optionally whole hives.

**Usage**

```r
readRegistry(key, hive = c("HLM", "HCR", "HCU", "HU", "HCC", "HPD"),
maxdepth = 1, view = c("default", "32-bit", "64-bit"))
```

**Arguments**

- `key` character string, the path to the key in the Windows Registry.
- `hive` The ‘hive’ containing the key. The abbreviations are for `HKEY_LOCAL_MACHINE`, `HKEY_CLASSES_ROOT`, `HKEY_CURRENT_USER`, `HKEY_USERS`, `HKEY_CURRENT_CONFIG` and `HKEY_PERFORMANCE_DATA`.
- `maxdepth` How far to recurse into the subkeys of the key. By default only the values of the key and the names of subkeys are returned.
- `view` On 64-bit Windows, the view of the Registry to be used: see ‘Details’.

**Details**

Registry access is done using the security settings of the current R session: this means that some Registry keys may not be accessible even if they exist. This may result in NULL values in the object returned, and, possibly, empty element names.

On 64-bit Windows, this will by default read the 32-bit view of the Registry when run from 32-bit R, and the 64-bit view when run from 64-bit R: see https://docs.microsoft.com/en-us/windows/win32/winprog64/registry-redirector.

**Value**

A named list of values and subkeys (which may themselves be named lists). The default value (if any) precedes named values which precede subkeys, and both the latter sets are sorted alphabetically.

**Note**

This is only available on Windows.

**Examples**

```r
if(.Platform$OS.type == "windows") withAutoprint({
  ## only in HLM if set in an admin-mode install.
  try(readRegistry("SOFTWARE\R-core", maxdepth = 3))

  gmt <- file.path("SOFTWARE", "Microsoft", "Windows NT",
                 "CurrentVersion", "Time Zones",
                 "GMT Standard Time", fsep = "\")
  readRegistry(gmt, "HLM")
})
```
recover

Browsing after an Error

Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression options(error = recover) will make this the error option.

Usage

recover()

Details

When called, recover prints the list of current calls, and prompts the user to select one of them. The standard R browser is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type c to return to recover from the browser. Type another frame number to browse some more, or type 0 to exit recover.

The use of recover largely supersedes dump.frames as an error option, unless you really want to wait to look at the error. If recover is called in non-interactive mode, it behaves like dump.frames. For computations involving large amounts of data, recover has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call dump.frames directly while browsing in any frame (see the examples).

Value

Nothing useful is returned. However, you can invoke recover directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type 0 to exit recover.

Compatibility Note

The R recover function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands up and down do not exist in the R version; instead, exit the browser and select another frame.

References

[6] -0.9772989 0.7888790 -0.1919154 -0.3026882
Browse[1]> dump.frames() # save for offline debugging
Browse[1]> c # exit the browser

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...) 
Selection: 0 # exit recover
>
``` 

## End(Not run)

---

relist

Allow Re-Listing an unlist()ed Object

Description

relist() is an S3 generic function with a few methods in order to allow easy inversion of unlist(obj) when that is used with an object obj of (S3) class "relistable".

Usage

relist(flesh, skeleton)

## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))

## S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))
as.relistable(x)
is.relistable(x)
## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)

Arguments

flesh
  a vector to be relisted
skeleton
  a list, the structure of which determines the structure of the result
x
  an \texttt{R} object, typically a list (or vector).
recursive
  logical. Should unlisting be applied to list components of \texttt{x}?
use.names
  logical. Should names be preserved?

Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in \texttt{R}, including \texttt{optim} and \texttt{nlm} can only operate on functions whose domain is a vector. \texttt{R} has \texttt{unlist()} to convert nested list objects into a vector representation. \texttt{relist()}, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as \texttt{optim()}) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

\[
\text{list(mean} = \text{c}(0, 1), \text{vcov} = \text{cbind(c}(1, 1), \text{c}(1, 0)))
\]

However, \texttt{optim} cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function \texttt{mvdnorm(x, mean, vcov, log = FALSE)} which computes the required probability density, then

```r
ipar <- \text{list(mean} = \text{c}(0, 1), \text{vcov} = \text{cbind(c}(1, 1), \text{c}(1, 0)))
initial.param <- \text{as.relistable(ipar)}
ll <- \text{function(param.vector)}
\{
  param <- \text{relist(param.vector, skeleton} = \text{ipar})
  \text{-sum(mvdnorm(x, mean} = \text{param$mean}, \text{vcov} = \text{param$vcov},
  \text{log} = \text{TRUE})
\}
optim(\text{unlist(initial.param)}, ll)
```

relist takes two parameters: skeleton and flesh. Skeleton is a sample object that has the right shape but the wrong content. flesh is a vector with the right content but the wrong shape. Invoking
relist(flesh, skeleton)

will put the content of flesh on the skeleton. You don’t need to specify skeleton explicitly if the
skeleton is stored as an attribute inside flesh. In particular, if flesh was created from some object
obj with unlist(as.relistable(obj)) then the skeleton attribute is automatically set. (Note that
this does not apply to the example here, as optim is creating a new vector to pass to ll and not its
par argument.)

As long as skeleton has the right shape, it should be a precise inverse of unlist. These equalities
hold:

relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y

x <- as.relistable(x)
relist(unlist(x)) == x

Value

an object of (S3) class "relistable" (and "list").

Author(s)

R Core, based on a code proposal by Andrew Clausen.

See Also

unlist

Examples

ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))

---

**REMOVE**

Remove Add-on Packages

**Description**

Utility for removing add-on packages.

**Usage**

R CMD REMOVE [options] [-l lib] pkgs

**Arguments**

pkgs a space-separated list with the names of the packages to be removed.

lib the path name of the R library tree to remove from. May be absolute or relative.

Also accepted in the form `--library=lib`.

options further options for help or version.
Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by `R` run in the current environment.

To remove from the library tree `lib` instead of the default one, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

Note

Some binary distributions of `R` have `REMOVE` in a separate bundle, e.g. an `R-devel` RPM.

See Also

`INSTALL`, `remove.packages`

---

```
remove.packages     Remove Installed Packages
```

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

```
remove.packages(pkgs, lib)
```

Arguments

- `pkgs`: a character vector with the names of the packages to be removed.
- `lib`: a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in `.libPaths()`.

See Also

On Unix-alikes, `REMOVE` for a command line version;
`install.packages` for installing packages.
Description

When `options("keep.source")` is TRUE, a copy of the original source code to a function is stored with it. Similarly, `parse()` may keep formatted source for an expression. Such source reference attributes are removed from the object by `removeSource()`.

Usage

`removeSource(fn)`

Arguments

- `fn` a function or another language object (fulfilling `is.language`) from which to remove the source.

Details

This removes the "srcref" and related attributes, via recursive cleaning of `body(fn)` in the case of a function or the recursive language parts, otherwise.

Value

A copy of the `fn` object with the source removed.

See Also

- `is.language` about language objects.
- `srcref` for a description of source reference records, `deparse` for a description of how functions are deparsed.

Examples

```r
## to make this act independently of the global 'options()' setting:
op <- options(keep.source = TRUE)
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}
fn
names(attributes(fn)) # "srcref" (only)
names(attributes(body(fn))) # "srcref" "srcfile" "wholeSrcref"
f2 <- removeSource(fn)
f2
stopifnot(length(attributes(fn)) > 0,
  is.null(attributes(f2)),
  is.null(attributes(body(f2))))

## Source attribute of parse()d expressions,
## have ("srcref", "srcfile", "wholeSrcref") :
E <- parse(text = "a <- x^y # power") ; names(attributes(E))
E. <- removeSource(E) ; names(attributes(E.))
```
Description

Returns the location of the \texttt{R} home directory, which is the root of the installed \texttt{R} tree.

Usage

\begin{verbatim}
R RHOME
\end{verbatim}

roman

\textit{Roman Numerals}

Description

Simple manipulation of (a small set of) integer numbers as roman numerals.

Usage

\begin{verbatim}
as.roman(x)
.romans
r1 + r2
r1 <= r2
max(r1)
sum(r2)
\end{verbatim}

Arguments

- \texttt{x}: a numeric or character vector of arabic or roman numerals.
- \texttt{r1, r2}: a roman number vector, i.e., of \texttt{class} "roman".

Details

\texttt{as.roman} creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, coercion, etc, see \texttt{methods(class = "roman")}.

Arithmetic ("Arith"), Comparison ("Compare") and ("Logic"), i.e., all "Ops" group operations work as for regular numbers via \texttt{R}'s integer functionality.

Only numbers between 1 and 3899 have a unique representation as roman numbers, and hence others result in \texttt{as.roman(NA)}.

\texttt{.romans} is the basic dictionary, a named \texttt{character} vector.
roman

References

Examples

```r
## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## Today, and 10, 20, 30, and 100 years ago ...
y - 10*rc(0:3,10)

## mixture of arabic and roman numbers :
as.roman(c(NA, 1:3, "", strrep("I", 1:6))) # + NA with a warning for "IIIIII"
cc <- c(NA, 1:3, strrep("I", 0:5))
(rc <- as.roman(cc)) # two NAs: 0 is not "roman"
(ic <- as.integer(rc)) # works automatically [without an explicit method]
rNA <- as.roman(NA)
## simple consistency checks -- arithmetic when result is in {1,2,...,3899} :
stopifnot(identical(rc, as.roman(rc)), # as.roman(.) is "idempotent"
  identical(rc + rc + (3*rc), rc*5),
  identical(ic, c(NA, 1:3, NA, 1:5)),
  identical(as.integer(5*rc), 5L*ic),
  identical(as.numeric(rc), as.numeric(ic)),
  identical(rc[1], rNA),
  identical(as.roman(0), rNA),
  identical(as.roman(NA_character_), rNA),
  identical(as.list(rc), as.list(ic)))

## Non-Arithmetic 'Ops':
stopifnot(exprs = {
  # Comparisons :
  identical(ic < 1:5, rc < 1:5)
  identical(ic < 1:5, rc < as.roman(1:5))
  # Logic [integers |-> logical] :
  identical(rc & TRUE , ic & TRUE)
  identical(rc & FALSE, ic & FALSE)
  identical(rc | FALSE, ic | FALSE)
  identical(rc | NA , ic | NA)
})

## 'Summary' group functions (and comparison):
(rc. <- rc[!is.na(rc)])
stopifnot(exprs = {
  identical(min(rc), as.roman(NA))
  identical(min(rc, na.rm=TRUE),
    as.roman(min(ic, na.rm=TRUE))))
  identical(range(rc.),
    as.roman(range(as.integer(rc.))))
  identical(sum (rc, na.rm=TRUE), as.roman("XXI"))
  identical(format(prod(rc, na.rm=TRUE)), "DCCXX")
  format(prod(rc.)) == "DCCXX"
})
}
Rprof

Enable Profiling of R’s Execution

Description

Enable or disable profiling of the execution of R expressions.

Usage

Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
memory.profiling = FALSE, gc.profiling = FALSE,
line.profiling = FALSE, filter.callframes = FALSE,
umfiles = 100L, bufsize = 10000L)

Arguments

filename The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
append logical: should the file be over-written or appended to?
interval real: time interval between samples.
memory.profiling logical: write memory use information to the file?
gc.profiling logical: record whether GC is running?
line.profiling logical: write line locations to the file?
filter.callframes logical: filter out intervening call frames of the call tree. See the filtering out call frames section.
umfiles, bufsize integers: line profiling memory allocation

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every interval seconds, to the file specified. Either the summaryRprof function or the wrapper script R CMD Rprof can be used to process the output file to produce a summary of the usage; use R CMD Rprof --help for usage information.

How time is measured varies by platform:

On Windows: Exactly what the time interval measures is subtle: it is time that the R process is running and executing an R command. It is not however just CPU time, for if readline() is waiting for input, that counts (on Windows, but not on a Unix-alike).

Note that the timing interval cannot be too small, for the time spent in each profiling step is added to the interval. What is feasible is machine-dependent, but 10ms seemed as small as advisable on a 1GHz machine.

On Unix-alikes it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by system to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10 ms).
Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some primitive functions do not do so: specifically those which are of type "special" (see the ‘R Internals’ manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is `TRUE`, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

Filtering Out Call Frames

Lazy evaluation makes the call stack more complex because intervening call frames are created between the time arguments are applied to a function, and the time they are effectively evaluated. When the call stack is represented as a tree, these intervening frames appear as sibling nodes. For instance, evaluating `try(EXPR)` produces the following call tree, at the time `EXPR` gets evaluated:

```
1. +-base::try(EXPR)
  2. | \-base::tryCatch(...)
  3. | \-base:::tryCatchList(expr, classes, parentenv, handlers)
  4. | \-base:::tryCatchOne(expr, names, parentenv, handlers[[1L]])
  5. | \-base:::doTryCatch(return(expr), name, parentenv, handler)
  6. \-EXPR
```

Lines 2 to 5 are intervening call frames, the last of which finally triggered evaluation of `EXPR`. Setting `filter.callframes` to `TRUE` simplifies the profiler output by removing all sibling nodes of intervening frames.

The same kind of call frame filtering is applied with `eval()` frames. When you call `eval()`, two frames are pushed on the stack to ensure a continuity between frames. Say we have these definitions:

```
calling <- function() evaluator(quote(called()), environment())
evaluator <- function(expr, env) eval(expr, env)
called <- function() EXPR()
```

calling() calls called() in its own environment, via `eval()`. The latter is called indirectly through evaluator(). The net effect of this code is identical to just calling called() directly, without the intermediaries. However, the full call stack looks like this:

```
1. calling()
  3. \-evaluator(quote(called()), environment())
  4. \-base::eval(expr, env)
  5. \-called()
  6. \-EXPR()
```

When call frame filtering is turned on, the true calling environment of called() is looked up, and the filtered call stack looks like this:

```
1. calling()
  5. \-called()
  6. \-EXPR()
```

If the calling environment is not on the stack, the function called by `eval()` becomes a root node. Say we have:
calling <- function() evaluator(quote(called()), new.env())

With call frame filtering we then get the following filtered call stack:

5. called()
6. \-EXPR()

**Note**

**On Unix-alikes:** Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with `--disable-R-profiling` to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use Rprof in an executable built for C-level profiling.

**On Windows:** filename can be a UTF-8-encoded filepath that cannot be translated to the current locale.

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The numfiles and bufsize arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when Rprof(NULL) is called to finish profiling.

**See Also**

The chapter on “Tidying and profiling R code” in ‘Writing R Extensions’ (see the ‘doc/manual’ subdirectory of the R source tree).

summaryRprof to analyse the output file.

tracemem, Rprofmem for other ways to track memory use.

**Examples**

```r
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
## ...
## Now post-process the output as described in Details

## End(Not run)
```

---

**Enable Profiling of R’s Memory Use**

**Description**

Enable or disable reporting of memory allocation in R.
Rprofmem

Usage

Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)

Arguments

filename  The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append  logical: should the file be over-written or appended to?
threshold  numeric: allocations on R’s “large vector” heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. (It is enabled in a standard Windows build of R.)

The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.
tracemem traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"

Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
**Description**

This is an alternative front end for use in '#!' scripts and other scripting applications.

**Usage**

```
Rscript [options] [-e expr [-e expr2 ...] | file] [args]
```

**Arguments**

- `options` a list of options, all beginning with `--`. These can be any of the options of the standard R front-end, and also those described in the details.
- `expr`, `expr2` R expression(s), properly quoted.
- `file` the name of a file containing R commands. `-' indicates `stdin'.
- `args` arguments to be passed to the script in file or expressions supplied via `-e`.

**Details**

`Rscript --help` gives details of usage, and `Rscript --version` gives the version of Rscript. Other invocations invoke the R front-end with selected options. This front-end is convenient for writing '#!' scripts since it is an executable and takes file directly as an argument. Options `--no-echo --no-restore` are always supplied: these imply `--no-save`. Arguments that contain spaces cannot be specified directly on the '#!' line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the '#!' line. (The standard Windows command line has no concept of '#!' scripts, but Cygwin shells do.)

Either one or more `-e` options or file should be supplied. When using `-e` options be aware of the quoting rules in the shell used: see the examples.

The prescribed order of arguments is important: e.g. `--verbose` specified after `-e` will be part of `args` and passed to the expression; the same will happen to `-e` specified after file.

Additional options accepted as part of `options` (before file or `-e`) are

- `-verbose` gives details of what Rscript is doing.
- `-default-packages=list` where list is a comma-separated list of package names or `NULL`. Sets the environment variable `R_DEFAULT_PACKAGES` which determines the packages loaded on startup.

Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If `--default-packages` is not used, then Rscript checks the environment variable `R_SCRIPT_DEFAULT_PACKAGES`. If this is set, then it takes precedence over `R_DEFAULT_PACKAGES`. Normally the version of R is determined at installation, but this can be overridden by setting the environment variable `RHOME`.

`stdin()` refers to the input file, and `file("stdin")` to the stdin file stream of the process.
Note

Rscript is only supported on systems with the execv system call.

Examples

```r
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

# Get the same initial packages in the same order as default R:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()

## example #! script for a Unix-alike
## (arguments given on the #! line end up as [options] to Rscript, while
## arguments passed to the #! script end up as [args], so available to
## commandArgs())
#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()
```
