For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

Note

Using style 2 or 3 or reducing the value with style = 1 uses ‘\r’ to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when stdout() is redirected to a file.

See Also

- \text{winProgressBar} (Windows only), \text{tkProgressBar} (Unix-alike platforms).
Examples

    # slow
testit <- function(x = sort(runif(20)), ...) 
    { 
        pb <- txtProgressBar(...)
        for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
        Sys.sleep(1)
        close(pb)
    }
    testit()
testit(runif(10))
testit(style = 3)

## Convert Data to Appropriate Type

Description

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

Usage

    type.convert(x, ...)
    ## Default S3 method:
    type.convert(x, na.strings = "NA", as.is, dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"), ...)
    ## S3 method for class 'data.frame'
    type.convert(x, ...)
    ## S3 method for class 'list'
    type.convert(x, ...)

Arguments

- **x**: a vector, matrix, array, data frame, or list.
- **na.strings**: a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- **as.is**: whether convert to factors. When false (was default before R 4.0.0), convert character vectors to factors. See ‘Details’.
- **dec**: the character to be assumed for decimal points.
- **numerals**: string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when x has more digits than can be stored in a double. Can be abbreviated. Possible values are numerals = "allow.loss", default: the conversion happens with some accuracy loss. This was the behavior of R versions 3.0.3 and earlier, and the default from 3.1.1 onwards.
  numerals = "warn.loss": a warning about accuracy loss is signalled and the conversion happens as with numerals = "allow.loss".
  numerals = "no.loss": x is not converted to a number, but to a factor or character, depending on as.is. This was the behavior of R version 3.1.0.

... arguments to be passed to or from methods.
Details

This helper function is used by `read.table`. When the data object `x` is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and when additionally `as.is = FALSE` (no longer the default!), converts a character vector to `factor`. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since `NA` is primarily logical.

Vectors containing just `F`, `T`, `FALSE`, `TRUE` and values from `na.strings` are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see `NumericConstants`), or `NaN`, `Inf` or infinity (ignoring case) or values from `na.strings` are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings or (for `as.is = FALSE`) factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

Value

An object like `x` but using another storage mode when appropriate.

Author(s)

R Core, with a contribution by Arni Magnusson

See Also

`read.table`, `class`, `storage.mode`.

Examples

```r
## Numeric to integer
class(rivers)
x <- type.convert(rivers)
class(x)

## Convert many columns
auto <- type.convert(mtcars)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones)
storage.mode(WorldPhones)
storage.mode(phones)

## Factor or character
chr <- c("A", "B", "B", "A")
fac <- factor(c("A", "B", "B", "A"))
type.convert(chr) # -> factor
type.convert(fac) # -> factor
type.convert(chr, as.is = TRUE) # -> character
type.convert(fac, as.is = TRUE) # -> character
```
untar Extract or List Tar Archives

**Description**

Extract files from or list the contents of a tar archive.

**Usage**

```r
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
      compressed = NA, extras = NULL, verbose = FALSE,
      restore_times = TRUE,
      support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE),
      tar = Sys.getenv("TAR"))
```

**Arguments**

- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary reads. For a compressed tarfile, and if a connection is to be used, that should be created by `gzfile(.)` (or `gzcon(.)` which currently only works for "gzip", whereas `gzfile()` works for all compressions available in `tar()`).
- **files**: A character vector of recorded filepaths to be extracted: the default is to extract all files.
- **list**: If TRUE, list the files (the equivalent of `tar -tf`). Otherwise extract the files (the equivalent of `tar -xf`).
- **exdir**: The directory to extract files to (the equivalent of `tar -C`). It will be created if necessary.
- **compressed**: Logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression, and NA (the default) indicates that the type is to be inferred from the file header. The external command may ignore the selected compression type but detect a type automagically.
- **extras**: NULL or a character string: further command-line flags such as ‘-p’ to be passed to an external `tar` program.
- **verbose**: logical: if true echo the command used for an external `tar` program.
- **restore_times**: logical. If true (default) restore file modification times. If false, the equivalent of the ‘-m’ flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded. Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).
- **support_old_tars**: logical. If false (the default), the external `tar` command is assumed to be able handle compressed tarfiles and if compressed does not specify it, to automagically detect the type of compression. (The major implementations have done so since 2009; for GNU tar since version 1.22.)
If true, the \texttt{R} code calls an appropriate decompressor and pipes the output to \texttt{tar}, for \texttt{compressed} = \texttt{NA} examining the tarfile header to determine the type of compression.

\texttt{tar} character string: the path to the command to be used or "internal". If the command itself contains spaces it needs to be quoted – but \texttt{tar} can also contain flags separated from the command by spaces.

**Details**

This is either a wrapper for a \texttt{tar} command or for an internal implementation written in \texttt{R}. The latter is used if \texttt{tarfile} is a connection or if the argument \texttt{tar} is "internal" or "" (except on Windows, when \texttt{tar.exe} is tried first).

Unless otherwise stated three types of compression of the tar file are supported: \texttt{gzip}, \texttt{bzip2} and \texttt{xz}.

What options are supported will depend on the \texttt{tar} implementation used: the "internal" one is intended to provide support for most in a platform-independent way.

**GNU tar:** Modern GNU tar versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for \texttt{xz} compression.

On a Unix-alike, \texttt{configure} will set environment variable TAR, preferring GNU tar if found.

**bsdtar:** macOS 10.6 and later (and FreeBSD and some other OSes) have a \texttt{tar} from the libarchive project which detects all three forms of compression automagically (even if undocumented in macOS).

**NetBSD:** It is undocumented if NetBSD’s \texttt{tar} can detect compression automagically: for versions before 8 the flag for \texttt{xz} compression was ‘--xz’ not ‘-J’. So \texttt{support_old_tars = TRUE} is recommended (or use bsdtar if installed).

**OpenBSD:** OpenBSD’s \texttt{tar} does not detect compression automagically. It has no support for \texttt{xz} beyond reporting that the file is \texttt{xz}-compressed. So \texttt{support_old_tars = TRUE} is recommended.

**Heirloom Toolchest:** This \texttt{tar} does automatically detect \texttt{gzip} and \texttt{bzip2} compression (undocumented) but has no support for \texttt{xz} compression.

**Older support:** Environment variable \texttt{R_GZIPCMD} gives the command to decompress \texttt{gzip} files, and \texttt{R_BZIPCMD} for \texttt{bzip2} files. (On Unix-alikes these are set at installation if found.) \texttt{xz} is used if available: if not decompression is expected to fail.

Arguments \texttt{compressed}, \texttt{extras} and \texttt{verbose} are only used when an external \texttt{tar} is used.

Some external \texttt{tar} commands will detect some of \texttt{lzop}, \texttt{lzma}, \texttt{lz4}, \texttt{lzop} and \texttt{zstd} compression in addition to \texttt{gzip}, \texttt{bzip2} and \texttt{xz}. (For some external \texttt{tar} commands, compressed tarfiles can only be read if the appropriate utility program is available.) For GNU \texttt{tar}, further (de)compression programs can be specified by e.g. \texttt{extras = "-I lz4"}. For bsdtar this could be \texttt{extras = "--use-compress-program lz4"}. Most commands will detect (the nowadays rarely seen) ‘.tar.Z’ archives compressed by compress.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses \texttt{gzfile} to read a file it can handle files compressed by any of the methods that function can handle: at least \texttt{compress}, \texttt{gzip}, \texttt{bzip2} and \texttt{xz} compression, and some types of \texttt{lzma} compression. It does not guard against restoring absolute file paths, as some \texttt{tar} implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the USTAR/POSIX, GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.
You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a tar program that handles it, and look carefully at the resulting files. There may also be the warning

```
using pax extended headers
```

This indicates that additional information may have been discarded, such as ACLs, encodings . . . .

The former standards only supported ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). untar makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

The internal implementation does not special-case ‘resource forks’ in macOS: that system’s tar command does. This may lead to unexpected files with names with prefix ‘._’.

**Value**

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive. Otherwise the return code from `system` with an external tar or 0L, invisibly.

**See Also**

tar, unzip.

---

### unzip

`unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE, junkpaths = FALSE, exdir = ".", unzip = "internal", setTimes = FALSE)`

**Arguments**

- **zipfile**
  The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.

- **files**
  A character vector of recorded filepaths to be extracted: the default is to extract all files.

- **list**
  If TRUE, list the files and extract none. The equivalent of `unzip -l`.

- **overwrite**
  If TRUE, overwrite existing files (the equivalent of `unzip -o`), otherwise ignore such files (the equivalent of `unzip -n`).

**Description**

Extract files from or list a zip archive.

**Usage**

`unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE, junkpaths = FALSE, exdir = ".", unzip = "internal", setTimes = FALSE)`

**Arguments**

- **zipfile**
  The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.

- **files**
  A character vector of recorded filepaths to be extracted: the default is to extract all files.

- **list**
  If TRUE, list the files and extract none. The equivalent of `unzip -l`.

- **overwrite**
  If TRUE, overwrite existing files (the equivalent of `unzip -o`), otherwise ignore such files (the equivalent of `unzip -n`).
junkpaths  If TRUE, use only the basename of the stored filepath when extracting. The equivalent of unzip -j.

exdir  The directory to extract files to (the equivalent of unzip -d). It will be created if necessary.

unzip  The method to be used. An alternative is to use getOption("unzip"), which on a Unix-alike may be set to the path to a unzip program.

setTimes  logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.)

Value

If list = TRUE, a data frame with columns Name (character) Length (the size of the uncompressed file, numeric) and Date (of class "POSIXct"). Otherwise for the "internal" method, a character vector of the filepaths extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows’ users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use unzip = "unzip" with unzip 6.00 or later. It does have some support for bzip2 compression and > 2GB zip files (but not >= 4GB files pre-compression contained in a zip file: like many builds of unzip it may truncate these, in R’s case with a warning if possible).

If unzip specifies a program, the format of the dates listed with list = TRUE is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from unzip 6.00).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses zlib and is in particular based on the contributed ‘minizip’ application in the zlib sources (from http://zlib.net) by Gilles Vollant.

See Also

unz to read a single component from a zip file.

zip for packing, i.e., the “inverse” of unzip(); further untar and tar, the corresponding pair for (un)packing tar archives ("tarballs") such as R source packages.

Description

old.packages indicates packages which have a (suitable) later version on the repositories whereas update.packages offers to download and install such packages.

new.packages looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.
update.packages

Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  method, instlib = NULL,
  ask = TRUE, available = NULL,
  oldPkgs = NULL, ..., checkBuilt = FALSE,
  type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  instPkgs = installed.packages(lib.loc = lib.loc, ...),
  method, available = NULL, checkBuilt = FALSE, ...
  type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  instPkgs = installed.packages(lib.loc = lib.loc, ...),
  method, available = NULL, ask = FALSE, ...
  type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and
  update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a
  CRAN mirror such as "https://cloud.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your
  repository is incomplete. Overrides argument repos. Incompatible with
  type = "both".
method Download method, see download.file. Unused if a non-NULL available is
  supplied.
instlib character string giving the library directory where to install the packages.
ask logical indicating whether to ask the user to select packages before they are
  downloaded and installed, or the character string "graphics", which brings up
  a widget to allow the user to (de-)select from the list of packages which could
  be updated. The latter value only works on systems with a GUI version of
  select.list, and is otherwise equivalent to ask = TRUE. ask does not control
  questions asked before installing packages from source via type = "both" (see
  option "install.packages.compile.from.source").
available an object as returned by available.packages listing packages available at the
  repositories, or NULL which makes an internal call to available.packages. Incompatible with type = "both".
checkBuilt If TRUE, a package built under an earlier major.minor version of R (e.g., 3.4) is
  considered to be ‘old’.
oldPkgs if specified as non-NULL, update.packages() only considers these packages
  for updating. This may be a character vector of package names or a matrix as
  returned by old.packages.
instPkgs by default all installed packages, installed.packages(lib.loc = lib.loc).
  A subset can be specified; currently this must be in the same (character matrix)
  format as returned by installed.packages().
Arguments such as destdir and dependencies to be passed to install.packages and ignore_repo_cache, max_repo_cache_age and noCache to available.packages or installed.packages.

type character, indicating the type of package to download and install. See install.packages.

Details

old.packages compares the information from available.packages with that from instPkgs (computed by installed.packages by default) and reports installed packages that have newer versions on the repositories or, if checkBuilt = TRUE, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

new.packages does the same comparison but reports uninstalled packages that are available at the repositories. If ask != FALSE it asks which packages should be installed in the first element of lib.loc.

The main function of the set is update.packages. First a list of all packages found in lib.loc is created and compared with those available at the repositories. If ask = TRUE (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or instlib if specified).

For how the list of suitable available packages is determined see available.packages. available = NULL make a call to available.packages(available.packages(contriburl = contriburl, method = method) and hence by default filters on R version, OS type and removes duplicates.

Value

update.packages returns NULL invisibly.

For old.packages, NULL or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For new.packages a character vector of package names, after any selected via ask have been installed.

Warning

Take care when using dependencies (passed to install.packages) with update.packages, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

See Also

install.packages, available.packages, download.packages, installed.packages, contrib.url.

The options listed for install.packages under options.

See download.file for how to handle proxies and other options to monitor file transfers.

INSTALL, REMOVE, remove.packages, library, .packages, read.dcf

The "R Installation and Administration" manual for how to set up a repository.
url.show  Display a Text URL

Description

Extension of file.show to display text files from a remote server.

Usage

url.show(url, title = url, file = tempfile(),
          delete.file = TRUE, method, ...)

Arguments

url  The URL to read from.
title Title for the browser.
file  File to copy to.
delete.file  Delete the file afterwards?
method  File transfer method: see download.file
...  Arguments to pass to file.show.

Note

Since this is for text files, it will convert to CRLF line endings on Windows.

See Also

url, file.show, download.file

Examples

## Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")

URLencode  Encode or Decode (partial) URLs

Description

Functions to percent-encode or decode characters in URLs.

Usage

URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)

Arguments

URL  a character vector.
reserved  logical: should ‘reserved’ characters be encoded? See ‘Details’.
repeated  logical: should apparently already-encoded URLs be encoded again?
Details

Characters in a URL other than the English alphanumeric characters and ‘- . ~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’.

In addition, ‘! $ & ’ ( ) * + , ; = : / ? @ # [ ]’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLencode is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.

Value

A character vector.

References

Examples

(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted

## both functions support character vectors of length > 1
y <- URLdecode(URLencode(c("url with space", "another one")))

Description

(Originally none)

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

Deprecated, Defunct
Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

View(x, title)

Arguments

x  
an R object which can be coerced to a data frame with non-zero numbers of rows and columns.

title  
title for viewer window. Defaults to name of x prefixed by Data:

Details

Object x is coerced (if possible) to a data frame, then columns are converted to character using format.data.frame. The object is then viewed in a spreadsheet-like data viewer, a read-only version of data.entry.

If there are row names on the data frame that are not 1:nrow, they are displayed in a separate first column called row.names.

Objects with zero columns or zero rows are not accepted.

On Unix-alikes, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

On Windows, the array of cells can be navigated via the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see Rconsole), but adjusted downwards to show a whole number of rows and columns.

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

edit.data.frame, data.entry.
vignette

View, List or Get R Source of Package Vignettes

Description

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

Usage

vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)

## S3 method for class 'vignette'
edit(name, ...)

Arguments

topic a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

package a character vector with the names of packages to search through, or NULL in which ‘all’ packages (as defined by argument all) are searched.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.

all logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.

x, name object of class vignette.

... ignored by the print method, passed on to file.edit by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it.

On Unix-alikes, The program specified by the pdfviewer option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class “packageIQR”.

See Also

browseVignettes for an HTML-based vignette browser; RShowDoc(<basename>,package = "<pkg>") displays a “rendered” vignette (pdf or html).
Examples

```r
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## The grid intro vignette -- open it
## Not run: vignette("grid") # calling print()
## The same (conditional on existence of the vignette).
## Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
  ## Not run: v1 # calling print(.)
  str(v1)
  ## Now let us have a closer look at the code

## Not run: edit(v1) # e.g., to send lines ... 
} # if( has vignette "installed")
## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
  ## vignette("rotated")
  ## The same, but without searching for it:
  vignette("rotated", package = "grid")
}
```

warnErrList

### Collect and Summarize Errors From List

Collect errors (class "error", typically from `tryCatch`) from a list `x` into a “summary warning”, by default produce a `warning` and keep that message as "warningMsg" attribute.

#### Usage

```r
warnErrList(x, warn = TRUE, errValue = NULL)
```

#### Arguments

- **x**: a `list`, typically from applying models to a list of data (sub)sets, e.g., using `tryCatch(*, error = identity)`.
- **warn**: logical indicating if `warning()` should be called.
- **errValue**: the value with which errors should be replaced.

#### Value

a `list` of the same length and names as the `x` argument, with the error components replaced by `errValue`, `NULL` by default, and summarized in the "warningMsg" attribute.
See Also

The `warnErrList()` utility has been used in `lmList()` and `nlsList()` in recommended package `nlme` forever.

Examples

```r
## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[, "Chick"])
sapply(ChWtgrps, nrow)# typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
    lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning:
## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors -- all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
    lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
    lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
    , identical(nl3[-1], nlis3[-1])
    , is.null(nl3[[1]]))

## With different error messages
if(requireNamespace("nlme")){ # almost always, as it is recommended
data(Soybean, package="nlme")
attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
L <- lapply(split(Soybean, Soybean[, "Plot"]),
    function(DD) tryCatch(error = identity,
        nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
Lw <- warnErrList(L)
}
```

---

**winDialog**

**Dialog Boxes under Windows**

Description

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

Usage

```r
winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
    message)

winDialogString(message, default)
```
Arguments

type character. The type of dialog box. It will have the buttons implied by its name.
message character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R).
default character. The default string.

Value

For winDialog a character string giving the name of the button pressed (in capitals) or NULL (invis-
ibly) if the user had no choice.
For winDialogString a string giving the contents of the text box when Ok was pressed, or NULL if Cancel was pressed.

Note

The standard keyboard accelerators work with these dialog boxes: where appropriate Return ac-
cepts the default action, Esc cancels and the underlined initial letter (Y or N) can be used.
These functions are only available on Windows.

See Also

winMenuAdd
file.choose to select a file
package windlgs in the package source distribution for ways to program dialogs in C in the GraphApp toolkit.

Examples

## Not run: winDialog("yesno", "Is it OK to delete file blah")

---

**winextras**

Get Windows Version

Description

Get the self-reported Microsoft Windows version number.

Usage

win.version()

Details

win.version is an auxiliary function for sessionInfo and bug.report.

Value

A character string describing the version of Windows reported to be in use.
Note

This function is only available on Microsoft Windows.
The result is based on the Windows GetVersionEx API function, which for recent versions of Windows reports the compatibility version, and not necessarily the actual version (hence 8.1 and 10 may be reported as 8). If the API call reports 8, this function returns \( \geq 8 \).

Examples

```r
if(.Platform$OS.type == "windows")
  print(win.version())
```

Description

Enables users to add, delete and program menus for the Rgui in MS Windows.

Usage

```r
winMenuAdd(menuname)
winMenuAddItem(menuname, itemname, action)
winMenuDel(menuname)
winMenuDelItem(menuname, itemname)
winMenuNames()
winMenuItems(menuname)
```

Arguments

- `menuname` a character string naming a menu.
- `itemname` a character string naming a menu item on an existing menu.
- `action` a character string describing the action when that menu is selected, or "enable" or "disable".

Details

User menus are added to the right of existing menus, and items are added at the bottom of the menu. By default the action character string is treated as R input, being echoed on the command line and parsed and executed as usual.
If the `menuname` parameter of `winMenuAddItem` does not already exist, it will be created automatically.
Normally new submenus and menu items are added to the main console menu. They may be added elsewhere using the following special names:

- `$ConsoleMain` The console menu (the default)
- `$ConsolePopup` The console popup menu
- `$Graph<n>Main` The menu for graphics window \(<n>\)
- `$Graph<n>Popup` The popup menu for graphics window \(<n>\)
Specifying an existing item in `winMenuAddItem` enables the action to be changed.

Submenus can be specified by separating the elements in `menuname` by slashes: as a consequence menu names may not contain slashes.

If the action is specified as "none" no action is taken: this can be useful to reserve items for future expansion.

The function `winMenuNames` can be used to find out what menus have been created by the user and returns a vector of the existing menu names.

The `winMenuItems` function will take the name of a menu and return the items that exist in that menu. The return value is a named vector where the names correspond to the names of the items and the values of the vector are the corresponding actions.

The `winMenuDel` function will delete a menu and all of its items and submenus. `winMenuDelItem` just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu string cannot exceed 500 bytes.

**Value**

`NULL`, invisibly. If an error occurs, an informative error message will be given.

**Note**

These functions are only available on Windows and only when using the `Rgui`, hence not in ESS nor RStudio.

**See Also**

`winDialog`

**Examples**

```r
## Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit extras")
winMenuAddItem("Testit", ",-", ",")
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit extras", "one more", "ddd")
winMenuAddItem("Testit extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")

## End(Not run)
```
**Description**

Put up a Windows progress bar widget, update and access it.

**Usage**

```r
winProgressBar(title = "R progress bar", label = ",
    min = 0, max = 1, initial = 0, width = 300)

getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'winProgressBar'
close(con, ...)
```

**Arguments**

- `title`, `label` character strings, giving the window title and the label on the dialog box respectively.
- `min`, `max` (finite) numeric values for the extremes of the progress bar.
- `initial`, `value` initial or new value for the progress bar.
- `width` the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb`, `con` an object of class "winProgressBar".
- `...` for consistency with the generic.

**Details**

`winProgressBar` will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.

`setWinProgressBar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be closed when finished with, but it will be garbage-collected once no R object refers to it.

**Value**

- For `winProgressBar` an object of class "winProgressBar".
- For `getWinProgressBar` and `setWinProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setWinProgressBar`).

**Note**

These functions are only available on Windows.
write.table

See Also

On all platforms, `txtProgressBar`, `tkProgressBar`

Examples

```r
pb <- winProgressBar("test progress bar", "Some information in %", 
0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setWinProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

write.table | Data Output

Description

write.table prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

Usage

```r
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
eol = "\n", na = "NA", dec = ",", row.names = TRUE,
col.names = TRUE, qmethod = c("escape", "double"),
fileEncoding = "")
```

write.csv(...)
write.csv2(...)

Arguments

- `x` the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce `x` to a data frame.
- `file` either a character string naming a file or a connection open for writing. "" indicates output to the console.
- `append` logical. Only relevant if `file` is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
- `quote` a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.
- `sep` the field separator string. Values within each row of `x` are separated by this string.
write.table

eol  the character(s) to print at the end of each line (row). For example, eol = "\r\n" will produce Windows' line endings on a Unix-alike OS, and eol = "\r" will produce files as expected by Excel:mac 2004.

na  the string to use for missing values in the data.

dec  the string to use for decimal points in numeric or complex columns: must be a single character.

row.names  either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.

col.names  either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on 'CSV files' for the meaning of col.names = NA.

qmethod  a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for write.table), in which case the quote character is escaped in C style by a backslash, or "double" (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter.

fileEncoding  character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file.

...  arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered.

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via as.matrix) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use options("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see options), but with the internal equivalent of digits = 15. For finer control, use format to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename","wb").
CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```r
read.csv(file = "<filename>", row.names = 1)
```

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "." for the decimal point and a comma for the separator.
write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use fileEncoding = "UTF-16LE") or perhaps in the current Windows codepage (e.g., "CP1252"), but the ‘Text Import Wizard’ (from the ‘Data’ tab) allows far more choice of encodings. Excel:mac 2004/8 can import only ‘Macintosh’ (which seems to mean Mac Roman), ‘Windows’ (perhaps Latin-1) and ‘PC-8’ files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (https://tools.ietf.org/html/rfc4180) for CSV files, which mandates comma as the separator and CRLF line endings. write.csv writes compliant files on Windows: use eol = "\r\n" on other platforms.

Note

write.table can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

The ‘R Data Import/Export’ manual.
read.table, write.
write.matrix in package MASS.

Examples

```r
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".
```
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)

---

**zip**

*Create Zip Archives*

**Description**

A wrapper for an external `zip` command to create zip archives.

**Usage**

```r
zip(zipfile, files, flags = ":r9X", extras = ":",
    zip = Sys.getenv("R_ZIPCMD", "zip"))
```

**Arguments**

- `zipfile`  The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.
- `files`  A character vector of recorded filepaths to be included.
- `flags`  A character string of flags to be passed to the command: see ‘Details’.
- `extras`  An optional character vector: see ‘Details’.
- `zip`  A character string specifying the external command to be used.

**Details**

On a Unix-alike, the default for `zip` will by default use the value of `R_ZIPCMD`, which is set in `etc/Renviron` if an `unzip` command was found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.

The default for `flags` is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the `zip` command for other possibilities.

Argument `extras` can be used to specify `-x` or `-i` followed by a list of filepaths to exclude or include. Since `extras` will be treated as if passed to `system`, if the filepaths contain spaces they must be quoted e.g. by `shQuote`.

**Value**

The status value returned by the external command, invisibly.

**See Also**

`unzip`, `unz`; further, `tar` and `untar` for (un)packing tar archives.
Part II
Chapter 15

The KernSmooth package

---

**bkde**

*Compute a Binned Kernel Density Estimate*

---

**Description**

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

**Usage**

```
bkde(x, kernel = "normal", canonical = FALSE, bandwidth, gridsize = 401L, range.x, truncate = TRUE)
```

**Arguments**

- **x**
  numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.

- **bandwidth**
  the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the 'oversmoothed bandwidth selector' of Wand and Jones (1995, page 61).

- **kernel**
  character string which determines the smoothing kernel. kernel can be:
  - "normal" - the Gaussian density function (the default).
  - "box" - a rectangular box.
  - "epanech" - the centred beta(2,2) density.
  - "biweight" - the centred beta(3,3) density.
  - "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.

- **canonical**
  logical flag: if TRUE, canonically scaled kernels are used.

- **gridsize**
  the number of equally spaced points at which to estimate the density.

- **range.x**
  vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.

- **truncate**
  logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each x value in the sample, the kernel is centered on that x and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding y value in the output.

Value

a list containing the following components:

x  vector of sorted x values at which the estimate was computed.
y  vector of density estimates at the corresponding x.

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")

bkde2D  Compute a 2D Binned Kernel Density Estimate

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

bkde2D(x, bandwidth, gridsize = c(51L, 51L), range.x, truncate = TRUE)
Arguments

- **x**: a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth**: numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.
- **gridsize**: vector containing the number of equally spaced points in each direction over which the density is to be estimated.
- **range.x**: a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

A list containing the following components:

- **x1**: vector of values of the grid points in the first coordinate direction at which the estimate was computed.
- **x2**: vector of values of the grid points in the second coordinate direction at which the estimate was computed.
- **fhat**: matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1, x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

persp(est$fhat)
Compute a Binned Kernel Functional Estimate

**Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```r
bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

- `x`: numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- `drv`: order of derivative in the density functional. Must be a non-negative even integer.
- `bandwidth`: the kernel bandwidth smoothing parameter. Must be supplied.
- `gridsize`: the number of equally-spaced points over which binning is performed.
- `range.x`: vector containing the minimum and maximum values of `x` at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- `binned`: logical flag: if TRUE, then `x` and `y` are taken to be grid counts rather than raw data.
- `truncate`: logical flag: if TRUE, data with `x` values outside the range specified by `range.x` are ignored.

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

**Examples**

```r
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

---

**dpih**  
*Select a Histogram Bin Width*

**Description**

Uses direct plug-in methodology to select the bin width of a histogram.

**Usage**

```r
dpih(x, scalest = "minim", level = 2L, gridsize = 401L,  
range.x = range(x), truncate = TRUE)
```

**Arguments**

- `x`: numeric vector containing the sample on which the histogram is to be constructed.
- `scalest`: estimate of scale.  
  - "stdev" - standard deviation is used.  
  - "iqr" - inter-quartile range divided by 1.349 is used.  
  - "minim" - minimum of "stdev" and "iqr" is used.
- `level`: number of levels of functional estimation used in the plug-in rule.
- `gridsize`: number of grid points used in the binned approximations to functional estimates.
- `range.x`: range over which functional estimates are obtained. The default is the minimum and maximum data values.
- `truncate`: if `truncate` is `TRUE` then observations outside of the interval specified by `range.x` are omitted. Otherwise, they are used to weight the extreme grid points.

**Details**

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

**Value**

the selected bin width.

**Background**

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

```

---

**dpik**

*Select a Bandwidth for Kernel Density Estimation*

**Description**

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

**Usage**

```r
dpik(x, scalest = "minim", level = 2L, kernel = "normal",
    canonical = FALSE, gridsize = 401L, range.x = range(x),
    truncate = TRUE)
```

**Arguments**

- `x` numeric vector containing the sample on which the kernel density estimate is to be constructed.
- `scalest` estimate of scale.
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- `level` number of levels of functional estimation used in the plug-in rule.
- `kernel` character string which determines the smoothing kernel. kernel can be:
  - "normal" - the Gaussian density function (the default).
  - "box" - a rectangular box.
  - "epanech" - the centred beta(2,2) density.
  - "biweight" - the centred beta(3,3) density.
  - "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- `canonical` logical flag: if TRUE, canonically scaled kernels are used
- `gridsize` the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
range.x  vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values.

truncate  logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

dpill  

*Select a Bandwidth for Local Linear Regression*

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05, gridsize = 401L, range.x, truncate = TRUE)
Arguments

- **x**: numeric vector of x data. Missing values are not accepted.
- **y**: numeric vector of y data. This must be same length as x, and missing values are not accepted.
- **blockmax**: the maximum number of blocks of the data for construction of an initial parametric estimate.
- **divisor**: the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
- **trim**: the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
- **proptrun**: the proportion of the range of x at each end truncated in the functional estimates.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s $C_p$ is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

fit <- locpoly(x, y, bandwidth = h)
lines(fit)
```

locpoly

Estimate Functions Using Local Polynomials

Description

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage

```r
locpoly(x, y, drv = 0L, degree, kernel = "normal",
bandwidth, gridsize = 401L, bwdisc = 25,
range.x, binned = FALSE, truncate = TRUE)
```

Arguments

- **x**: numeric vector of x data. Missing values are not accepted.
- **bandwidth**: the kernel bandwidth smoothing parameter. It may be a single number or an array having length `gridsize`, representing a bandwidth that varies according to the location of estimation.
- **y**: vector of y data. This must be same length as x, and missing values are not accepted.
- **drv**: order of derivative to be estimated.
- **degree**: degree of local polynomial used. Its value must be greater than or equal to the value of `drv`. The default value is of `degree` is `drv + 1`.
- **kernel**: "normal" - the Gaussian density function. Currently ignored.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **bwdisc**: number of logarithmically-equally-spaced bandwidths on which `bandwidth` is discretised, to speed up computation.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate.
- **binned**: logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by `range.x` are ignored.
Value

if y is specified, a local polynomial regression estimate of E[Y|X] (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

- x vector of sorted x values at which the estimate was computed.
- y vector of smoothed estimates for either the density or the regression at the corresponding x.

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length gridsize.

**accdeaths**

*Accidental Deaths in the US 1973-1978*

**Description**

A regular time series giving the monthly totals of accidental deaths in the USA.

**Usage**

`accdeaths`

**Details**

The values for first six months of 1979 (p. 326) were 7798 7406 8363 8460 9217 9316.
addterm

Try All One-Term Additions to a Model

Description
Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes \texttt{lm} and \texttt{glm} and the default method will work for many other classes.

Usage

\begin{verbatim}
addterm(object, ...)  
## Default S3 method:  
addterm(object, scope, scale = 0, test = c("none", "Chisq"),  
k = 2, sorted = FALSE, trace = FALSE, ...)  
## S3 method for class 'lm'  
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
k = 2, sorted = FALSE, ...)  
## S3 method for class 'glm'  
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
k = 2, sorted = FALSE, trace = FALSE, ...)  
\end{verbatim}

Arguments

- \texttt{object}: An object fitted by some model-fitting function.
- \texttt{scope}: a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
- \texttt{scale}: used in the definition of the AIC statistic for selecting the models, currently only for \texttt{lm}, \texttt{aov} and \texttt{glm} models. Specifying \texttt{scale} asserts that the residual standard error or dispersion is known.
- \texttt{test}: should the results include a test statistic relative to the original model? The F test is only appropriate for \texttt{lm} and \texttt{aov} models, and perhaps for some over-dispersed \texttt{glm} models. The Chisq test can be an exact test (\texttt{lm} models with known scale) or a likelihood-ratio test depending on the method.
- \texttt{k}: the multiple of the number of degrees of freedom used for the penalty. Only \texttt{k=2} gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
- \texttt{sorted}: should the results be sorted on the value of AIC?
- \texttt{trace}: if \texttt{TRUE} additional information may be given on the fits as they are tried.
- \texttt{...}: arguments passed to or from other methods.
The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

See Also

dropterm, stepAIC

Examples

```r
quine.hi <- aov(log(Days + 2.5) ~ .^4, quine)
quine.lo <- aov(log(Days+2.5) ~ 1, quine)
addterm(quine.lo, quine.hi, test="F")

house.glm0 <- glm(Freq ~ Infl*Type*Cont + Sat, family=poisson,
data=housing)
addterm(house.glm0, ~. + Sat:(Infl+Type+Cont), test="Chisq")
house.glm1 <- update(house.glm0, . ~ . + Sat*(Infl+Type+Cont))
addterm(house.glm1, ~. + Sat:(Infl+Type+Cont)^2, test = "Chisq")
```

**Australian AIDS Survival Data**

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

Usage

Aids2

Format

This data frame contains 2843 rows and the following columns:

- **state** Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.
- **sex** Sex of patient.
- **diag** (Julian) date of diagnosis.
- **death** (Julian) date of death or end of observation.
- **status** "A" (alive) or "D" (dead) at end of observation.
- **T.categ** Reported transmission category.
- **age** Age (years) at diagnosis.
Note

This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

Description

The anorexia data frame has 72 rows and 3 columns. Weight change data for young female anorexia patients.

Usage

anorexia

Format

This data frame contains the following columns:

- Treat: Factor of three levels: "Cont" (control), "CBT" (Cognitive Behavioural treatment) and "FT" (family treatment).
- Prewt: Weight of patient before study period, in lbs.
- Postwt: Weight of patient after study period, in lbs.

Source

(Note that the original source mistakenly says that weights are in kg.)

References

Description

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

Usage

```r
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```
Arguments

object | Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of glm.nb().

... | Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.

test | Argument to match the test argument of anova.glm. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function anova() for class "negbin". It can be invoked by calling anova(x) for an object x of the appropriate class, or directly by calling anova.negbin(x) regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The theta parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case theta is assumed to have been re-estimated for each model.

anova(m2, m1)
anova(m2)

---

area

Adaptive Numerical Integration

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
      limit = 10, eps = 1e-05)
bacteria

Arguments

- **f**: The integrand as an S function object. The variable of integration must be the first argument.
- **a**: Lower limit of integration.
- **b**: Upper limit of integration.
- **...**: Additional arguments needed by the integrand.
- **fa**: Function value at the lower limit.
- **fb**: Function value at the upper limit.
- **limit**: Limit on the depth to which recursion is allowed to go.
- **eps**: Error tolerance to control the process.

Details

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

Value

The integral from a to b of f(x).

References

Examples

area(sin, 0, pi) # integrate the sin function from 0 to pi.

bacteria

*Presence of Bacteria after Drug Treatments*

Description

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

Usage

bacteria

Format

This data frame has 220 rows and the following columns:

- **y**: presence or absence: a factor with levels n and y.
- **ap**: active/placebo: a factor with levels a and p.
- **hilo**: hi/low compliance: a factor with levels hi and lo.
- **week**: numeric: week of test.
- **ID**: subject ID: a factor.
- **trt**: a factor with levels placebo, drug and drug+, a re-coding of ap and hilo.
Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

Source

Dr Amanda Leach *via* Mr James McBroom.

summary(glm(y ~ trt + week, binomial, data = bacteria))
summary(glm(y ~ trt + I(week > 2), binomial, data = bacteria))

# conditional random-effects analysis
library(survival)
bacteria$Time <- rep(1, nrow(bacteria))
coxph(Surv(Time, unclass(y)) ~ week + strata(ID),
   data = bacteria, method = "exact")
coxph(Surv(Time, unclass(y)) ~ factor(week) + strata(ID),
   data = bacteria, method = "exact")
coxph(Surv(Time, unclass(y)) ~ I(week > 2) + strata(ID),
   data = bacteria, method = "exact")

# PQL glmm analysis
library(nlme)
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
   family = binomial, data = bacteria))
```

bandwidth.nrd

*Bandwidth for density() via Normal Reference Distribution*

Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

Usage

`bandwidth.nrd(x)`
Arguments

- \( x \): A data vector.

Value

A bandwidth on a scale suitable for the width argument of \texttt{density}.

References

Examples

```r
# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}
```

Description

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

\texttt{bcv(x, nb = 1000, lower, upper)}

Arguments

- \( x \): a numeric vector
- \( nb \): number of bins to use.
- \( lower, upper \): Range over which to minimize. The default is almost always satisfactory.

Value

A bandwidth

**birthwt**

**Risk Factors Associated with Low Infant Birth Weight**

**Description**

The *birthwt* data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

**Usage**

`birthwt`

**Format**

This data frame contains the following columns:

- `low` indicator of birth weight less than 2.5 kg.
- `age` mother's age in years.
- `lwt` mother's weight in pounds at last menstrual period.
- `race` mother's race (1 = white, 2 = black, 3 = other).
- `smoke` smoking status during pregnancy.
- `ptl` number of previous premature labours.
- `ht` history of hypertension.
- `ui` presence of uterine irritability.
- `ftv` number of physician visits during the first trimester.
- `bwt` birth weight in grams.

**Source**

**References**

**Examples**

```r
bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))
  ptd <- factor(ptl > 0)
  ftv <- factor(ftv)
  levels(ftv)[-c(1,2)] <- "2+"
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
             ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```
Boston

Housing Values in Suburbs of Boston

Description

The Boston data frame has 506 rows and 14 columns.

Usage

Boston

Format

This data frame contains the following columns:

- crim: per capita crime rate by town.
- zn: proportion of residential land zoned for lots over 25,000 sq.ft.
- indus: proportion of non-retail business acres per town.
- chas: Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).
- nox: nitrogen oxides concentration (parts per 10 million).
- rm: average number of rooms per dwelling.
- age: proportion of owner-occupied units built prior to 1940.
- dis: weighted mean of distances to five Boston employment centres.
- rad: index of accessibility to radial highways.
- tax: full-value property-tax rate per \$10,000.
- ptratio: pupil-teacher ratio by town.
- black: \(1000(Bk - 0.63)^2\) where \(Bk\) is the proportion of blacks by town.
- lstat: lower status of the population (percent).
- medv: median value of owner-occupied homes in \$1000s.

Source

**Box-Cox Transformations for Linear Models**

**Description**

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```r
boxcox(object, ...) 
## Default S3 method: 
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, 
      interp, eps = 1/50, xlab = expression(lambda), 
      ylab = "log-Likelihood", ...) 
## S3 method for class 'formula' 
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, 
       interp, eps = 1/50, xlab = expression(lambda), 
       ylab = "log-Likelihood", ...) 
## S3 method for class 'lm' 
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, 
       interp, eps = 1/50, xlab = expression(lambda), 
       ylab = "log-Likelihood", ...) 
```

**Arguments**

- `object` a formula or fitted model object. Currently only `lm` and `aov` objects are handled.
- `lambda` vector of values of `lambda` – default (`-2, 2`) in steps of 0.1.
- `plotit` logical which controls whether the result should be plotted.
- `interp` logical which controls whether spline interpolation is used. Default to `TRUE` if plotting with `lambda` of length less than 100.
- `eps` Tolerance for `lambda = 0`; defaults to 0.02.
- `xlab` defaults to “`lambda`”.
- `ylab` defaults to “`log-Likelihood`”.
- `...` additional parameters to be used in the model fitting.

**Value**

A list of the `lambda` vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Side Effects**

If `plotit = TRUE` plots log-likelihood vs `lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.
cabbages

References

Examples

```r
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length = 10))
boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))
```

---

cabbages

*Data from a cabbage field trial*

Description

The cabbages data set has 60 observations and 4 variables

Usage

cabbages

Format

This data frame contains the following columns:

- **Cult**: Factor giving the cultivar of the cabbage, two levels: c39 and c52.
- **Date**: Factor specifying one of three planting dates: d16, d20 or d21.
- **HeadWt**: Weight of the cabbage head, presumably in kg.
- **VitC**: Ascorbic acid content, in undefined units.

Cars93

Data from 93 Cars on Sale in the USA in 1993

Description

The Cars93 data frame has 93 rows and 27 columns.

Usage

Cars93
Format

This data frame contains the following columns:

- **Manufacturer**
- **Model**
- **Type**
  - A factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".
- **Min.Price**
  - Minimum Price (in \$1,000): price for a basic version.
- **Price**
  - Midrange Price (in \$1,000): average of Min.Price and Max.Price.
- **Max.Price**
  - Maximum Price (in \$1,000): price for "a premium version".
- **MPG.city**
  - City MPG (miles per US gallon by EPA rating).
- **MPG.highway**
  - Highway MPG.
- **AirBags**
  - Air Bags standard. Factor: none, driver only, or driver & passenger.
- **DriveTrain**
  - Drive train type: rear wheel, front wheel or 4WD; (factor).
- **Cylinders**
  - Number of cylinders (missing for Mazda RX-7, which has a rotary engine).
- **EngineSize**
  - Engine size (litres).
- **Horsepower**
  - Horsepower (maximum).
- **RPM**
  - RPM (revs per minute at maximum horsepower).
- **Rev.per.mile**
  - Engine revolutions per mile (in highest gear).
- **Man.trans.avail**
  - Is a manual transmission version available? (yes or no, Factor).
- **Fuel.tank.capacity**
  - Fuel tank capacity (US gallons).
- **Passengers**
  - Passenger capacity (persons)
- **Length**
  - Length (inches).
- **Wheelbase**
  - Wheelbase (inches).
- **Width**
  - Width (inches).
- **Turn.circle**
  - U-turn space (feet).
- **Rear.seat.room**
  - Rear seat room (inches) (missing for 2-seater vehicles).
- **Luggage.room**
  - Luggage capacity (cubic feet) (missing for vans).
- **Weight**
  - Weight (pounds).
- **Origin**
  - Of non-USA or USA company origins? (factor).
- **Make**
  - Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993).

**con2tr**

*Convert Lists to Data Frames for use by lattice*

Description
Convert lists to data frames for use by lattice.

Usage
```r
con2tr(obj)
```

Arguments
```r
obj
```
A list of components x, y and z as passed to contour.

Details
`con2tr` repeats the x and y components suitably to match the vector z.
Value

A data frame suitable for passing to lattice (formerly trellis) functions.

References

Description

Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage

```r
## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

Arguments

- `object`: a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `trace`: logical. Should profiling be traced?
- `...`: additional argument(s) for methods.

Details

confint is a generic function in package stats.

These confint methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1 - level)/2 and 1 - (1 - level)/2 in % (by default 2.5% and 97.5%).

confint(budworm.lg0, "ldose")

contr.sdif

Successive Differences Contrast Coding

Description

A coding for factors based on successive differences.

Usage

contr.sdif(n, contrasts = TRUE, sparse = FALSE)

Arguments

n
  The number of levels required.

contrasts
  logical: Should there be n - 1 columns orthogonal to the mean (the default) or n
  columns spanning the space?
sparse logical. If true and the result would be sparse (only true for contrasts = FALSE), return a sparse matrix.

Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

Value

If contrasts is TRUE, a matrix with n rows and n -1 columns, and the n by n identity matrix if contrasts is FALSE.

**corresp**  
*Simple Correspondence Analysis*

**Description**

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

**Usage**

```r
corresp(x, ...)  
## S3 method for class 'matrix'
corresp(x, nf = 1, ...)

## S3 method for class 'factor'
corresp(x, y, ...)

## S3 method for class 'data.frame'
corresp(x, ...)

## S3 method for class 'xtabs'
corresp(x, ...)

## S3 method for class 'formula'
corresp(formula, data, ...)
```

**Arguments**

- **x, formula**  
The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulae of the form ~ F1 + F2, where F1 and F2 are factors.

- **nf**  
The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.

- **y**  
a second factor for a cross-classification.

- **data**  
an optional data frame, list or environment against which to preferentially resolve variables in the formula.

- **...**  
If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.
cov.rob

Details

See Venables & Ripley (2002). The plot method produces a graphical representation of the table if \( nf=1 \), with the areas of circles representing the numbers of points. If \( nf \) is two or more the biplot method is called, which plots the second and third columns of the matrices \( A = Dr^*(−1/2) U L \) and \( B = Dc^*(−1/2) V L \) where the singular value decomposition is \( U L V \). Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does not have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class "correspondence" for which print, plot and biplot methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

References

See Also

svd, princomp.

Examples

\((ct <- corresp(~ Age + Eth, data = quine))\)
plot(ct)

corresp(caith)
biplot(corresp(caith, nf = 2))

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. cov.mve and cov.mcd are compatibility wrappers.

Usage

\(\text{cov.rob}(x, \text{cor} = \text{FALSE}, \text{quantile.used} = \text{floor}((n + p + 1)/2), \text{method} = \text{c("mve", "mcd", "classical")}, \text{nsamp} = \text{"best", seed})\)

\(\text{cov.mve}(\ldots)\)
\(\text{cov.mcd}(\ldots)\)
cov.rob

Arguments

x
a matrix or data frame.
cor
should the returned result include a correlation matrix?
quantile.used
the minimum number of the data points regarded as good points.
method
the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using cov.mve or cov.mcd forces mve or mcd respectively.
nsamp
the number of samples or "best" or "exact" or "sample". The limit If "sample" the number chosen is \(\min(5p,3000)\), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted.
seed
the seed to be used for random sampling: see RNGkind. The current value of .Random.seed will be preserved if it is set.
...
arguments to cov.rob other than method.

Details

For method "mve", an approximate search is made of a subset of size quantile.used with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an ad hoc finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of \(p\) of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size quantile.used is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

There is a hard limit on the allowed number of samples, \(2^{31} - 1\). However, practical limits are likely to be much lower and one might check the number of samples used for exhaustive enumeration, \(\text{combn(NROW(x),NCOL(x) + 1)}\), before attempting it.

Value

A list with components

center
the final estimate of location.
cov
the final estimate of scatter.
cor
(only is cor = TRUE) the estimate of the correlation matrix.
sing
message giving number of singular samples out of total
crit
the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
best
the subset used. For MVE the best sample, for MCD the best set of size quantile.used.
n.obs
total number of observations.

cov.rob(stack.x, method = "mcd", nsamp = "exact")
```

cov.trob

**Covariance Estimation for Multivariate t Distribution**

Description

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

Usage

```r
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
maxit = 25, tol = 0.01)
```

Arguments

- `x` data matrix. Missing values (NAs) are not allowed.
- `wt` A vector of weights for each case: these are treated as if the case i actually occurred wt[i] times.
- `cor` Flag to choose between returning the correlation (cor = TRUE) or covariance (cor = FALSE) matrix.
- `center` a logical value or a numeric vector providing the location about which the covariance is to be taken. If center = FALSE, no centering is done; if center = TRUE the MLE of the location vector is used.
- `nu` ’degrees of freedom’ for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
- `maxit` Maximum number of iterations in fitting.
- `tol` Convergence tolerance for fitting.
Value

A list with the following components

- **cov**: the fitted covariance matrix.
- **center**: the estimated or specified location vector.
- **wt**: the specified weights: only returned if the wt argument was given.
- **n.obs**: the number of cases used in the fitting.
- **cor**: the fitted correlation matrix: only returned if cor = TRUE.
- **call**: The matched call.
- **iter**: The number of iterations used.

denumerate

Transform an Allowable Formula for `loglm` into one for `terms`

Description

`loglm` allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that `terms` can process.

Usage

denumerate(x)

Arguments

x A formula conforming to the conventions of `loglm`, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

Details

The model fitting function `loglm` fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, … for the first, second, third, … margins in a similar way to variable names. As the model formula has to be parsed by `terms`, which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely n is replaced by .vn. This allows `terms` to parse the formula in the usual way.
A linear model formula like that presented, except that where dimension numbers, say \( n \), have been used to specify fixed margins these are replaced by names of the form \(.v_n\) which may be processed by terms.

## Predict Doses for Binomial Assay model

dose.p

Description

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

dose.p(obj, cf = 1:2, p = 0.5)

Arguments

obj A fitted model object of class inheriting from "glm".

\( \text{cf} \) The terms in the coefficient vector giving the intercept and coefficient of (log-)dose

p Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p") and standard error (attribute "SE") at each response probability.

References

Examples

ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)

dropterm  Try All One-Term Deletions from a Model

Description

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes \texttt{lm} and \texttt{glm} and the default method will work for many other classes.

Usage

dropterm (object, ...)

## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
          k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
          k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
          k = 2, sorted = FALSE, trace = FALSE, ...)

Arguments

object A object fitted by some model-fitting function.
scope a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
scale used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
test should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known scale) or a likelihood-ratio test depending on the method.
k the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
sorted should the results be sorted on the value of AIC?
trace if TRUE additional information may be given on the fits as they are tried.
... arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (\( lm \) models with specified `scale`) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

Seizure Counts for Epileptics

Description
Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

Usage
epil

Format
This data frame has 236 rows and the following 9 columns:
y the count for the 2-week period.
trt treatment, “placebo” or “progabide”.
base the counts in the baseline 8-week period.
age subject’s age, in years.
V4 0/1 indicator variable of period 4.
subject subject number, 1 to 59.
period period, 1 to 4.
lbase log-counts for the baseline period, centred to have zero mean.
lage log-ages, centred to have zero mean.

**eqscplot**

*Plots with Geometrically Equal Scales*

**Description**

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

**Usage**

```
eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

**Arguments**

- `x` vector of x values, or a 2-column matrix, or a list with components x and y
- `y` vector of y values
- `ratio` desired ratio of units on the axes. Units on the y axis are drawn at ratio times the size of units on the x axis. Ignored if uin is specified and of length 2.
- `tol` proportion of white space at the margins of plot
- `uin` desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
- `...` further arguments for plot and graphical parameters. Note that par(xaxs="i",yaxs="i") is enforced, and xlim and ylim will be adjusted accordingly.

**Details**

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by ratio. Finally both are stretched by 1 + tol to move points away from the axes, and the points plotted.

**Value**

invisibly, the values of uin used for the plot.
Side Effects

performs the plot.

Note

Arguments ratio and uin were suggested by Bill Dunlap.

fgl

Measurements of Forensic Glass Fragments

Description

The fgl data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

Usage

fgl

Format

This data frame contains the following columns:

RI  refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

Na  sodium.
Mg  manganese.
Al  aluminium.
Si  silicon.
K  potassium.
Ca  calcium.
Ba  barium.
Fe  iron.

type The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (WinF: 70), window non-float glass (WinNF: 76), vehicle window glass (Veh: 17), containers (Con: 13), tableware (Tabl: 9) and vehicle headlamps (Head: 29).

References

Maximum-likelihood Fitting of Univariate Distributions

Description

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

Usage

fitdistr(x, densfun, start, ...)

Arguments

x
A numeric vector of length at least one containing only finite values.

densfun
Either a character string or a function returning a density evaluated at its first argument.

Distributions "beta", "cauchy", "chi-squared", "exponential", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.

start
A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).

...
Additional parameters, either for densfun or for optim. In particular, it can be used to specify bounds via lower or upper or both. If arguments of densfun (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and start should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using optim. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named lower or upper are supplied (when L-BFGS-B is used) or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location m and scale s.

For the following named distributions, reasonable starting values will be computed if start is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by mu and size), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are print, coef, vcov and logLik methods for class "fitdistr".
Value

An object of class "fitdistr", a list with four components,

- estimate: the parameter estimates,
- sd: the estimated standard errors,
- vcov: the estimated variance-covariance matrix, and
- loglik: the log-likelihood.

Note

Numerical optimization cannot work miracles: please note the comments in optim on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter parscale.

forbes

Forbes’ Data on Boiling Points in the Alps

Description

A data frame with 17 observations on boiling point of water and barometric pressure in inches of mercury.
fractions

Usage
forbes

Format
bp  boiling point (degrees Farenheit).
pres  barometric pressure in inches of mercury.

Source

<table>
<thead>
<tr>
<th>fractions</th>
<th>Rational Approximation</th>
</tr>
</thead>
</table>

Description
Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage
fractions(x, cycles = 10, max.denominator = 2000, ...)

Arguments
x  Any object of mode numeric. Missing values are now allowed.
cycles  The maximum number of steps to be used in the continued fraction approximation process.
max.denominator  An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
...  arguments passed to or from other methods.

Details
Each component is first expanded in a continued fraction of the form
\[ x = \text{floor}(x) + \frac{1}{(p_1 + \frac{1}{(p_2 + \ldots)})} \]
where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \) max.denominator. The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.
The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.
Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.
Value

An object of class "fractions". A structure with .Data component the same as the input numeric x, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

Examples

X <- matrix(runif(25), 5, 5)
 zapsmal(solve(X, X/5)) # print near-zeroes as zero
 fractions(solve(X, X/5))
 fractions(solve(X, X/5)) + 1

GAGurine

Level of GAG in Urine of Children

Description

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrican to assess if a child’s GAG concentration is ‘normal’.

Usage

GAGurine

Format

This data frame contains the following columns:

Age  age of child in years.
GAG concentration of GAG (the units have been lost).

Source

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

References

**galaxies**

**Velocities for 82 Galaxies**

**Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

**Usage**

galaxies

**Note**

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

**Source**

**References**

**Examples**

gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", bty = "l",
xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)

**gamma.dispersion**

*Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit*

**Description**

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

**Usage**

gamma.dispersion(object, ...)

---

`gamma.dispersion`
gamma.shape

Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit

**Description**

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

**Usage**

```r
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10, 
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

**Arguments**

- `object` Fitted model object from a Gamma family or quasi family with variance = 
  "mu^2".
- `it.lim` Upper limit on the number of iterations.
- `eps.max` Maximum discrepancy between approximations for the iteration process to continue.
- `verbose` If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
- `...` further arguments passed to or from other methods.

**Details**

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.
Remission Times of Leukaemia Patients

Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug 6-mercaptopurine and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

Usage

datanames

Format

This data frame contains the following columns:

pair label for pair.
time remission time in weeks.
cens censoring, 0/1.
treat treatment, control or 6-MP.
Source

References

Examples

```r
library(survival)
gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan, conf.type = "log-log")
summary(gehan.surv)
survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exponential")
summary(survreg(Surv(time, cens) ~ treat, gehan, dist = "exponential"))
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

Rat Genotype Data

Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

Usage

genotype

Format

The data frame has the following components:

- **Litter** genotype of the litter.
- **Mother** genotype of the foster mother.
- **Wt** Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

**gilgais**

*Line Transect of Soil in Gilgai Territory*

**Description**

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.
Usage
gilgais

Format
This data frame contains the following columns:

- pH00 pH at depth 0–10 cm.
- pH30 pH at depth 30–40 cm.
- pH80 pH at depth 80–90 cm.
- e00 electrical conductivity in mS/cm (0–10 cm).
- e30 electrical conductivity in mS/cm (30–40 cm).
- e80 electrical conductivity in mS/cm (80–90 cm).
- c00 chloride content in ppm (0–10 cm).
- c30 chloride content in ppm (30–40 cm).
- c80 chloride content in ppm (80–90 cm).

### ginv

**Generalized Inverse of a Matrix**

Description
Calculates the Moore-Penrose generalized inverse of a matrix $X$.

Usage
ginv(X, tol = sqrt(.Machine$double.eps))

Arguments
- $X$  
  Matrix for which the Moore-Penrose inverse is required.
- $tol$  
  A relative tolerance to detect zero singular values.

Value
A MP generalized inverse matrix for $X$. 

**ginv**

glm.convert

Change a Negative Binomial fit to a GLM fit

Description
This function modifies an output object from glm.nb() to one that looks like the output from glm() with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage
glm.convert(object)

Arguments
object

An object of class "negbin", typically the output from glm.nb().

Details
Convenience function needed to effect some low level changes to the structure of the fitted model object.

Value
An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

See Also
glm.nb, negative.binomial, glm

Examples
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age*Lrn)
anova(quine.nbA, quine.nbB)
glm.nb

Fit a Negative Binomial Generalized Linear Model

Description

A modification of the system function glm() to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

Usage

glm.nb(formula, data, weights, subset, na.action, start = NULL, etastart, mustart, control = glm.control(...), method = "glm.fit", model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ..., init.theta, link = log)

Arguments

formula, data, weights, subset, na.action, start, etastart, mustart, control, method, model, x, y, contrasts, ...

arguments for the glm() function. Note that these exclude family and offset (but offset() can be used).

init.theta

Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

link

The link function. Currently must be one of log, sqrt or identity.

Details

An alternating iteration process is used. For given theta the GLM is fitted using the same process as used by glm(). For fixed means the theta parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating theta are controlled by the maxit parameter of glm.control.)

Setting trace > 0 traces the alternating iteration process. Setting trace > 1 traces the glm fit, and setting trace > 2 traces the estimation of theta.

Value

A fitted model object of class negbin inheriting from glm and lm. The object is like the output of glm but contains three additional components, namely theta for the ML estimate of theta, SE.theta for its approximate standard error (using observed rather than expected information), and twologlik for twice the log-likelihood function.

There is a simulate method.
**Examples**

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

**glmmPQL**

*Fit Generalized Linear Mixed Models via PQL*

**Description**

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

**Usage**

```r
glmmPQL(fixed, random, family, data, correlation, weights, control, niter = 10, verbose = TRUE, ...)
```

**Arguments**

- `fixed` a two-sided linear formula giving fixed-effects part of the model.
- `random` a formula or list of formulae describing the random effects.
- `family` a GLM family.
- `data` an optional data frame, list or environment used as the first place to find variables in the formulae, weights and if present in ..., subset.
- `correlation` an optional correlation structure.
- `weights` optional case weights as in `glm`.
- `control` an optional argument to be passed to `lme`.
- `niter` maximum number of iterations.
- `verbose` logical: print out record of iterations?
- `...` Further arguments for `lme`.

**Details**

`glmmPQL` works by repeated calls to `lme`, so package `nlme` will be loaded at first use if necessary.

**Value**

A object of class "lme": see `lmeObject`.

**References**

hills

Record Times in Scottish Hill Races

Description

The record times in 1984 for 35 Scottish hill races.

Usage

hills

Format

The components are:

- **dist**: distance in miles (on the map).
- **climb**: total height gained during the route, in feet.
- **time**: record time in minutes.

Source

[A.C. Atkinson (1988) Transformations unmasked. *Technometrics* **30**, 311–318 “corrects” the time for Knock Hill from 78.65 to 18.65. It is unclear if this based on the original records.]

hist.scott

Plot a Histogram with Automatic Bin Width Selection

Description

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

Usage

hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)  
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)

Arguments

x A data vector
prob Should the plot have unit area, so be a density estimate?
xlab, ... Further arguments to hist.

Value

For the nclass.* functions, the suggested number of classes.

Side Effects

Plot a histogram.

*Huber Proposal 2 Robust Estimator of Location and/or Scale*

Description

Finds the Huber M-estimator for location with scale specified, scale with location specified, or both if neither is specified.

Usage

hubers(y, k = 1.5, mu, s, initmu = median(y), tol = 1e-06)

Arguments

- `y`: vector y of data values
- `k`: Winsorizes at k standard deviations
- `mu`: specified location
- `s`: specified scale
- `initmu`: initial value of mu
- `tol`: convergence tolerance

Value

- `mu`: location estimate
- `s`: scale estimate

summary(immer.aov)
immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```
The data given in data frame Insurance consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

This data frame contains the following columns:

- **District**: factor: district of residence of policyholder (1 to 4): 4 is major cities.
- **Group**: an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
- **Age**: an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.
- **Holders**: numbers of policyholders.
- **Claims**: numbers of claims

```r
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
   data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```
**isoMDS**  

**Kruskal’s Non-metric Multidimensional Scaling**

**Description**
One form of non-metric multidimensional scaling

**Usage**

\[
\text{isoMDS}(d, y = \text{cmdscale}(d, k), k = 2, \text{maxit} = 50, \text{trace} = \text{TRUE},
\text{tol} = 1e-3, p = 2)
\]

\[
\text{Shepard}(d, x, p = 2)
\]

**Arguments**

- **d**: distance structure of the form returned by \text{dist}, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.
- **y**: An initial configuration. If none is supplied, \text{cmdscale} is used to provide the classical solution, unless there are missing or infinite dissimilarities.
- **k**: The desired dimension for the solution, passed to \text{cmdscale}.
- **maxit**: The maximum number of iterations.
- **trace**: Logical for tracing optimization. Default \text{TRUE}.
- **tol**: Convergence tolerance.
- **p**: Power for Minkowski distance in the configuration space.
- **x**: A final configuration.

**Details**
This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an \(O(n^2)\) calculation, it is slow for large datasets. Further, since for the default \(p = 2\) the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**
Two components:
- **points**: A k-column vector of the fitted configuration.
- **stress**: The final stress achieved (in percent).

**Side Effects**
If \text{trace} is true, the initial stress and the current stress are printed out every 5 iterations.
kde2d

Two-Dimensional Kernel Density Estimation

Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

Usage

kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))

Arguments

x
y
h
n
lims

x coordinate of data
y coordinate of data
vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see bandwidth.nrd). A scalar value will be taken to apply to both directions.
Number of grid points in each direction. Can be scalar or a length-2 integer vector.
The limits of the rectangle covered by the grid as c(x1,xu,y1,yu).

Value

A list of three components.

x, y
z

The x and y coordinates of the grid points, vectors of length n.
lda

Linear Discriminant Analysis

Description

Linear discriminant analysis.

Usage

lda(x, ...)

## S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

## Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
   method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
lda(x, ...)

## S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
Arguments

- **formula**: A formula of the form `groups ~ x1 + x2 + ...`. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- **data**: An optional data frame, list or environment from which variables specified in `formula` are preferentially to be taken.
- **x**: (required if no formula is given as the principal argument) a matrix or data frame or Matrix containing the explanatory variables.
- **grouping**: (required if no formula principal argument is given) a factor specifying the class for each observation.
- **prior**: the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
- **tol**: A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than `tol^2`.
- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- **method**: "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a t distribution.
- **CV**: If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
- **nu**: degrees of freedom for `method = "t"`.
- **...**: arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If `CV` = `TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

- **prior**: the prior probabilities used.
means  the group means.
scaling a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
svd  the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.
N  The number of observations used.
call  The (matched) function call.

Note
This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but subset= and na.action=, if required, must be fully named.
If a formula is given as the principal argument the object may be modified using update() in the usual way.

(z1 <- update(z, . ~ . ~ Petal.W.))
Usage

`ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,` 
`xlim = range(breaks), ymax = 0, width,` 
`type = c("histogram", "density", "both"),` 
`sep = (type != "density"),` 
`col = 5, xlab = deparse(substitute(data)), bty = "n", ...)`

Arguments

data vector of data. Missing values (NA) are allowed and omitted.
g factor or vector giving groups, of the same length as data.
nbins Suggested number of bins to cover the whole range of the data.
h The bin width (takes precedence over nbins).
x0 Shift for the bins - the breaks are at x0 + h * (...,-1,0,1,...)
breaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
xlim The limits for the x-axis.
ymax The upper limit for the y-axis.
width Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
type Type of plot.
sep Whether there is a separate plot for each group, or one combined plot.
col The colour number for the bar fill.
xlab label for the plot x-axis. By default, this will be the name of data.
bty The box type for the plot - defaults to none.
... additional arguments to polygon.

Side Effects

Histogram and/or density plots are plotted on the current device.

plot.lda.
Description

A data frame of data from 33 leukaemia patients.

Usage

leuk

Format

A data frame with columns:

- **wbc**: white blood count.
- **ag**: a test result, "present" or "absent".
- **time**: survival time in weeks.

Details

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

summary(leuk.cox)
```
Fit Linear Models by Generalized Least Squares

Description

Fit linear models by Generalized Least Squares

Usage

`lm.gls(formula, data, W, subset, na.action, inverse = FALSE, method = "qr", model = FALSE, x = FALSE, y = FALSE, contrasts = NULL, ...)`

Arguments

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `data`: an optional data frame, list or environment in which to interpret the variables occurring in `formula`.
- `W`: a weight matrix.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `inverse`: logical: if true `W` specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
- `method`: method to be used by `lm.fit`.
- `model`: should the model frame be returned?
- `x`: should the design matrix be returned?
- `y`: should the response be returned?
- `contrasts`: a list of contrasts to be used for some or all of
- `...`: additional arguments to `lm.fit`.

Details

The problem is transformed to uncorrelated form and passed to `lm.fit`.

Value

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

See Also

gls, lm, lm.ridge
lm.ridge

Ridge Regression

Description

Fit a linear model by ridge regression.

Usage

lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE, 
x = FALSE, y = FALSE, contrasts = NULL, ...)

Arguments

- formula: a formula expression as for regression models, of the form response ~ predictors. See the documentation of formula for other details. offset terms are allowed.
- data: an optional data frame, list or environment in which to interpret the variables occurring in formula.
- subset: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- na.action: a function to filter missing data.
- lambda: A scalar or vector of ridge constants.
- model: should the model frame be returned? Not implemented.
- x: should the design matrix be returned? Not implemented.
- y: should the response be returned? Not implemented.
- contrasts: a list of contrasts to be used for some or all of factor terms in the formula. See the contrasts.arg of model.matrix.default.
- ... additional arguments to lm.fit.

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

- coef: matrix of coefficients, one row for each value of lambda. Note that these are not on the original scale and are for use by the coef method.
- scales: scalings used on the X matrix.
- Inter: was intercept included?
- lambda: vector of lambda values
- ym: mean of y
- xm: column means of x matrix
- GCV: vector of GCV values
- kHKB: HKB estimate of the ridge constant.
- kLW: L-W estimate of the ridge constant.

loglm

Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, *loglin*, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as *glm*.

Usage

loglm(formula, data, subset, na.action, ...)

Arguments

formula A linear model formula specifying the log-linear model. If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the *dimnames* attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ...dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for 'all other variables in the data frame' is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.

data Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to *xtabs*.

subset Specifies a subset of the rows in the data frame to be used. The default is to take all rows.

na.action Specifies a method for handling missing observations. The default is to fail if missing values are present.

... May supply other arguments to the function *loglm*. 
loglm

Details

If the left-hand side of the formula is empty the data argument supplies the frequency array and the
right-hand side of the formula is used to construct the list of fixed faces as required by loglin.
Structural zeros may be specified by giving a start argument with those entries set to zero, as
described in the help information for loglin.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying
factors and an array of frequencies is constructed. If some cells in the complete array are not
specified they are treated as structural zeros. The right-hand side of the formula is again used to
construct the list of faces on which the observed and fitted totals must agree, as required by loglin.
Hence terms such as a:b, a*b and a/b are all equivalent.

Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for
the generic functions print, summary, deviance, fitted, coef, resid, anova and update, which
perform the expected tasks. Only log-likelihood ratio tests are allowed using anova.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current
model within a saturated model, in accordance with standard usage in generalized linear models.

Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. loglin
itself takes no action to allow for structural zeros. loglm deducts one degree of freedom for each
structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of
dimension in the model space. (This would require checking the rank of the model matrix, but since
iterative proportional scaling methods are developed largely to avoid constructing the model matrix
explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be avail-
able due to infinite estimates. The deviances will normally continue to be correct, though.

logtrans

Estimate log Transformation Parameter

Description

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form log(y + alpha) ~ x1 + x2 + ....

Usage

logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
plotit = TRUE, interp =, xlab = "alpha",
ylab = "log Likelihood")

## S3 method for class 'formula'
logtrans(object, data, ...)

## S3 method for class 'lm'
logtrans(object, ...)

Arguments

object      Fitted linear model object, or formula defining the untransformed model that is y ~ x1 + x2 + .... The function is generic.
...

If object is a formula, this argument may specify a data frame as for lm.
alpha  Set of values for the transformation parameter, alpha.
plotit Should plotting be done?
interp Should the marginal log-likelihood be interpolated with a spline approximation? (Default is TRUE if plotting is to be done and the number of real points is less than 100.)
xlab  as for plot.
ylab  as for plot.
data  optional data argument for lm fit.

Value
List with components x (for alpha) and y (for the marginal log-likelihood values).

Side Effects
A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

boxcox

Examples
logtrans(Days ~ Age*Sex*Eth*Lrn, data = quine,
       alpha = seq(0.75, 6.5, len=20))

lqs
Resistant Regression

Description
Fit a regression to the good points in the dataset, thereby achieving a regression estimator with a high breakdown point. lmsreg and ltsreg are compatibility wrappers.

Usage
lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ..., 
    method = c("lts", "lqs", "lms", "S", "model.frame"),
    subset, na.action, model = TRUE,
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
    ...
quantile, control = lqs.control(...), k0 = 1.548, seed, ...

lmsreg(...)
ltsreg(...)

Arguments

formula a formula of the form y ~ x1 + x2 + ....
data an optional data frame, list or environment from which variables specified in formula are preferentially to be taken.
subset an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
na.action function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include na.omit and na.exclude, which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
model, x.ret, y.ret logical. If TRUE the model frame, the model matrix and the response are returned, respectively.
contrasts an optional list. See the contrasts.arg of model.matrix.default.
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
intercept should the model include an intercept?
method the method to be used. model.frame returns the model frame: for the others see the Details section. Using lmsreg or ltsreg forces "lms" and "lts" respectively.
quantile the quantile to be used: see Details. This is over-ridden if method = "lms".
control additional control items: see Details.
k0 the cutoff / tuning constant used for \( \chi() \) and \( \psi() \) functions when method = "S", currently corresponding to Tukey’s ‘biweight’.
seed the seed to be used for random sampling: see .Random.seed. The current value of .Random.seed will be preserved if it is set...
...
arguments to be passed to lqs.default or lqs.control, see control above and Details.

Details

Suppose there are \( n \) data points and \( p \) regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are \( \text{floor}\left(\frac{n+p+1}{2}\right) \) and \( \text{floor}\left(\frac{n+1}{2}\right) \) respectively. For "lts" the default is \( \text{floor}\left(\frac{n}{2}\right) + \text{floor}\left(\frac{p+1}{2}\right) \).

The "S" estimation method solves for the scale \( s \) such that the average of a function chi of the residuals divided by \( s \) is equal to a given constant.

The control argument is a list with components

psamp: the size of each sample. Defaults to \( p \).
nsamp: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is min(5*p,3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

adjust: should the intercept be optimized for each sample? Defaults to TRUE.

Value

An object of class "lqs". This is a list with components

- crit: the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.
- sing: character. A message about the number of samples which resulted in singular fits.
- coefficients: of the fitted linear model
- bestone: the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
- fitted.values: the fitted values.
- residuals: the residuals.
- scale: estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

Note

There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate n^{-1/3}) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of (floor((n-p)/2) + 1)/n attained if floor((n+p)/2) <= quantile <= floor((n+p+1)/2). The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if n is large and p small.

Opinions differ over the choice of psamp. Rousseeuw and Hubert (1997) only consider p; Marazzi (1993) recommends p+1 and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

*Multiple Correspondence Analysis*

**Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```r
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

- `df` A data frame containing only factors
- `nf` The number of dimensions for the MCA. Rarely 3 might be useful.
- `abbrev` Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if `abbrev = TRUE` they are just ‘level’ which will suffice if the factors have distinct levels.

**Value**

An object of class "mca", with components

- `rs` The coordinates of the rows, in `nf` dimensions.
- `cs` The coordinates of the column vertices, one for each level of each factor.
- `fs` Weights for each row, used to interpolate additional factors in `predict.mca`.
- `p` The number of factors
- `d` The singular values for the `nf` dimensions.
- `call` The matched call.

Effect of Calcium Chloride on Muscle Contraction in Rat Hearts

Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

Usage

muscle

Format

This data frame contains the following columns:

- Strip: which heart muscle strip was used?
- Conc: concentration of calcium chloride solution, in multiples of 2.2 mM.
- Length: the change in length (shortening) of the strip, (allegedly) in mm.

Source

References

Examples

```r
## IGNORE_RDIFF_BEGIN
A <- model.matrix(~ Strip - 1, data=muscle)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),
data = muscle, start = c(rho=0.1), algorithm="plinear")
(B <- coef(rats.nls1))

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho^Conc,
data = muscle, start = st))
## IGNORE_RDIFF_END
```

```r
Muscle <- with(muscle, {
Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
```

```r
plot(survfit(motor.cox, newdata = data.frame(temp=200),
conf.type = "log-log"))
summary( survfit(motor.cox, newdata = data.frame(temp=130)) )
```
Simulate from a Multivariate Normal Distribution

Description

Produces one or more samples from the specified multivariate normal distribution.

Usage

mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)

Arguments

n the number of samples required.
mu a vector giving the means of the variables.
Sigma a positive-definite symmetric matrix specifying the covariance matrix of the variables.
tol tolerance (relative to largest variance) for numerical lack of positive-definiteness in Sigma.
empirical logical. If true, mu and Sigma specify the empirical not population mean and covariance matrix.
EISPACK logical: values other than FALSE are an error.

Details

The matrix decomposition is done via eigen; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

Value

If n = 1 a vector of the same length as mu, otherwise an n by length(mu) matrix with one sample in each row.

Side Effects

Causes creation of the dataset .Random.seed if it does not already exist, otherwise its value is updated.
negative.binomial

Family function for Negative Binomial GLMs

Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known
theta parameter, using glm().

Usage

negative.binomial(theta = stop("'theta' must be specified"), link = "log")

Arguments

theta The known value of the additional parameter, theta.
link The link function, as a character string, name or one-element character vector
specifying one of log, sqrt or identity, or an object of class "link-glm".

Value

An object of class "family", a list of functions and expressions needed by glm() to fit a Negative
Binomial generalized linear model.

References

Springer.

#
glm(Days ~ .^4, family = negative.binomial(2), data = quine)
**newcomb**

Newcomb’s Measurements of the Passage Time of Light

**Description**

A numeric vector giving the ‘Third Series’ of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The ‘true’ value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
36 23 27 27 28 27 31 27 26 33 26 32 32 24 39 28 24 25 32 25
29 27 28 29 16 23

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

**Usage**

newcomb

**nlschools**

Eighth-Grade Pupils in the Netherlands

**Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

**Usage**

nlschools
**Format**

This data frame contains 2287 rows and the following columns:

- `lang` language test score.
- `IQ` verbal IQ.
- `class` class ID.
- `GS` class size: number of eighth-grade pupils recorded in the class (there may be others: see `COMB`, and some may have been omitted with missing values).
- `SES` social-economic status of pupil’s family.
- `COMB` were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

**Source**

**References**

**Examples**

```r
nl1l <- within(nlschools, {
  IQave <- tapply(IQ, class, mean)[as.character(class)]
  IQ <- IQ - IQave
})

**Description**

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

**Usage**

npk
**Format**

The npk data frame has 24 rows and 5 columns:

- **block**: which block (label 1 to 6).
- **N**: indicator (0/1) for the application of nitrogen.
- **P**: indicator (0/1) for the application of phosphate.
- **K**: indicator (0/1) for the application of potassium.
- **yield**: yield of peas, in pounds/plot (the plots were (1/70) acre).

**Note**

This dataset is also contained in R 3.0.2 and later.

**Source**

**References**

**Examples**

```r
options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
summary(npk.aov)
alias(npk.aov)
coef(npk.aov)
options(contrasts = c("contr.treatment", "contr.poly"))
npk.aov1 <- aov(yield ~ block + N + K, data = npk)
summary.lm(npk.aov1)
se.contrast(npk.aov1, list(N=="0", N=="1"), data = npk)
## IGNORE_RDIFF_BEGIN
model.tables(npk.aov1, type = "means", se = TRUE)
## IGNORE_RDIFF_END
```

**npr1**

US Naval Petroleum Reserve No. 1 data

**Description**

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

**Usage**

npr1
Format

This data frame contains the following columns:

- \( x \) x coordinates, in miles (origin unspecified).
- \( y \) y coordinates, in miles.
- \( \text{perm} \) permeability in milli-Darcies.
- \( \text{por} \) porosity (%).

Source

References

Null

### Description

Given a matrix, \( M \), find a matrix \( N \) giving a basis for the (left) null space. That is \( \text{crossprod}(N,M) = t(N) \%\% M \) is an all-zero matrix and \( N \) has the maximum number of linearly independent columns.

### Usage

\[ \text{Null}(M) \]

### Arguments

- \( M \) Input matrix. A vector is coerced to a 1-column matrix.

### Details

For a basis for the (right) null space \( \{x : Mx = 0\} \), use \( \text{Null}(t(M)) \).

### Value

The matrix \( N \) with the basis for the (left) null space, or a matrix with zero columns if the matrix \( M \) is square and of maximal rank.

### References

### See Also

\( \text{qr} \), \( \text{qr.Q} \).
Examples

# The function is currently defined as
function(M)
{
  tmp <- qr(M)
  set <- if(tmp$rank == 0L) seq_len(ncol(M)) else -seq_len(tmp$rank)
  qr.Q(tmp, complete = TRUE)[, set, drop = FALSE]
}

oats

Data from an Oats Field Trial

Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

Usage

oats

Format

This data frame contains the following columns:

- B Blocks, levels I, II, III, IV, V and VI.
- V Varieties, 3 levels.
- N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.
- Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

Tests of Auditory Perception in Children with OME

Description

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

Usage

OME

Format

The OME data frame has 1129 rows and 7 columns:

ID  Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
OME  "low" or "high" or "N/A" (at ages other than 30 and 60 months).
Age  Age of the subject (months).
Loud  Loudness of stimulus, in decibels.
Noise Whether the signal in the stimulus was "coherent" or "incoherent".
Correct  Number of correct responses from Trials trials.
Trials  Number of trials performed.

Background

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term 'binaural hearing' is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of
severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

**The Painter’s Data of de Piles**
pairs.lda

Description
The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

Usage

```r
painters
```

Format
The row names of the data frame are the painters. The components are:

- **Composition** Composition score.
- **Drawing** Drawing score.
- **Colour** Colour score.
- **Expression** Expression score.
- **School** The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

pairs.lda

Produce Pairwise Scatterplots from an 'lda' Fit

Description
Pairwise scatterplot of the data on the linear discriminants.

Usage

```r
## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```
Arguments

x Object of class "lda".
labels vector of character strings for labelling the variables.
panel panel function to plot the data in each panel.
dimen The number of linear discriminant(s) to be used for the plot; if this exceeds the number determined by x the smaller value is used.
abbrev whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
... additional arguments for pairs.default.
cex graphics parameter cex for labels on plots.
type type of plot. The default is in the style of pairs.default; the style "trellis" uses the Trellis function splom.

Details

This function is a method for the generic function pairs() for class "lda". It can be invoked by calling pairs(x) for an object x of the appropriate class, or directly by calling pairs.lda(x) regardless of the class of the object.

parcoord

Parallel Coordinates Plot

Description

Parallel coordinates plot

Usage

parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)

Arguments

x a matrix or data frame who columns represent variables. Missing values are allowed.
col A vector of colours, recycled as necessary for each observation.
lty A vector of line types, recycled as necessary for each observation.
var.label If TRUE, each variable’s axis is labelled with maximum and minimum values.
... Further graphics parameters which are passed to matplot.
Side Effects

a parallel coordinates plots is drawn.

Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples

```r
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])
ir <- rbind(iris3[,,1], iris3[,,2], iris3[,,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

---

petrol  

*N. L. Prater’s Petrol Refinery Data*

Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

Usage

```r
petrol
```

Format

The variables are as follows

- **No**: crude oil sample identification label. (Factor.)
- **SG**: specific gravity, degrees API. (Constant within sample.)
- **VP**: vapour pressure in pounds per square inch. (Constant within sample.)
- **V10**: volatility of crude; ASTM 10% point. (Constant within sample.)
- **EP**: desired volatility of gasoline. (The end point. Varies within sample.)
- **Y**: yield as a percentage of crude.

Source

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.
References

Examples

```r
library(nlme)
Petrol <- petrol
Petrol[, 2:5] <- scale(as.matrix(Petrol[, 2:5]), scale = FALSE)
pet3.lme <- lme(Y ~ SG + VP + V10 + EP, 
    random = ~ 1 | No, data = Petrol)
pet3.lme <- update(pet3.lme, method = "ML")
pet4.lme <- update(pet3.lme, fixed = Y ~ V10 + EP)
anova(pet4.lme, pet3.lme)
```

**Diabetes in Pima Indian Women**

Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

- `Pima.tr`
- `Pima.tr2`
- `Pima.te`

Format

These data frames contain the following columns:

- `npreg` number of pregnancies.
- `glu` plasma glucose concentration in an oral glucose tolerance test.
- `bp` diastolic blood pressure (mm Hg).
- `skin` triceps skin fold thickness (mm).
- `bmi` body mass index (weight in kg/height in m)^2.
- `ped` diabetes pedigree function.
- `age` age in years.
- `type` Yes or No, for diabetic according to WHO criteria.

Details

The training set `Pima.tr` contains a randomly selected set of 200 subjects, and `Pima.te` contains the remaining 332 subjects. `Pima.tr2` contains `Pima.tr` plus 100 subjects with missing values in the explanatory variables.
plot.lda

Description

Plots a set of data on one, two or more linear discriminants.

Usage

## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
     abbrev = FALSE, xlab = "LD1", ylab = "LD2")

Arguments

x

the panel function used to plot the data.

... additional arguments to pairs.lda or eqscplot.

cex graphics parameter cex for labels on plots.

dimen The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.

abbrev whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.

xlab label for the x axis

ylab label for the y axis

Details

This function is a method for the generic function plot() for class "lda". It can be invoked by calling plot() for an object x of the appropriate class, or directly by calling plot.lda(x) regardless of the class of the object.

The behaviour is determined by the value of dimen. For dimen > 2, a pairs plot is used. For dimen = 2, an equiscaled scatter plot is drawn. For dimen = 1, a set of histograms or density plots are drawn. Use argument type to match "histogram" or "density" or "both".

plot.mca  

Plot Method for Objects of Class 'mca'

Description

Plot a multiple correspondence analysis.

Usage

## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)

Arguments

x
An object of class "mca".

rows
Should the coordinates for the rows be plotted, or just the vertices for the levels?

col, cex
The colours and cex to be used for the row points and level vertices respectively.

...
Additional parameters to plot.

References

See Also

mca, predict.mca

Examples

plot(mca(farms, abbrev = TRUE))

plot.profile  

Plotting Functions for 'profile' Objects

Description

plot and pairs methods for objects of class "profile".

Usage

## S3 method for class 'profile'
plot(x, ...)

## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)

Arguments

x
an object inheriting from class "profile".

colours
Colours to be used for the mean curves conditional on x and y respectively.

...
arguments passed to or from other methods.
Details

This is the main plot method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters x and y, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of y|x and x|y, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also

`profile.glm, profile.nls`.

Examples

```r
## see ?profile.glm for an example using glm fits.
## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

polr

*Ordered Logistic or Probit Regression*

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

Usage

```r
polr(formula, data, weights, start, ..., subset, na.action,
    contrasts = NULL, Hess = FALSE, model = TRUE,
    method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```
Arguments

formula  a formula expression as for regression models, of the form response ~ predictors. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of formula for other details.

data an optional data frame, list or environment in which to interpret the variables occurring in formula.

weights optional case weights in fitting. Default to 1.

start initial values for the parameters. This is in the format c(coefficients,zeta): see the Values section.

... additional arguments to be passed to optim, most often a control argument.

subset expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

na.action a function to filter missing data.

contrasts a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

Hess logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call summary or vcov on the fit.

model logical for whether the model matrix should be returned.

method logistic or probit or (complementary) log-log or cauchit (corresponding to a Cauchy latent variable).

Details

This model is what Agresti (2002) calls a cumulative link model. The basic interpretation is as a coarsened version of a latent variable \( Y_i \) which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin \( Y_i \) falls into with breakpoints \( \zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty \)

This leads to the model

\[
\text{logit} P(Y \leq k|x) = \zeta_k - \eta
\]

with logit replaced by probit for a normal latent variable, and \( \eta \) being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for \( \eta \) (and hence the coefficients beta).

In the logistic case, the left-hand side of the last display is the log odds of category \( k \) or less, and since these are log odds which differ only by a constant for different \( k \), the odds are proportional. Hence the term proportional odds logistic regression.

The log-log and complementary log-log links are the increasing functions \( F^{-1}(p) = -\log(-\log(p)) \) and \( F^{-1}(p) = \log(-\log(1 - p)) \); some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A proportional hazards model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

predict, summary, vcov, anova, model.frame and an extractAIC method for use with stepAIC (and step). There are also profile and confint methods.
Value

A object of class "polr". This has components

- **coefficients**: the coefficients of the linear predictor, which has no intercept.
- **zeta**: the intercepts for the class boundaries.
- **deviance**: the residual deviance.
- **fitted.values**: a matrix, with a column for each level of the response.
- **lev**: the names of the response levels.
- **terms**: the terms structure describing the model.
- **df.residual**: the number of residual degrees of freedoms, calculated using the weights.
- **edf**: the (effective) number of degrees of freedom used by the model
- **n, nobs**: the (effective) number of observations, calculated using the weights. (nobs is for use by `stepAIC`.
- **call**: the matched call.
- **method**: the matched method used.
- **convergence**: the convergence code returned by `optim`.
- **niter**: the number of function and gradient evaluations used by `optim`.
- **lp**: the linear predictor (including any offset).
- **Hessian**: (if Hess is true). Note that this is a numerical approximation derived from the optimization process.
- **model**: (if model is true).

Note

The `vcov` method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, `method = "cloglog"` confusingly gave the log-log link, implicitly assuming the first response level was the ‘best’.

References

See Also

`optim`, `glm`, `multinom`.

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
house.plr <- polr(Sat ~ Infl + Type + Cont, weights = Freq, data = housing)
house.plr
summary(house.plr, digits = 3)
## slightly worse fit from
summary(update(house.plr, method = "probit", Hess = TRUE), digits = 3)
## although it is not really appropriate, can fit
summary(update(house.plr, method = "loglog", Hess = TRUE), digits = 3)
```
predict.glmmPQL

Predict Method for glmmPQL Fits

Description

Obtains predictions from a fitted generalized linear model with random effects.

Usage

## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
level, na.action = na.pass, ...)

Arguments

object
  a fitted object of class inheriting from "glmmPQL".
newdata
  optionally, a data frame in which to look for variables with which to predict.
type
  the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
level
  an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
na.action
  function determining what should be done with missing values in newdata. The default is to predict NA.
...
  further arguments passed to or from other methods.

Value

If level is a single integer, a vector otherwise a data frame.

See Also

glmmPQL, predict.lme.
Examples

```r
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
    family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

---

### predict.lda

Classify Multivariate Observations by Linear Discrimination

#### Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

#### Usage

```r
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
    method = c("plug-in", "predictive", "debiased"), ...)
```

#### Arguments

- `object`: object of class `"lda"`
- `newdata`: data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lda` object.
- `prior`: The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to `lda`.
- `dimen`: the dimension of the space to be used. If this is less than \(\min(p,ng-1)\), only the first `dimen` discriminant components are used (except for method="predictive"), and only those dimensions are returned in `x`.
- `method`: This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
- `...`: arguments based from or to other methods

#### Details

This function is a method for the generic function `predict()` for class "1da". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.
Value

- **class**: The MAP classification (a factor)
- **posterior**: posterior probabilities for the classes
- **x**: the scores of test cases on up to `dimen` discriminant variables

**predict.lqs**

*Predict from an lqs Fit*

Description

Predict from an resistant regression fitted by `lqs`.

Usage

```r
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

Arguments

- **object**: object inheriting from class "lqs"
- **newdata**: matrix or data frame of cases to be predicted or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lqs` object.
- **na.action**: function determining what should be done with missing values in `newdata`. The default is to predict `NA`.
- **...**: arguments to be passed from or to other methods.
Details

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

Value

A vector of predictions.

predict(fm, stackloss)
```

predict.mca

Predict Method for Class 'mca'

Description

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

Usage

```r
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)  # predict.mca
```

Arguments

- `object`: An object of class "mca", usually the result of a call to `mca`.
- `newdata`: A data frame containing either additional rows of the factors used to fit `object` or additional factors for the cases used in the original fit.
- `type`: Are predictions required for further rows or for new factors?
- `...`: Additional arguments from `predict`: unused.

Value

If `type = "row"`, the coordinates for the additional rows.
If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.
References

`mca`, `plot.mca`

predict.qda

Classify from Quadratic Discriminant Analysis

Description

Classify multivariate observations in conjunction with qda

Usage

```r
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
          method = c("plug-in", "predictive", "debiased", "looCV"), ...)
```

Arguments

- `object` object of class "qda"
- `newdata` data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `qda` object.
- `prior` The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to `qda`.
- `method` This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned.
- `...` arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.
profile.glm

Method for Profiling glm Objects

Value

- a list with components
  - class: The MAP classification (a factor)
  - posterior: posterior probabilities for the classes

References

See Also

qda, lda, predict.lda

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
zq <- qda(train, cl)
predict(zq, test)$class
```

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```r
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, ...)
```

Arguments

- fitted: the original fitted model object.
- which: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- alpha: highest significance level allowed for the profile t-statistics.
- maxsteps: maximum number of points to be used for profiling each parameter.
- del: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- trace: logical: should the progress of profiling be reported?
- ...: further arguments passed to or from other methods.
Details

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

par.vals a matrix of parameter values for each fitted model.
tau the profile t-statistics.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

glm, profile, plot.profile

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

qda Quadratic Discriminant Analysis

Description

Quadratic discriminant analysis.

Usage

`qda(x, ...)`

```r
## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)
```
## S3 method for class 'matrix'

```r
qda(x, grouping, ..., subset, na.action)
```

### Arguments

- **formula**: A formula of the form `groups ~ x1 + x2 + ...`. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- **data**: An optional data frame, list or environment from which variables specified in `formula` are preferentially to be taken.
- **x**: (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
- **grouping**: (required if no formula principal argument is given.) a factor specifying the class for each observation.
- **prior**: the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.
- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- **method**: "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a t distribution.
- **CV**: If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
- **nu**: degrees of freedom for `method = "t"`.
- **...**: arguments passed to or from other methods.

### Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

### Value

An object of class "qda" containing the following components:

- **prior**: the prior probabilities used.
- **means**: the group means.
- **scaling**: for each group `i`, `scaling[,i]` is an array which transforms observations so that within-groups covariance matrix is spherical.
- **ldet**: a vector of half log determinants of the dispersion matrix.
- **lev**: the levels of the grouping factor.
- **terms**: (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

class The MAP classification (a factor)
posterior posterior probabilities for the classes

train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z,test)$class

quine Absenteeism from School in Rural New South Wales

Description
The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

Usage
quine

Format
This data frame contains the following columns:

Eth  ethnic background: Aboriginal or Not, ("A" or "N").
Sex  sex: factor with levels ("F" or "M").
Age  age group: Primary ("F0"), or forms "F1", "F2" or "F3".
Lrn  learner status: factor with levels Average or Slow learner, ("AL" or "SL").
Days  days absent from school in the year.

Source
Blood Pressure in Rabbits

Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the $5-HT_3$ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of $5-HT_3$ receptors.

Usage

Rabbit

Format

This data frame contains 60 rows and the following variables:

BPchange  change in blood pressure relative to the start of the experiment.
Dose     dose of Phenylbiguanide in micrograms.
Run      label of run ("C1" to "C5", then "M1" to "M5").
Treatment placebo or the $5-HT_3$ antagonist MDL 72222.
Animal   label of animal used ("R1" to "R5").

Source

[The numerical data are not in the paper but were supplied by Professor Ludbrook]

References

rational  

**Rational Approximation**

**Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

```r
rational(x, cycles = 10, max.denominator = 2000, ...)
```

**Arguments**

- `x`  
  Any object of mode numeric. Missing values are now allowed.

- `cycles`  
  The maximum number of steps to be used in the continued fraction approximation process.

- `max.denominator`  
  An early termination criterion. If any partial denominator exceeds `max.denominator` the continued fraction stops at that point.

- `...`  
  Arguments passed to or from other methods.

**Details**

Each component is first expanded in a continued fraction of the form

\[ x = \text{floor}(x) + \frac{1}{p_1 + \frac{1}{p_2 + \ldots}} \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at `cycles` terms or when a \( p_j > \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

**Value**

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

**See Also**

- `fractions`

**Examples**

```r
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```
### renumerate

Convert a Formula Transformed by 'denumerate'

**Description**

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

**Usage**

```r
renumerate(x)
```

**Arguments**

- **x**
  - A formula, normally as modified by `denumerate`.

**Details**

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

**Value**

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

**See Also**

`denumerate`

**Examples**

```r
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

---

### rlm

Robust Fitting of Linear Models

**Description**

Fit a linear model by robust regression using an M estimator.
Usage

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
method = c("M", "MM", "model.frame"),
wt.method = c("inv.var", "case"),
model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
init = "ls", psi = psi.huber,
scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
method = c("M", "MM"), wt.method = c("inv.var", "case"),
maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
 psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
 psi.bisquare(u, c = 4.685, deriv = 0)

Arguments

formula a formula of the form y ~ x1 + x2 + ....
data an optional data frame, list or environment from which variables specified in formula are preferentially to be taken.
weights a vector of prior weights for each case.
subset An index vector specifying the cases to be used in fitting.
na.action A function to specify the action to be taken if NAs are found. The 'factory-fresh' default action in R is na.omit, and can be changed by options(na.action=).
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
method currently either M-estimation or MM-estimation or (for the formula method only) find the model frame. MM-estimation is M-estimation with Tukey’s biweight initialized by a specific S-estimator. See the ‘Details’ section.
wt.method are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?
model should the model frame be returned in the object?
x.ret should the model matrix be returned in the object?
y.ret should the response be returned in the object?
contrasts optional contrast specifications: see lm.
w (optional) initial down-weighting for each case.
init (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a coef component. Known methods are "ls" (the default) for an initial least-squares fit using weights w*weights, and "lts" for an unweighted least-trimmed squares fit with 200 samples.
psi the psi function is specified by this argument. It must give (possibly by name) a function g(x,...,deriv) that for deriv=0 returns psi(x)/x and for deriv=1 returns psi'(x). Tuning constants will be passed in via ....
scale.est  method of scale estimation: re-scaled MAD of the residuals (default) or Huber’s proposal 2 (which can be selected by either "Huber" or "proposal 2").

k2  tuning constant used for Huber proposal 2 scale estimation.

maxit  the limit on the number of IWLS iterations.

acc  the accuracy for the stopping criterion.

test.vec  the stopping criterion is based on changes in this vector.

...  additional arguments to be passed to rlm.default or to the psi function.

lqs.control  An optional list of control values for lqs.

u  numeric vector of evaluation points.

k, a, b, c  tuning constants.

deriv  0 or 1: compute values of the psi function or of its first derivative.

Details

Fitting is done by iterated re-weighted least squares (IWLS).

Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as psi.huber, psi.hampel and psi.bisquare. Huber’s corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting method = "MM" selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with k0 = 1.548; this gives (for n \gg p) breakdown point 0.5. The final estimator is an M-estimator with Tukey’s biweight and fixed scale that will inherit this breakdown point provided c > k0; this is true for the default value of c that corresponds to 95% relative efficiency at the normal. Case weights are not supported for method = "MM".

Value

An object of class "rlm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.

The additional components not in an lm object are

s  the robust scale estimate used

w  the weights used in the IWLS process

psi  the psi function with parameters substituted

conv  the convergence criteria at each iteration

converged  did the IWLS converge?

wresid  a working residual, weighted for "inv.var" weights only.

Note

Prior to version 7.3-52, offset terms in formula were omitted from fitted and predicted values.
rms.curv

Relative Curvature Measures for Non-Linear Regression

Description

Calculates the root mean square parameter effects and intrinsic relative curvatures, $c^\theta$ and $c^\iota$, for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

Usage

rms.curv(obj)

Arguments

obj Fitted model object of class "nls". The model must be fitted using the default algorithm.

Details

The method of section 7.3.1 of Bates & Watts is implemented. The function deriv3 should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model. A print method, print.rms.curv, prints the pc and ic components only, suitably annotated. If either pc or ic exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

Value

A list of class rms.curv with components pc and ic for parameter effects and intrinsic relative curvatures multiplied by $\sqrt{F}$, $c^\theta$ and $c^\iota$ (unmultiplied), and C the C-array as used in section 7.3.1 of Bates & Watts.
rnegbin

Simulate Negative Binomial Variates

Description

Function to generate random outcomes from a Negative Binomial distribution, with mean \( \mu \) and variance \( \mu + \mu^2/\theta \).

Usage

\[
\text{rnegbin}(n, \mu = n, \theta = \text{stop}("'\theta' must be specified"))
\]

Arguments

- **n**: If a scalar, the number of sample values required. If a vector, length(n) is the number required and n is used as the mean vector if \( \mu \) is not specified.
- **mu**: The vector of means. Short vectors are recycled.
- **theta**: Vector of values of the \( \theta \) parameter. Short vectors are recycled.

Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike \texttt{rnbinom} the index can be arbitrary.

Value

Vector of random Negative Binomial variate values.

Side Effects

Changes \texttt{.Random.seed} in the usual way.

road

Road Accident Deaths in US States

Description

A data frame with the annual deaths in road accidents for half the US states.

Usage

`road`

Format

Columns are:

- `state` name.
- `deaths` number of deaths.
- `drivers` number of drivers (in 10,000s).
- `popden` population density in people per square mile.
- `rural` length of rural roads, in 1000s of miles.
- `temp` average daily maximum temperature in January.
- `fuel` fuel consumption in 10,000,000 US gallons per year.

Source

Imperial College, London M.Sc. exercise

rotifer

Numbers of Rotifers by Fluid Density

Description

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, *P. Polyartha major* and *Kc. Keratella cochlearis* and for each species the number falling out and the total number are given.

Usage

`rotifer`
**Rubber**

**Format**

- density specific density of fluid.
- pm. y number falling out for *P. major*.
- pm. total total number of *P. major*.
- kc. y number falling out for *K. cochlearis*.
- kc. tot total number of *K. cochlearis*.

**Source**

**Rubber**

*Accelerated Testing of Tyre Rubber*

**Description**

Data frame from accelerated testing of tyre rubber.

**Usage**

Rubber

**Format**

- loss the abrasion loss in gm/hr.
- hard the hardness in Shore units.
- tens tensile strength in kg/sq m.

**Source**

**References**

Sammon’s Non-Linear Mapping

Description

One form of non-metric multidimensional scaling.

Usage

```r
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
       magic = 0.2, tol = 1e-4)
```

Arguments

- **d**: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.
- **y**: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution. (If there are missing values in `d`, an initial configuration must be provided.) This must not have duplicates.
- **k**: The dimension of the configuration.
- **niter**: The maximum number of iterations.
- **trace**: Logical for tracing optimization. Default `TRUE`.
- **magic**: Initial value of the step size constant in diagonal Newton method.
- **tol**: Tolerance for stopping, in units of stress.

Details

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

Value

Two components:

- **points**: A two-column vector of the fitted configuration.
- **stress**: The final stress achieved.

Side Effects

If trace is true, the initial stress and the current stress are printed out every 10 iterations.
ships

shrimp

Percentage of Shrimp in Shrimp Cocktail

Description
A numeric vector with 18 determinations by different laboratories of the amount (percentage of the declared total weight) of shrimp in shrimp cocktail.

Usage
shrimp

Source

**Description**

The `shuttle` data frame has 256 rows and 7 columns. The first six columns are categorical variables giving example conditions; the seventh is the decision. The first 253 rows are the training set, the last 3 are the test conditions.

**Usage**

`shuttle`

**Format**

This data frame contains the following factor columns:

- `stability`: stable positioning or not (`stab`/`xstab`).
- `error`: size of error (`MM`/`SS`/`LX`/`XL`).
- `sign`: sign of error, positive or negative (`pp`/`nn`).
- `wind`: wind sign (`head`/`tail`).
- `magn`: wind strength (`Light`/`Medium`/`Strong`/`Out of Range`).
- `vis`: visibility (`yes`/`no`).
- `use`: use the autolander or not (`auto`/`noauto`).

**Sitka**

**Description**

The `Sitka` data frame has 395 rows and 4 columns. It gives repeated measurements on the log-size of 79 Sitka spruce trees, 54 of which were grown in ozone-enriched chambers and 25 were controls. The size was measured five times in 1988, at roughly monthly intervals.

**Usage**

`Sitka`
Sitka89

Format

This data frame contains the following columns:

- **size**: measured size (height times diameter squared) of tree, on log scale.
- **Time**: time of measurement in days since 1 January 1988.
- **tree**: number of tree.
- **treat**: either "ozone" for an ozone-enriched chamber or "control".

```
snails

Snail Mortality Data

Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

Usage

snails

Format

The data frame contains the following components:

- Species: snail species A (1) or B (2).
- Exposure: exposure in weeks.
- Rel.Hum: relative humidity (4 levels).
- Temp: temperature, in degrees Celsius (3 levels).
- Deaths: number of deaths.
- N: number of snails exposed.

stepAIC  Choose a model by AIC in a Stepwise Algorithm

Description
Performs stepwise model selection by AIC.

Usage
stepAIC(object, scope, scale = 0,
       direction = c("both", "backward", "forward"),
       trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
       k = 2, ...)

Arguments
object  an object representing a model of an appropriate class. This is used as the initial
        model in the stepwise search.
scope  defines the range of models examined in the stepwise search. This should be
        either a single formula, or a list containing components upper and lower, both
        formulae. See the details for how to specify the formulae and how they are used.
scale  used in the definition of the AIC statistic for selecting the models, currently only
        for lm and aov models (see extractAIC for details).
direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".

trace | if positive, information is printed during the running of stepAIC. Larger values may give more information on the fitting process.

keep | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.

steps | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

use.start | if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for glm (and other fits), but it can also slow them down. Not used in R.

k | the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.

... | any additional arguments to extractAIC. (None are currently used.)

Details

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by update.formula.

There is a potential problem in using glm fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The glm method for extractAIC makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

Where a conventional deviance exists (e.g. for lm, aov and glm fits) this is quoted in the analysis of variance table: it is the unscaled deviance.

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the keep= argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding lm, aov and survreg fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an na.action other than na.fail is used (as is the default in R). We suggest you remove the missing values first.

References

stomer

The Stormer Viscometer Data

Description

The Stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form \( \text{Time} = \frac{(B_1 \times \text{Viscosity})}{(\text{Weight} - B_2)} + E \) where \( B_1 \) and \( B_2 \) are unknown parameters to be estimated, and \( E \) is error.

Usage

stomer
**Format**

The data frame contains the following components:

- **Viscosity**: viscosity of fluid.
- **Wt**: actuating weight.
- **Time**: time taken.

`residuals, stdres`
Summary Method Function for Objects of Class 'loglm'

Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using \texttt{loglm}.

Usage

```r
## S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)
```

Arguments

- `object`: a fitted \texttt{loglm} model object.
- `fitted`: if \texttt{TRUE} return observed and expected frequencies in the result. Using \texttt{fitted = TRUE} may necessitate re-fitting the object.
- `...`: arguments to be passed to or from other methods.

Details

This function is a method for the generic function \texttt{summary()} for class "\texttt{loglm}". It can be invoked by calling \texttt{summary(x)} for an object \texttt{x} of the appropriate class, or directly by calling \texttt{summary.loglm(x)} regardless of the class of the object.

Value

A list is returned for use by \texttt{print.summary.loglm}. This has components

- `formula`: the formula used to produce \texttt{object}
- `tests`: the table of test statistics (likelihood ratio, Pearson) for the fit.
- `oe`: if \texttt{fitted = TRUE}, an array of the observed and expected frequencies, otherwise \texttt{NULL}.

\texttt{loglm, summary}
Summary Method Function for Objects of Class 'negbin'

Description

Identical to summary.glm, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

Usage

## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)

Arguments

- **object**: fitted model object of class negbin inheriting from glm and lm. Typically the output of glm.nb.
- **dispersion**: as for summary.glm, with a default of 1.
- **correlation**: as for summary.glm.
- **...**: arguments passed to or from other methods.

Details

summary.glm is used to produce the majority of the output and supply the result. This function is a method for the generic function summary() for class "negbin". It can be invoked by calling summary(x) for an object x of the appropriate class, or directly by calling summary.negbin(x) regardless of the class of the object.

Value

As for summary.glm; the additional lines of output are not included in the resultant object.

Side Effects

A summary table is produced as for summary.glm, with the additional information described above.

Summary Method for Robust Linear Models

Description

summary method for objects of class "rlm"

Usage

## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)

Arguments

object the fitted model. This is assumed to be the result of some fit that produces an
object inheriting from the class rlm, in the sense that the components returned
by the rlm function will be available.
method Should the weighted (by the IWLS weights) or unweighted cross-products ma-
trix be used?
correlation logical. Should correlations be computed (and printed)?
... arguments passed to or from other methods.

Details

This function is a method for the generic function summary() for class "rlm". It can be invoked by
calling summary(x) for an object x of the appropriate class, or directly by calling summary.rlm(x)
regardless of the class of the object.

Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following
components. Printing always takes place if this function is invoked automatically as a method for
the summary function.

correlation The computed correlation coefficient matrix for the coefficients in the model.
cov.unscaled The unscaled covariance matrix; i.e, a matrix such that multiplying it by an
estimate of the error variance produces an estimated covariance matrix for the
coefficients.
sigma The scale estimate.
stddev A scale estimate used for the standard errors.
df The number of degrees of freedom for the model and for residuals.
coefficients A matrix with three columns, containing the coefficients, their standard errors
and the corresponding t statistic.
terms The terms object used in fitting this model.

**Student Survey Data**

**Description**

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

**Usage**

```r
survey
```

**Format**

The components of the data frame are:

- **Sex** The sex of the student. (Factor with levels "Male" and "Female").
- **Wr.Hnd** span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.
- **NW.Hnd** span of non-writing hand.
- **W.Hnd** writing hand of student. (Factor, with levels "Left" and "Right").
- **Fold** “Fold your arms! Which is on top” (Factor, with levels "R on L", "L on R", "Neither").
- **Pulse** pulse rate of student (beats per minute).
- **Clap** ‘Clap your hands! Which hand is on top?’ (Factor, with levels "Right", "Left", "Neither").
- **Exer** how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None").
- **Smoke** how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never").
- **Height** height of the student in centimetres.
- **M.I** whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial").
- **Age** age of the student in years.

**synth.tr**  
*Synthetic Classification Problem*

**Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```r
synth.tr
synth.te
```

**Format**

These data frames contain the following columns:

- **xs**: x-coordinate
- **ys**: y-coordinate
- **yc**: class, coded as 0 or 1.

**Source**

---

**theta.md**  
*Estimate theta of the Negative Binomial*

**Description**

Given the estimated mean vector, estimate theta of the Negative Binomial Distribution.

**Usage**

```r
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)
theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25, trace = FALSE)
theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```
Arguments

- **y**: Vector of observed values from the Negative Binomial.
- **mu**: Estimated mean vector.
- **n**: Number of data points (defaults to the sum of weights).
- **dfr**: Residual degrees of freedom (assuming theta known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
- **weights**: Case weights. If missing, taken as 1.
- **limit**: Limit on the number of iterations.
- **eps**: Tolerance to determine convergence.
- **trace**: logical: should iteration progress be printed?

Details

theta.md estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

theta.ml uses maximum likelihood.

theta.mm calculates the moment estimator of theta by equating the Pearson chi-square $\sum (y - \mu)^2 / (\mu + \mu^2 / \theta)$ to the residual degrees of freedom.

Value

The required estimate of theta, as a scalar. For theta.ml, the standard error is given as attribute "SE".

Traffic  

*Effect of Swedish Speed Limits on Accidents*

**Description**

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day \( j \) in 1962 was comparable to day \( j \) in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

Traffic

**Format**

This data frame contains the following columns:

- **year**  
  1961 or 1962.

- **day**  
  of year.

- **limit**  
  was there a speed limit?

- **y**  
  traffic accident count for that day.
truehist

Source

References

truehist

Plot a Histogram

Description

Creates a histogram on the current graphics device.

Usage

```r
truehist(data, nbins = "Scott", h, x0 = -h/1000, 
breaks, prob = TRUE, xlim = range(breaks), 
ymax = max(est), col = "cyan", 
xlabs = deparse(substitute(data)), bty = "n", ...) 
```

Arguments

- **data**: numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.
- **nbins**: The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman–Diaconis" or "FD". (Case is ignored.)
- **h**: The bin width, a strictly positive number (takes precedence over nbins).
- **x0**: Shift for the bins - the breaks are at x0 + h * (...,-1,0,1,...)
- **breaks**: The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
- **prob**: If true (the default) plot a true histogram. The vertical axis has a relative frequency density scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.
- **xlim**: The limits for the x-axis.
- **ymax**: The upper limit for the y-axis.
- **col**: The colour for the bar fill: the default is colour 5 in the default R palette.
- **xlabs**: label for the plot x-axis. By default, this will be the name of data.
- **bty**: The box type for the plot - defaults to none.
- **...**: additional arguments to `rect` or `plot`.
Details

This plots a true histogram, a density estimate of total area 1. If breaks is specified, those breakpoints are used. Otherwise if h is specified, a regular grid of bins is used with width h. If neither breaks nor h is specified, nbins is used to select a suitable h.

Side Effects

A histogram is plotted on the current device.

width.SJ

Bandwidth Selection by Pilot Estimation of Derivatives

Description

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))

Arguments

x a numeric vector

nb number of bins to use.

upper, lower range over which to search for solution if method = "ste".

method Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

a bandwidth.

Note

A faster version for large n (thousands) is available in R ≥ 3.4.0 as part of bw.SJ: quadruple its value for comparability with this version.

write.matrix

Write a Matrix or Data Frame

Description

Wrote a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

write.matrix(x, file = "", sep = " ", blocksize)

Arguments

x matrix or data frame.
file name of output file. The default ("") is the console.
sep The separator between columns.
blocksize If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available.

Details

If x is a matrix, supplying blocksize is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.
If x is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects

A formatted file is produced, with column headings (if x has them) and columns of data.

References

write.table
Description

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

Usage

wtloss

Format

This data frame contains the following columns:

Days  time in days since the start of the programme.
Weight  weight in kilograms of the patient.

Source

Dr T. Davies, Adelaide.

References

Examples

```R
## IGNORE_RDIFF_BEGIN
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),
                 data = wtloss, start = list(b0=90, b1=95, th=120))
wtloss.fm
# IGNORE_RDIFF_END
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```

The Matrix package

---

**abIndex-class**

Class "abIndex" of Abstract Index Vectors

**Description**

The "abIndex" class, short for "Abstract Index Vector", is used for dealing with large index vectors more efficiently, than using integer (or numeric) vectors of the kind 2:1000000 or c(0:1e5,1000:1e6).

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (packageDescription("Matrix")$Maintainer).

**Objects from the Class**

Objects can be created by calls of the form new("abIndex",...), but more easily and typically either by as(x,"abIndex") where x is an integer (valued) vector, or directly by abIseq() and combination c(...).

**Slots**

- **kind**: a character string, one of ("int32","double","rleDiff"), denoting the internal structure of the abIndex object.
- **x**: Object of class "numLike"; is used (i.e., not of length 0) only if the object is not compressed, i.e., currently exactly when kind != "rleDiff".
- **rleD**: object of class "rleDiff", used for compression via rle.

**Methods**

- `as.numeric`, `as.integer`, `as.vector` signature(x = "abIndex"): ...
- `length` signature(x = "abIndex"): ...
- `coerce` signature(from = "numeric", to = "abIndex"): ...
- `coerce` signature(from = "abIndex", to = "numeric"): ...
- `coerce` signature(from = "abIndex", to = "integer"): ...

2257
**abIseq**

Sequence Generation of "abIndex", Abstract Index Vectors

Description

Generation of abstract index vectors, i.e., objects of class "abIndex". 

abIseq() is designed to work entirely like seq, but producing "abIndex" vectors. 

abIseq1() is its basic building block, where abIseq1(n,m) corresponds to n:m. 

c(x, ...) will return an "abIndex" vector, when x is one.

Usage

abIseq1(from = 1, to = 1) 
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)), 

length.out = NULL, along.with = NULL) 

## S3 method for class 'abIndex'
c(...)

---

**Note**

This is currently experimental and not yet used for our own code. Please contact us (packageDescription("Matrix")$Maintainer), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package ff.

See Also

rle (base) which is used here; numeric

Examples

showClass("abIndex")

ii <- c(-3:40, 20:70)

str(ai <- as(ii, "abIndex"))# note

ai # -> show() method

stopifnot(identical(-3:20,

as(abIseq1(-3,20), "vector")))

---

**abIseq**

Ops signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**; see Ops for a list of these (S4) group methods.

Ops signature(e1 = "abIndex", e2 = "abIndex"): ...

Ops signature(e1 = "abIndex", e2 = "numeric"): ...

Summary signature(x = "abIndex"): ...

show ("abIndex"): simple show method, building on show(<rleDiff>).

is.na ("abIndex"): works analogously to regular vectors.

is.finite, is.infinite ("abIndex"): ditto.
Arguments

- **from**, **to**: the starting and (maximal) end value of the sequence.
- **by**: number: increment of the sequence.
- **length.out**: desired length of the sequence. A non-negative number, which for `seq` and `seq.int` will be rounded up if fractional.
- **along.with**: take the length from the length of this argument.
- **...**: in general an arbitrary number of R objects; here, when the first is an "abIndex" vector, these arguments will be concatenated to a new "abIndex" object.

Value

An abstract index vector, i.e., object of class "abIndex".

See Also

the class `abIndex` documentation; `rep2abI()` for another constructor; `rle` (base).

Examples

```r
stopifnot(identical(-3:20,
    as(abIseq(-3,20), "vector")))
	ry( ## (arithmetic) not yet implemented
   abIseq(1, 50, by = 3)
)
```

---

**all-methods**

"Matrix" Methods for Functions `all()` and `any()`

Description

The basic R functions `all` and `any` now have methods for `Matrix` objects and should behave as for `matrix` ones.

Methods

- **all** signature(x = "Matrix",...,na.rm = FALSE): ...
- **any** signature(x = "Matrix",...,na.rm = FALSE): ...
- **all** signature(x = "ldenseMatrix",...,na.rm = FALSE): ...
- **all** signature(x = "lsparseMatrix",...,na.rm = FALSE): ...

Examples

```r
M <- Matrix(1:12 +0, 3,4)
all(M >= 1) # TRUE
any(M < 0 ) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0 ) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
```
**all.equal-methods**

Matrix Package Methods for Function `all.equal()`

**Description**

Methods for function `all.equal()` (from R package `base`) are defined for all `Matrix` classes.

**Methods**

- `target = "Matrix", current = "Matrix"`
- `target = "ANY", current = "Matrix"`
- `target = "Matrix", current = "ANY"`

These three methods are simply using `all.equal.numeric` directly and work via `as.vector()`.

There are more methods, notably also for "sparseVector"’s, see `showMethods("all.equal")`.

**Examples**

```r
showMethods("all.equal")
(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
                     lu.@L %*% lu.@U),
             with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
                                L %*% U)),
             with(ex, all.equal(as(A, "CsparseMatrix"),
                                t(P) %*% L %*% U %*% t(Q))))
```

**atomicVector-class**

Virtual Class "atomicVector" of Atomic Vectors

**Description**

The `class` "atomicVector" is a virtual class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Methods**

In the `Matrix` package, the "atomicVector" is used in signatures where typically "old-style" "matrix" objects can be used and can be substituted by simple vectors.

**Extends**

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".
**band**

**Author(s)**

Martin Maechler

**See Also**

is.atomic, integer, numeric, complex, etc.

**Examples**

```r
showClass("atomicVector")
```

---

**band**

*Extract bands of a matrix*

**Description**

Returns a new matrix formed by extracting the lower triangle (tril) or the upper triangle (triu) or a general band relative to the diagonal (band), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

**Usage**

```r
band(x, k1, k2, ...)
tril(x, k = 0, ...)
triu(x, k = 0, ...)
```

**Arguments**

- `x`: a matrix-like object
- `k,k1,k2`: integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is k=0. A negative value of k indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal.
- `...`: Optional arguments used by specific methods. (None used at present.)

**Value**

An object of an appropriate matrix class. The class of the value of tril or triu inherits from triangularMatrix when appropriate. Note that the result is of class sparseMatrix only if x is.

**Methods**

- `x = "CsparseMatrix"` method for compressed, sparse, column-oriented matrices.
- `x = "TsparseMatrix"` method for sparse matrices in triplet format.
- `x = "RsparseMatrix"` method for compressed, sparse, row-oriented matrices.
- `x = "ddenseMatrix"` method for dense numeric matrices, including packed numeric matrices.

**See Also**

bandSparse for the construction of a banded sparse matrix directly from its non-zero diagonals.
Examples

```r
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm) # lower triangle
tril(mm, -1) # strict lower triangle
triu(mm, 1) # strict upper triangle
band(mm, -1, 2) # general band

(m5 <- Matrix(rnorm(25), nc = 5))
tril(m5) # lower triangle
tril(m5, -1) # strict lower triangle
triu(m5, 1) # strict upper triangle
band(m5, -1, 2) # general band

(m65 <- Matrix(rnorm(30), nc = 5)) # not square
triu(m65) # result in not dtrMatrix unless square

(sm5 <- crossprod(m65)) # symmetric
band(sm5, -1, 1) # symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
```

---

**bandSparse**

**Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals**

**Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

`bandSparse(n, m = n, k, diagonals, symmetric = FALSE, giveCsparse = TRUE)`

**Arguments**

- `n, m` the matrix dimension \((n, m)\) = \((nrow, ncol)\).
- `k` integer vector of “diagonal numbers”, with identical meaning as in `band(*, k)`, i.e., relative to the main diagonal, which is \(k=0\).
- `diagonals` optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class `nMatrix`. diagonals can also be \(n' \times d\) matrix, where \(d \leq \text{length}(k)\) and \(n' \geq \min(n, m)\). In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals.
- `symmetric` logical; if true the result will be symmetric (inheriting from class `symmetricMatrix`) and only the upper or lower triangle must be specified (via `k` and `diagonals`).
- `giveCsparse` logical indicating if the result should be a `CsparseMatrix` or a `TsparseMatrix`. The default, `TRUE` is very often more efficient subsequently, but not always.
**Value**

a sparse matrix (of class `CsparseMatrix`) of dimension $n \times m$ with diagonal “bands” as specified.

**See Also**

`band`, for extraction of matrix bands; `bdiag`, `diag`, `sparseMatrix`, `Matrix`.

**Examples**

```r
diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1,"dsCMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7,9)
s3 <- bandSparse(30, k = bk, symm=TRUE)

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
lLis <- lapply(list(rpois(20, 2), rpois(20,1), rpois(20,3)[c(1:3,2:3,3:2)],
                   as.logical)
   (s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lLis))
(s4. <- as(drop0(s4), "nsparseMatrix"))

n <- 1e4
bk <- c(0:5, 7,11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
bLis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]

## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
          identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE))
          inherits(B, "dtCMatrix") # triangular!
)
```

---

**Description**

Build a block diagonal matrix given several building block matrices.

**Usage**

`bdiag(...)`

`.bdiag(lst)`
Arguments

... individual matrices or a list of matrices.

lst non-empty list of matrices.

Details

For non-trivial argument list, bdiag() calls .bdiag(). The latter maybe useful to programmers.

Value

A sparse matrix obtained by combining the arguments into a block diagonal matrix.

The value of bdiag() inherits from class CsparseMatrix, whereas .bdiag() returns a TsparseMatrix.

Note

This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.

It is currently inefficient for the case of many small dense block matrices. For the case of many dense $k \times k$ matrices, the bdiag_m() function in the ‘Examples’ is an order of magnitude faster.

Author(s)

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on TsparseMatrix objects.

See Also

Diagonal for constructing matrices of class diagonalMatrix, or kronecker which also works for "Matrix" inheriting matrices.

bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of bdiag() which return traditional matrices.

Examples

bdiag(matrix(1:4, 2), diag(3))
## combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
bdiag(lapply(mlist, as.matrix))))

ml <- c(as(matrix((1:24)%% 11 == 0, 6,4),"nMatrix"),
rep(list(Diagonal(2, x=TRUE)), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
is(bdiag(mln),"dsparseMatrix") )

## random (diagonal-)block-triangular matrices:
rblockTri <- function(nb, max.ni, lambda = 3) {
```r
.bdiag(replicate(nb, {
    n <- sample.int(max.ni, 1)
    tril(Matrix(rpois(n*n, lambda=lambda), n,n)) ))
}
(T4 <- rblockTri(4, 10, lambda = 1))
image(T1 <- rblockTri(12, 20))
```

## Fast version of Matrix :: .bdiag() -- for the case of *many* (k x k) matrices:

@param lmat list(<mat1>, <mat2>, ..., <mat_N>) where each mat_j is a k x k 'matrix'

@return a sparse (N*k x N*k) matrix of class \
\texttt{\textbackslash linkS4class{dgCMatrix}}.

```r
dl12 <- replicate(12, matrix(rpois(16, lambda = 6.4), 4,4), simplify=FALSE)
dim(T12 <- bdiag_m(dl12))# 48 x 48
T12[1:20, 1:20]
```

---

### Description

The Bunch-Kaufman Decomposition of a square symmetric matrix \( A \) is \( A = PLDL'P' \) where \( P \) is a permutation matrix, \( L \) is unit-lower triangular and \( D \) is block-diagonal with blocks of dimension \( 1 \times 1 \) or \( 2 \times 2 \).

### Usage

```r
BunchKaufman(x, ...)```

### Arguments

- \( x \) a symmetric square matrix.
- ... potentially further arguments passed to methods.

### Value

an object of class \texttt{BunchKaufman}, which can also be used as a (triangular) matrix directly.
Methods

Currently, only methods for **dense** numeric symmetric matrices are implemented.

x = "dspMatrix" uses Lapack routine `dsptrf`.

x = "dsyMatrix" uses Lapack routine `dsytrf`, computing the Bunch-Kaufman decomposition.

References

The original LAPACK source code, including documentation; [http://www.netlib.org/lapack/ double/dsytrf.f](http://www.netlib.org/lapack/double/dsytrf.f) and [http://www.netlib.org/lapack/double/dsptrf.f](http://www.netlib.org/lapack/double/dsptrf.f)

See Also

The resulting class, `BunchKaufman`. Related decompositions are the LU, `lu`, and the Cholesky, `chol` (and for *sparse* matrices, `Cholesky`).

Examples

data(CAex)
dim(CAex)
isSymmetric(CAex)# TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
  bk <- BunchKaufman(CAs)
## does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA

image(bkCA)# shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
## an upper triangular 72x72 matrix with only 144 non-zero entries

---

CAex  

**Albers’ example Matrix with "Difficult" Eigen Factorization**

Description

An example of a sparse matrix for which `eigen()` seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (https://stat.ethz.ch/mailman/listinfo/r-help), by Casper J Albers, Open University, UK.

Usage

data(CAex)

Format

This is a 72 × 72 symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

Details

Historical note (2006-03-30): In earlier versions of R, `eigen(CAex)` fell into an infinite loop whereas `eigen(CAex, EISPACK=TRUE)` had been okay.
Examples

```r
data(CAex)
str(CAex) # of class "dgCMatrix"

image(CAex)# -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
## and
stopifnot(class(sCA) == "dsCMatrix",
          as(sCA, "matrix") == as(CAex, "matrix"))
```

Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument .... For that reason, in the past S4 methods could easily be defined for binding together matrices inheriting from `Matrix`.

For that reason, `cbind2` and `rbind2` have been provided for binding together two matrices, and we have defined methods for these and the 'Matrix'-matrices.

Before R version 3.2.0 (April 2015), we have needed a substitute for S4-enabled versions of `cbind` and `rbind`, and provided `cBind` and `rBind` with identical syntax and semantic in order to bind together multiple matrices ("matrix" or "Matrix" and vectors. With R version 3.2.0 and newer, `cBind` and `rBind` are deprecated and produce a deprecation warning (via `.Deprecated`), and your code should start using `cbind()` and `rbind()` instead.

Usage

```r
cBind(..., deparse.level = 1)
rBind(..., deparse.level = 1)
```

Arguments

- `...` matrix-like R objects to be bound together, see `cbind` and `rbind`.
- `deparse.level` integer determining under which circumstances column and row names are built from the actual arguments' ‘expression', see `cbind`.

Details

The implementation of these is recursive, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

Value

typically a ‘matrix-like’ object of a similar class as the first argument in ....

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries is than non-zero ones (as the default sparse in `Matrix()`).
Author(s)
Martin Maechler

See Also
cbind2, cbind, Documentation in base R's methods package.

Examples

```r
(a <- matrix(c(2:1,1:2), 2,2))
D <- Diagonal(2)
if(getRversion() < "3.2.0") {
  M1 <- cbind(0, rBind(a, 7))
  print(M1) # remains traditional matrix
  M2 <- cBind(4, a, D, -1, D, 0) # a sparse Matrix
  print(M2)
}
else { ## newer versions of R do not need cBind / rBind:
  M1 <- cbind(0, suppressWarnings(rBind(a, 7)))
  print(M1) # remains traditional matrix
  M2 <- suppressWarnings(cBind(4, a, D, -1, D, 0)) # a sparse Matrix
  print(M2)
  stopifnot(identical(M1, cbind(0, rbind(a, 7))),
            identical(M2, cbind(4, a, D, -1, D, 0)))
}
# R >= 3.2.0
```

---

CHMfactor-class  
CHOLMOD-based Cholesky Factorizations

Description
The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "dCHMsimpl") or supernodal (virtual class "dCHMsuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMsimpl" and "dCHMsuper") or symbolic factorizations (classes "nCHMsimpl" and "nCHMsuper").

Usage

```r
isLDL(x)
```

## S4 method for signature 'CHMfactor'
update(object, parent, mult = 0, ...)
.updateCHMfactor(object, parent, mult)

## and many more methods, notably,
## solve(a, b, system = c("A","LDLt","LD","DLt","L","Lt","D","P","Pt"), ...)
## ----- see below
Arguments

`x`, `object`, `a`

- `x`: an "CHMfactor" object (almost always the result of `Cholesky()`).
- `object`: a "dsCMat\{x\}" or "dgCMat\{x\}" matrix object with the same nonzero pattern as the matrix that generated object. If parent is symmetric, of class "dsCMat\{x\}", then object should be a decompo\{sition\} of a matrix with the same nonzero pattern as parent. If parent is not symmetric then object should be the decompo\{sition\} of a matrix with the same nonzero pattern as `tcrossprod(parent)`.
- `parent`: a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated `object`. If `parent` is symmetric, of class "dsCMatrix", then `object` should be a decomposition of a matrix with the same nonzero pattern as `tcrossprod(parent)`.
- Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to `dsparseMatrix` and `CsparseMatrix` if needed.
- `mult`: a numeric scalar (default 0). `mult` times the identity matrix is (implicitly) added to parent or `tcrossprod(parent)` before updating the decomposition object.
- `...`: potentially further arguments to the methods.

Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper",...)` but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

Slots

of "CHMfactor" and all classes inheriting from it:

- `perm`: An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.
- `colcount`: Object of class "integer" ....
- `type`: Object of class "integer" ....

Slots of the non virtual classes "[dl]CHM(super|simpl)":

- `p`: Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHM\{simpl\}".
- `i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHM\{simpl\}".
- `x`: For the "d*" classes: "numeric" - the non-zero elements of the matrix.

Methods

- `isLDL` (`x`) returns a `logical` indicating if `x` is an \(LDL'\) decomposition or (when `FALSE`) an \(LL'\) one.
- `coerce` signature(`from = "CHMfactor","to = "sparseMatrix"`) (or equivalently, `to = "Matrix"` or `to = "triangularMatrix"`)

  - `as(*,"sparseMatrix")` returns the lower triangular factor \(L\) from the \(LL'\) form of the Cholesky factorization. Note that (currently) the factor from the \(LL'\) form is always returned, even if the "CHMfactor" object represents an \(LDL'\) decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the expand method for obtaining both the permutation matrix, \(P\), and the lower Cholesky factor, \(L\).
- `coerce` signature(`from = "CHMfactor","to = "pMatrix"`) returns the permutation matrix \(P\), representing the fill-reducing permutation used in the decomposition.
expand signature(x = "CHMfactor") returns a list with components P, the matrix representing the fill-reducing permutation, and L, the lower triangular Cholesky factor. The original positive-definite matrix A corresponds to the product \( A = P'LL'P \). Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying drop0 to it. However, the extra "non-zeros" should be very small in magnitude.

image signature(x = "CHMfactor"): Plot the image of the lower triangular factor, L, from the decomposition. This method is equivalent to image(as(x,"sparseMatrix")) so the comments in the above description of the coerce method apply here too.

solve signature(a = "CHMfactor",b = "ddenseMatrix"),system= *:
The solve methods for a "CHMfactor" object take an optional third argument system whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve \( Ax = b \) for \( x \) where \( A \) is the sparse, positive-definite matrix that was factored to produce a. Analogously, system = "L" returns the solution \( x \), of \( Lx = b \). Similarly, for all system codes but "P" and "Pt" where, e.g., \( x <-\text{solve}(a,b,\text{system}="P") \) is equivalent to \( x <-P %*% b \). See also solve-methods.

determinant signature(x = "CHMfactor",logarithm = "logical") returns the determinant (or the logarithm of the determinant, if logarithm = TRUE, the default) of the factor L from the \( LL' \) decomposition (even if the decomposition represented by \( x \) is of the \( LDL' \) form (!)). This is the square root of the determinant (half the logarithm of the determinant when logarithm = TRUE) of the positive-definite matrix that was decomposed.

update signature(object = "CHMfactor"),parent. The update method requires an additional argument parent, which is either a "dsCMatrix" object, say A, (with the same structure of nonzeros as the matrix that was decomposed to produce object) or a general "dgCMatrix", say M, where \( A := MM' (= \text{tcrossprod}(\text{parent})) \) is used for A. Further it provides an optional argument mult, a numeric scalar. This method updates the numeric values in object to the decomposition of \( A + mI \) where \( A \) is the matrix above (either the parent or \( MM' \)) and \( m \) is the scalar mult. Because only the numeric values are updated this method should be faster than creating and decomposing \( A + mI \). It is not uncommon to want, say, the determinant of \( A + mI \) for many different values of \( m \). This method would be the preferred approach in such cases.

See Also

Cholesky, also for examples; class dgCMatrix.

Examples

```r
## An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
  i = sample(n, nnz, replace = TRUE),
  j = sample(m, nnz, replace = TRUE),
  x = round(rnorm(nnz),1))
XX <- crossprod(M1) ## = M1/quotesingle.Var
M1 = M M/quotesingle.Var
where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
str(CX) ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P)) ## == L'P
PLLP <- crossprod(L.P) ## == (L'P)' L'P == P'LL'P = XX = M M/quotesingle.Var
```
b <- sample(m)
stopifnot(all.equal(PLLP, XX),
  all(as.vector(solve(CX, b, system="P" )) == r$P %*% b),
  all(as.vector(solve(CX, b, system="Pt")) == t(r$P) %*% b) )

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M1), mult=pi) # with the original M, where XX = M M'
stopifnot(all.equal(u1,u2, tol=1e-14))

## [ See help(Cholesky) for more examples ]
## ----------------------

chol Choleski Decomposition - 'Matrix' S4 Generic and Methods

Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

Usage

chol(x, ...)
## S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
## S4 method for signature 'dsparseMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)

Arguments

x a (sparse or dense) square matrix, here inheriting from class Matrix; if x is not positive definite, an error is signalled.
pivot logical indicating if pivoting is to be used. Currently, this is not made use of for dense matrices.
cache logical indicating if the result should be cached in x@factors; note that this argument is experimental and only available for some sparse matrices.
... potentially further arguments passed to methods.

Details

Note that these Cholesky factorizations are typically cached with x currently, and these caches are available in x@factors, which may be useful for the sparse case when pivot = TRUE, where the permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider Cholesky() in such situations, since chol(x,pivot=TRUE) uses the same algorithm (but not the same return value!) as Cholesky(x,LDL=FALSE) and chol(x) corresponds to Cholesky(x,perm=FALSE,LDL=FALSE).

Value

a matrix of class Cholesky, i.e., upper triangular: $R$ such that $R' R = x$ (if pivot=FALSE) or $P' R' RP = x$ (if pivot=TRUE and $P$ is the corresponding permutation matrix).
Methods

Use `showMethods(chol)` to see all; some are worth mentioning here:

`chol` signature(x = "dgeMatrix"): works via "dpoMatrix", see class `dpoMatrix`.

`chol` signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, via LAPACK routines `dlacpy` and `dpotrf`.

`chol` signature(x = "dppMatrix"): Returns (and stores) the Cholesky decomposition via LAPACK routine `dpptrf`.

`chol` signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x. If pivot is true, the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of x so as to reduce fill-in.

References

See Also

The default from `base`, `chol`; for more flexibility (but not returning a matrix!) Cholesky.

Examples

```r
showMethods(chol, inherited = FALSE) # show different methods

sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77))
(c2 <- chol(sy2)) #-> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)

## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector"))) # 5 x 5
(R <- chol(mm)) # default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot(identical(R, R2), all.equal(crossprod(R), mm))

(R. <- chol(mm, pivot=TRUE))# nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
  all.equal(prod(diag(R)), det(R)),
  all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
(M2 <- toeplitz(as(c(1,.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)

## For the experts, check the caching of the factorizations:
ff <- M2@factors["spdCholesky"]
```
chol2inv-methods

Inverse from Choleski or QR Decomposition – Matrix Methods

Description
Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute \((X'X)^{-1}\) from the \((R\text{ part})\) of the QR decomposition of \(X\).
Even more generally, given an upper triangular matrix \(R\), compute \((R'R)^{-1}\).

Methods

- **x = "ANY"** the default method from base, see chol2inv, for traditional matrices.
- **x = "dtrMatrix"** method for the numeric triangular matrices, built on the same LAPACK DPOTRI function as the base method.
- **x = "denseMatrix"** if \(x\) is coercable to a triangularMatrix, call the "dtrMatrix" method above.
- **x = "sparseMatrix"** if \(x\) is coercable to a triangularMatrix, use solve() currently.

See Also
chol (for Matrix objects); further, chol2inv (from the base package), solve.

Examples

\[
(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
\]
\[
(cM <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
\]
\[
chol2inv(cM) %% M # the identity
\]
\[
stopifnot(all(chol2inv(cM) %% M - Diagonal(nrow(M))) < 1e-10)
\]

Cholesky

Cholesky Decomposition of a Sparse Matrix

Description
Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically chol() should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

Usage

\[
\text{Cholesky}(A, \text{ perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...})
\]
Arguments

A
sparse symmetric matrix. No missing values or IEEE special values are allowed.

perm
logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of A. Default is TRUE.

LDL
logical scalar indicating if the decomposition should be computed as LDL’ where L is a unit lower triangular matrix. The alternative is LL’ where L is lower triangular with arbitrary diagonal elements. Default is TRUE. Setting it to NA leaves the choice to a CHOLMOD-internal heuristic.

super
logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is FALSE. Setting it to NA leaves the choice to a CHOLMOD-internal heuristic.

Imult
numeric scalar which defaults to zero. The matrix that is decomposed is $A+m*I$ where m is the value of Imult and I is the identity matrix of order ncol(A).

Details

This is a generic function with special methods for different types of matrices. Use showMethods("Cholesky") to list all the methods for the Cholesky generic.

The method for class dsCMatrix of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use chol(.).

Note that if perm=TRUE (default), the decomposition is

$$A = P' \tilde{L} \tilde{D} \tilde{L}' P = P' LL' P,$$

where L can be extracted by as(*,"Matrix"), P by as(*,"pMatrix") and both by expand(*), see the class CHMfactor documentation.

Note that consequently, you cannot easily get the “traditional” cholesky factor $R$, from this decomposition, as

$$R' R = A = P' LL' P = P' \tilde{R}' \tilde{R} P = (\tilde{R} P)' (\tilde{R} P),$$

but $\tilde{R} P$ is not triangular even though $\tilde{R}$ is.

Value

an object inheriting from either "CHMsuper", or "CHMsimpl", depending on the super argument; both classes extend "CHMfactor" which extends "MatrixFactorization".

In other words, the result of Cholesky() is not a matrix, and if you want one, you should probably rather use chol(), see Details.

References

See Also

Class definitions CHMfactor and dsCMatrix and function expand. Note the extra solve(*, system = . ) options in CHMfactor.

Note that chol() returns matrices (inheriting from "Matrix") whereas Cholesky() returns a "CHMfactor" object, and hence a typical user will rather use chol(A).

Examples

data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'sPDCholesky' (simpl)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'sPDCholesky' *and* 'SPdCholesky'
str(cm1 <- as(C1, "sparseMatrix"))

(Cm <- Cholesky(mtm, super = TRUE))
c(Cm = isLDL(Cm))
str(cm1 <- as(Cm, "sparseMatrix"))

b <- matrix(c(rep(0, 711), 1), nc = 1)
## solve(Cm, b) by default solves Ax = b, where A = Cm’Cm (= mtm)!
## hence, the identical() check *should* work, but fails on some GOTOblas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b, system = "A")),
          all.equal(x, solve(mtm, b)))

cn <- Cholesky(mtm, perm = FALSE)# no permutation -- much worse:
sizes <- c(simple = object.size(C1),
          super = object.size(Cm),
          noPerm = object.size(Cn))
## simple is 100, super= 137, noPerm= 812 :
noquote(cbind(format(100 * sizes / sizes[1], digits=4)))

## Visualize the sparseness:
dq <- function(ch) paste("", ch,"", sep="") ## dQuote(<UTF-8>) gives bad plots
image(mtm, main=paste("crossprod(mm) : Sparse", dq(class(mtm))))
image(cm1, main= paste("as(Cholesky(crossprod(mm)),"sparseMatrix")":",
          dq(class(cm1))))

## Smaller example, with same matrix as in help(chol) :

mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)) # 5 x 5
(o <- expand.grid(perm = c(TRUE, FALSE), LDL = c(TRUE,FALSE), super = c(FALSE,TRUE)))
rr <- lapply(seq_len(nrow(o)), function(i)
  do.call(Cholesky, c(list(A = mm), o[i,])))
nn <- do.call(expand.grid, c(attr(o, "out.attr")$dimnames,
                          stringsAsFactors=FALSE,KEEP.OUT.ATTRS=FALSE))
names(rr) <- apply(nn, 1, function(r)
  paste(sub("=.*","\1", r), collapse="",))
str(rr, max=1)

str(re <- lapply(rr, expand), max=2) ## each has a 'P' and a 'L' matrix
R0 <- chol(mm, pivot=FALSE)
R1 <- chol(mm, pivot=TRUE )
stopifnot(all.equal(t(R1), re[[1]]$L),
    all.equal(t(R0), re[[2]]$L),
    identical(as(1:5, "pMatrix"), re[[2]]$P), # no pivoting
TRUE)

# Version of the underlying SuiteSparse library by Tim Davis :
.SuiteSparse_version()

---

Cholesky-class

### Cholesky and Bunch-Kaufman Decompositions

#### Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "BunchKaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their packed storage versions.

#### Objects from the Class

Objects can be created by calls of the form `new("Cholesky",...)` or `new("BunchKaufman",...)`, etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "dpoMatrix" or "dsyMatrix" class or as a side-effect of other functions applied to "dpoMatrix" objects (see `dpoMatrix`).

#### Slots

A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "dtrMatrix" class.

- `uplo`: inherited from the "dtrMatrix" class.
- `diag`: inherited from the "dtrMatrix" class.
- `x`: inherited from the "dtrMatrix" class.
- `Dim`: inherited from the "dtrMatrix" class.
- `Dimnames`: inherited from the "dtrMatrix" class.

A Bunch-Kaufman decomposition also extends the "dtrMatrix" class and has a `perm` slot representing a permutation matrix. The packed versions extend the "dtpMatrix" class.

#### Extends

Class "MatrixFactorization" and "dtrMatrix", directly. Class "dgeMatrix", by class "dtrMatrix". Class "Matrix", by class "dtrMatrix".

#### Methods

Both these factorizations can directly be treated as (triangular) matrices, as they extend "dtrMatrix", see above. There are currently no further explicit methods defined with class "Cholesky" or "BunchKaufman" in the signature.
Note

1. Objects of class "Cholesky" typically stem from chol(D), applied to a dense matrix D.
   On the other hand, the function Cholesky(S) applies to a sparse matrix S, and results in
   objects inheriting from class CHMfactor.

2. For traditional matrices m, chol(m) is a traditional matrix as well, triangular, but simply an n \times n numeric matrix. Hence, for compatibility, the "Cholesky" and "BunchKaufman" classes
   (and their "p*" packed versions) also extend triangular Matrix classes (such as "dtrMatrix").
   Consequently, determinant(R) for R <- chol(A) returns the determinant of R, not of A. This
   is in contrast to class CHMfactor objects C, where determinant(C) gives the determinant of
   the original matrix A, for C <- Cholesky(A), see also the determinant method documentation
   on the class CHMfactor page.

See Also

Classes dtrMatrix, dpoMatrix; function chol.
Function Cholesky resulting in class CHMfactor objects, not class "Cholesky" ones, see the section
'Note'.

Examples

(sm <- as(as(Matrix(diag(5) + 1), "dsyMatrix"), "dspMatrix"))
signif(csm <- chol(sm), 4)

(pm <- crossprod(Matrix(rnorm(18), nrow = 6, ncol = 3)))
(ch <- chol(pm))
if (toupper(ch@uplo) == "U") # which is TRUE
crossprod(ch)
stopifnot(all.equal(as(crossprod(ch), "matrix"),
                   as(pm, "matrix"), tolerance=1e-14))

colSums

Form Row and Column Sums and Means

Description

Form row and column sums and means for objects, for sparseMatrix the result may optionally be
sparse (sparseVector), too. Row or column names are kept respectively as for base matrices and
colSums methods, when the result is numeric vector.

Usage

colSums(x, na.rm = FALSE, dims = 1, ...)
rowSums (x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE, dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE, dims = 1, sparseResult = FALSE)
## Arguments

- **x**: a Matrix, i.e., inheriting from `Matrix`.
- **na.rm**: logical. Should missing values (including NaN) be omitted from the calculations?
- **dims**: completely ignored by the `Matrix` methods.
- **...**: potentially further arguments, for method `<-` generic compatibility.
- **sparseResult**: logical indicating if the result should be sparse, i.e., inheriting from class `sparseVector`. Only applicable when `x` is inheriting from a `sparseMatrix` class.

## Value

returns a numeric vector if `sparseResult` is FALSE as per default. Otherwise, returns a `sparseVector`.

`dimnames(x)` are only kept (as `names(v)`) when the resulting `v` is numeric, since `sparseVectors` do not have names.

## See Also

`colSums` and the `sparseVector` classes.

## Examples

```r
(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0'; drop those:
MM <- drop0(MM)
length(MM@x) # 32
cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
  identical(cm, as.numeric(scm)))
rowSums (MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
## Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
  rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
rowMeans(Diagonal(16)) == 1/16,
colSums(Diagonal(7)) == 1)
```

```r
## dimnames(x) --> names(<value>) :
dimnames(M) <- list(paste0("r", 1:7), paste0("V",1:8))
M
dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE,
dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE,
dims = 1, sparseResult = FALSE)
```
colSums(M)
rowMeans(M)

## Assertions :
stopifnot(all.equal(colSums(M),
    setNames(c(1,1,6,6,6,6,3,2), colnames(M))),
all.equal(rowMeans(M), structure(c(1,1,4,8,12,3,2) / 8,
    .Names = paste0("r", 1:7))))

compMatrix-class

Class "compMatrix" of Composite (Factorizable) Matrices

Description

Virtual class of composite matrices; i.e., matrices that can be factorized, typically as a product of simpler matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

factors: Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e., list(), initially and is updated automatically whenever a matrix factorization is computed.

Dim, Dimnames: inherited from the Matrix class, see there.

Extends

Class "Matrix", directly.

Methods

dimnames<- signature(x = "compMatrix", value = "list"): set the dimnames to a list of length 2, see dimnames<-. The factors slot is currently reset to empty, as the factorization dimnames would have to be adapted, too.

See Also

The matrix factorization classes "MatrixFactorization" and their generators, lu(), qr(), chol() and Cholesky(), BunchKaufman(), Schur().
condest

Compute Approximate CONDition number and 1-Norm of (Large) Matrices

Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix A. It works by applying a fast randomized approximation of the 1-norm, \( \|A\|_1 \), through onenormest(.)

Usage

condest(A, t = min(n, 5), normA = norm(A, "1"), silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n, silent = FALSE, quiet = silent, iter.max = 10, eps = 4 * .Machine$double.eps)

Arguments

A a square matrix, optional for onenormest(), where instead of A, A.x and At.x can be specified, see there.

t number of columns to use in the iterations.
normA number; (an estimate of) the 1-norm of A, by default \( \|A\|_1 \); may be replaced by an estimate.
silent logical indicating if warning and (by default) convergence messages should be displayed.
quiet logical indicating if convergence messages should be displayed.
A.x, At.x when A is missing, these two must be given as functions which compute \( A \times x \) or \( t(A) \times x \), respectively.
n == nrow(A), only needed when A is not specified.
iter.max maximal number of iterations for the 1-norm estimator.
eps the relative change that is deemed irrelevant.

Details

condest() calls lu(A), and subsequently onenormest(A.x = , At.x = ) to compute an approximate norm of the inverse of A, \( A^{-1} \), in a way which keeps using sparse matrices efficiently when A is sparse.

Note that onenormest() uses random vectors and hence both functions’ results are random, i.e., depend on the random seed, see, e.g., set.seed().

Value

Both functions return a list; condest() with components,

- est a number > 0, the estimated (1-norm) condition number \( \hat{\kappa} \); when \( r := \text{rcond}(A) \), \( 1/\hat{\kappa} \approx r \).
The function `onenormest()` returns a list with components,

- `est` a number > 0, the estimated `norm(A,"1")`.
- `v` 0-1 integer vector length `n`, with an 1 at the index `j` with maximal column `A[,j]` in `A`.
- `w` numeric vector, the largest `Ax` found.
- `iter` the number of iterations used.

**Author(s)**

This is based on octave’s `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

**References**

**See Also**

`norm`, `rcond`.

**Examples**

data(KNex)
mtm <- with(KNex, crossprod(mm))
system.time(ce <- condest(mtm))
sum(abs(ce$v)) # || v ||_1 == 1
  ## Prove that || A v || = || A || / est (as ||v|| = 1):
  stopifnot(all.equal(norm(mtm %*% ce$v),
                    norm(mtm) / ce$est))

  ## reciprocal
  1 / ce$est
  system.time(rc <- rcond(mtm)) # takes ca 3 x longer
  rc
  all.equal(rc, 1/ce$est) # TRUE -- the approximation was good

  one <- onenormest(mtm)
  str(one) # est = 12.3
  # the maximal column:
  which(one$v == 1) # mostly 4, rarely 1, depending on random seed
The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("CsparseMatrix")` for its subclasses.

Slots

- `i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the 0-based row numbers for each non-zero element in the matrix, i.e., `i` must be in `0:(nrow(.)-1)`.
- `p`: integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. `.@p` is of length `ncol(.) + 1`, with `p[1] == 0` and `p[length(p)] == nnzero`, such that in fact, `diff(.@p)` are the number of non-zero elements for each column. In other words, `m@p[1:ncol(m)]` contains the indices of those elements in `m@x` that are the first elements in the respective column of `m`.

- `Dim`, `Dimnames`: inherited from the superclass, see the `sparseMatrix` class.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

- matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:
  - `signature(e1 = "CsparseMatrix", e2 = "numeric")`: ...
- `Arith`:

  - `signature(x = "CsparseMatrix")`: ...
### ddenseMatrix-class

The virtual class of all dense numeric (i.e., double, hence “ddense”) S4 matrices. Its most important subclass is the dgeMatrix class.

#### Description

This is the virtual class of all dense numeric (i.e., double, hence “ddense”) S4 matrices.

#### Extends

Class "dMatrix" directly; class "Matrix", by the above.

#### Slots

the same slots at its subclass dgeMatrix, see there.

#### Methods

Most methods are implemented via as(*,"dgeMatrix") and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method.

Use showMethods(class = "ddenseMatrix", where = "package:Matrix") for an overview.
See Also

The virtual classes Matrix, dMatrix, and dsparseMatrix.

Examples

```
showClass("ddenseMatrix")
showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

**ddiMatrix-class**

Class "ddiMatrix" of Diagonal Numeric Matrices

Description

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend sparseMatrix, whereas they did extend dense matrices earlier.

Objects from the Class

Objects can be created by calls of the form `new("ddiMatrix",...)` but typically rather via `Diagonal`.

Slots

- **x**: numeric vector. For an $n \times n$ matrix, the $x$ slot is of length $n$ or 0, depending on the `diag` slot:
  - `diag`: "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.
- `Dim`, `Dimnames`: matrix dimension and `dimnames`, see the Matrix class description.

Extends

Class "diagonalMatrix", directly. Class "dMatrix", directly. Class "sparseMatrix", indirectly, see `showClass("ddiMatrix")`.

Methods

```
%*% signature(x = "ddiMatrix", y = "ddiMatrix"): ...
```

See Also

Class `diagonalMatrix` and function `Diagonal`. 
Examples

(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> ‘fast’ multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
  all.equal(cd2@x, c(sqrt(10),1)))

---

denseMatrix-class

Virtual Class "denseMatrix" of All Dense Matrices

Description

This is the virtual class of all dense (S4) matrices. It is the direct superclass of `ddenseMatrix`, `ldenseMatrix`

Extends

class "Matrix" directly.

Slots

exactly those of its superclass "Matrix".

Methods

Use `showMethods(class = "denseMatrix", where = "package:Matrix")` for an overview of methods.

Extraction ("[") methods, see `[-methods`.

See Also

`colSums`, `kronecker`, and other such methods with own help pages.

Its superclass `Matrix`, and main subclasses, `ddenseMatrix` and `sparseMatrix`.

Examples

`showClass("denseMatrix")`
**Description**

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the “standard” class for sparse numeric matrices in the **Matrix** package.

**Objects from the Class**

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE)`, or most efficiently via `sparseMatrix()`.

**Slots**

- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- ... all other slots are inherited from the superclass "CsparseMatrix".

**Methods**

Matrix products (e.g., `crossprod-methods`), and (among other)

- `coerce` signature(from = "matrix", to = "dgCMatrix")
- `coerce` signature(from = "dgCMatrix", to = "matrix")
- `coerce` signature(from = "dgCMatrix", to = "dgTMatrix")
- `diag` signature(x = "dgCMatrix"): returns the diagonal of x
- `dim` signature(x = "dgCMatrix"): returns the dimensions of x
- `image` signature(x = "dgCMatrix"): plots an image of x using the `levelplot` function
- `solve` signature(a = "dgCMatrix", b = "..."): see `solve-methods`, notably the extra argument sparse.
- `lu` signature(x = "dgCMatrix"): computes the LU decomposition of a square dgCMatrix object

**See Also**

Classes `dsCMatrix`, `dtCMatrix`, `lu`

**Examples**

```r
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```
Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices

Description
A general numeric dense matrix in the S4 Matrix representation. dgeMatrix is the "standard" class for dense numeric matrices in the Matrix package.

Objects from the Class
Objects can be created by calls of the form new("dgeMatrix",...) or, more commonly, by coercion from the Matrix class (see Matrix) or by Matrix(...).

Slots
x: Object of class "numeric" - the numeric values contained in the matrix, in column-major order.
Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
Dimnames: a list of length two - inherited from class Matrix.
factors: Object of class "list" - a list of factorizations of the matrix.

Methods
The are group methods (see, e.g., Arith)
Arith signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...
Arith signature(e1 = "dgeMatrix", e2 = "numeric"): ...
Arith signature(e1 = "numeric", e2 = "dgeMatrix"): ...
Math signature(x = "dgeMatrix"): ...
Math2 signature(x = "dgeMatrix", digits = "numeric"): ...

matrix products %*%, crossprod() and tcrossprod(), several solve methods, and other matrix methods available:
Schur signature(x = "dgeMatrix", vectors = "logical"): ...
Schur signature(x = "dgeMatrix", vectors = "missing"): ...
chol signature(x = "dgeMatrix"): see chol.
coerce signature(from = "dgeMatrix", to = "lgeMatrix"): ...
coerce signature(from = "dgeMatrix", to = "matrix"): ...
coerce signature(from = "matrix", to = "dgeMatrix"): ...
colMeans signature(x = "dgeMatrix"): columnwise means (averages)
colSums signature(x = "dgeMatrix"): columnwise sums
diag signature(x = "dgeMatrix"): ...
dim signature(x = "dgeMatrix"): ...
dimnames signature(x = "dgeMatrix"): ...
eigen signature(x = "dgeMatrix", only.values = "logical"): ...
The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., `dgCMatrix`, are preferred and better supported in the `Matrix` package.

**Objects from the Class**

Objects can be created by calls of the form `new("dgRMatrix",...)`.

**Slots**

- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.
- **p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- **x**: Object of class "numeric" - the non-zero elements of the matrix.
- **Dim**: Object of class "integer" - the dimensions of the matrix.

**Methods**

- **coerce** signature(from = "matrix", to = "dgRMatrix")
- **coerce** signature(from = "dgRMatrix", to = "matrix")
- **coerce** signature(from = "dgRMatrix", to = "dgTMatrix")
- **diag** signature(x = "dgRMatrix"): returns the diagonal of x
- **dim** signature(x = "dgRMatrix"): returns the dimensions of x
- **image** signature(x = "dgRMatrix"): plots an image of x using the `levelplot` function

**See Also**

the `RsparseMatrix` class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The `dgCMatrix` class (column compressed sparse) is really preferred.
Description

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class dgCMatrix.

Objects from the Class

Objects can be created by calls of the form new("dgTMatrix",...), but more typically via as(*,"dgTMatrix"), spMatrix(), or sparseMatrix(*,giveCsparse=FALSE).

Slots

i: integer row indices of non-zero entries in 0-base, i.e., must be in θ:(nrow(.)-1).

j: integer column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in θ:(ncol(.)-1).

x: numeric vector - the (non-zero) entry at position (i,j). Must be the same length as slot i. If an index pair occurs more than once, the corresponding values of slot x are added to form the element of the matrix.

Dim: Object of class "integer" of length 2 - the dimensions of the matrix.

Methods

+ signature(e1 = "dgTMatrix",e2 = "dgTMatrix")

coerce signature(from = "dgTMatrix",to = "dgCMatrix")

coerce signature(from = "dgTMatrix",to = "dgeMatrix")

coerce signature(from = "dgTMatrix",to = "matrix"), and typically coercion methods for more specific signatures, we are not mentioning here.

Note that these are not guaranteed to continue to exist, but rather you should use calls like as(x,"CsparseMatrix"), as(x,"generalMatrix"), as(x,"dMatrix"), i.e. coercion to higher level virtual classes.

coerce signature(from = "matrix",to = "dgTMatrix"),(direct coercion from tradition matrix).

image signature(x = "dgTMatrix"): plots an image of x using the levelplot function

t signature(x = "dgTMatrix"): returns the transpose of x

Note

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to dgCMatrix objects.

Note that both new(.) and spMatrix constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add $x_k$'s that belong to identical $(i_k,j_k)$ pairs.

However this means that a matrix typically can be stored in more than one possible "TsparseMatrix" representations. Use uniqTsparse() in order to ensure uniqueness of the internal representation of such a matrix.
See Also

Class `dgCMatrix` or the superclasses `dsparseMatrix` and `TsparseMatrix`; `uniqTsparse`.

Examples

```r
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
    m[ lower.tri(m) ]))

# Triplet representation with repeated (i,j) entries
# *adds* the corresponding x's:
T2 <- new("dgTMatrix",
    i = as.integer(c(1,1,0,3,3)),
    j = as.integer(c(2,2,4,0,0)), x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
    ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)
```

Diagonal

Create Diagonal Matrix Object

**Description**

Create a diagonal matrix object, i.e., an object inheriting from `diagonalMatrix` (or a “standard” `CsparseMatrix` diagonal matrix in cases that is preferred).

**Usage**

```r
Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1,n), uplo = "U", kind)
.trDiagonal(n, x = 1, uplo = "U", untri=TRUE, kind)
.sparseDiagonal(n, x = 1, uplo = "U",
    shape = if(missing(cols)) "t" else "g",
    untri, kind, cols = if(n) 0:(n - 1L) else integer(0))
```

**Arguments**

- `n` integer specifying the dimension of the (square) matrix. If missing, `length(x)` is used.
- `x` numeric or logical; if missing, a unit diagonal $n \times n$ matrix is created.
- `uplo` for `.symDiagonal` (.trDiagonal), the resulting sparse `symmetricMatrix` (or `triangularMatrix`) will have slot `uplo` set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default.
Diagonal

shape string of 1 character, one of c("t", "s", "g"), to choose a triangular, symmetric or general result matrix.

unitri optional logical indicating if a triangular result should be “unit-triangular”, i.e., with diag = "U" slot, if possible. The default, missing, is the same as TRUE.

kind string of 1 character, one of c("d", "l", "n"), to choose the storage mode of the result, from classes dsparseMatrix, lsparseMatrix, or nsparseMatrix, respectively.

cols integer vector with values from 0:(n-1), denoting the columns to subselect conceptually, i.e., get the equivalent of Diagonal(n, *)[, cols + 1].

Value

Diagonal() returns an object of class ddiMatrix or ldiMatrix (with “superclass” diagonalMatrix).

.symDiagonal() returns an object of class dsCMatrix or lsCMatrix, i.e., a sparse symmetric matrix. Analogously, .triDiagonal gives a sparse triangularMatrix. This can be more efficient than Diagonal(n) when the result is combined with further symmetric (sparse) matrices, e.g., in kronecker, however not for matrix multiplications where Diagonal() is clearly preferred.

.sparseDiagonal(), the workhorse of .symDiagonal and .triDiagonal returns a CsparseMatrix (the resulting class depending on shape and kind) representation of Diagonal(n), or, when cols are specified, of Diagonal(n)[, cols+1].

Author(s)

Martin Maechler

See Also

the generic function diag for extraction of the diagonal from a matrix works for all “Matrices”. bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals. band(A) returns a band matrix containing some sub-/super - diagonals of A.
Matrix for general matrix construction; further, class diagonalMatrix.

Examples

Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2)#-> "ldiMatrix"

## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2,3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t")# now (2012-10) unitriangular stopifnot(I4@diag == "U", all(I4 == diag(4)))
diagonalMatrix-class  
Class "diagonalMatrix" of Diagonal Matrices

Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

diag: code "character" string, either "U" or "N", where "U" means 'unit-diagonal'.

Dim: matrix dimension, and

Dimnames: the dimnames, a list, see the Matrix class description. Typically list(NULL,NULL) for diagonal matrices.

Extends

Class "sparseMatrix", directly.

Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

coerce signature(from = "matrix", to = "diagonalMatrix"): ...

coerce signature(from = "Matrix", to = "diagonalMatrix"): ...

coerce signature(from = "diagonalMatrix", to = "generalMatrix"): ...

coerce signature(from = "diagonalMatrix", to = "triangularMatrix"): ...

coerce signature(from = "diagonalMatrix", to = "nMatrix"): ...

coerce signature(from = "diagonalMatrix", to = "matrix"): ...

coerce signature(from = "diagonalMatrix", to = "sparseVector"): ...

t signature(x = "diagonalMatrix"): ...

and many more methods

solve signature(a = "diagonalMatrix", b,...): is trivially implemented, of course; see also solve-methods.

which signature(x = "nMatrix"), semantically equivalent to base function which(x, arr.ind).

"Math" signature(x = "diagonalMatrix"): all these group methods return a "diagonalMatrix", apart from cumsum() etc which return a vector also for base matrix.

* signature(e1 = "ddiMatrix", e2="denseMatrix"): arithmetic and other operators from the Ops group have a few dozen explicit method definitions, in order to keep the results diagonal in many cases, including the following:

/ signature(e1 = "ddiMatrix", e2="denseMatrix"): the result is from class ddiMatrix which is typically very desirable. Note that when e2 contains off-diagonal zeros or NAs, we implicitly use 0/x = 0, hence differing from traditional R arithmetic (where 0/0 ↦ NaN), in order to preserve sparsity.
**summary** (object = "diagonalMatrix"): Returns an object of S3 class "diagSummary" which is the summary of the vector object@x plus a simple heading, and an appropriate print method.

See Also

Diagonal() as constructor of these matrices, and isDiagonal. ddiMatrix and ldiMatrix are “actual” classes extending "diagonalMatrix".

Examples

I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
identical(tcrossprod(I5), I5),
identical(crossprod(I5, D5), D5),
identical(tcrossprod(D5, I5), D5),
identical(solve(D5), solve(D5, I5)), all.equal(D5, solve(solve(D5)), tolerance = 1e-12)
)
solve(D5)# efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
cbind2(D5, I5))

diagU2N

Transform Triangular Matrices from Unit Triangular to General Triangular and Back

Description

Transform a triangular matrix x, i.e., of class "triangularMatrix", from (internally!) unit triangular ("unitriangular") to “general” triangular (diagU2N(x)) or back (diagN2U(x)). Note that the latter, diagN2U(x), also sets the diagonal to one in cases where diag(x) was not all one.

.diagU2N(x) assumes but does not check that x is a triangularMatrix with diag slot "U", and should hence be used with care.

Usage

diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

.diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)

Arguments

x a triangularMatrix, often sparse.
cl (optional, for speedup only:) class (definition) of x.
checkDense logical indicating if dense (see denseMatrix) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when x is dense.
Details

The concept of unit triangular matrices with a diag slot of "U" stems from LAPACK.

Value

a triangular matrix of the same class but with a different diag slot. For diagU2N (semantically) with identical entries as x, whereas in diagN2U(x), the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

Note

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather internal utilities.

See Also

"triangularMatrix", "dtCMatrix".

Examples

(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unitriangular"
(t.u <- diagN2U(10*T))# changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
    identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T,"triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dT)
dtU <- diagN2U(dT, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
    all(dT == dt.), all(dT == dtU),
    dt.@diag == "U", dtU@diag == "U")
Methods

There are (relatively simple) group methods (see, e.g., `Arith`)

- **Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...
- **Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...
- **Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...
- **Math** signature(x = "dMatrix"): ...
- **Math2** signature(x = "dMatrix", digits = "numeric"): this group contains `round()` and `signif()`.
- **Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...
- **Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...
- **Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...
- **Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions `max()`, `min()`, `range()`, `prod()`, `sum()`, `any()`, and `all()`.

The following methods are also defined for all double matrices:

- **coerce** signature(from = "dMatrix", to = "matrix"): ...
- **expm** signature(x = "dMatrix"): computes the “Matrix Exponential”, see `expm`.
- **zapsmall** signature(x = "dMatrix"): ...

The following methods are defined for all logical matrices:

- **which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the base function `which(x, arr.ind)` returns the indices of the TRUE entries in x; if arr.ind is true, as a 2-column matrix of row and column indices. Since Matrix version 1.2-9, if useNames is true, as by default, with `dimnames`, the same as base::which.

See Also

The nonzero-pattern matrix class `nMatrix`, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes `dgeMatrix`, `dgCMatrix`, and `Matrix`.

`drop0(x, tol=1e-10)` is sometimes preferable to (and more efficient than) `zapsmall(x, digits=10)`.

Examples

```r
showClass("dMatrix")
set.seed(101)
round(Matrix(rnorm(28), 4,7), 2)
M <- Matrix(rlnorm(56, sd=10), 4,14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```
dpoMatrix-class
Positive Semi-definite Dense (Packed \ Non-packed) Numeric Matrices

Description

- The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked storage.
- The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.
- The "corMatrix" class of correlation matrices extends "dpoMatrix" with a slot sd, which allows to restore the original covariance matrix.

Objects from the Class

Objects can be created by calls of the form new("dpoMatrix",...) or from \texttt{crossprod} applied to an "dgeMatrix" object.

Slots

- \texttt{uplo}: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- \texttt{x}: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- \texttt{Dim}: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.
- \texttt{Dimnames}: inherited from class "Matrix"
- \texttt{factors}: Object of class "list". A named list of factorizations that have been computed for the matrix.
- \texttt{sd}: (for "corMatrix") a \texttt{numeric} vector of length n containing the (original) \(\sqrt{\text{var}(.)}\) entries which allow reconstruction of a covariance matrix from the correlation matrix.

Extends

Class "dsyMatrix", directly.
Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

Methods

- \texttt{chol} \texttt{signature(x = "dpoMatrix")}: Returns (and stores) the Cholesky decomposition of \texttt{x}, see \texttt{chol}.
- \texttt{determinant} \texttt{signature(x = "dpoMatrix")}: Returns the determinant of \texttt{x}, via \texttt{chol(x)}, see above.
- \texttt{rcond} \texttt{signature(x = "dpoMatrix", norm = "character")}: Returns (and stores) the reciprocal of the condition number of \texttt{x}. The \texttt{norm} can be "O" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.
- \texttt{solve} \texttt{signature(a = "dpoMatrix", b = "....")}. and
- \texttt{solve} \texttt{signature(a = "dppMatrix", b = "....")} work via the Cholesky composition, see also the Matrix solve-methods.
Arith signature(e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically not positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with positive length(.) == 1 numbers (or logicals).

See Also

Classes dsysMatrix and dgeMatrix; further, Matrix, rcond, chol, solve, crossprod.

Examples

```r
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is `integer'
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))

### Note that as(*, "corMatrix") scales the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
          all.equal(ch6@sd^(-2), 2*(1:6)-1, tolerance= 1e-12))

chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors$Cholesky),
          all(abs(crossprod(chch) - ch6) < 1e-10))
```

Description

Returns a sparse matrix with no “explicit zeroes”, i.e., all zero or FALSE entries are dropped from the explicitly indexed matrix entries.

Usage

```r
drop0(x, tol = 0, is.Csparse = NA)
```

Arguments

- `x` a Matrix, typically sparse, i.e., inheriting from `sparseMatrix`.
- `tol` non-negative number to be used as tolerance for checking if an entry x\_i,j should be considered to be zero.
- `is.Csparse` logical indicating prior knowledge about the “Csparseness” of x. This exists for possible speedup reasons only.

Value

a Matrix like x but with no explicit zeros, i.e., !any(x@x == 0), always inheriting from `CsparseMatrix`. 
Note

When a sparse matrix is the result of matrix multiplications, you may want to consider combining
\texttt{drop0()} with \texttt{zapsmall()}, see the example.

See Also

\texttt{spMatrix}, class \texttt{sparseMatrix}; \texttt{nnzero}

Examples

\begin{verbatim}
  m <- spMatrix(10,20, i= 1:8, j=2:9, x = c(0:2,3:-1))
  m
  drop0(m)

  ## A larger example:
  t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
            x = c(10, 1, 10, 1, 10, 10, 10),
            i = c(0L, 2L, 4L, 1L, 3L, 2L, 4L),
            p = c(0L, 3L, 5L, 7:9))
  TT <- kronecker(t5, kronecker(kronecker(t5,t5), t5))
  IT <- solve(TT)
  I. <- TT %*% IT ; nnzero(I.) # 697 ( = 625 + 72 )
  I.0 <- drop0(zapsmall(I.))
  ## which actually can be more efficiently achieved by
  I.. <- drop0(I., tol = 1e-15)
  stopifnot(all(I.0 == Diagonal(625)),
            nnzero(I..) == 625)
\end{verbatim}

\section*{dsCMat}
j: (only in class "dsTMatrix"): Object of class "integer" of length nnZ (as i). These are the column numbers for each non-zero element in the lower triangle of the matrix.

x: Object of class "numeric" of length nnZ – the non-zero elements of the matrix (to be duplicated for full matrix).

factors: Object of class "list" - a list of factorizations of the matrix.

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Extends

Both classes extend classes and symmetricMatrix dsparseMatrix directly; dsMatrix further directly extends CsparseMatrix, where dsTMatrix does TsparseMatrix.

Methods

solve signature(a = "dsCMatrix",b = "..."): x <- solve(a,b) solves Ax = b for x; see solve-methods.

col signature(x = "dsCMatrix",pivot = "logical"): Returns (and stores) the Cholesky decomposition of x, see chol.

Cholesky signature(A = "dsCMatrix",...): Computes more flexibly Cholesky decompositions, see Cholesky.

determinant signature(x = "dsCMatrix",logarithm = "missing"): Evaluate the determinant of x on the logarithm scale. This creates and stores the Cholesky factorization.

determinant signature(x = "dsCMatrix",logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.

t signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the uplo slot is swapped, and the row and column indices are interchanged.

t signature(x = "dsTMatrix"): Transpose. The uplo slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

coerce signature(from = "dsCMatrix",to = "dgTMatrix")

coerce signature(from = "dsCMatrix",to = "dgeMatrix")

coerce signature(from = "dsCMatrix",to = "matrix")

coerce signature(from = "dsTMatrix",to = "dgeMatrix")

coerce signature(from = "dsTMatrix",to = "dsCMatrix")

coerce signature(from = "dsTMatrix",to = "dsyMatrix")

coerce signature(from = "dsTMatrix",to = "matrix")

Classes dgCMatrix, dgTMatrix, dgeMatrix and those mentioned above.
Examples

```r
mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)

## how would we go from a manually constructed Tsparse* :
mT <- as(mm, "dgTMatrix")

## Either
(symM <- as(mT, "symmetricMatrix")) # dsT
(symC <- as(symM, "CsparseMatrix")) # dsC
## or
sC <- Matrix(mT, sparse=TRUE, forceCheck=TRUE)

sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"
```

---

dsparseMatrix-class  Virtual Class "dsparseMatrix" of Numeric Sparse Matrices

Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

Slots

- `Dim`: the matrix dimension, see class "Matrix".
- `Dimnames`: see the "Matrix" class.
- `x`: a numeric vector containing the (non-zero) matrix entries.

Extends

Class "dMatrix" and "sparseMatrix", directly.
Class "Matrix", by the above classes.

See Also

the documentation of the (non virtual) sub classes, see showClass("dsparseMatrix"); in particular, dgTMatrix, dgCMatrix, and dgRMatrix.

Examples

showClass("dsparseMatrix")
dsRMatrix-class

Symmetric Sparse Compressed Row Matrices

Description

The dsRMatrix class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Objects from the Class

These ".RMatrix" classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix",...)`.

Slots

- `uplo`: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.
- `j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- `p`: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- `factors`: Object of class "list" - a list of factorizations of the matrix.
- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- `Dim`: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- `Dimnames`: List of length two, see `Matrix`.

Extends

Classes RsparseMatrix, dsparseMatrix and symmetricMatrix, directly.

Class "dMatrix", by class "dsparseMatrix", class "sparseMatrix", by class "dsparseMatrix" or "RsparseMatrix"; class "compMatrix" by class "symmetricMatrix" and of course, class "Matrix".

Methods

- `forceSymmetric` signature(x = "dsRMatrix", uplo = "missing"): a trivial method just returning x
- `forceSymmetric` signature(x = "dsRMatrix", uplo = "character"): if uplo == x@uplo, this trivially returns x; otherwise t(x).
- `coerce` signature(from = "dsCMatrix", to = "dsRMMatrix")

See Also

the classes dgCMatrix, dgTMatrix, and dgeMatrix.
Examples

```r
(m0 <- new("dsyMatrix"))
m2 <- new("dsyMatrix", Dim = c(2L,2L), 
        x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
```

(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMatrix

---

dsyMatrix-class

Symmetric Dense (Packed \ Non-packed) Numeric Matrices

Description

- The "dsyMatrix" class is the class of symmetric, dense matrices in non-packed storage and
- "dspMatrix" is the class of symmetric dense matrices in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form `new("dsyMatrix",...)` or `new("dspMatrix",...)`, respectively.

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"dsyMatrix" extends class "dgeMatrix", directly, whereas
"dspMatrix" extends class "ddenseMatrix", directly.
Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use `showClass("dsyMatrix"), e.g., for details.

Methods

- `coerce` signature(from = "ddenseMatrix",to = "dgeMatrix")
- `coerce` signature(from = "dspMatrix",to = "matrix")
- `coerce` signature(from = "dsyMatrix",to = "matrix")
- `coerce` signature(from = "dsyMatrix",to = "dspMatrix")
**dtCMatrix-class**

The **dtCMatrix** class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The **dtTMatrix** class is a class of triangular, sparse matrices in triplet format.

**Objects from the Class**

Objects can be created by calls of the form `new("dtCMatrix",...)` or calls of the form `new("dtTMatrix",...)`, but more typically automatically via `Matrix()` or coercion such as `as(x,"triangularMatrix"),` or `as(x,"dtCMatrix")`.

**Examples**

```r
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"
```

```r
## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite
```
Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

p: (only present in "dtCMatric") an integer vector for providing pointers, one for each column, see the detailed description in CsparseMatrix.

i: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the dtTMatrix class.)

x: Object of class "numeric" - the non-zero elements of the matrix.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

Methods

coerce signature(from = "dtCMatric",to = "dgTMatrix")

coerce signature(from = "dtCMatric",to = "dgeMatrix")

coerce signature(from = "dtTMatrix",to = "dgeMatrix")

coerce signature(from = "dtTMatrix",to = "dtrMatrix")

coerce signature(from = "dtTMatrix",to = "matrix")

solve signature(a = "dtCMatric",b = "..."); sparse triangular solve (aka "backsolve" or "forwardsolve"), see solve-methods.

t signature(x = "dtCMatric"): returns the transpose of x

t signature(x = "dtTMatrix"): returns the transpose of x

\text{)}

---

**dtpMatrix-class**

**Packed Triangular Dense Matrices - "dtpMatrix"**

**Description**

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

**Objects from the Class**

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

**Slots**

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- `x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension \(d \times d\), \text{length}(x) is of length \(d(d+1)/2\) (also when \text{diag} == "U").
- `Dim`, `Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.
dtRMatrix-class

Triangular Sparse Compressed Row Matrices

Description

The dtRMatrix class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

Methods

%*% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see showMethods("%*%", class = "dtpMatrix").

coerce signature(from = "dtpMatrix", to = "dtrMatrix")

coerce signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the determinant(x) trivially is prod(diag(x)), but computed on log scale to prevent over- and underflow.

diag signature(x = "dtpMatrix"): ...
	norm signature(x = "dtpMatrix", type = "character"): ...

recond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forward-solve, see solve-methods.

t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x is upper triangular, and vice versa.

  l.r@uplo == T2@uplo, u.r@uplo == T@uplo,

  identical(c(u1), solve(pp), is(ip1, "dtpMatrix"),

  all.equal(as(solve(ip1, p1), "diagonalMatrix"), Diagonal(2)))

Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`. 

Slots

- uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.
- diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- j: Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- p: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the dsRMatrix class.)
- x: Object of class "numeric" - the non-zero elements of the matrix.
- Dim: The dimension (a length-2 "integer")
- Dimnames: corresponding names (or `NULL`), inherited from the `Matrix`, see there.

Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

Methods

No methods currently with class "dsRMatrix" in the signature.

See Also

Classes `dgCMatrix`, `dgTMatrix`, `dgeMatrix`

Examples

```r
(m0 <- new("dtRMatrix"))
(m2 <- new("dtRMatrix", Dim = c(2L,2L), 
          x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)) )
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix
```

---

**dtrMatrix-class**  
*Triangular, dense, numeric matrices*

**Description**

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage.
Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix",...)`.

Slots

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- **x**: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- **Dim**: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

Methods

Among others (such as matrix products, e.g. `?crossprod-methods`),

- **coerce** signature(from = "dgeMatrix", to = "dtrMatrix")
- **coerce** signature(from = "dtrMatrix", to = "matrix")
- **coerce** signature(from = "dtrMatrix", to = "ltpMatrix")
- **coerce** signature(from = "dtMatrix", to = "matrix")
- **coerce** signature(from = "matrix", to = "dtrMatrix")
- **norm** signature(x = "dtrMatrix", type = "character")
- **rcond** signature(x = "dtrMatrix", norm = "character")
- **solve** signature(a = "dtrMatrix", b = "...") efficiently use a “forward solve” or back solve for a lower or upper triangular matrix, respectively, see also `solve-methods`.

All the **Ops** group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

See Also

Classes `ddenseMatrix`, `dtpMatrix`, `triangularMatrix`.

Examples

```r
(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))

(T <- as(M, "dtrMatrix")) ## upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))
```
expand

Expand a Decomposition into Factors

Description

Expands decompositions stored in compact form into factors.

Usage

expand(x, ...)

Arguments

x

a matrix decomposition.

...

further arguments passed to or from other methods.

Details

This is a generic function with special methods for different types of decompositions, see showMethods(expand) to list them all.

Value

The expanded decomposition, typically a list of matrix factors.

Note

Factors for decompositions such as lu and qr can be stored in a compact form. The function expand allows all factors to be fully expanded.

See Also

The LU lu, and the Cholesky decompositions which have expand methods; facmul.

Examples

(x <- Matrix(round(rnorm(9),2), 3, 3))
(ex <- expand(lux <- lu(x)))
Description
Compute the exponential of a matrix.

Usage
expm(x)

Arguments
x a matrix, typically inheriting from the dMatrix class.

Details
The exponential of a matrix is defined as the infinite Taylor series $\expm(A) = I + A + A^2/2! + A^3/3! + \ldots$ (although this is definitely not the way to compute it). The method for the dgeMatrix class uses Ward’s diagonal Pade’ approximation with three step preconditioning.

Value
The matrix exponential of x.

Note
The expm package contains newer (partly faster and more accurate) algorithms for expm() and includes logm and sqrtm.

Author(s)
This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

References
http://en.wikipedia.org/wiki/Matrix_exponential

See Also
Schur; additionally, expm, logm, etc in package expm.
externalFormats

Examples

```R
(m1 <- Matrix(c(1,0,1,1), nc = 2))
(e1 <- expm(m1)); e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(6*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

Description

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

Usage

```R
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

Arguments

- **obj**: a real sparse matrix
- **file**: for `writeMM` - the name of the file to be written. For `readHB` and `readMM` the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in ".rua" or ".rsa". Those storing matrices in the MatrixMarket format usually end in ".mtx". Alternatively, `readHB` and `readMM` accept connection objects.
- **...**: optional additional arguments. Currently none are used in any methods.

Value

The `readHB` and `readMM` functions return an object that inherits from the "Matrix" class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to file in the MatrixMarket format (`writeMM`).

Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

Examples

str(pores <- readMM(system.file("external/pores_1.mtx", package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua", package = "Matrix")))
str(lundA <- readMM(system.file("external/lund_a.mtx", package = "Matrix")))
str(lundA <- readHB(system.file("external/lund_a.rsa", package = "Matrix")))
## Not run:
## NOTE: The following examples take quite some time
## ---- even on a fast internet connection:
if(FALSE) # the URL has been corrected, but we need an un-tar step!
str(sm <- readHB(gzcon(url("http://www.cise.ufl.edu/research/sparse/RC/Boeing/msc00726.tar.gz"))))
str(jgl009 <- readMM(gzcon(url("ftp://math.nist.gov/pub/MatrixMarket2/Harwell-Boeing/counterx/jgl009.mtx.gz"))))
## End(Not run)
data(KNex)
data(KNex)
## Store as MatrixMarket (".mtx") file, here inside temporary dir./folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)  
file.info(MMfile)[,c("size", "ctime")]
## very simple export - in triplet format - to text file:
data(CAex)
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
## has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))

facmul

Multiplication by Decomposition Factors

Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

Usage

facmul(x, factor, y, transpose, left, ...)

Arguments

x a matrix decomposition. No missing values or IEEE special values are allowed.
forceSymmetric

factor  an indicator for selecting a particular factor for multiplication.
y     a matrix or vector to be multiplied by the factor or its transpose. No missing
values or IEEE special values are allowed.
transpose  a logical value. When FALSE (the default) the factor is applied. When TRUE the
transpose of the factor is applied.
left     a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right.
...     the method for "qr.Matrix" has additional arguments.

Value
the product of the selected factor (or its transpose) and y

NOTE
Factors for decompositions such as lu and qr can be stored in a compact form. The function facmul allows multiplication without explicit formation of the factors, saving both storage and operations.

References

Examples
library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qr <- qr(x) # QR factorization of x
y <- rnorm(3)
facmul(qr(x), factor = "Q", y) # form Q y
## End(Not run)

forceSymmetric  Force a Matrix to 'symmetricMatrix' Without Symmetry Checks

Description
Force a square matrix x to a symmetricMatrix, without a symmetry check as it would be applied for as(x,"symmetricMatrix").

Usage
forceSymmetric(x, uplo)

Arguments
x     any square matrix (of numbers), either ""traditional"" (matrix) or inheriting from Matrix.
uplo  optional string. "U" or "L" indicating which “triangle” half of x should determine the result. The default is "U" unless x already has a uplo slot (i.e., when it is symmetricMatrix, or triangularMatrix), where the default will be x@uplo.
Value

a square matrix inheriting from class `symmetricMatrix`.

See Also

`symmpart` for the symmetric part of a matrix, or the coercions `as(x, <symmetricMatrix class>)`.

Examples

```r
## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try(as(hh, "symmetricMatrix")) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

formatSparseM

Formatting Sparse Numeric Matrices Utilities

Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the `format` and `print` methods for sparse matrices and can be applied as well to standard R matrices. Note that all arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of `formatSpMatrix`, the format method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

Usage

`formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
m = as(x,"matrix"), asLogical=NULL, uniDiag=NULL,
digits=NULL, cx, iN0, dn = dimnames(m))`

`.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
col.names, note.dropping.colnames = TRUE,
dn=dimnames(m))`
formatSparseM

Arguments

- **x**: an R object inheriting from class `sparseMatrix`.
- **zero.print**: character which should be used for *structural* zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like `print()`ing of non-sparse matrices.
- **align**: a string specifying how the zero.print codes should be aligned, see `formatSpMatrix`.
- **m** (optional): a (standard R) matrix version of x.
- **asLogical**: should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for `formatSparseM()`.
- **uniDiag**: logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").
- **digits**: significant digits to use for printing, see `print.default`.
- **cx** (optional): character matrix; a formatted version of x, still with strings such as "0.00" for the zeros.
- **iN0** (optional): integer vector, specifying the location of the non-zeroes of x.
- **col.names, note.dropping.colnames**: see `formatSpMatrix`.
- **dn**: dimnames to be used; a list (of length two) with row and column names (or NULL).

Value

A character matrix like cx, where the zeros have been replaced with (padded versions of) zero.print. As this is a dense matrix, do not use these functions for really large (really) sparse matrices!

Author(s)

Martin Maechler

See Also

- `formatSpMatrix` which calls `formatSparseM()` and is the format method for sparse matrices.
- `printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

Examples

```r
m <- suppressWarnings(matrix(c(0, 3.2, 0,0, 11,0,0,0,0,-7,0), 4,9))
f <- formatSparseM(m)
noquote(f)
## nice, but this is nicer (with "units" vertically aligned):
print(f, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m,align="r"))
stopifnot(f2 == f | m == 0, dim(f2) == dim(m),
          (f2 == ".") == (m == 0))
```
generalMatrix-class

Class "generalMatrix" of General Matrices

Description

Virtual class of "general" matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

factors,
Dim,
Dimnames: all slots inherited from compMatrix; see its description.

Extends

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

See Also

Classes compMatrix, and the non-general virtual classes: symmetricMatrix, triangularMatrix, diagonalMatrix.

---

graph-sparseMatrix

Conversions "graph" <- (sparse) Matrix

Description

The Matrix package has supported conversion from and to "graph" objects from (Bioconductor) package graph since summer 2005, via the usual as(.,
"<class>") coercion,

as(from, Class)

Since 2013, this functionality is further exposed as the graph2T() and T2graph() functions (with further arguments than just from), which convert graphs to and from the triplet form of sparse matrices (of class "TsparseMatrix").

Usage

graph2T(from, use.weights = )
T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)
Arguments

from for `graph2T()` an `R` object of class "graph";
for `T2graph()`, a sparse matrix inheriting from "TsparseMatrix".
use.weights logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class `dgTMatrix`; otherwise the result will be `ngTMatrix` or `nsTMatrix`, the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used.
need.uniq a logical indicating if `from` may need to be internally “uniqified”; do not set this and hence rather use the default, unless you know what you are doing!
edgemode one of `NULL`, "directed", or "undirected". The default `NULL` looks if the matrix is symmetric and assumes "undirected" in that case.

Value

For `graph2T()`, a sparse matrix inheriting from "TsparseMatrix".
For `T2graph()` an `R` object of class "graph".

See Also

Note that the CRAN package `igraph` also provides conversions from and to sparse matrices (of package `Matrix`) via its `graph.adjacency()` and `get.adjacency()`.

Examples

```r
if(isTRUE(try(require(graph)))) {  ## super careful .. for "checking reasons"
  n4 <- LETTERS[1:4]; dns <- list(n4,n4)
  show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
  show(g1 <- as(a1, "graph")) # directed
  unlist(edgeWeights(g1)) # all '2'

  show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
  show(g2 <- as(a2, "graph")) # directed
  # now if you want it undirected:
  show(g3 <- T2graph(as(a2,"TsparseMatrix"), edgemode="undirected"))
  show(m3 <- as(g3,"Matrix"))
  show( graph2T(g3) ) # a "pattern Matrix" (nsTMatrix)

  a. <- sparseMatrix(i= 4:1, j=1:4, dimnames=list(n4,n4), giveC=FALSE) # no 'x'
  show(a.) # "ngTMatrix"
  show(g. <- as(a., "graph"))
}
```

Hilbert

Generate a Hilbert matrix

Description

Generate the n by n symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large n, they are often used for testing numerical linear algebra code.
Usage
Hilbert(n)

Arguments
n  a non-negative integer.

Value
the n by n symmetric Hilbert matrix as a "dpoMatrix" object.

See Also
the class dpoMatrix

Examples
Hilbert(6)

Methods for function image in package Matrix. An image of a matrix simply color codes all matrix entries and draws the \( n \times m \) matrix using an \( n \times m \) grid of (colored) rectangles.

The Matrix package image methods are based on levelplot() from package lattice; hence these methods return an "object" of class "trellis", producing a graphic when (auto-) print()ed.

Usage
## S4 method for signature 'dgTMatrix'
image(x,  
xlim = c(1, di[2]),  
ylim = c(di[1], 1), aspect = "iso",  
sub = sprintf("Dimensions: %d x %d", di[1], di[2]),  
xlab = "Column", ylab = "Row", cuts = 15,  
useRaster = FALSE,  
useAbs = NULL, colorkey = !useAbs,  
col.regions = NULL,  
lwd = NULL, border.col = NULL, ...)

Arguments
  x  a Matrix object, i.e., fulfilling is(x, "Matrix").
  xlim, ylim  x- and y-axis limits; may be used to "zoom into" matrix. Note that \( x, y \) "feel reversed": \( y \)lim is for the rows (= 1st index) and \( x \)lim for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, \( y \)lim is always used decreasingly.
  aspect  aspect ratio specified as number \((y/x)\) or string; see levelplot.
sub, xlab, ylab axis annotation with sensible defaults; see `plot.default`.
cuts number of levels the range of matrix values would be divided into.
useRaster logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, `panel.levelplot.raster` (from `lattice` package) is used, and the colorkey is also done via rasters, see also `levelplot` and possibly `grid.raster`.
Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions).
useAbs logical indicating if `abs(x)` should be shown; if TRUE, the former (implicit) default, the default `col.regions` will be grey colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.
colorkey logical indicating if a color key aka 'legend' should be produced. Default is to draw one, unless useAbs is true. You can also specify a list, see `levelplot`, such as list(raster=TRUE) in the case of rastering.
col.regions vector of gradually varying colors; see `levelplot`.
lwd (only used when useRaster is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by `grid.rect`). The default depends on the matrix dimension and the device size.
border.col color for the border of each rectangle. NA means no border is drawn. When NULL as by default, `border.col < - if(lwd < .01) NA else NULL` is used. Consider using an opaque color instead of NULL which corresponds to `grid::get.gpar("col")`.
...
... further arguments passed to methods and `levelplot`, notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseding cuts above).

Value

as all `lattice` graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

Methods

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

See Also

`levelplot`, and `print.trellis` from package `lattice`.

Examples

```r
showMethods(image)  # If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE")
```
cCA <- Cholesky(crossprod(CAex), Imult = .01)

## See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)"),
      split=(x=1,y=1, nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE),
      split=(x=2,y=1, nx=2, ny=1))

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
  # how the result looks, may depend heavily on
  # the device, screen resolution, antialiasing etc
  # e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
  # again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5 )
image(USCounties, c(1,300), c(1,200), lwd=.01)
## These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2), all.equal(I2, I3))
## using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyblue", 1/2))

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) ||
   identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))) {
  ## Using raster graphics: For PDF this would give a 77 MB file,
  ## however, for such a large matrix, this is typically considerably
  ## slower* (than vector graphics rectangles) in most cases :
  if(doPNG <- !dev.interactive())
    png("image-USCounties-raster.png", width=3200, height=3200)
  image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
  if(doPNG)
    dev.off()
  ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)

---

## index-class

Virtual Class "index" - Simple Class for Matrix Indices

### Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of Matrix matrices.

In fact, it is currently implemented as a simple class union (setClassUnion) of "numeric", "logical" and "character".

### Objects from the Class

Since it is a virtual Class, no objects may be created from it.
See Also
- `methods`, and
  `Subassign-methods`, also for examples.

Examples

```r
showClass("index")
```

---

### Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or “sampling rows with replacement”, and is implemented that way in the Matrix package, see the 'Details' below.

### Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting columns.) The crossproduct of an index matrix \( M \) with itself is a diagonal matrix with the number of entries in each column of \( M \) on the diagonal, i.e., \( M'M = \text{Diagonal}(x=\text{table}(M@\text{perm})) \).

Permutation matrices (of class \( \text{pMatrix} \)) are special cases of index matrices: They are square, of dimension, say, \( n \times n \), and their index vectors contain exactly all of \( 1:n \).

While “row-indexing” (of more than one row or using \( \text{drop}=\text{FALSE} \)) stays within the "indMatrix" class, all other subsetting/indexing operations (“column-indexing”, including \( \text{diag} \)) on "indMatrix" objects treats them as nonzero-pattern matrices ("ngTMatrix" specifically), such that non-matrix subsetting results in logical vectors. Sub-assignment (\( M[i,j] <- v \)) is not sensible and hence an error for these matrices.

### Objects from the Class

Objects can be created by calls of the form `new("indMatrix",...)` or by coercion from an integer index vector, see below.

### Slots

- **perm**: An integer, 1-based index vector, i.e. an integer vector of length \( \text{Dim}[1] \) whose elements are taken from \( 1:\text{Dim}[2] \).
- **Dim**: integer vector of length two. In some applications, the matrix will be skinny, i.e., with at least as many rows as columns.
- **Dimnames**: a list of length two where each component is either \( \text{NULL} \) or a character vector of length equal to the corresponding Dim element.
Extends

Class "sparseMatrix" and "generalMatrix", directly.

Methods

%*% signature(x = "matrix", y = "indMatrix") and other signatures (use showMethods("%*%", class="indMatrix")):

coerce signature(from = "integer", to = "indMatrix"): This enables typical "indMatrix" construction, given an index vector from elements in 1:D[2], see the first example.

coerce signature(from = "numeric", to = "indMatrix"): A user convenience, to allow as(perm, "indMatrix") for numeric perm with integer values.

coerce signature(from = "list", to = "indMatrix"): The list must have two (integer-valued) entries: the first giving the index vector with elements in 1:D[2], the second giving D[2]. This allows "indMatrix" construction for cases in which the values represented by the right-most column(s) are not associated with any observations, i.e., in which the index does not contain values D[2], D[2]-1, D[2]-2,...

coerce signature(from = "indMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE matrix of mode logical.

coerce signature(from = "indMatrix", to = "ngTMatrix"): coercion to sparse logical matrix of class ngTMatrix.

t signature(x = "indMatrix"): return the transpose of the index matrix (which is no longer an indMatrix, but of class ngTMatrix).

colSums, colMeans, rowSums, rowMeans signature(x = "indMatrix"): return the column or row sums or means.

rbind2 signature(x = "indMatrix", y = "indMatrix"): a fast method for rowwise catenation of two index matrices (with the same number of columns).

kronecker signature(X = "indMatrix", Y = "indMatrix"): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

Author(s)

Fabian Scheipl, Uni Muenchen, building on existing "pMatrix", after a nice hike's conversation with Martin Maechler; diverse tweaks by the latter. The crossprod(x, y) and kronecker(x, y) methods when both arguments are "indMatrix" have been made considerably faster thanks to a suggestion by Boris Vaillant.

See Also

The permutation matrices pMatrix are special index matrices. The “pattern” matrices, nMatrix and its subclasses.

Examples

pl <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == pl[rep(1:3, each=3),]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(pl[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
### invPerm

**Inverse Permutation Vector**

#### Description

From a permutation vector \( p \), compute its *inverse* permutation vector.

#### Usage

```r
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

#### Arguments

- \( p \) an integer vector of length, say, \( n \).
- \( \text{zero.p} \) logical indicating if \( p \) contains values \( 0: (n-1) \) or rather (by default, \( \text{zero.p} = \text{FALSE} \)) \( 1: n \).
- \( \text{zero.res} \) logical indicating if the result should contain values \( 0: (n-1) \) or rather (by default, \( \text{zero.res} = \text{FALSE} \)) \( 1: n \).

#### Value

an integer vector of the same length \( (n) \) as \( p \). By default, \( \text{zero.p} = \text{FALSE}, \text{zero.res} = \text{FALSE} \), \( \text{invPerm(p)} \) is the same as \( \text{order(p)} \) or \( \text{sort.list(p)} \) and for that case, the function is equivalent to \( \text{invPerm.} \) \(<\text{function(p) \{ p[p] <- seq_along(p) ; p \}}\).
is.na-methods

Author(s)

Martin Maechler

See Also

the class of permutation matrices, pMatrix.

Examples

```r
p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
## they are indeed inverse of each other:
stopifnot(
  identical(p[ip], 1:10),
  identical(ip[p], 1:10),
  identical(invPerm(ip), p)
)
```

Description

Methods for function is.na(), is.finite(), and is.infinite() for all Matrices (objects extending the Matrix class):

- `x = "denseMatrix"` returns a "nMatrix" object of same dimension as x, with TRUE’s whenever x is NA, finite, or infinite, respectively.
- `x = "sparseMatrix"` ditto.

Usage

```r
## S4 method for signature 'sparseMatrix'
is.na(x)
## S4 method for signature 'dsparseMatrix'
is.finite(x)
## S4 method for signature 'ddenseMatrix'
is.infinite(x)
## ...
## and for other classes

## S4 method for signature 'xMatrix'
anyNA(x)
## S4 method for signature 'nsparseMatrix'
anyNA(x)
## S4 method for signature 'sparseVector'
anyNA(x)
## S4 method for signature 'nsparseVector'
anyNA(x)
```
is.null.DN

Arguments

x    sparse or dense matrix or sparse vector (here; any R object in general).

See Also

NA, is.na; is.finite, is.infinite; nMatrix, denseMatrix, sparseMatrix.

The sparseVector class.

Examples

M <- Matrix(1:6, nrow=4, ncol=3,
            dimnames = list(c("a", "b", "c", "d"), c("A", "B", "C")))
stopifnot(all(!is.na(M)))
M[2:3,2] <- NA
is.na(M)
if(exists("anyNA", mode="function"))
  anyNA(M)

A <- spMatrix(10,20, i = c(1,3:8),
              j = c(2,9,6:10),
              x = 7 * (1:7))
stopifnot(all(!is.na(A)))
inA <- is.na(A)
stopifnot(sum(inA) == 1+1+5)

Description

Are the Dimnames dn NULL-like?

is.null.DN(dn) is less strict than is.null(dn), because it is also true (TRUE) when the dim-
names dn are "like" NULL, or llist(NULL,NULL), as they can easily be for the traditional R matrices
(matrix) which have no formal class definition, and hence much freedom in how their dimnames
look like.

Usage

is.null.DN(dn)

Arguments

dn    dimnames() of a matrix-like R object.

Value

logical TRUE or FALSE.
Note

This function is really to be used on “traditional” matrices rather than those inheriting from `Matrix`, as the latter will always have dimnames `list(NULL,NULL)` exactly, in such a case.

Author(s)

Martin Maechler

See Also

`is.null`, `dimnames`, `matrix`.

Examples

```r
m <- matrix(round(100 * rnorm(6)), 2,3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)

m4        ## prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
          identical(capture.output(m) -> cm,
                     capture.output(m1)),
          identical(cm, capture.output(m2)),
          identical(cm, capture.output(m3)),
          identical(cm, capture.output(m4)))
```

isSymmetric-methods

Methods for Function `isSymmetric` in Package ‘Matrix’

Description

`isSymmetric(M)` returns a logical indicating if `M` is a symmetric matrix. This (now) is a base function with a default method for the traditional matrices of class "matrix". Methods here are defined for virtual Matrix classes such that it works for all objects inheriting from class `Matrix`.

See Also

`forceSymmetric`, `symmpart`, and the formal class (and subclasses) "symmetricMatrix".

Examples

```r
isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

## Look at implementations:
showMethods("isSymmetric", includeDefs=TRUE)#"ANY": base's S3 generic; 6 more
```
isTriangular

isTriangular() and isDiagonal() Methods

Description

isTriangular(M) returns a logical indicating if M is a triangular matrix. Analogously, isDiagonal(M) is true iff M is a diagonal matrix.

Contrary to isSymmetric(), these two functions are generically from package Matrix, and hence also define methods for traditional (class "matrix") matrices.

By our definition, triangular, diagonal and symmetric matrices are all square, i.e. have the same number of rows and columns.

Usage

isDiagonal(object)

isTriangular(object, upper = NA, ...)

Arguments

object any R object, typically a matrix (traditional or Matrix package).
upper logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE.
...

potentially further arguments for other methods.

Value

a ("scalar") logical, TRUE or FALSE, never NA. For isTriangular(), if the result is TRUE, it may contain an attribute (see attributes "kind", either "L" or "U" indicating if it is a lower or upper triangular matrix.

See Also

isSymmetric; formal class (and subclasses) "triangularMatrix" and "diagonalMatrix".

Examples

isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular

(M <- Matrix(c(1,2,0,1), 2,2))

isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")

isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"

isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE
Khatri-Rao Matrix Product

Description

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

Usage

KhatriRao(X, Y = X, FUN = "*", make.dimnames = FALSE)

Arguments

X, Y matrices of with the same number of columns.
FUN the (name of the) function to be used for the column-wise Kronecker products, see kronecker, defaulting to the usual multiplication.
make.dimnames logical indicating if the result should inherit dimnames from X and Y in a simple way.

Value

a "CsparseMatrix", say R, the Khatri-Rao product of X (n × k) and Y (m × k), is of dimension (n · m) × k, where the j-th column, R[,j] is the kronecker product kronecker(X[,j],Y[,j]).

Note

The current implementation is efficient for large sparse matrices.

Author(s)

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

References

See Also

kronecker.
## Example with very small matrices:

```r
m <- matrix(1:12, 3, 4)
d <- diag(1:4)
KhatriRao(m, d)
KhatriRao(d, m)
dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatriRao(m, d, make.dimnames=TRUE)
KhatriRao(d, m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatriRao(m, d, make.dimnames=TRUE)
KhatriRao(d, m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("d", 10*1:4), paste0("D", 1:4))
(Kmd <- KhatriRao(m, d, make.dimnames=TRUE))
(Kdm <- KhatriRao(d, m, make.dimnames=TRUE))

dm <- as(m, "nMatrix")
nd <- as(d, "nMatrix")
KhatriRao(dm, nd, make.dimnames=TRUE)
KhatriRao(nd, dm, make.dimnames=TRUE)

stopifnot(dim(KhatriRao(m, d)) == c(nrow(m)*nrow(d), ncol(d)))
```

## border cases / checks:

```r
zm <- nm; zm[] <- 0 # all 0 matrix
stopifnot(all(K1 <- KhatriRao(nd, zm) == 0), identical(dim(K1), c(12L, 4L)),
          all(K2 <- KhatriRao(zm, nd) == 0), identical(dim(K2), c(12L, 4L)))
d0 <- d; d0[] <- 0; m0 <- Matrix(d0[-1,])
stopifnot(all(K3 <- KhatriRao(d0, m) == 0), identical(dim(K3), dim(Kdm)),
          all(K4 <- KhatriRao(m, d0) == 0), identical(dim(K4), dim(Kmd)),
          all(KhatriRao(d0, d0) == 0), all(KhatriRao(m0, d0) == 0),
          all(KhatriRao(d0, m0) == 0), all(KhatriRao(m0, m0) == 0),
          identical(dimnames(KhatriRao(m, d0, make.dimnames=TRUE)), dimnames(Kmd)))
```

### Description

A model matrix `mm` and corresponding response vector `y` used in an example by Koenker and Ng. The matrix `mm` is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector `y` is just `numeric` of length 1850.

### Usage

```r
data(KNEx)
```

### References

Examples

data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time(  # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y)))))

head(round(sparse.sol,3))

## Compare with QR-based solution ("more accurate, but slightly slower"):

system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y) ))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE

kronecker-methods  Methods for Function 'kronecker()' in Package 'Matrix'

Description

Computes Kronecker products for objects inheriting from "Matrix".

In order to preserve sparseness, we treat $0 \times NA$ as $0$, not as NA as usually in R (and as used for the base function kronecker).

Methods

kronecker signature(X = "Matrix", Y = "ANY")
kronecker signature(X = "ANY", Y = "Matrix")
kronecker signature(X = "diagonalMatrix", Y = "ANY")
kronecker signature(X = "sparseMatrix", Y = "ANY")
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix")
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix")
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix")
kronecker signature(X = "indMatrix", Y = "indMatrix")

Examples

(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "ntCMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix") # (lost "t"riangularity)
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dtTMatrix" i.e. did keep
ldenseMatrix-class

Virtual Class "ldenseMatrix" of Dense Logical Matrices

Description

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

x: logical vector containing the entries of the matrix.
Dim, Dimnames: see Matrix.

Extends

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

Methods

coerce signature(from = "matrix", to = "ldenseMatrix"):
coerce signature(from = "ldenseMatrix", to = "matrix"):
as.vector signature(x = "ldenseMatrix", mode = "missing"):
which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x, arr.ind): for details, see the lMatrix class documentation.

See Also

Class lgeMatrix and the other subclasses.

Examples

showClass("ldenseMatrix")
as(diag(3) > 0, "ldenseMatrix")
lgeMatrix-class

Class "lgeMatrix" of General Dense Logical Matrices

Description

This is the class of general dense logical matrices.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Examples

(lM <- Diagonal(x = c(TRUE, FALSE, FALSE)))
str(lM)# gory details (slots)
crossprod(lM) # numeric
(nM <- as(lM, "nMatrix"))# -> sparse (not formally `diagonal`) crossprod(nM) # logical sparse
Extend

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

Methods

Currently, mainly \( t() \) and coercion methods (for \( \text{as}(.) \)); use, e.g., \( \text{showMethods}(\text{class}="lgeMatrix") \) for details.

See Also

Non-general logical dense matrix classes such as \( \text{ltrMatrix} \), or \( \text{lsyMatrix} \): sparse logical classes such as \( \text{lgCMatrix} \).

Examples

\begin{verbatim}
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgCMatrix
as(lM, "lgCMatrix")
\end{verbatim}

lsparseMatrix-classes Sparse logical matrices

Description

The \texttt{lsparseMatrix} class is a virtual class of sparse matrices with TRUE/FALSE or NA entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (class \texttt{TsparseMatrix}, subclasses \texttt{lgTMatrix}, \texttt{lsTMatrix}, and \texttt{ltTMatrix}) or in compressed column-oriented form (class \texttt{CsparseMatrix}, subclasses \texttt{lgCMatrix}, \texttt{lsCMatrix}, and \texttt{ltCMatrix}) or--rarely--in compressed row-oriented form (class \texttt{RsparseMatrix}, subclasses \texttt{lgRMatrix}, \texttt{lsRMatrix}, and \texttt{ltRMatrix}).

The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

Details

Note that triplet stored (\texttt{TsparseMatrix}) matrices such as \texttt{lgTMatrix} may contain duplicated pairs of indices \( (i,j) \) as for the corresponding numeric class \texttt{dgTMatrix} where for such pairs, the corresponding \text{X} slot entries are added. For logical matrices, the \text{X} entries corresponding to duplicated index pairs \( (i,j) \) are “added” as well if the addition is defined as logical or, i.e., “TRUE + TRUE \( \rightarrow \) TRUE” and “TRUE + FALSE \( \rightarrow \) TRUE”. Note the use of \texttt{uniqT sparse\ldots} for getting an internally unique representation without duplicated \( (i,j) \) entries.
Objects from the Class

Objects can be created by calls of the form `new("lgCMatrix","...`) and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

Slots

- `x`: Object of class "logical", i.e., either `TRUE`, `NA`, or `FALSE`.
- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- `p`: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- `i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- `j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.
- `Dim`: Object of class "integer" - the dimensions of the matrix.

Methods

- `coerce` signature(from = "dgCMatrix",to = "lgCMatrix")
- `t` signature(x = "lgCMatrix"): returns the transpose of `x`
- `which` signature(x = "lsparseMatrix"), semantically equivalent to base function `which(x,arr.ind)`; for details, see the `IMatrix` class documentation.

the class `dgCMatrix` and `dgTMatrix`

Examples

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
           identical(!lm, m <= 1))
```

data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1)# "lgC..."
```
```
## from logical to nz_pattern -- okay when there are no NA's:

```r
nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
```

## from logical to "double"

```r
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included
```

```r
stopifnot(identical(nmG.1, as((KNex $ mm) != 0,"nMatrix")),
  validObject(lmG.1), all(lmG.1@x),
  # same "logical" but lmG.1 has no 'FALSE' in x slot:
  all(lmG.1 == mmG.1))
```

class(xnx <- crossprod(nmG.1))# "nsC.."
class(xlx <- crossprod(mmG.1))# "dsC.." : numeric

```r
is0 <- (xlx == 0)
mean(as.vector(is0))# 99.3% zeros: quite sparse, but
```

table(xlx@x == 0)# more than half of the entries are (non-structural!) 0

```r
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
  # compare xnx and xlx: have the *same* non-structural 0s:
  sapply(slotNames(xnx),
    function(n) identical(slot(xnx, n), slot(xlx, n))))
```

---

**lsyMatrix-class**  
**Symmetric Dense Logical Matrices**

### Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

### Objects from the Class

Objects can be created by calls of the form `new("lsyMatrix",...)`.

### Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

### Extends

Both extend classes "ldenseMatrix" and "symmetricMatrix", directly; further, class "Matrix" and others, indirectly. Use `showClass("lsyMatrix")`, e.g., for details.

### Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="dsyMatrix")` for details.
ltrMatrix-class

Triangular Dense Logical Matrices

Description

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltpMatrix" class is the same except in packed storage.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Both extend classes "ldenseMatrix" and "triangularMatrix", directly; further, class "Matrix", "lMatrix" and others, indirectly. Use showClass("ltrMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as()); use, e.g., showMethods(class="ltpMatrix") for details.

See Also

Classes lgeMatrix, Matrix; function t
Examples

showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(,4,4)), "ltrMatrix"))
str(lutp <- as(lutr, "ltpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!lutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(lutp, as(!lutp, "ltpMatrix")))

lu  (Generalized) Triangular Decomposition of a Matrix

Description

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

Usage

lu(x, ...)
## S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1,
   keep.dimnames = TRUE, ...)

Arguments

x     a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.
warnSing (when x is a "denseMatrix") logical specifying if a warning should be signalled when x is singular.
errSing (when x is a "sparseMatrix") logical specifying if an error (see stop) should be signalled when x is singular. When x is singular, lu(x,errSing=FALSE) returns NA instead of an LU decomposition. No warning is signalled and the useR should be careful in that case.
order logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.
tol positive number indicating the pivoting tolerance used in cs_lu. Do only change with much care.
keep.dimnames logical indicating that dimnames should be propagated to the result, i.e., “kept”. This was hardcoded to FALSE in upto Matrix version 1.2-0. Setting to FALSE may gain some performance.
...
    further arguments passed to or from other methods.
Details

lu() is a generic function with special methods for different types of matrices. Use showMethods("lu") to list all the methods for the lu generic.

The method for class dgeMatrix (and all dense matrices) is based on LAPACK’s "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class dgCMatrix (and all sparse matrices) is based on functions from the CSparse library. It signals an error (or returns NA, when errSing = FALSE, see above) when the decomposition algorithm fails, as when x is (too close to) singular.

Value

An object of class "LU", i.e., "denseLU" (see its separate help page), or "sparseLU", see sparseLU; this is a representation of a triangular decomposition of x.

Note

Because the underlying algorithm differ entirely, in the dense case (class denseLU), the decomposition is

\[ A = PLU, \]

where as in the sparse case (class sparseLU), it is

\[ A = P'LUQ. \]

Examples

```r
##--- Dense -------------------------
x <- Matrix(rnorm(9), 3, 3)
lu(x)
dim(x2 <- round(10 * x[,,-3])) # non-square
expand(lu2 <- lu(x2))
##--- Sparse (see more in "sparseLU-class")----- % ./sparseLU-class.Rd

pm <- as(readMM(system.file("external/pores_1.mtx", package = "Matrix"),
    "CsparseMatrix"),
"CsparseMatrix")
str(pmLU <- lu(pm)) # p is a 0-based permutation of the rows
# q is a 0-based permutation of the columns
ppm <- pm[pmLU@p + 1L, pmLU@q + 1L]
pLU <- drop0(pmLU@L %*% pmLU@U) # L %*% U -- dropping extra zeros
## equal up to "rounding"
```
LU-class

LU-class

LU (dense) Matrix Decompositions

Description

The "LU" class is the virtual class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

Details

The decomposition is of the form

\[ A = PLU \]

where typically all matrices are of size \( n \times n \), and the matrix \( P \) is a permutation matrix, \( L \) is lower triangular and \( U \) is upper triangular (both of class \( \text{dtrMatrix} \)).

Note that the dense decomposition is also implemented for a \( m \times n \) matrix \( A \), when \( m \neq n \).

If \( m < n \) ("wide case"), \( U \) is \( m \times n \), and hence not triangular.
If \( m > n \) ("long case"), \( L \) is \( m \times n \), and hence not triangular.

Objects from the Class

Objects can be created by calls of the form \texttt{new("denseLU",...)}\texttt{.} More commonly the objects are created explicitly from calls of the form \texttt{lu(mm)} where \( mm \) is an object that inherits from the "\text{dgeMatrix}" class or as a side-effect of other functions applied to "\text{dgeMatrix}" objects.

Extends

"LU" directly extends the virtual class "\text{MatrixFactorization}".
"denseLU" directly extends "LU".

Slots

\( x \): object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can retrieved by the \texttt{expand()} method, see below.

\( perm \): Object of class "\text{integer}" - a vector of length \( \min(\text{Dim}) \) that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.

\( \text{Dim} \): the dimension of the original matrix; inherited from class \text{MatrixFactorization}.

Methods

\texttt{expand} signature(x = "denseLU")\texttt{:} Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

\texttt{solve} signature(a = "denseLU", b = "missing")\texttt{:} Compute the inverse of \( A \), \( A^{-1} \), solve\texttt{(A)} using the LU decomposition, see also \texttt{solve-methods}. 

ppm[1:14, 1:5]
pLU[1:14, 1:5]
Matrix

Construct a Classed Matrix

Description

Construct a Matrix of a class that inherits from Matrix.

Usage

Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
sparse = NULL, doDiag = TRUE, forceCheck = FALSE)

Arguments

data an optional numeric data vector or matrix.
nrow when data is not a matrix, the desired number of rows
ncol when data is not a matrix, the desired number of columns
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
dimnames a dimnames attribute for the matrix: a list of two character components. They are set if not NULL (as per default).
sparse logical or NULL, specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0. Note that when the resulting matrix is diagonal ("mathematically"), sparse=FALSE results in a diagonalMatrix, unless doDiag=FALSE as well, see the first examples.
doDiag only when sparse = FALSE, logical indicating if a diagonalMatrix object should be considered (default). Otherwise, in such a case, a dense (symmetric) matrix will be returned.
forceCheck logical indicating if the checks for structure should even happen when data is already a "Matrix" object.

See Also

class sparseLU for LU decompositions of sparse matrices; further, class dgeMatrix and functions lu, expand.

Examples

set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
str(lum <- lu(mm))
elu <- expand(lum)
elu # three components: "L", "U", and "P", the permutation
elu$L %*% elu$U
(m2 <- with(elu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"), as(m2, "matrix")))
Details

If either of nrow or ncol is not given, an attempt is made to infer it from the length of data and the
other parameter. Further, Matrix() makes efforts to keep logical matrices logical, i.e., inheriting
from class lMatrix, and to determine specially structured matrices such as symmetric, triangular
or diagonal ones. Note that a symmetric matrix also needs symmetric dimnames, e.g., by specifying
dimnames = list(NULL,NULL), see the examples.

Most of the time, the function works via a traditional (full) matrix. However,
Matrix(0,nrow,ncol) directly constructs an “empty” sparseMatrix, as does Matrix(FALSE,*,
sparsesparse=FALSE).

Although it is sometime possible to mix unclassed matrices (created with matrix) with ones of
class "Matrix", it is much safer to always use carefully constructed ones of class "Matrix".

Value

Returns matrix of a class that inherits from "Matrix". Only if data is not a matrix and does not
already inherit from class Matrix are the arguments nrow, ncol and byrow made use of.

See Also

The classes Matrix, symmetricMatrix, triangularMatrix, and diagonalMatrix; further,
matrix.

Special matrices can be constructed, e.g., via sparseMatrix (sparse), bdiag (block-diagonal),
bdiagSparse (banded sparse), or Diagonal.

Examples

Matrix(0, 3, 2)   # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE)# -> 'dense'
Matrix(0, 2, 2, sparse=FALSE)# diagonal !
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE)# -> dense
Matrix(1:6, 3, 2)  # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)
Matrix(diag(4) > 0)# -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE)# -> sparse...
Matrix(diag(4) >= 0)# -> "lsyMatrix" (of all 'TRUE')
## triangular
l3 <- upper.tri(matrix(1,3,3))
(M <- Matrix(l3))  # -> "ltCMatrix"
Matrix(! l3)# -> "ltrMatrix"
as(l3, "CsparseMatrix")
Matrix(1:9, nrow=3,
dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3)))# identity, i.e., unit "diagonalMatrix"
str(I3) # note the empty 'x' slot
(A <- cbind(a=c(2,1), b=1:2))# symmetric *apart* from dimnames
Matrix(A)  # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL,NULL)))# -> symmetric
stopifnot(is(As, "symmetricMatrix"),
is(Matrix(0, 3,3), "sparseMatrix"),
is(Matrix(FALSE, 1,1), "sparseMatrix"))
Matrix-class

Virtual Class "Matrix" Class of Matrices

Description

The Matrix class is a class contained by all actual classes in the Matrix package. It is a “virtual” class.

Slots

Common to all matrix objects in the package:

- Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

Methods

determinant signature(x = "Matrix", logarithm = "missing"): and
determinant signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that det also works for all our matrices, calling the appropriate determinant() method. The Matrix::det is an exact copy of base::det, but in the correct namespace, and hence calling the S4-aware version of determinant().

diff signature(x = "Matrix"): As diff() for traditional matrices, i.e., applying diff() to each column.

dim signature(x = "Matrix"): extract matrix dimensions dim.

dim<- signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to reshape Matrix objects, but only when prod(value) == prod(dim(x)).

dimnames signature(x = "Matrix"): extract dimnames.

dimnames<- signature(x = "Matrix", value = "list"): set the dimnames to a list of length 2, see dimnames<-

length signature(x = "Matrix"): simply defined as prod(dim(x)) (and hence of mode "double").

show signature(object = "Matrix"): show method for printing. For printing sparse matrices, see printSpMatrix.

image signature(object = "Matrix"): draws an image of the matrix entries, using levelplot() from package lattice.

head signature(object = "Matrix"): return only the “head”, i.e., the first few rows.

tail signature(object = "Matrix"): return only the “tail”, i.e., the last few rows of the respective matrix.

as.matrix, as.array signature(x = "Matrix"): the same as as(x,"matrix"); see also the note below.

as.vector signature(x = "Matrix", mode = "missing"): as.vector(m) should be identical to as.vector(as(m,"matrix")), implemented more efficiently for some subclasses.
as(x, "vector"), as(x, "numeric") etc. similarly.

coerce signature(from = "ANY", to = "Matrix"): This relies on a correct as.matrix() method for from.

There are many more methods that (conceptually) should work for all "Matrix" objects, e.g., 
colSums, rowMeans. Even base functions may work automatically (if they first call as.matrix() on their principal argument), e.g., apply, eigen, svd or kappa all do work via coercion to a "traditional" (dense) matrix.

Note

Loading the Matrix namespace “overloads” as.matrix and as.array in the base namespace by the equivalent of function(x) as(x,"matrix"). Consequently, as.matrix(m) or as.array(m) will properly work when m inherits from the "Matrix" class — also for functions in package base and other packages. E.g., apply or outer can therefore be applied to "Matrix" matrices.

Examples

slotNames("Matrix")

c1 <- getClass("Matrix")
names(c1@subclasses) # more than 40 ..

showClass("Matrix") #> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cy <- M[1:4,] + 10*Diagonal(4)
diff(M)
## can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
  all.equal(det(cm),
  determinant(as(cm,"matrix"), log=FALSE)$modulus,
  check.attributes=FALSE))
The basic matrix product, `%*%` is implemented for all our `Matrix` and also for `sparseVector` classes, fully analogously to R’s base matrix and vector objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing t(.)’s unnecessarily. They also return `symmetricMatrix` classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

tcrossprod() takes the cross-product of the transpose of a matrix. tcrossprod(x) is formally equivalent to, but faster than, the call x `%*%` t(x), and so is tcrossprod(x, y) instead of x `%*%` t(y).

**Boolean** matrix products are computed via either `%&%` or boolArith = TRUE.

For some classes in the Matrix package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith` = TRUE for regular (“non cross”) matrix products, `%*%` cannot be specified. Instead, we provide the `%&%` operator for boolean matrix products.

A `Matrix` object, in the one argument case of an appropriate `symmetric` matrix class, i.e., inheriting from `symmetricMatrix`. 
Methods

%*% signature(x = "dgeMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see showMethods("%*%", class = "dgeMatrix").

%*% signature(x = "dtrMatrix", y = "matrix") and other signatures (use showMethods("%*%", class = "dtrMatrix"): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class triangular-Matrix).

crossprod signature(x = "dgeMatrix", y = "dgeMatrix"): ditto for several other signatures, use showMethods("crossprod", class = "dgeMatrix"), matrix crossproduct, an efficient version of t(x) %*% y.

crossprod signature(x = "CsparseMatrix", y = "missing") returns t(x) %*% x as an dsCMatrix object.

crossprod signature(x = "TsparseMatrix", y = "missing") returns t(x) %*% x as an dsCMatrix object.

crossprod,tcrossprod signature(x = "dtrMatrix", y = "matrix") and other signatures, see "%*%" above.

Note

boolArith = TRUE, FALSE or NA has been newly introduced for Matrix 1.2.0 (March 2015). Its implementation may be incomplete and partly missing. Please report such omissions if detected!

Currently, boolArith = TRUE is implemented via CsparseMatrix coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

MatrixClass

The Matrix (Super-) Class of a Class

Description

Return the (maybe super-)class of class cl from package Matrix, returning character(0) if there is none.

Usage

MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE, dropVirtual = TRUE, ...)

Arguments

cl string, class name

cld its class definition

...Matrix logical indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind.

dropVirtual logical indicating if virtual classes are included or not.

... further arguments are passed to .selectSuperClasses().

Value

a character string

Author(s)

Martin Maechler, 24 Mar 2009

See Also

Matrix, the mother of all Matrix classes.

Examples

mkA <- setClass("A", contains="dgCMatrix")
(A <- mkA())
stopifnot(identical(
   MatrixClass("A"),
   "dgCMatrix"))
MatrixFactorization-class

Class "MatrixFactorization" of Matrix Factorizations

Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package Matrix.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from Matrix (and trivial sub class of "MatrixFactorization").

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

Dim: Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

Methods

dim (x) simply returns x@Dim, see above.

expand signature(x = "MatrixFactorization"): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original Matrix object.

show signature(object = "MatrixFactorization"): simple printing, see show.

solve signature(a = "MatrixFactorization", b = .): solve $Ax = b$ for $x$; see solve-methods.

See Also

classes inheriting from "MatrixFactorization", such as LU, Cholesky, CHMfactor, and sparseQR.

Examples

showClass("MatrixFactorization")
getClass("CholeskyFactorization")
Virtual Class "ndenseMatrix" of Dense Logical Matrices

Description

ndenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

x: logical vector containing the entries of the matrix.
Dim, Dimnames: see Matrix.

Extends

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix". Class "Matrix", by class "denseMatrix".

Methods

%*% signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
%*% signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
coerce signature(from = "matrix", to = "ndenseMatrix"): ...
coerce signature(from = "ndenseMatrix", to = "matrix"): ...
crossprod signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
crossprod signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
as.vector signature(x = "ndenseMatrix", mode = "missing"): ...
diag signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic diag().
which signature(x = "ndenseMatrix"). semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

See Also

Class ngeMatrix and the other subclasses.

Examples

showClass("ndenseMatrix")
as(diag(3) > 0, "ndenseMatrix") # -> "nge"
nearPD

Nearest Positive Definite Matrix

Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

Usage

nearPD(x, corr = FALSE, keepDiag = FALSE, do2eigen = TRUE, doSym = FALSE, doDykstra = TRUE, only.values = FALSE, ensureSymmetry = !isSymmetric(x), eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08, maxit = 100, conv.norm.type = "I", trace = FALSE)

Arguments

x numeric \(n \times n\) approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If \(x\) is not symmetric (and \(\text{ensureSymmetry}\) is not false), \(\text{symmpart}(x)\) is used.

corr logical indicating if the matrix should be a correlation matrix.

keepDiag logical, generalizing \(\text{corr}\): if \(\text{TRUE}\), the resulting matrix should have the same diagonal (\(\text{diag}(x)\)) as the input matrix.

do2eigen logical indicating if \(\text{posdefify()}\) eigen step should be applied to the result of the Higham algorithm.

doSym logical indicating if \(X \leftarrow (X + t(X))/2\) should be done, after \(X \leftarrow \text{tcrossprod}(Q,d,Q)\); some doubt if this is necessary.

doDykstra logical indicating if Dykstra's correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration \(Y_k = P_U(P_S(Y_{k-1}))\).

only.values logical; if \(\text{TRUE}\), the result is just the vector of eigenvalues of the approximating matrix.

ensureSymmetry logical; by default, \(\text{symmpart}(x)\) is used whenever \(\text{isSymmetric}(x)\) is not true. The user can explicitly set this to \(\text{TRUE}\) or \(\text{FALSE}\), saving the symmetry test. \textit{Beware} however that setting it \(\text{FALSE}\) for an \(\text{asymmetric input} x\), is typically nonsense!

eig.tol defines relative positiveness of eigenvalues compared to largest one, \(\lambda_1\). Eigenvalues \(\lambda_k\) are treated as if zero when \(\lambda_k/\lambda_1 \leq \text{eig.tol}\).

conv.tol convergence tolerance for Higham algorithm.

posd.tol tolerance for enforcing positive definiteness (in the final \(\text{posdefify}\) step when \(\text{do2eigen}\) is \(\text{TRUE}\)).

maxit maximum number of iterations allowed.

conv.norm.type convergence norm type (\(\text{norm}(\ast, \text{type})\)) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham's proposal.

trace logical or integer specifying if convergence monitoring should be traced.
Details

This implements the algorithm of Higham (2002), and then (if do2eigen is true) forces positive
definiteness using code from posdefify. The algorithm of Knol and ten Berge (1989) (not imple-
mented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the
matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting corr = TRUE just sets diag(.) <-1 within the algorithm.

Higham (2002) uses Dykstra’s correction, but the version by Jens Oehlschlaegel did not use it
(accidentally), and still gave reasonable results; this simplification, now only used if doDykstra =
FALSE, was active in nearPD() up to Matrix version 0.999375-40.

Value

If only.values = TRUE, a numeric vector of eigenvalues of the approximating matrix; Otherwise,
as by default, an S3 object of class "nearPD", basically a list with components

- mat: a matrix of class dpoMatrix, the computed positive-definite matrix.
- eigenvalues: numeric vector of eigenvalues of mat.
- corr: logical, just the argument corr.
- normF: the Frobenius norm (norm(x-X,"F")) of the difference between the original and
  the resulting matrix.
- iterations: number of iterations needed.
- converged: logical indicating if iterations converged.

Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

See Also

A first version of this (with non-optional corr=TRUE) has been available as nearcor(); and more
simple versions with a similar purpose posdefify(), both from package sfsmisc.

Examples

```r
# Higham(2002), p.334f - simple example
A <- matrix(1, 3,3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
stopifnot(all.equal(n.A$mat[1,2], 0.760689917),
  all.equal(n.A$normF, 0.52779033, tolerance=1e-9)
set.seed(27)
```

```r
```
```r
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(require("sfsmisc")) {
  m2 <- posdefify(m) # a simpler approach
  norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1, 0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1, 0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1, 0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1, 0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1, 0.798,
               0.826, 0.75, 0.742, 0.8, 0.798, 1),
nrow = 6, ncol = 6)
nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr)# still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.1 $ iterations # 27 / 30 !
ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF))# norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently :

norm(pr - cov2cor(ncr$mat)) # = 0.08994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805

### 3) a real data example from a 'systemfit' model (3 eq.):
/load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW)# "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV)# all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(require("sfsmisc")) {
  plot(pmax(1e-3,EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
eaxis(1); eaxis(2)
```

Class "ngeMatrix" of General Dense Nonzero-pattern Matrices

Description

This is the class of general dense nonzero-pattern matrices, see nMatrix.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="ngeMatrix") for details.

See Also

Non-general logical dense matrix classes such as ntrMatrix, or nsyMatrix; sparse logical classes such as ngCMatrix.

Examples

showClass("ngeMatrix")
## "lgeMatrix" is really more relevant
The \texttt{nMatrix} class is the virtual “mother” class of all \textit{non-zero pattern} (or simply \textit{pattern}) matrices in the \texttt{Matrix} package.

### Slots

Common to \textit{all} matrix object in the package:

- \texttt{Dim}: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

- \texttt{Dimnames}: list of length two; each component containing NULL or a \texttt{character} vector length equal the corresponding \texttt{Dim} element.

### Methods

There is a bunch of coercion methods (for \texttt{as(...)}, e.g.,

- \texttt{coerce signature(from = "matrix", to = "nMatrix")}: Note that these coercions (must) coerce \texttt{NA}s to non-zero, hence conceptually \texttt{TRUE}. This is particularly important when \texttt{sparseMatrix} objects are coerced to \texttt{nMatrix} and hence to \texttt{nsparseMatrix}.

- \texttt{coerce signature(from = "dMatrix", to = "nMatrix"), and}

- \texttt{coerce signature(from = "lMatrix", to = "nMatrix")}: For dense matrices with \texttt{NA}s, these coercions are valid since \texttt{Matrix} version 1.2.0 (still with a warning or a message if "Matrix.warn", or "Matrix.verbose" options are set.)

- \texttt{coerce signature(from = "nMatrix", to = "matrix"): ...}

- \texttt{coerce signature(from = "nMatrix", to = "dMatrix"): ...}

- \texttt{coerce signature(from = "nMatrix", to = "lMatrix"): ...}

Additional methods contain group methods, such as

- \texttt{Ops signature(e1 = "nMatrix", e2 = "....")},....

- \texttt{Arith signature(e1 = "nMatrix", e2 = "....")},....

- \texttt{Compare signature(e1 = "nMatrix", e2 = "....")},....

- \texttt{Logic signature(e1 = "nMatrix", e2 = "....")},....

- \texttt{Summary signature(x = "nMatrix","....")},....

### See Also

The classes \texttt{lMatrix}, \texttt{nsparseMatrix}, and the mother class, \texttt{Matrix}.
Examples

```r
getClass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntC*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix")# currently "ngTMatrix"
```

### nnzero

The Number of Non-Zero Values of a Matrix

**Description**

Returns the number of non-zero values of a numeric-like R object, and in particular an object x inheriting from class `Matrix`.

**Usage**

```r
nnzero(x, na.counted = NA)
```

**Arguments**

- `x`: an R object, typically inheriting from class `Matrix` or `numeric`.
- `na.counted`: a logical describing how `NA`s should be counted. There are three possible settings for `na.counted`:
  - `TRUE`: `NA`s are counted as non-zero (since “they are not zero”).
  - `NA` (default): the result will be `NA` if there are `NA`s in `x` (since “`NA`s are not known, i.e., may be zero”).
  - `FALSE`: `NA`s are omitted from `x` before the non-zero entries are counted.

For sparse matrices, you may often want to use `na.counted = TRUE`.

**Value**

the number of non zero entries in `x` (typically `integer`).

Note that for a **symmetric** sparse matrix `S` (i.e., inheriting from class `symmetricMatrix`), `nnzero(S)` is typically `twice` the `length(S@x)`.

**Methods**

- `signature(x = "ANY")`: the default method for non-`Matrix` class objects, simply counts the number of `0`s in `x`, counting NA’s depending on the `na.counted` argument, see above.
- `signature(x = "denseMatrix")`: conceptually the same as for traditional `matrix` objects, care has to be taken for "`symmetricMatrix" objects.
- `signature(x = "diagonalMatrix")`, and `signature(x = "indMatrix")`: fast simple methods for these special "`sparseMatrix" classes.
- `signature(x = "sparseMatrix")`: typically, the most interesting method, also carefully taking "`symmetricMatrix" objects into account.
See Also

The Matrix class also has a length method; typically, length(M) is much larger than nnzero(M) for a sparse matrix M, and the latter is a better indication of the size of M.
drop0, zapsmall.

Examples

m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
  nnzero(mT)
  (S <- crossprod(mT))
  nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0)) # failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
  nnzero(M) # more relevant than length
## the above are also visible from
str(M)

norm

Matrix Norms

Description

Computes a matrix norm of x, using Lapack for dense matrices. The norm can be the one ("O", or "1") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of type.

Usage

  norm(x, type, ...)

Arguments

x a real or complex matrix.

type A character indicating the type of norm desired.

"O", "o" or "1" specifies the one norm, (maximum absolute column sum);
"I" or "i" specifies the infinity norm (maximum absolute row sum);
"F" or "f" specifies the Frobenius norm (the Euclidean norm of x treated as if
  it were a vector);
"M" or "m" specifies the maximum modulus of all the elements in x; and
"2" specifies the "spectral norm" or 2-norm, which is the largest singular value
  (svd) of x.

The default is "O". Only the first character of type[1] is used.

... further arguments passed to or from other methods.
Details

For dense matrices, the methods eventually call the Lapack functions dlange, dlansy, dlantr, zlange, zlansy, and zlantr.

Value

A numeric value of class "norm", representing the quantity chosen according to type.

References

(allnorms(A) -> na)

allnorms(sA)
allnorms(tA)

stopifnot(all.equal(nA, allnorms(as(A, "matrix"))),
all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)
A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error

nsparseMatrix-classes Sparse "pattern" Matrices

Description

The nsparseMatrix class is a virtual class of sparse “pattern” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (TsparseMatrix, subclasses ngTMatrix, nsTMatrix, and ntTMatrix) which really contain pairs, not triplets) or in compressed column-oriented form (class CsparseMatrix, subclasses ngCMatrix, nsCMatrix, and ntCMatrix) or rarely in compressed
row-oriented form (class RsparseMatrix, subclasses ngRMatrix, nsRMatrix, and ntRMatrix). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

**Objects from the Class**

Objects can be created by calls of the form `new("ngCMatrix",...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

**Slots**

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- **p**: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- **i**: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- **j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- **Dim**: Object of class "integer" - the dimensions of the matrix.

**Methods**

- **coerce** signature(from = "dgCMatrix", to = "ngCMatrix"), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.
- **t** signature(x = "ngCMatrix"): returns the transpose of x
- **which** signature(x = "lsparseMatrix"). Semantically equivalent to base function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

**See Also**

the class `dgCMatrix`

**Examples**

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
## [1] 0 0 0 2 0
##      0 0 0 0 0
##      0 0 0 0 0
##      0 0 0 0 0

m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL))
## [1] 0 0 0 2 0
##      0 0 0 0 0
##      0 0 0 0 0
##      0 0 0 0 0

# extract the nonzero-pattern of (m) into an nMatrix'

nm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"

str(nm) # no 'x' slot
```
nsyMatrix-class

Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix",...).`

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim`, `Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas "nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use `showClass("nsyMatrix"), e.g., for details.

Methods

Currently, mainly `t()` and coercion methods (for `as(.);` use, e.g., `showMethods(class="dsyMatrix")` for details.
See Also

ngeMatrix, Matrix, t

Examples

(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2,2)) # logical dense (ltr)
(sM <- M2 & t(M2))    # "lge"
class(sM <- as(sM, "nMatrix")) # -> "nge"
(sM <- as(sM, "nsyMatrix")) # -> "nsy"
str (sM <- as(sM, "nspMatrix")) # -> "nsp": packed symmetric

ntrMatrix-class  Triangular Dense Logical Matrices

Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas "ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, indirectly, use showClass("nsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.); use, e.g., showMethods(class="nsyMatrix") for details.

See Also

Classes ngeMatrix, Matrix; function t
Examples

showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(,4,4), "ntrMatrix"))
str(nutp <- as(nutr, "ntpMatrix"));# packed matrix: only 10 = (4+1)*4/2 entries
!nutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(nutp, as(!nutp, "ntpMatrix")))

number-class

Class "number" of Possibly Complex Numbers

Description

The class "number" is a virtual class, currently used for vectors of eigen values which can be
"numeric" or "complex".
It is a simple class union (setClassUnion) of "numeric" and "complex".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

Examples

showClass("number")
stopifnot( is(1i, "number"), is(pi, "number"), is(1:3, "number") )

pMatrix-class

Permutation matrices

Description

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation
vectors.
Matrix (vector) multiplication with permutation matrices is equivalent to row or column permuta-
tion, and is implemented that way in the Matrix package, see the ‘Details’ below.

Details

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here
are the four different cases for an arbitrary matrix $M$ and a permutation matrix $P$ (where we assume
matching dimensions):

\[
MP = M \% \% P = M[i(p)]
\]
\[
PM = P \% \% M = M[p,]
\]
\[
P'M = \text{crossprod}(P,M) (\approx t(P) \% \% M) = M[i(p),]
\]
\[
MP' = \text{tcrossprod}(M,P) (\approx M \% \% t(P)) = M[,p]
\]
where $p$ is the “permutation vector” corresponding to the permutation matrix $P$ (see first note), and $i(p)$ is short for $\text{invPerm}(p)$.

Also one could argue that these are really only two cases if you take into account that inversion ($\text{solve}$) and transposition ($t$) are the same for permutation matrices $P$.

**Objects from the Class**

Objects can be created by calls of the form `new("pMatrix",...)` or by coercion from an integer permutation vector, see below.

**Slots**

- **perm**: An integer, 1-based permutation vector, i.e. an integer vector of length $\text{Dim}[1]$ whose elements form a permutation of $1:\text{Dim}[1]$.
- **Dim**: Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.
- **Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

**Extends**

Class "`indMatrix`", directly.

**Methods**

- `%*%` signature(x = "matrix", y = "pMatrix") and other signatures (use `showMethods("%*%",class="pMatrix")`): ...

- **coerce** signature(from = "integer", to = "pMatrix"): This is enables typical "pMatrix" construction, given a permutation vector of $1:n$, see the first example.

- **coerce** signature(from = "numeric", to = "pMatrix"): a user convenience, to allow as(perm, "pMatrix") for numeric perm with integer values.

- **coerce** signature(from = "pMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE matrix of mode logical. (in earlier version of Matrix, it resulted in a 0/1-integer matrix; logical makes slightly more sense, corresponding better to the “natural” sparseMatrix counterpart, "ngTMatrix").

- **coerce** signature(from = "pMatrix", to = "ngTMatrix"): coercion to sparse logical matrix of class `ngTMatrix`.

- **determinant** signature(x = "pMatrix", logarithm="logical"): Since permutation matrices are orthogonal, the determinant must be $+1$ or $-1$. In fact, it is exactly the sign of the permutation.

- **solve** signature(a = "pMatrix", b = "missing"): return the inverse permutation matrix; note that $\text{solve}(P)$ is identical to $t(P)$ for permutation matrices. See `solve-methods` for other methods.

- **t** signature(x = "pMatrix"): return the transpose of the permutation matrix (which is also the inverse of the permutation matrix).
Note

For every permutation matrix P, there is a corresponding permutation vector p (of indices, 1:n), and these are related by

\[ P \leftarrow \text{as}(p, \text{"pMatrix"}) \]
\[ p \leftarrow P@\text{perm} \]

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an “indMatrix”. See “indMatrix” for all other subsetting/indexing and subassignment (A[..] <-v) operations.

See Also

\texttt{invPerm}(p) computes the inverse permutation of an integer (index) vector p.

Examples

\begin{verbatim}
(pm1 <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pm1) # is the same as
solve(pm1)
pm1 %*% t(pm1) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pm1 %*% t(pm1), "matrix")),
         is.logical(as(pm1, "matrix")))

set.seed(11)
## random permutation matrix :
(p10 <- as(sample(10),"pMatrix"))

## Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))

try(as(as.integer(c(3,3,1)), "pMatrix"))# Error: not a permutation

as(pm1, "ngTMatrix")

p10[1:7, 1:4] # gives an ngTMatrix (most economic!)

## row-indexing of a <pMatrix> keeps it as an <indMatrix>:

##

\end{verbatim}

printSpMatrix

Format and Print Sparse Matrices Flexibly

Description

Format and print sparse matrices flexibly. These are the “workhorses” used by the \texttt{format}, \texttt{show} and \texttt{print} methods for sparse matrices. If \texttt{x} is large, \texttt{printSpMatrix2(x)} calls \texttt{printSpMatrix()} twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when \texttt{x} is too wide.

\texttt{printSpMatrix()} basically prints the result of \texttt{formatSpMatrix()}. 
printSpMatrix

Usage

formatSpMatrix(x, digits = NULL, maxp = 1e9,
    cld = getClassDef(class(x)), zero.print = ".",
    col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
    align = c("fancy", "right"))

printSpMatrix(x, digits = NULL, maxp = max(100L, getOption("max.print")),
    cld = getClassDef(class(x)),
    zero.print = ".", col.names, note.dropping.colnames = TRUE,
    uniDiag = TRUE, col.trailer = "",
    align = c("fancy", "right"))

printSpMatrix2(x, digits = NULL, maxp = max(100L, getOption("max.print")),
    zero.print = ".", col.names, note.dropping.colnames = TRUE,
    uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
    col.trailer = if(suppCols) "......" else ",",
    align = c("fancy", "right"),
    width = getOption("width"), fitWidth = TRUE)

Arguments

x  an R object inheriting from class `sparseMatrix`.
digits  significant digits to use for printing, see `print.default`, the default, `NULL`, corresponds to using `getOption("digits")`.
maxp  integer, default from `options(max.print)`, influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently "rounded up" to 100.
cld  the class definition of `x`; must be equivalent to `getClassDef(class(x))` and exists mainly for possible speedup.
zero.print  character which should be printed for structural zeroes. The default "." may occasionally be replaced by ":" (blank); using "0" would look almost like `print()`ing of non-sparse matrices.
col.names  logical or string specifying if and how column names of `x` should be printed, possibly abbreviated. The default is taken from `options("sparse.colnames")` if that is set, otherwise `FALSE` unless there are less than ten columns. When `TRUE` the full column names are printed.
    When `col.names` is a string beginning with "abb" or "sub" and ending with an integer `n` (i.e., of the form "abb...<n>")`, the column names are `abbreviate()`d or `substring()`ed to (target) length `n`, see the examples.
note.dropping.colnames  logical specifying, when `col.names` is `FALSE` if the dropping of the column names should be noted, `TRUE` by default.
uniDiag  logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "1" instead of "1" (to emphasize that the 1's are "structural").
col.trailer  a string to be appended to the right of each column; this is typically made use of by `show(<sparseMatrix>)` only, when suppressing columns.
suppRows, suppCols  logicals or `NULL`, for `printSpMatrix2()` specifying if rows or columns should be suppressed in printing. If `NULL`, sensible defaults are determined from `dim(x)`
and \texttt{options(c("width","max.print"))}. Setting both to \texttt{FALSE} may be a very bad idea.

\textbf{align} \hspace{1cm} \textbf{width} \hspace{1cm} \textbf{fitWidth} \\
\begin{itemize}
\item a string specifying how the zero.print codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical zero.print = "." with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas align = "right" just makes use of \texttt{print(*,right = TRUE)}.
\item number, a positive integer, indicating the approximately desired (line) width of the output, see also \texttt{fitWidth}.
\item logical indicating if some effort should be made to match the desired width or temporarily enlarge that if deemed necessary.
\end{itemize}

\textbf{Details}

\textbf{formatSpMatrix:} If \texttt{x} is large, only the first rows making up the approximately first \texttt{maxp} entries is used, otherwise all of \texttt{x}. \texttt{formatSparseSimple()} is applied to (a dense version of) the matrix. Then, \texttt{formatSparseM} is used, unless in trivial cases or for sparse matrices without \texttt{x} slot.

\textbf{Value}

- \texttt{formatSpMatrix()} returns a character matrix with possibly empty column names, depending on \texttt{col.names} etc, see above.
- \texttt{printSpMatrix*()} returns \texttt{x} \texttt{invisibly}, see \texttt{invisible}.

the virtual class \texttt{sparseMatrix} and the classes extending it; maybe \texttt{sparseMatrix} or \texttt{spMatrix} as simple constructors of such matrices.

The underlying utilities \texttt{formatSparseM} and \texttt{formatSparseSimple()} (on the same page).

\textbf{Examples}

\texttt{f1 <- gl(5, 3, labels = LETTERS[1:5])}
\texttt{X <- as(f1, "sparseMatrix")}
\texttt{X} \texttt{## \leftrightarrow show(X) \leftrightarrow print(X)}
\texttt{t(X)} \texttt{## shows column names, since only 5 columns}
\texttt{X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12],"c",sep=".")), "sparseMatrix")}
\texttt{X2} \texttt{## less nice, but possible:}
\texttt{print(X2, col.names = TRUE) \# use [,1] [,2] .. \leftrightarrow does not fit}
\texttt{## Possibilities with column names printing:}
\texttt{t(X2)} \texttt{\# suppressing column names}
\texttt{print(t(X2), col.names=TRUE)}
\texttt{print(t(X2), zero.print = ",", col.names="abbr. 1")}
The Matrix package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses qr as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

Usage

```r
qr(x, ...)  
qrR(qr, complete=FALSE, backPermute=TRUE, row.names = TRUE)
```

Arguments

- `x`: a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
- `qr`: a QR decomposition of the type computed by qr.
- `complete`: logical indicating whether the $R$ matrix is to be completed by binding zero-value rows beneath the square upper triangle.
- `backPermute`: logical indicating if the rows of the $R$ matrix should be back permuted such that `qrR()`’s result can be used directly to reconstruct the original matrix $X$.
- `row.names`: logical indicating if `rownames` should propagated to the result.
- `...`: further arguments passed to or from other methods.

Methods

- `x = "dgCMatrix"` QR decomposition of a general sparse double-precision matrix with `nrow(x) >= ncol(x)`. Returns an object of class "sparseQR".
- `x = "sparseMatrix"` works via "dgCMatrix".

See Also

- `qr`; then, the class documentations, mainly `sparseQR`, and also `dgCMatrix`.

Examples

```r
#------------- example of pivoting -- from base’ qraux.Rd --------------
X <- cbind(int = 1,  
b1=rep(1:0, each=3), b2=rep(0:1, each=3),  
c1=rep(c(1,0,0), 2), c2=rep(c(0,1,0), 2), c3=rep(c(0,0,1),2))  
rownames(X) <- paste0("r", seq_len(nrow(X)))  
dnX <- dimnames(X)  
bX <- X # [b]ase version of X  
X <- as(bX, "sparseMatrix")
```
X is singular, columns "b2" and "c3" are "extra"
stopifnot(identical(dimnames(X), dnX)) # some versions changed X's dimnames!
c(rankMatrix(X)) # = 4 (not 6)
m <- function(.) as(., "matrix")

### regular case ------------------------------------------
Xr <- X[, -c(3,6)] # the "regular" (non-singular) version of X
stopifnot(rankMatrix(Xr) == ncol(Xr))
Y <- cbind(y <- setNames(1:6, paste0("y", 1:6)))

### rank-deficient ("singular") case -----------------------
(qX <- qr( X)) # both @p and @q are non-trivial permutations
qx <- qr(m(X)) ; str(qx) # $pivot is non-trivial, too

drop0(R. <- qr.R(qX), tol=tolE) # columns *permuted*: c3 b1 ..
Q. <- qr.Q(qX)
qI <- sort.list(qX@q) # the inverse 'q' permutation
(X. <- drop0(Q. %*% rbind(qI, tol=tolE))) # just = X, incl. correct colnames
stopifnot(all(X - X.) < 8*.Machine$double.eps,
  identical(R.[-, qI], qrR(qX))
)

### rank-deficient ("singular") case -----------------------
(qX <- qr( X)) # both @p and @q are non-trivial permutations
qx <- qr(m(X)) ; str(qx) # $pivot is non-trivial, too

# In this sense, classical qr.coef() is fine:
 cfqx <- qr.coef(qx, y) # quite different from
 nna <- !is.na(cfqx)
stopifnot(all.equal(unname(qr.fitted(qx,y)),
  as.numeric(X[,nna] %*% cfqx[nna])))

# FIXME: do these make *any* sense? --- should give warnings!
qr.coef(qX, y)
qr.coef(qX, Y)
rm(m)
rankMatrix

Rank of a Matrix

Description

Compute ‘the’ matrix rank, a well-defined functional in theory(*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(*) The rank of a \( n \times m \) matrix \( A \), \( \text{rk}(A) \) is the maximal number of linearly independent columns (or rows); hence \( \text{rk}(A) \leq \min(n,m) \).

Usage

```
rankMatrix(x, tol = NULL, 
method = c("tolNorm2", "qr.R", "qrLINPACK", "qr", 
"useGrad", "maybeGrad"),
sval = svd(x, 0, 0)$d, warn.t = TRUE)
```

Arguments

- **x** numeric matrix, of dimension \( n \times m \), say.
- **tol** nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, \( \max(\dim(x)) \times .\text{Machine}$.double.\text{eps} \) is according to Matlab’s default (for its only method which is our method="tolNorm2").
- **method** a character string specifying the computational method for the rank, can be abbreviated:
  - "tolNorm2": the number of singular values >= tol * max(sval);
  - "qrLINPACK": for a dense matrix, this is the rank of \( \text{qr}(x, \text{tol}, \text{LAPACK=FALSE}) \) (which is \( \text{qr}(...) \$\text{rank} \));
    - This ("qr*", dense) version used to be the recommended way to compute a matrix rank for a while in the past.
    - For sparse x, this is equivalent to "qr .R".
  - "qr .R": this is the rank of triangular matrix \( R \), where \( \text{qr}() \) uses LAPACK or a "sparseQR" method (see \( \text{qr-methods} \)) to compute the decomposition \( QR \).
    - The rank of \( R \) is then defined as the number of “non-zero” diagonal entries \( d_1 \) of \( R \), and “non-zero”s fulfill \( |d_i| \geq \text{tol} \cdot \max(|d_i|) \).
  - "qr": is for back compatibility; for dense x, it corresponds to "qrLINPACK", whereas for sparse x, it uses "qr .R".
    - For all the "qr*" methods, singular values sval are not used, which may be crucially important for a large sparse matrix x, as in that case, when sval is not specified, the default, computing \( \text{svd}() \) currently coerces x to a dense matrix.
  - "useGrad": considering the “gradient” of the (decreasing) singular values, the index of the smallest gap.
  - "maybeGrad": choosing method "useGrad" only when that seems reasonable; otherwise using "tolNorm2".
- **sval** numeric vector of non-increasing singular values of x; typically unspecified and computed from x when needed, i.e., unless method = "qr".
warn.t

logical indicating if rankMatrix() should warn when it needs t(x) instead of x. Currently, for method = "qr" only, gives a warning by default because the caller often could have passed t(x) directly, more efficiently.

Value

If x is a matrix of all 0, the rank is zero; otherwise, a positive integer in 1:min(dim(x)) with attributes detailing the method used.

Note

For large sparse matrices x, unless you can specify sval yourself, currently method = "qr" may be the only feasible one, as the others need sval and call svd() which currently coerces x to a denseMatrix which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse x, method = "qr", all non-strictly zero diagonal entries d, where counted, up to including Matrix version 1.1-0, i.e., that method implicitly used tol = 0, see also the seed(42) example below.

Author(s)

Martin Maechler; for the "*Grad" methods, building on suggestions by Ravi Varadhan.

qr, svd.

Examples

rankMatrix(cbind(1, 0, 1:3)) # 2

(meths <- eval(formals(rankMatrix)$method))

## a "border" case:
H12 <- Hilbert(12)
rankMatrix(H12, tol = 1e-20) # 12; but 11 with default method & tol.
sapply(meths, function(.m.) rankMatrix(H12, method = .m.))

## tolNorm2 qr qr.R qrLINPACK useGrad maybeGrad
## 11 12 11 12 11 11
## The meaning of 'tol' for method="qrLINPACK" and *dense* x is not entirely "scale free"
rMQL <- function(ex, M) rankMatrix(M, method="qrLINPACK", tol = 10^-ex)
rMQR <- function(ex, M) rankMatrix(M, method="qr.R", tol = 10^-ex)
sapply(5:15, rMQL, M = H12) # result is platform dependent
## 7 7 8 10 10 11 11 12 12 12 (x86_64)
sapply(5:15, rMQL, M = 1000 * H12) # not identical unfortunately
## 7 7 8 10 11 11 12 12 12 12
sapply(5:15, rMQR, M = H12)
## 5 6 7 8 8 9 9 10 10 11
sapply(5:15, rMQR, M = 1000 * H12) # the *same*

## "sparse" case:
M15 <- kronecker(diag(x=c(100,1,1)), Hilbert(5))
sapply(meths, function(.m.) rankMatrix(M15, method = .m.))
#--> all 15, but 'useGrad' has 14.

## "large" sparse
n <- 250000; p <- 33; nnz <- 10000
L <- sparseMatrix(i = sample.int(n, nnz, replace=TRUE),
  j = sample.int(p, nnz, replace=TRUE), x = rnorm(nnz))
(st1 <- system.time(r1 <- rankMatrix(L))) # warning+ ~1.5 sec (2013)
(st2 <- system.time(r2 <- rankMatrix(L, method = "qr"))) # considerably faster!
r1[[1]] == print(r2[[1]]) ## --> ( 33 TRUE )

## another sparse-"qr" one, which `\failed` till 2013-11-23:
set.seed(42)
f1 <- factor(sample(50, 1000, replace=TRUE))
f2 <- factor(sample(50, 1000, replace=TRUE))
f3 <- factor(sample(50, 1000, replace=TRUE))
rbind. <- if(getRversion() < "3.2.0") rBind else rbind
D <- t(do.call(rbind., lapply(list(f1,f2,f3), as,
  \sparseMatrix))
dim(D); nnzero(D) ## 1000 x 150 // 3000 non-zeros (= 2%)
stopifnot(rankMatrix(D, method="qr") == 148,
  rankMatrix(crossprod(D),method="qr") == 148)

## zero matrix has rank 0 :
stopifnot(sapply(meths, function(.m.)
  rankMatrix(matrix(0, 2, 2), method = .m.) == 0)

---

rcond

Estimate the Reciprocal Condition Number

**Description**

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by `showMethods(rcond)`.

**Usage**

```r
rcond(x, norm, ...) 
```

**Arguments**

- `x`: an R object that inherits from the Matrix class.
- `norm`: character string indicating the type of norm to be used in the estimate. The default is "0" for the 1-norm ("0" is equivalent to "1"). For sparse matrices, when `useInv=TRUE`, `norm` can be any of the kinds allowed for `norm`; otherwise, the other possible value is "I" for the infinity norm, see also `norm`.
- `useInv`: logical (or "Matrix" containing `solve(x)`). If not false, compute the reciprocal condition number as \(1/(\|x\| \cdot \|x^{-1}\|)\), where \(x^{-1}\) is the inverse of \(x\), `solve(x)`. This may be an efficient alternative (only) in situations where `solve(x)` is fast (or known), e.g., for (very) sparse or triangular matrices.

Note that the result may differ depending on `useInv`, as per default, when it is false, an approximation is computed.

... further arguments passed to or from other methods.
Value

An estimate of the reciprocal condition number of \( x \).

BACKGROUND

The condition number of a regular (square) matrix is the product of the norm of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices \( A \)) as

\[
\kappa(A) = \frac{\max_{\|v\| = 1} \|Av\|}{\min_{\|v\| = 1} \|Av\|}.
\]

Whenever \( x \) is not a square matrix, in our method definitions, this is typically computed via \( \text{rcond}(\text{qr.R(qr}(X)), ...) \) where \( X \) is \( x \) or \( t(x) \).

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

\( \text{rcond}() \) computes the reciprocal condition number \( 1/\kappa \) with values in \([0, 1]\) and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka “singular”).

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

References

See Also

\( \text{norm}, \text{kappa}() \) from package *base* computes an approximate condition number of a “traditional” matrix, even non-square ones, with respect to the \( p = 2 \) (Euclidean) norm. *solve*.

\( \text{condest} \), a newer approximate estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

Examples

```r
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9)) # should be about 9.1e-13
## For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank
## sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))
```
## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example ---------
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)

if(interactive()) ## the values are not the same
c(r, r.) # 0.05555 0.013888
## for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
  function(N) rcond(M3, norm=N, useInv=TRUE)))

---

rep2abI

Replicate Vectors into 'abIndex' Result

Description

rep2abI(x, times) conceptually computes rep.int(x, times) but with an abIndex class result.

Usage

rep2abI(x, times)

Arguments

x numeric vector
times integer (valued) scalar: the number of repetitions

Value

a vector of class abIndex

See Also

rep.int(), the base function; abIseq, abIndex.

Examples

(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
  rep(2:7, 4)))
**replValue-class**  
*Virtual Class "replValue" - Simple Class for subassignment Values*

**Description**

The class "replValue" is a virtual class used for values in signatures for sub-assignment of Matrix matrices.

In fact, it is a simple class union (setClassUnion) of "numeric" and "logical" (and maybe "complex" in the future).

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**See Also**

Subassign-methods, also for examples.

**Examples**

showClass("replValue")

---

**rleDiff-class**  
*Class "rleDiff" of rle(diff(.)) Stored Vectors*

**Description**

Class "rleDiff" is for compactly storing long vectors which mainly consist of linear stretches. For such a vector x, diff(x) consists of constant stretches and is hence well compressable via rle().

**Objects from the Class**

Objects can be created by calls of the form new("rleDiff",...).

Currently experimental, see below.

**Slots**

- `first`: A single number (of class "numLike", a class union of "numeric" and "logical").
- `rle`: Object of class "rle", basically a list with components "lengths" and "values", see rle(). As this is used to encode potentially huge index vectors, lengths may be of type double here.

**Methods**

There is a simple show method only.

**Note**

This is currently an experimental auxiliary class for the class abIndex, see there.
rsparsematrix

Random Sparse Matrix

Description
Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and \( \text{rand.} \ \times = \text{NULL} \) generates random pattern matrices, i.e. inheriting from \text{nsparseMatrix}.

Usage
```r
rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
    symmetric = FALSE,
    rand.x = function(n) signif(rnorm(n), 2), ...)
```

Arguments
- `nrow, ncol` number of rows and columns, i.e., the matrix dimension (\text{dim}).
- `density` optional number in \([0, 1]\), the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for \text{nnz}, otherwise \text{nnz} needs to be specified.
- `nnz` number of non-zero entries, for a sparse matrix typically considerably smaller than \text{nrow}*\text{ncol}. Must be specified if \text{density} is not.
- `symmetric` logical indicating if result should be a matrix of class \text{symmetricMatrix}. Note that in the symmetric case, \text{nnz} denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.
- `rand.x` \text{NULL} or the random number generator for the \text{x} slot, a \text{function} such that \text{rand.} \ \times(n) \ generates a numeric vector of length \text{n}. Typical examples are \text{rand.} \ \times = \text{rnorm}, or \text{rand.} \ \times = \text{runif}; the default is nice for didactical purposes.
- `...` optionally further arguments passed to \text{sparseMatrix()}, notably giveCsparse.

Details
The algorithm first samples “encoded” \((i,j)\)s without replacement, via one dimensional indices, if not symmetric \text{sample.int}(\text{nrow}\times\text{ncol},\text{nnz}), then—if \text{rand.} \ \times is \text{NOT}—gets \text{x} \leftarrow \text{rand.} \ \times(\text{nnz}) and calls \text{sparseMatrix}(i=i,j=j,x=x,...). When \text{rand.} \ \times=\text{NULL}, \text{sparseMatrix}(i=i,j=j,...) will return a pattern matrix (i.e., inheriting from \text{nsparseMatrix}).

Value
a \text{sparseMatrix}, say \text{M} of dimension (\text{nrow, ncol}), i.e., with \text{dim(}M\text{)} == \text{c(}\text{nrow, ncol}\text{), if symmetric is not true, with \text{nzM} \leftarrow \text{nnzero}(M) fulfilling \text{nzM} \leq \text{nnz} and typically, \text{nzM} == \text{nnz}.

Examples

```r
set.seed(17)# to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

## a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9)# ~ 20: as 'nnz' only counts one "triangle"

## a random pattern aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

## a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, giveCsparse=FALSE)
head(T2)
```

RsparseMatrix-class Class “RsparseMatrix” of Sparse Matrices in Column-compressed Form

Description

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("RsparseMatrix") for its subclasses.

Slots

- **j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- **p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- **Dim,Dimnames**: inherited from the superclass, see sparseMatrix.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Only few methods are defined currently on purpose, since we rather use the CsparseMatrix in Matrix. Recently, more methods were added but beware that these typically do not return "RsparseMatrix" results, but rather Csparse* or Tsparse* ones.

- **t** signature(x = "RsparseMatrix"): ...
- **coerce** signature(from = "RsparseMatrix", to = "CsparseMatrix"): ...
- **coerce** signature(from = "RsparseMatrix", to = "TsparseMatrix"): ...
Schur

showClass("RsparseMatrix")
```

Schur -- Schur Decomposition of a Matrix

Description

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

Usage

```r
Schur(x, vectors, ...)
```

Arguments

- `x`: numeric square Matrix (inherting from class "Matrix") or traditional `matrix`. Missing values (NAs) are not allowed.
- `vectors`: logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper `MatrixFactorization` of class `Schur`.
- `...`: further arguments passed to or from other methods.

Details

Based on the Lapack subroutine dgees.

Value

If vectors are TRUE, as per default: If x is a `matrix` an object of class `Schur`, otherwise, for a traditional `matrix` x, a list with components `T`, `Q`, and `EValues`.

If vectors are FALSE, a list with components

- `T`: the upper quasi-triangular (square) matrix of the Schur decomposition.
- `EValues`: the vector of numeric or complex eigen values of `T` or `A`.

BACKGROUND

If `A` is a square matrix, then `A = Q T t(Q)`, where `Q` is orthogonal, and `T` is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of `A` are the same as those of `T`, which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

References

Examples

```r
Schur(Hilbert(9))  # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE)) # no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
    all.equal(eTA$values,
        local({z <- Sch.A@EValues
            z[order(Mod(z), decreasing=TRUE)]}), tolerance = 1e-13),
    identical(SchA$T, Sch.A@T),
    identical(SchA$EValues, Sch.A@EValues))

## For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
    T = a.m(Sch.A @ T),
    EValues = Sch.A@EValues)),
    all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))
```

---

Schur-class

Class "Schur" of Schur Matrix Factorizations

Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or "spectral") decompositions for general (possibly asymmetric) square matrices, see the Schur() function.

Objects from the Class

Objects of class "Schur" are typically created by Schur().

Slots

"Schur" has slots

- **T**: Upper Block-triangular Matrix object.
- **Q**: Square orthogonal "Matrix".
- **EValues**: numeric or complex vector of eigenvalues of T.
- **Dim**: the matrix dimension: equal to c(n,n) of class "integer".

Extends

Class "MatrixFactorization", directly.

str(Schur(Diagonal(5)))
## for more examples, see Schur()

solve-methods

Methods in Package Matrix for Function solve()

Description

Methods for function solve to solve a linear system of equations, or equivalently, solve for \( X \) in

\[
AX = B
\]

where \( A \) is a square matrix, and \( X, B \) are matrices or vectors (which are treated as 1-column matrices), and the \( R \) syntax is

\[
X <- \texttt{solve}(A,B)
\]

In \texttt{solve}(a,b) in the \texttt{Matrix} package, a may also be a \texttt{MatrixFactorization} instead of directly a matrix.

Usage

## S4 method for signature 'CHMfactor,ddenseMatrix'
solve(a, b,
     system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

## S4 method for signature 'dgCMatrix,matrix'
solve(a, b, sparse = FALSE, tol = .Machine$double.eps, ...)

solve(a, b, ...) ## *the* two-argument version, almost always preferred to
# solve(a)          ## the *rarely* needed one-argument version

Arguments

a
a square numeric matrix, \( A \), typically of one of the classes in \texttt{Matrix}. Logical matrices are coerced to corresponding numeric ones.

b
numeric vector or matrix (dense or sparse) as RHS of the linear system \( Ax = b \).

system
only if \( a \) is a \texttt{CHMfactor}: character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does not solve the triangular system (but "L" does).
sparse only when a is a sparseMatrix, i.e., typically a dgCMatrix: logical specifying if the result should be a (formally) sparse matrix.

tol only used when a is sparse, in the isSymmetric(a, tol=*) test, where that applies.

... potentially further arguments to the methods.

Methods

signature(a = "ANY", b = "ANY") is simply the base package’s S3 generic solve.

signature(a = "CHMfactor", b = "...."), system=* The solve methods for a "CHMfactor" object take an optional third argument system whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve $Ax = b$ for $x$ where $A$ is sparse, positive-definite matrix that was factored to produce a. Analogously, system = "L" returns the solution $x$, of $Lx = b$; similarly, for all system codes but "P" and "Pt" where, e.g., $x \leftarrow solve(a,b,system="P")$ is equivalent to $x \leftarrow P %*% b$.

If b is a sparseMatrix, system is used as above the corresponding sparse CHOLMOD algorithm is called.

signature(a = "ddenseMatrix", b = "....") (for all b) work via as(a,"dgeMatrix"), using the its methods, see below.

signature(a = "denseLU", b = "missing") basically computes uses triangular forward- and back-solve.

signature(a = "dgCMatrix", b = "matrix") , and

signature(a = "dgCMatrix", b = "ddenseMatrix") with extra argument list ( sparse = FALSE, tol = .Machine$double.eps ): Uses the sparse lu(a) decomposition (which is cached in a’s factor slot). By default, sparse=FALSE, returns a denseMatrix, since $U^{-1}L^{-1}B$ may not be sparse at all, even when $L$ and $U$ are.

If sparse=TRUE, returns a sparseMatrix (which may not be very sparse at all, even if a was sparse).

signature(a = "dgCMatrix", b = "dsparseMatrix") , and

signature(a = "dgCMatrix", b = "missing") with extra argument list ( sparse=FALSE, tol = .Machine$double.eps ): Checks if a is symmetric, and in that case, coerces it to "symmetricMatrix", and then computes a sparse solution via sparse Cholesky factorization, independently of the sparse argument. If a is not symmetric, the sparse lu decomposition is used and the result will be sparse or dense, depending on the sparse argument, exactly as for the above (b = "ddenseMatrix") case.

signature(a = "dgeMatrix", b = "....") solve the system via internal LU, calling LAPACK routines dgetri or dgetrs.

signature(a = "diagonalMatrix", b = "matrix") and other bs: Of course this is trivially implemented, as $D^{-1}$ is diagonal with entries $1/D[i,i]$.

signature(a = "dpoMatrix", b = "....Matrix"), and

signature(a = "dppMatrix", b = "....Matrix") The Cholesky decomposition of a is calculated (if needed) while solving the system.

signature(a = "dsCMatrix", b = "....") All these methods first try Cholmod’s Cholesky factorization; if that works, i.e., typically if a is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the “general” matrices of class "dgCMatrix".

signature(a = "dspMatrix", b = "...."), and
solve-methods

signature(a = "dsyMatrix", b = "....") all end up calling LAPACK routines dsptri, dsptrs, dsytrs and dsytri.

signature(a = "dtCMatrix", b = "CsparseMatrix") ,
signature(a = "dtCMatrix", b = "dgeMatrix") , etc sparse triangular solve, in traditional S/R also known as backsolve, or forwardsolve. solve(a,b) is a sparseMatrix if b is, and hence a denseMatrix otherwise.

signature(a = "dtrMatrix", b = "ddenseMatrix") , and
signature(a = "dtpMatrix", b = "matrix") , and similar b, including "missing", and "diagonalMatrix":
all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.
signature(a = "Matrix", b = "diagonalMatrix") works via as(b,"CsparseMatrix").
signature(a = "sparseQR", b = "ANY") simply uses qr.coef(a,b).
signature(a = "pMatrix", b = ".....") these methods typically use crossprod(a,b), as the inverse of a permutation matrix is the same as its transpose.

signature(a = "TsparseMatrix", b = "ANY") all work via as(a,"CsparseMatrix").

Examples

## A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))

image(i0 <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))###-> *no* error
if(R.version$arch == "x86_64")## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
stopifnot(all.equal(as(i0, "diagonalMatrix"), Diagonal(n)),
all.equal(as(i0, "diagonalMatrix"), Diagonal(n)))

I. <- iad %*% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %*% iad
.I0 <- drop0(zapsmall(.I))
stopifnot( all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
   all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)) )
Construct Sparse Design / Model Matrices

**Description**

Construct a sparse model or “design” matrix, form a formula and data frame (sparse.model.matrix) or a single factor (fac2sparse).

The fac2[Ss]parse() functions are utilities, also used internally in the principal user level function sparse.model.matrix().

**Usage**

sparse.model.matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
drop.unused.levels = FALSE, row.names = TRUE,
verbose = FALSE, ...)

fac2sparse(from, to = c("d", "i", "l", "n", "z"),
drop.unused.levels = TRUE, giveCsparse = TRUE)

fac2Sparse(from, to = c("d", "i", "l", "n", "z"),
drop.unused.levels = TRUE, giveCsparse = TRUE,
factorPatt12, contrasts.arg = NULL)

**Arguments**

- **object**: an object of an appropriate class. For the default method, a model formula or terms object.
- **data**: a data frame created with `model.frame`. If another sort of object, `model.frame` is called first.
- **contrasts.arg**:
  - for `sparse.model.matrix()`: A list, whose entries are contrasts suitable for input to the `contrasts` replacement function and whose names are the names of columns of data containing factors.
  - for `fac2Sparse()`: character string or NULL or (coercable to) "sparseMatrix", specifying the contrasts to be applied to the factor levels.
- **xlev**: to be used as argument of `model.frame` if data has no "terms" attribute.
- **transpose**: logical indicating if the `transpose` should be returned; if the transposed is used anyway, setting `transpose = TRUE` is more efficient.
- **drop.unused.levels**: should factors have unused levels dropped? The default for `sparse.model.matrix` has been changed to FALSE, 2010-07, for compatibility with R’s standard (dense) `model.matrix()`.
- **row.names**: logical indicating if row names should be used.
- **verbose**: logical or integer indicating if (and how much) progress output should be printed.
- **...**: further arguments passed to or from other methods.
- **from** (for fac2sparse): a factor.
sparse.model.matrix

to a character indicating the “kind” of sparse matrix to be returned. The default, "d" is for double.

giveCsparse (for fac2sparse): logical indicating if the result must be a CsparseMatrix.
factorPatt12 logical vector, say fp, of length two; when fp[1] is true, return “contrasted” t(X); when fp[2] is true, the original (“dummy”) t(X), i.e, the result of fac2sparse().

Value

a sparse matrix, extending CsparseMatrix (for fac2sparse() if giveCsparse is true as per default; a TsparseMatrix, otherwise).

For fac2Sparse(), a list of length two, both components with the corresponding transposed model matrix, where the corresponding factorPatt12 is true.

Note that model.Matrix(*, sparse=TRUE) from package MatrixModels may be often be preferable to sparse.model.matrix() nowadays, as model.Matrix() returns modelMatrix objects with additional slots assign and contrasts which relate back to the variables used.

fac2sparse(), the basic workhorse of sparse.model.matrix(), returns the transpose (t) of the model matrix.

Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

See Also

model.matrix in standard R’s package stats.
model.Matrix which calls sparse.model.matrix or model.matrix depending on its sparse argument may be preferred to sparse.model.matrix.

as(f,"sparseMatrix") (see coerce(from = "factor",...) in the class doc sparseMatrix) produces the transposed sparse model matrix for a single factor f (and no contrasts).

Examples

dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
    Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
all(sparse.model.matrix(~ 0+ a + b, dd) ==
    Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))

(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgOMatrix"

## X 1 1 1 1 1 1 1 1 1 1 1 1
## Y . . . . 1 1 1 1 . . . .
## Z . . . . 1 1 1 1 . . . .

(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgOMatrix"

## X 1 1 1 1 1 1 1 1 1 1 1 1
## Y . . . . 1 1 1 1 . . . .
## Z . . . . 1 1 1 1 . . . .
## can also be computed via sparse.model.matrix():

```r
f30 <- gl(3, 0)
f12 <- gl(3, 0, 12)
stopifnot(
  all.equal(t(fac2sparse(ff)),
            sparse.model.matrix(~ 0 + ff),
            tolerance = 0, check.attributes = FALSE),
  is(M <- fac2sparse(f30, drop = TRUE), "CsparseMatrix"), dim(M) == c(0, 0),
  is(M <- fac2sparse(f30, drop = FALSE), "CsparseMatrix"), dim(M) == c(3, 0),
  is(M <- fac2sparse(f12, drop = TRUE), "CsparseMatrix"), dim(M) == c(0, 12),
  is(M <- fac2sparse(f12, drop = FALSE), "CsparseMatrix"), dim(M) == c(3, 12)
)
```

---

### sparseLU-class

#### Sparse LU decomposition of a square sparse matrix

**Description**

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

**Objects from the Class**

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

**Slots**

- **L**: Object of class "dtCMatrix", the lower triangular factor from the left.
- **U**: Object of class "dtCMatrix", the upper triangular factor from the right.
- **p**: Object of class "integer", permutation applied from the left.
- **q**: Object of class "integer", permutation applied from the right.
- **Dim**: the dimension of the original matrix; inherited from class `MatrixFactorization`.

**Extends**

Class "LU", directly. Class "MatrixFactorization", by class "LU".

**Methods**

- **expand** signature(x = "sparseLU") Returns a list with components P, L, U, and Q, where P and Q represent fill-reducing permutations, and L and U the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product $P'LUQ$.

**Note**

The decomposition is of the form

$$A = P'LUQ,$$

or equivalently $PAQ' = LU$, where all matrices are sparse and of size $n \times n$. The matrices P and Q, and their transposes $P'$ and $Q'$ are permutation matrices, L is lower triangular and U is upper triangular.
Examples

```r
## Extending the one in examples(lu), calling the matrix A,
## and confirming the factorization identities :
A <- as(readMM(system.file("external/pores_1.mtx",
   package = "Matrix")),
   "CsparseMatrix")
## with dimnames(.) - to see that they propagate to L, U :
dimnames(A) <- dnA <- list(paste0("r", seq_len(nrow(A))),
   paste0("C", seq_len(ncol(A))))
str(luA <- lu(A)) # p is a 0-based permutation of the rows
# q is a 0-based permutation of the columns
xA <- expand(luA)
## which is simply doing
stopifnot(identical(xA$L, luA$L),
   identical(xA$U, luA$U),
   identical(xA$P, as(luA$p +1L, "pMatrix")),
   identical(xA$Q, as(luA$q +1L, "pMatrix")))
P.LUQ <- with(xA, t(P) %*% L %*% U %*% Q)
stopifnot(all.equal(A, P.LUQ, tolerance = 1e-12),
   identical(dimnames(P.LUQ), dnA))
## permute rows and columns of original matrix
pA <- A[luA$p + 1L, luA$q + 1L]
stopifnot(identical(pA, with(xA, P %*% A %*% t(Q))))
pLU <- drop0(luA$L %*% luA$U) # L %*% U -- dropping extra zeros
stopifnot(all.equal(pA, pLU, tolerance = 1e-12))
```

sparseMatrix

General Sparse Matrix Construction from Nonzero Entries

Description

User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from class CsparseMatrix (or TsparseMatrix if giveCsparse is false), from locations (and values) of its non-zero entries.

This is the recommended user interface rather than direct new("***Matrix",.....) calls.

Usage

sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
  symmetric = FALSE, triangular = FALSE, index1 = TRUE,
  giveCsparse = TRUE, check = TRUE, use.last.ij = FALSE)

Arguments

i, j   integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix. Note that for repeated pairs \((i_k,j_k)\), when \(x\) is not missing, the corresponding \(x_k\) are added, in consistency with the definition of the "TsparseMatrix" class, unless use.last.ij is true, in which case only the last of the corresponding \((i_k,j_k,x_k)\) triplet is used.

p   numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of \(i\) or \(p\) must be missing.

x   optional values of the matrix entries. If specified, must be of the same length as \(i/j\), or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class nsparseMatrix.

dims   optional, non-negative, integer, dimensions vector of length 2. Defaults to c(max(i),max(j)).

dimnames   optional list of dimnames; if not specified, none, i.e., NULL ones, are used.

symmetric   logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via \((i/j/p)\).

triangular   logical indicating if the resulting matrix should be triangular. In that case, the lower or upper triangle needs to be specified via \((i/j/p)\).
index1 logical scalar. If TRUE, the default, the index vectors i and/or j are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If FALSE the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.
giveCsparse logical indicating if the result should be a CsparseMatrix or a TsparseMatrix. The default, TRUE is very often more efficient subsequently, but not always.
check logical indicating if a validity check is performed; do not set to FALSE unless you know what you’re doing!
use.last.ij logical indicating if in the case of repeated, i.e., duplicated pairs (i_k, j_k) only the last one should be used. The default, FALSE, corresponds to the "TsparseMatrix" definition.

Details

Exactly one of the arguments i, j and p must be missing.

In typical usage, p is missing, i and j are vectors of positive integers and x is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If i or j is missing then p must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of p, rep(seq_along(dp), dp) where dp <-diff(p), is used as the (1-based) row or column indices.

You cannot set both singular and triangular to true; rather use Diagonal() (or its alternatives, see there).

The values of i, j, p and index1 are used to create 1-based index vectors i and j from which a TsparseMatrix is constructed, with numerical values given by x, if non-missing. Note that in that case, when some pairs (i_k, j_k) are repeated (aka “duplicated”), the corresponding x_k are added, in consistency with the definition of the “TsparseMatrix” class, unless use.last.ij is set to true.

By default, when giveCsparse is true, the CsparseMatrix derived from this triplet form is returned.

The reason for returning a CsparseMatrix object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in x then a CsparseMatrix is a unique representation of the sparse matrix.

Value

A sparse matrix, by default (see giveCsparse) in compressed, column-oriented form, as an R object inheriting from both CsparseMatrix and generalMatrix.

Note

You do need to use index1 = FALSE (or add +1 to i and j) if you want use the 0-based i (and j) slots from existing sparse matrices.

See Also

Matrix(*,sparse=TRUE) for the constructor of such matrices from a dense matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like sparseMatrix() is needed. Further bdiag and Diagonal for (block-)diagonal and bandSparse for banded sparse matrix constructors.
Random sparse matrices via `rsparsematrix()`.

The standard R `xtabs(*, sparse=TRUE)`, for sparse tables and `sparse.model.matrix()` for building sparse model matrices.

Consider `CsparseMatrix` and similar class definition help files.

**Examples**

```r
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"  
summary(A)  
str(A) # note that *internally* 0-based row indices are used

(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"  
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
stopifnot( all(sA == tA + t(tA)) ,  
    identical(sA, as(tA + t(tA), "symmetricMatrix")))

## dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)

## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

## The slots are 0-index based, so  
try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )
## fails and you should say so: 1-indexing is FALSE:  
sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

## the (i,j) pairs can be repeated, in which case the x's are summed
(Args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, Args))
## explicitly ask for elimination of such duplicates, so  
## that the last one is used:
(A. <- do.call(sparseMatrix, c(Args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, # 2+7 == 9  
    A.[1,2] == 2) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")])))

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
M <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
M
str(M)
stopifnot(identical(dimnames(M), dn))

}

---

**sparseMatrix-class**

### Virtual Class "sparseMatrix" — Mother of Sparse Matrices

**Description**

Virtual Mother Class of All Sparse Matrices

**Slots**

- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.  
- **Dimnames**: a list of length two - inherited from class Matrix, see Matrix.

**Extends**

Class "Matrix", directly.

**Methods**

- **show** (object = "sparseMatrix"): The show method for sparse matrices prints "structural" zeroes as "." using printSpMatrix() which allows further customization.
- **print** signature(x = "sparseMatrix").

The print method for sparse matrices by default is the same as show() but can be called with extra optional arguments, see printSpMatrix().
format signature(x = "sparseMatrix").

The format method for sparse matrices, see formatSpMatrix() for details such as the extra optional arguments.

summary (object = "sparseMatrix"): Returns an object of S3 class "sparseSummary" which is basically a data.frame with columns (i,j,x) (or just (i,j) for nsparseMatrix class objects) with the stored (typically non-zero) entries. The print method resembles Matlab’s way of printing sparse matrices, and also the MatrixMarket format, see writeMM.

cbind2 (x = *,y = *): several methods for binding matrices together, column-wise, see the basic cbind and rbind functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

rbind2 (x = *,y = *): binding matrices together row-wise, see cbind2 above.

determinant (x = "sparseMatrix",logarithm=TRUE): determinant() methods for sparse matrices typically work via Cholesky or lu decompositions.

diag (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

dim<- signature(x = "sparseMatrix",value = "ANY"): allows to reshape a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill prod(value) == prod(dim(x)).

do coercion to "sparseMatrix": Produces the matrix of indicator rows stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also colSums, norm, ... for methods with separate help pages.

Note

In method selection for multiplication operations (i.e. %*% and the two-argument form of crossprod) the sparseMatrix class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a dgeMatrix and the appropriate sparse matrix method is used.

See Also

sparseMatrix, and its references, such as xtabs(*,sparse=TRUE), or sparse.model.matrix(), for constructing sparse matrices.

T2graph for conversion of "graph" objects (package graph) to and from sparse matrices.

Examples

t( <sparse design matrix> ) :

M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M

# factor -> t( <sparse design matrix> ) :

data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

# factor -> t( <sparse design matrix> ) :

(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows
## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[,-i.mis] == X.[,-i.mis]))

---

### Sparse QR decomposition of a sparse matrix

**Description**

Objects class "sparseQR" represent a QR decomposition of a sparse $m \times n$ ("long": $m \geq n$) rectangular matrix $A$, typically resulting from `qr()`, see 'Details' notably about row and column permutations for pivoting.

**Details**

For a sparse $m \times n$ ("long": $m \geq n$) rectangular matrix $A$, the sparse QR decomposition is either of the form $PA = QR$ with a (row) permutation matrix $P$, (encoded in the p slot of the result) if the q slot is of length 0,

or of the form $PAP^* = QR$ with an extra (column) permutation matrix $P^*$ (encoded in the q slot). Note that the row permutation $PA$ in R is simply $A[p+1,]$ where $p$ is the p-slot, a 0-based permutation of 1:m applied to the rows of the original matrix.

If the q slot has length n it is a 0-based permutation of 1:n applied to the columns of the original matrix to reduce the amount of “fill-in” in the matrix $R$, and $AP^*$ in R is simply $A[,q+1]$.

$R$ is an $m \times n$ matrix that is zero below the main diagonal, i.e., upper triangular ($m \times m$) with $m - n$ extra zero rows.

The matrix $Q$ is a "virtual matrix". It is the product of $n$ Householder transformations. The information to generate these Householder transformations is stored in the V and beta slots. Note however that `qr.Q()` returns the row permuted matrix $Q^* := P^{-1}Q = P^*Q$ as permutation matrices are orthogonal; and $Q^*$ is orthogonal itself because $Q$ and $P$ are. This is useful because then, as in the dense matrix and base R matrix qr case, we have the mathematical identity

$$PA = Q^* R,$$

in R as

$$A[p+1,] == qr.Q(*) %*% R.$$

The "sparseQR" methods for the qr.* functions return objects of class "dgeMatrix" (see `dgeMatrix`). Results from `qr.coef`, `qr.resid` and `qr.fitted` (when k == ncol(R)) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix $Q$ is not uniquely defined, the results of `qr.qy` and `qr.qty` do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of `qr.qy` and `qr.qty` apply to the permuted column order when the q slot has length n.
Objects from the Class

Objects can be created by calls of the form `new("sparseQR",...)` but are more commonly created by function `qr` applied to a sparse matrix such as a matrix of class `dgCMatrix`.

Slots

- **V**: Object of class "dgCMatrix". The columns of V are the vectors that generate the Householder transformations of which the matrix Q is composed.
- **beta**: Object of class "numeric", the normalizing factors for the Householder transformations.
- **p**: Object of class "integer": Permutation (of 0:(n-1)) applied to the rows of the original matrix.
- **R**: Object of class "dgCMatrix": An upper triangular matrix of the same dimension as X.
- **q**: Object of class "integer": Permutation applied from the right, i.e., to the columns of the original matrix. Can be of length 0 which implies no permutation.

Methods

- `qr.R` signature(qr = "sparseQR") computes the upper triangular $R$ matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical `qr.R()` result, and you can suppress these warnings by setting `options()` either "Matrix.quiet.qr.R" or (the more general) either "Matrix.quiet" to TRUE.
- `qr.Q` signature(qr = "sparseQR"): compute the orthogonal $Q$ matrix of the QR decomposition.
- `qr.coef` signature(qr = "sparseQR",y = "ddenseMatrix"): ...
- `qr.coef` signature(qr = "sparseQR",y = "matrix"): ...
- `qr.fitted` signature(qr = "sparseQR",y = "ddenseMatrix"): ...
- `qr.fitted` signature(qr = "sparseQR",y = "matrix"): ...
- `qr.qty` signature(qr = "sparseQR",y = "ddenseMatrix"): ...
- `qr.qty` signature(qr = "sparseQR",y = "matrix"): ...
- `qr.qy` signature(qr = "sparseQR",y = "ddenseMatrix"): ...
- `qr.qy` signature(qr = "sparseQR",y = "matrix"): ...
- `qr.resid` signature(qr = "sparseQR",y = "ddenseMatrix"): ...
- `qr.resid` signature(qr = "sparseQR",y = "matrix"): ...
- `solve` signature(a = "sparseQR",b = "ANY"): For solve(a,b), simply uses `qr.coef(a,b)`.

See Also

- `qr`, `qr.Q`, `qr.R`, `qr.fitted`, `qr.resid`, `qr.coef`, `qr.qty`, `qr.qy`

Permutation matrices in the Matrix package: `pMatrix`; `dgCMatrix`, `dgeMatrix`.
Examples

```r
data(KNex)
mm <- KNex $ mm
y <- KNex $ y
y. <- as(as.matrix(y), "dgCMatrix")
str(qrm <- qr(mm))
qc <- qr.coef (qrm, y); qc. <- qr.coef (qrm, y.)  # 2nd failed in Matrix <= 1.1-0
qf <- qr.fitted(qrm, y); qf. <- qr.fitted(qrm, y.)
qs <- qr.resid (qrm, y); qs. <- qr.resid (qrm, y.)
stopifnot(all.equal(qc, as.numeric(qc.), tolerance=1e-12),
          all.equal(qf, as.numeric(qf.), tolerance=1e-12),
          all.equal(qs, as.numeric(qs.), tolerance=1e-12),
          all.equal(qf+qs, y, tolerance=1e-12))
```

Description

User friendly construction of sparse vectors, i.e., objects inheriting from class `sparseVector`, from indices and values of its non-zero entries.

Usage

```r
sparseVector(x, i, length)
```

Arguments

- `x` vector of the non zero entries; may be missing in which case a "nsparseVector" will be returned.
- `i` integer vector (of the same length as `x`) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector.
- `length` length of the sparse vector.

Details

zero entries in `x` are dropped automatically, analogously as `drop0()` acts on sparse matrices.

Value

a sparse vector, i.e., inheriting from class `sparseVector`.

Author(s)

Martin Maechler

See Also

`sparseMatrix()` constructor for sparse matrices; the class `sparseVector`. 
Examples

```r
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss, sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
                                      i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns,
                    new("nsparseVector", length = 10, i = c(2, 3, 7))))
```

---

**sparseVector-class**  
**Sparse Vector Classes**

**Description**

Sparse Vector Classes: The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the d*, l* and n* ones.

**Slots**

- **length**: class "numeric" - the length of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", \(\text{.Machine}\$\text{integer}\_max\), on purpose.
- **i**: class "numeric" - the (1-based) indices of the non-zero entries. Must not be NA and strictly sorted increasingly.
  
  Note that "integer" is "part of" "numeric", and can (and often will) be used for non-huge sparseVectors.
- **x**: (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.
  
  Note that "nsparseVector"s have no x slot. Further, mainly for ease of method definitions, we've defined the class union (see `setClassUnion`) of all sparse vector classes which have an x slot, as class "xsparseVector".

**Methods**

- **length** signature(x = "sparseVector"): simply extracts the length slot.

- **show** signature(object = "sparseVector"): The show method for sparse vectors prints "structural" zeroes as "." using the non-exported prSpVector function which allows further customization such as replacing "." by " " (blank).

  Note that `options(max.print)` will influence how many entries of large sparse vectors are printed at all.

- **as.vector** signature(x = "sparseVector", mode = "character") coersed sparse vectors to "regular", i.e., atomic vectors. This is the same as as(x, "vector").

- **as**: see coerce below

- **coerce** signature(from = "sparseVector", to = "sparseMatrix"), and
coerce signature(from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices (sparseMatrix) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.

dim< signature(x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from sparseMatrix, of the appropriate dimension.

head signature(x = "sparseVector"): as with R’s (package util) head, head(x, n) (for \( n \geq 1 \)) is equivalent to \( x[1:n] \), but here can be much more efficient, see the example.

tail signature(x = "sparseVector"): analogous to head, see above.
toeplitz signature(x = "sparseVector"): as toeplitz(x), produce the \( n \times n \) Toeplitz matrix from x, where \( n = \text{length}(x) \).

rep signature(x = "sparseVector"): repeat x, with the same argument list \((x, \text{times}, \text{length.out}, \text{each}, \ldots)\) as the default method for rep().

which signature(x = "sparseVector") and

which signature(x = "lsparseVector") return the indices of the non-zero entries (which is trivial for sparse vectors).

Ops signature(e1 = "sparseVector", e2 = "+") define arithmetic, compare and logic operations, (see Ops).

Summary signature(x = "sparseVector"): define all the Summary methods.

[ signature(x = "atomicVector", i = \ldots): not only can you subset (aka “index into”) sparseVectors \( x[i] \) using sparseVectors \( i \), but we also support efficient subsetting of traditional vectors \( x \) by logical sparse vectors (i.e., \( i \) of class "nsparseVector" or "lsparseVector").

is.na, is.finite, is.infinite \((x = "sparseVector")\) and

is.na, is.finite, is.infinite \((x = "nsparseVector")\): return logical or "nsparseVector" of the same length as \( x \), indicating if/where \( x \) is NA (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

c.sparseVector() is an S3 method for all "sparseVector"s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

See Also

c.sparseVector() for friendly construction of sparse vectors (apart from as(*, "sparseVector")).

Examples

generalize("sparseVector")
generalize("dsparseVector")
generalize("xsparseVector")# those with an ‘x’ slot

   all.equal(c2, .s(c(.v(ns), .v(is), FALSE)), tol=0),

"sparseVector-class"
spMatrix

Sparse Matrix Constructor From Triplet

Description

User friendly construction of a sparse matrix (inheriting from class TsparseMatrix) from the triplet representation.

This is much less flexible than sparseMatrix() and hence somewhat deprecated.

Usage

spMatrix(nrow, ncol, i = integer(), j = integer(), x = numeric())

Arguments

nrow, ncol integers specifying the desired number of rows and columns.
i, j integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.
x atomic vector of the same length as i and j, specifying the values of the non-zero entries.

Value

A sparse matrix in triplet form, as an R object inheriting from both TsparseMatrix and generalMatrix.
The matrix \( M \) will have \( M[i[k],j[k]] == x[k] \), for \( k = 1,2,...,n \), where \( n = \text{length}(i) \) and \( M[i',j'] == 0 \) for all other pairs \( (i',j') \).

See Also

Matrix(*,sparse=TRUE) for the more usual constructor of such matrices. Then, sparseMatrix is more general and flexible than spMatrix() and by default returns a CsparseMatrix which is often slightly more desirable. Further, bdiag and Diagonal for (block-)diagonal matrix constructors.

Consider TsparseMatrix and similar class definition help files.

Examples

```r
## simple example
A <- spMatrix(10,20, i = c(1,3:8),
               j = c(2,9,6:10),
               x = 7 * (1:7))
A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9,30, i = rep(1:9,3), 1:27,
```
## symmetricMatrix-class

Virtual Class of Symmetric Matrices in Package Matrix

### Description

The virtual class of symmetric matrices, "symmetricMatrix", from the package Matrix contains numeric and logical, dense and sparse matrices, e.g., see the examples with the "actual" subclasses.

The main use is in methods (and C functions) that can deal with all symmetric matrices, and in as(*,"symmetricMatrix").

### Slots

- **uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

- **Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there. See below, about storing only one of the two Dimnames components.

- **factors:** a list of matrix factorizations, also from the Matrix class.

### Extends

Class "Matrix", directly.
Methods

- **coerce** signature(from = "ddiMatrix", to = "symmetricMatrix"): and many other coercion methods, some of which are particularly optimized.

- **dimnames** signature(object = "symmetricMatrix"): returns symmetric dimnames, even when the Dimnames slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

- **isSymmetric** signature(object = "symmetricMatrix"): returns TRUE trivially.

There's a C function `symmetricMatrix_validate()` called by the internal validity checking functions, and also from `getValidity(getClass("symmetricMatrix"))`.

Validity and dimnames

The validity checks do not require a symmetric Dimnames slot, so it can be `list(NULL, <character>)`, e.g., for efficiency. However, `dimnames()` and other functions and methods should behave as if the dimnames were symmetric, i.e., with both list components identical.

See Also

- **isSymmetric** which has efficient methods (isSymmetric-methods) for the Matrix classes. Classes `triangularMatrix`, and, e.g., `dsyMatrix` for numeric dense matrices, or `lsCMatrix` for a logical sparse matrix class.

Examples

```r
## An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7),
                   symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
dimnames(sy) # both parts - as sy *is* symmetrical

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0

## Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
```

---

**symmpart**

Symmetric Part and Skew(symmetric) Part of a Matrix

**Description**

`symmpart(x)` computes the symmetric part \((x + t(x))/2\) and `skewpart(x)` the skew symmetric part \((x - t(x))/2\) of a square matrix \(x\), more efficiently for specific Matrix classes.

Note that \(x \equiv \text{symmpart}(x) + \text{skewpart}(x)\) for all square matrices – apart from extraneous NA values in the RHS.
symmpart

Usage

symmpart(x)
skewpart(x)

Arguments

x

A square matrix; either “traditional” of class "matrix", or typically, inheriting from the Matrix class.

Details

These are generic functions with several methods for different matrix classes, use e.g.,
showMethods(symmpart) to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

Value

symmpart() returns a symmetric matrix, inheriting from symmetricMatrix iff x inherited from Matrix.

skewpart() returns a skew-symmetric matrix, typically of the same class as x (or the closest “general” one, see generalMatrix).

See Also

isSymmetric.

Examples

m <- Matrix(1:4, 2,2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == symmpart(m) + skewpart(m)))

colnames(m) <- NULL
stopifnot(all(m == symmpart(m) + skewpart(m)))

dimnames(m) <- unname(dn)
stopifnot(all(m == symmpart(m) + skewpart(m)))

## investigate the current methods:
showMethods(skewpart, include = TRUE)
triangularMatrix-class

Virtual Class of Triangular Matrices in Package Matrix

Description

The virtual class of triangular matrices, "triangularMatrix", the package Matrix contains square (nrow == ncol) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

Slots

uplo: String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

diag: String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when diag is "U". For denseMatrix classes, they need to be allocated though, i.e., the length of the x slot does not depend on diag.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "Matrix", directly.

Methods

There's a C function triangularMatrix_validity() called by the internal validity checking functions.

Currently, Schur, isSymmetric and as() (i.e. coerce) have methods with triangularMatrix in their signature.

See Also

isTriangular() for testing any matrix for triangularity; classes symmetricMatrix, and, e.g., dtrMatrix for numeric dense matrices, or ltCMatrix for a logical sparse matrix subclass of "triangularMatrix".

Examples

showClass("triangularMatrix")

## The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")
Description

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See showClass("TsparseMatrix") for its subclasses.

Slots

Dim, Dimnames: from the "Matrix" class,

i: Object of class "integer" - the row indices of non-zero entries in 0-base, i.e., must be in 0:(nrow(.)-1).

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in 0:(nrow(.)-1). For numeric Tsparse matrices, (i,j) pairs can occur more than once, see dgTMatrix.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Extraction ("[" methods, see [-methods.

Note

Most operations with sparse matrices are performed using the compressed, column-oriented or CsparseMatrix representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a CsparseMatrix for further operations.

Note that all new(.,), spMatrix and sparseMatrix(*,giveCsparse=FALSE) constructors for "TsparseMatrix" classes implicitly add x_k's that belong to identical (i_k,j_k) pairs, see, the example below, or also "dgTMatrix".

For convenience, methods for some operations such as %*% and crossprod are defined for TsparseMatrix objects. These methods simply coerce the TsparseMatrix object to a CsparseMatrix object then perform the operation.

See Also

its superclass, sparseMatrix, and the dgTMatrix class, for the links to other classes.

Examples

showClass("TsparseMatrix")
## or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3, 4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
uniqTsparse

Unique (Sorted) TsparseMatrix Representations

Description

Detect or “unify” (or “standardize”) non-unique TsparseMatrix matrices, producing unique \((i, j, x)\) triplets which are sorted, first in \(j\), then in \(i\) (in the sense of order(j,i)).

Note that new(\(.\)), spMatrix or sparseMatrix constructors for “dgTMatrix” (and other “TsparseMatrix” classes) implicitly add \(x_k\)’s that belong to identical \((i_k, j_k)\) pairs.

anyDuplicatedT() reports the index of the first duplicated pair, or 0 if there is none.

uniqTsparse(x) replaces duplicated index pairs \((i, j)\) and their corresponding \(x\) slot entries by the triple \((i, j, sx)\) where \(sx = \text{sum}(x \{<\text{all pairs matching } (i,j)>\})\), and for logical \(x\), addition is replaced by logical or.

Usage

uniqTsparse(x, class.x = c(class(x)))

anyDuplicatedT(x, di = dim(x))

Arguments

- **x**: a sparse matrix stored in triplet form, i.e., inheriting from class TsparseMatrix.
- **class.x**: optional character string specifying class(x).
- **di**: the matrix dimension of \(x\), dim(x).

Value

uniqTsparse(x) returns a TsparseMatrix “like \(x\)”, of the same class and with the same elements, just internally possibly changed to “unique” \((i, j, x)\) triplets in sorted order.

anyDuplicatedT(x) returns an integer as anyDuplicated, the index of the first duplicated entry (from the \((i, j)\) pairs) if there is one, and 0 otherwise.

See Also

TsparseMatrix, for uniqueness, notably dgTMatrix.

Examples

example("dgTMatrix-class", echo=FALSE)
## -> 'T' with \((i,j,x)\) slots of length 5 each
T2u <- uniqTsparse(T2)
stopifnot(## They "are" the same (and print the same):
  all.equal(T2, T2u, tol=0),
  ## but not internally:
  anyDuplicatedT(T2) == 2,
  anyDuplicatedT(T2u) == 0,
  length(T2 @x) == 5,
  length(T2u @x) == 3)

## is 'x' a "uniq Tsparse" Matrix ? [requires x to be TsparseMatrix!]
non_uniqT <- function(x, di = dim(x))
**Description**

“Packed” matrix storage here applies to dense matrices (denseMatrix) only, and there is available only for symmetric (symmetricMatrix) or triangular (triangularMatrix) matrices, where only one triangle of the matrix needs to be stored.

unpack() unpacks “packed” matrices, where pack() produces “packed” matrices.

**Usage**

pack(x, ...)  
## S4 method for signature 'matrix'  
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)

**Arguments**

- **x**: for unpack(): a matrix stored in packed form, e.g., of class “d?pMatrix”  
  where “?” is “t” for triangular or “s” for symmetric.  
  for pack(): a (symmetric or triangular) matrix stored in full storage.

- **symmetric**: logical (including NA) for optionally specifying if x is symmetric (or rather triangular).

- **upperTri** (for the triangular case only) logical (incl. NA) indicating if x is upper (or lower) triangular.

- **...**: further arguments passed to or from other methods.
Details

These are generic functions with special methods for different types of packed (or non-packed) symmetric or triangular dense matrices. Use `showMethods("unpack")` to list the methods for `unpack()`, and similarly for `pack()`.

Value

for `unpack()`: A Matrix object containing the full-storage representation of x.

for `pack()`: A packed Matrix (i.e. of class ".pMatrix") representation of x.

Examples

```r
showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- as(cp4,"dtpMatrix")# [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
(mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s ) == dim(sp), all(s == sp),
  dim(mt) == dim(pt), all(mt == pt), all(mt == tt))
showMethods("pack")
```

---

**Unused-classes**

**Virtual Classes Not Yet Really Implemented and Used**

Description

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all complex (S4) matrices. It extends the `Matrix` class directly.

Examples

```r
showClass("iMatrix")
showClass("zMatrix")
```
updown

Up- and Down-Dating a Cholesky Decomposition

Description

Compute the up- or down-dated Cholesky decomposition

Usage

updown(update, C, L)

Arguments

update  logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.
C any R object, coercable to a sparse matrix (i.e., of subclass of sparseMatrix).
L a Cholesky factor, specifically, of class "CHMfactor".

Value

an updated Cholesky factor, of the same dimension as L. Typically of class "dCHMsimpl" (a sub class of "CHMfactor").

Methods

signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..

Examples

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA, "Matrix") ^ 2
uc1 <- updown("+", Diagonal(5), cA)
## Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA, "Matrix")))
image(show(c2 <- as(uc2,"Matrix")))# severely negative entries
##---> Warning
Description

This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

Usage

data(USCounties)

Format

A $3111^2$ symmetric sparse matrix of class dsCMatrix with 9101 non-zero entries.

Details

The data were read into R using read.gal, and row-standardised and transformed to symmetry using nb2listw and similar.listw. This spatial weights object was converted to class dsCMatrix using as_dsTMatrix_listw and coercion.

Source

The data were retrieved from http://sal.uiuc.edu/weights/zips/usc.zip, files “usc.txt” and “usc\_q.GAL”, with permission for use and distribution from Luc Anselin.

References

Examples

data(USCounties)

stopifnot(all.equal(MJ, MJ4))

--------------------------------------------------------------------------

[-methods

Methods for "[" : Extraction or Subsetting in Package 'Matrix'

Description

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package Matrix.

Methods

There are more than these:

x = "Matrix", i = "missing", j = "missing", drop= "ANY"  ...
x = "Matrix", i = "numeric", j = "missing", drop= "missing"  ...
x = "Matrix", i = "missing", j = "numeric", drop= "missing"  ...
x = "dsparseMatrix", i = "missing", j = "numeric", drop= "logical"  ...
x = "dsparseMatrix", i = "numeric", j = "missing", drop= "logical"  ...
x = "dsparseMatrix", i = "numeric", j = "numeric", drop= "logical"  ...

See Also

[]<-methods for subassignment to "Matrix" objects. Extract about the standard extraction.

Examples

str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))

stopifnot(identical(m, m[]))
m[2, 3]  # simple number
m[2:3]  # simple numeric of length 2
m[2, 3:4, drop=FALSE]  # sub matrix of class 'dgeMatrix'
# rows or columns only:
m[1,]   # first row, as simple numeric vector
m[,1:2]  # sub matrix of first two columns

showMethods("[", inherited = FALSE)
Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package Matrix.

**Note:** Contrary to standard matrix assignment in base R, in x[..] <- val it is typically an error (see stop) when the type or class of val would require the class of x to be changed, e.g., when x is logical, say "lsparseMatrix", and val is numeric. In other cases, e.g., when x is a "nsparseMatrix" and val is not TRUE or FALSE, a warning is signalled, and val is "interpreted" as logical, and (logical) NA is interpreted as TRUE.

**Methods**

There are many more than these:

x = "Matrix", i = "missing", j = "missing", value= "ANY" is currently a simple fallback method implementation which ensures "readable" error messages.

x = "Matrix", i = "ANY", j = "ANY", value= "ANY" currently gives an error

x = "denseMatrix", i = "index", j = "missing", value= "numeric" ...

x = "denseMatrix", i = "index", j = "index", value= "numeric" ...

x = "denseMatrix", i = "missing", j = "index", value= "numeric" ...

**See Also**

[-methods for subsetting "Matrix" objects; the index class; Extract about the standard subset assignment (and extraction).

**Examples**

set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <<- replaces **every** entry
a
## as do these:
a[,,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
m[3:4] <- 3:4 # simple numeric of length 2

## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

## rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6),] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")
Boolean Arithmetic Matrix Products: %&% and Methods

Description

For boolean or "pattern" matrices, i.e., R objects of class nMatrix, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package Matrix, we use the binary operator %&% (aka "infix") function) for this and provide methods for all our matrices and the traditional R matrices (see matrix).

Value

A pattern matrix, i.e., inheriting from "nMatrix", or an "ldiMatrix" in case of a diagonal matrix.

Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and sparseVectors in package Matrix.

signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "mMatrix", y = "mMatrix")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "mMatrix")
signature(x = "mMatrix", y = "sparseVector")
signature(x = "sparseVector", y = "sparseVector")

Note

The current implementation ends up coercing both x and y to (virtual) class nsparseMatrix which may be quite inefficient. A future implementation may well return a matrix with different class, but the “same” content, i.e., the same matrix entries m_{ij}.

Examples

set.seed(7)
L <- Matrix(rnorm(20) > 1, 4,5)
(N <- as(L, "nMatrix"))
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %&% D
stopifnot(identical(L %&% D, N %&% D),
          all(L %&% D == as((L %&% abs(D)) > 0, "sparseMatrix")))

## cross products, possibly with boolArith = TRUE :
crossprod(N) # -> sparse pattern 'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N +0) # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %&% N),
  identical(crossprod(N), crossprod(N +0, boolArith=TRUE)),
  identical(crossprod(L), crossprod(N , boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMatrix"
Chapter 18

The boot package

abc.ci

Nonparametric ABC Confidence Intervals

Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

Usage

abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95, eps=0.001/n, ...)

Arguments

data
statistic
index
strata
conf
eps
...

A data set expressed as a vector, matrix or data frame.

A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the ...() argument.

If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.

A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.

A scalar or vector containing the confidence level(s) of the required interval(s).

The value of epsilon to be used for the numerical differentiation.

Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.
Details

This function is based on the function abcnon written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is $2*n+2+2*length(conf)$ where $n$ is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A $length(conf)$ by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

Examples

```r
# 90% and 95% confidence intervals for the correlation
# coefficient between the columns of the bigcity data
abc.ci(bigcity, corr, conf=c(0.90,0.95))

# A 95% confidence interval for the difference between the means of
# the last two samples in gravity
mean.diff <- function(y, w)
{ gp1 <- 1:table(as.numeric(y$series))[1]
  sum(y[gp1, 1] * w[gp1]) - sum(y[-gp1, 1] * w[-gp1])
}
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
## IGNORE_RDIFF_BEGIN
abc.ci(grav1, mean.diff, strata = grav1$series)
## IGNORE_RDIFF_END
```
acme

**Monthly Excess Returns**

**Description**

The *acme* data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

**Usage**

*acme*

**Format**

This data frame contains the following columns:

- **month**: A character string representing the month of the observation.
- **market**: The excess return of the market as a whole.
- **acme**: The excess return for the Acme Cleveland Corporation.

aids

**Delay in AIDS Reporting in England and Wales**

**Description**

The *aids* data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

**Usage**

*aids*
aircondit

Format

This data frame contains the following columns:

- **year**: The year of the diagnosis.
- **quarter**: The quarter of the year in which diagnosis was made.
- **delay**: The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).
- **dud**: An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.
- **time**: The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.
- **y**: The number of AIDS cases reported.

Source

References

<table>
<thead>
<tr>
<th>aircondit</th>
<th>Failures of Air-conditioning Equipment</th>
</tr>

Car Speeding and Warning Signs

Description
The amis data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

Usage

amis

Format
This data frame contains the following columns:

- **speed**: Speeds of cars (in miles per hour).
- **period**: A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.
- **warning**: A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.
- **pair**: A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

References
Description

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

Usage

`aml`

Format

This data frame contains the following columns:

- `time` The length of the complete remission (in weeks).
- `cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.
- `group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

Note

Package `survival` also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

Description

The beaver data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

Usage

beaver

Format

This data frame contains the following columns:

day  The day number. The data includes only data from day 307 and early 308.
time  The time of day formatted as hour-minute.
temp  The body temperature in degrees Celsius.
activ  The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

boot

Bootstrap Resampling

Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to boot. Importance resampling weights may be specified.

Usage

```r
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
     strata = rep(1,n), L = NULL, m = 0, weights = NULL,
     ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
     parallel = c("no", "multicore", "snow"),
     ncpus =getOption("boot.ncpus", 1L), cl = NULL)
```
## Arguments

**data**
The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.

**statistic**
A function which when applied to data returns a vector containing the statistic(s) of interest. When `sim = "parametric"`, the first argument to `statistic` must be the data. For each replicate a simulated dataset returned by `ran.gen` will be passed. In all other cases `statistic` must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to `statistic` through the `...` argument.

**R**
The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case `R` would be a vector of integers where each component gives the number of resamples from each of the rows of weights.

**sim**
A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.

**stype**
A character string indicating what the second argument of `statistic` represents. Possible values of stype are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for `sim = "parametric"`.

**strata**
An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when `sim = "parametric"`. When `strata` is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.

**L**
Vector of influence values evaluated at the observations. This is used only when `sim` is "antithetic". If not supplied, they are calculated through a call to `empinf`. This will use the infinitesimal jackknife provided that `stype` is "w", otherwise the usual jackknife is used.

**m**
The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when `sim` is "ordinary". `m` will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of `statistic`, which should also take an argument giving the vector of indices of the errors to be used for the predictions.

**weights**
Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in data. When simulation from more than one set of weights is required, weights should be a matrix where each row of the matrix is one set of importance weights. If `weights` is a matrix then `R` must be a vector of length `nrow(weights)`. This parameter is ignored if `sim` is not "ordinary" or "balanced".

**ran.gen**
This function is used only when `sim = "parametric"` when it describes how random values are to be generated. It should be a function of two arguments.
The first argument should be the observed data and the second argument consists of any other information needed (e.g., parameter estimates). The second argument may be a list, allowing any number of items to be passed to ran.gen. The returned value should be a simulated data set of the same form as the observed data which will be passed to statistic to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If ran.gen is not specified, the default is a function which returns the original data in which case all simulation should be included as part of statistic. Use of sim = "parametric" with a suitable ran.gen allows the user to implement any types of nonparametric resampling which are not supported directly.

The second argument to be passed to ran.gen. Typically these will be maximum likelihood estimates of the parameters. For efficiency mle is often a list containing all of the objects needed by ran.gen which can be calculated using the original data set only.

simple logical, only allowed to be TRUE for sim = "ordinary", stype = "i", n = 0 (otherwise ignored with a warning). By default a n by R index array is created: this can be large and if simple = TRUE this is avoided by sampling separately for each replication, which is slower but uses less memory.

... Other named arguments for statistic which are passed unchanged each time it is called. Any such arguments to statistic should follow the arguments which statistic is required to have for the simulation. Beware of partial matching to arguments of boot listed above, and that arguments named X and FUN cause conflicts in some versions of boot (but not this one).

parallel The type of parallel operation to be used (if any). If missing, the default is taken from the option "boot.parallel" (and if that is not set, "no").

ncpus integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

cl An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the boot call.

Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. statistic is treated as a black box by the boot function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function ran.gen which will return a simulated data set from the observed data set and a set of parameter estimates specified in mle.

Value

The returned value is an object of class "boot", containing the following components:

t0 The observed value of statistic applied to data.
A matrix with \( \text{sum}(R) \) rows each of which is a bootstrap replicate of the result of calling \text{statistic}.

The value of \( R \) as passed to \text{boot}.

The data as passed to \text{boot}.

The value of \text{.Random.seed} when \text{boot} started work.

The function \text{statistic} as passed to \text{boot}.

Simulation type used.

Statistic type as passed to \text{boot}.

The original call to \text{boot}.

The strata used. This is the vector passed to \text{boot}, if it was supplied or a vector of ones if there were no strata. It is not returned if \( \text{sim} \) is "parametric".

The importance sampling weights as passed to \text{boot} or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if \( \text{sim} \) is not one of "ordinary" or "balanced".

If predictions are required (\( m > 0 \)) this is the matrix of indices at which predictions were calculated as they were passed to \text{statistic}. Omitted if \( m \) is 0 or \( \text{sim} \) is not "ordinary".

The influence values used when \( \text{sim} \) is "antithetic". If no such values were specified and \text{stype} is not "w" then \( L \) is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when \( \text{sim} \) is not "antithetic".

The random generator function used if \( \text{sim} \) is "parametric". This component is omitted for any other value of \text{sim}.

The parameter estimates passed to \text{boot} when \( \text{sim} \) is "parametric". It is omitted for all other values of \text{sim}.

There are \text{c}, \text{plot} and \text{print} methods for this class.

**Parallel operation**

When \( \text{parallel} = \) "multicore" is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when \( \text{parallel} = \) "snow" is used: the worker processes are newly created \( R \) processes, and \text{statistic} needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when \text{statistic} is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for \text{jack.after.boot} where ancillary functions are nested inside the \text{statistic} function.) \( \text{parallel} = \) "snow" is primarily intended to be used on multi-core Windows machine where \( \text{parallel} = \) "multicore" is not available.

For most of the \text{boot} methods the resampling is done in the master process, but not if \( \text{simple} = \) \text{TRUE} nor \( \text{sim} = \) "parametric". In those cases (or where \text{statistic} itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by \text{censboot}(\text{sim} = "wierd") and by most of the schemes in \text{tsboot} (the exceptions being \( \text{sim} = \) "fixed" and \( \text{sim} = \) "geom" with the default \text{ran.gen}).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with \( \text{parallel} = \) "multicore" or \( \text{parallel} = \) "snow" using the default cluster, a second approach is used if
RNGkind("L’Ecuyer-CMRG") has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if ncpus is unchanged, and for parallel = "multicore" if parallel::mc.reset.stream() is called: see the examples for mclapply.

Note that loading the parallel namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

References

There are many references explaining the bootstrap and its variations. Among them are:

Examples

# Usual bootstrap of the ratio of means using the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

# Stratified resampling for the difference of means. In this
# example we will look at the difference of means between the final
# two series in the gravity data.
diff.means <- function(d, f)
{ n <- nrow(d)
gp1 <- 1:table(as.numeric(d$series))[1]
m1 <- sum(d[gp1,1] * f[gp1]) / sum(f[gp1])
m2 <- sum(d[-gp1,1] * f[-gp1]) / sum(f[-gp1])
ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}
# In this example we show the use of boot in a prediction from
# regression based on the nuclear data. This example is taken
# from Example 6.8 of Davison and Hinkley (1997). Notice also
# that two extra arguments to 'statistic' are passed through boot.

```r
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)
```

# We set up a new data frame with the data, the standardized
# residuals and the fitted values for use in the bootstrap.

```r
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))
```

# Now we want a prediction of plant number 32 but at date 73.00

```r
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
                        ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)
```

```r
nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
              data = dat)
  pred.b <- predict(lm.b, x.pred)
  c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}
```

```r
nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
                  fit.pred = new.fit, x.pred = new.data)
```

# The bootstrap prediction squared error would then be found by

```r
mean(nuke.boot$t[, 8]^2)
```

# Basic bootstrap prediction limits would be

```r
new.fit - sort(nuke.boot$t[, 8]) [c(975, 25)]
```

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.

```r
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
  }
  khat <- nlm(ll, ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}
```

```r
air.rg <- function(data, mle) {
  # Function to generate random exponential variates.
  # mle will contain the mean of the original data
```
out <- data
out$hours <- rexp(nrow(out), 1/mle)
out
}

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
ran.gen = air.rg, mle = mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

---

### boot.array

#### Description

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

#### Usage

```r
boot.array(boot.out, indices)
```

#### Arguments

- **boot.out**: An object of class "boot" returned by one of the generation functions for such an object.
- **indices**: A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

#### Details

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

#### Value

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.
Side Effects

This function temporarily resets .Random.seed to the value in boot.out$seed and then returns it to its original value at the end of the function.

boot, censboot, freq.array, tilt.boot, tsboot

Examples

# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)

Description

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

Usage

boot.ci(boot.out, conf = 0.95, type = "all",
    index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
    var.t = NULL, t0 = NULL, t = NULL, L = NULL,
    h = function(t) t, hdot = function(t) rep(1,length(t)),
    hinv = function(t) t, ...)

Arguments

boot.out An object of class "boot" containing the output of a bootstrap calculation.
conf A scalar or vector containing the confidence level(s) of the required interval(s).
type A vector of character strings representing the type of intervals required. The value should be any subset of the values c("norm", "basic", "stud", "perc", "bca") or simply "all" which will compute all five types of intervals.
index This should be a vector of length 1 or 2. The first element of index indicates the position of the variable of interest in boot.out$t0 and the relevant column in boot.out$t. The second element indicates the position of the variance of the variable of interest. If both var.t0 and var.t are supplied then the second element of index (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in boot.out$t0).
If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and length(index) is 2 then var.t0 defaults to boot.out$t0[index[2]] otherwise var.t0 is undefined. For studentized intervals var.t0 must be defined. For the normal approximation, if var.t0 is undefined it defaults to var.t. If a transformation is supplied through the argument h then var.t0 should be the variance of the untransformed statistic.

This is a vector (of length boot.out$R) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and length(index) is 2 then var.t defaults to boot.out$t[index[2]], otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument h then var.t should be the variance of the untransformed bootstrap statistics.

The observed value of the statistic of interest. The default value is boot.out$t0[index[1]]. Specification of t0 and t allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions h, hdot, and hinv below.

The bootstrap replicates of the statistic of interest. It must be a vector of length boot.out$R. It is an error to supply one of t0 or t but not the other. Also if studentized intervals are required and t0 and t are supplied then so should be var.t0 and var.t. The default value is boot.out$t[,index].

The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter h then L should be the influence values for t; the values for h(t) are derived from these and hdot within the function. If L is not supplied then the values are calculated using empinf if they are needed.

A function defining a transformation. The intervals are calculated on the scale of h(t) and the inverse function hinv applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. h(c(t1,t2,t3)) should return c(h(t1),h(t2),h(t3)). The default is the identity function.

A function of one argument returning the derivative of h. It is a required argument if h is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of h(t0) and h(t) using the delta method, and also for finding the empirical influence values for BCa intervals. Like h it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.

A function, like h, which returns the inverse of h. It is used to transform the intervals calculated on the scale of h(t) back to the original scale. The default is the identity function. If h is supplied but hinv is not, then the intervals returned will be on the transformed scale.

Any extra arguments that boot.out$statistic is expecting. These arguments are needed only if BCa intervals are required and L is not supplied since in that case L is calculated through a call to empinf which calls boot.out$statistic.

Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function boot must be run prior to running this function to create the object to be passed as boot.out.
Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the R values in boot.out a warning is generated and such intervals should not be considered reliable.

Value

An object of type "bootci" which contains the intervals. It has components

- **R** The number of bootstrap replicates on which the intervals were based.
- **t0** The observed value of the statistic on the same scale as the intervals.
- **call** The call to boot.ci which generated the object.
  It will also contain one or more of the following components depending on the value of type used in the call to boot.ci.

- **normal** A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
- **basic** The intervals calculated using the basic bootstrap method.
- **student** The intervals calculated using the studentized bootstrap method.
- **percent** The intervals calculated using the bootstrap percentile method.
- **bca** The intervals calculated using the adjusted bootstrap percentile (BCa) method.
  These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

brambles

brambles

Spatial Location of Bramble Canes

Description

The brambles data frame has 823 rows and 3 columns.
The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of
distance so that the plot can be thought of as a unit square. The bramble canes were also classified
by their age.

Usage

brambles
Format

This data frame contains the following columns:

- $x$: The $x$ coordinate of the position of the cane in the plot.
- $y$: The $y$ coordinate of the position of the cane in the plot.
- $\text{age}$: The age classification of the canes; $0$ indicates a newly emerged cane, $1$ indicates a one year old cane and $2$ indicates a two year old cane.

*Smoking Deaths Among Doctors*

Description

The *breslow* data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The *breslow* data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

Usage

*breslow*

Format

This data frame contains the following columns:

- $\text{age}$: The mid-point of the 10 year age-group for the doctors.
- $\text{smoke}$: An indicator of whether the doctors smoked (1) or not (0).
- $n$: The number of person-years in the category.
- $y$: The number of deaths attributed to coronary artery disease.
- $ns$: The number of smoker years in the category ($\text{smoke} \times n$).

calciu	Calcium Uptake Data

Description

The calcium data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

Usage

calciu

Format

This data frame contains the following columns:

time The time (in minutes) that the cells were suspended in the solution.
cal The amount of calcium uptake (nmoles/mg).

Source

The data were obtained from

### Description

The cane data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

### Usage

`cane`

### Format

This data frame contains the following columns:

- **n**: The total number of shoots in each plot.
- **r**: The number of diseased shoots.
- **x**: The number of pieces of the stems, out of 50, planted in each plot.
- **var**: A factor indicating the variety of sugar-cane in each plot.
- **block**: A factor for the blocks.

### Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

### Source

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de Sao Paolo, Brazil.

**Description**

The capability data frame has 75 rows and 1 columns.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

**Usage**

`capability`

**Format**

This data frame contains the following column:

- `y` The simulated measurements.

**Source**

The data were obtained from

**Weight Data for Domestic Cats**

**Description**

The `catsM` data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The `catsM` data frame consists of the data for the male cats. The full data are in dataset `cats` in package `MASS`.

**Usage**

`catsM`
cav

Format

This data frame contains the following columns:

- **Sex**: A factor for the sex of the cat (levels are F and M; all cases are M in this subset).
- **Bwt**: Body weight in kg.
- **Hwt**: Heart weight in g.

cav  Position of Muscle Caveolae

Description

The cav data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65mm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset caveolae.dat in the spatial package by B.D. Ripley (1994).

Usage
cav

Format

This data frame contains the following columns:

- **x**: The x coordinate of the caveola’s position in the region.
- **y**: The y coordinate of the caveola’s position in the region.

References

Description

The cd4 data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

Usage

cd4

Format

This data frame contains the following columns:

- baseline  The CD4 counts (in 100’s) on admission to the trial.
- oneway   The CD4 counts (in 100’s) after one year of treatment with the new drug.

d4.nested  Nested Bootstrap of cd4 data

Description

This is an example of a nested bootstrap for the correlation coefficient of the cd4 data frame. It is used in a practical in Chapter 5 of Davison and Hinkley (1997).

References

See Also

cd4
This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
  sim = "ordinary", cox = NULL, index = c(1, 2), ....,
  parallel = c("no", "multicore", "snow"),
  ncpus = getOption("boot.ncpus", 1L), cl = NULL)

Arguments

data
The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for sim = "weird" when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of index are taken to be the times and censoring indicators.

statistic
A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the ... argument. In the case of sim = "weird", the data passed to statistic only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to statistic will be of the same form as the original data. When sim = "weird", the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if sim = "weird" and strata is supplied, statistic should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.

R
The number of bootstrap replicates.

F.surv
An object returned from a call to survfit giving the survivor function for the data. This is a required argument unless sim = "ordinary" or sim = "model" and cox is missing.

G.surv
Another object returned from a call to survfit but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to survfit. This is a required argument whenever sim = "cond" or when sim = "model" and cox is supplied.

strata
The strata used in the calls to survfit. It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When sim = "weird" only the strata for the survival distribution are used since the
censoring times are considered fixed. When \texttt{sim} = "ordinary", only one set of strata is used to stratify the observations, this is taken to be the first column of \texttt{strata} when it is a matrix.

\textbf{sim} \hspace{1cm} The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if \texttt{cox} is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if \texttt{cox} is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

\textbf{cox} \hspace{1cm} An object returned from \texttt{coxph}. If it is supplied, then \texttt{F.surv} should have been generated by a call of the form \texttt{survfit(cox)}.

\textbf{index} \hspace{1cm} A vector of length two giving the positions of the columns in \texttt{data} which correspond to the times and censoring indicators respectively.

\textbf{...} \hspace{1cm} Other named arguments which are passed unchanged to statistic each time it is called. Any such arguments to statistic must follow the arguments which statistic is required to have for the simulation. Beware of partial matching to arguments of \texttt{censboot} listed above, and that arguments named \texttt{X} and \texttt{FUN} cause conflicts in some versions of \texttt{boot} (but not this one).

\textbf{parallel, ncpus, cl} \hspace{1cm} See the help for \texttt{boot}.

\textbf{Details}

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of \texttt{Inf} and conversely if it is uncensored it is given a nominal censoring time of \texttt{Inf}. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (\texttt{sim} = "model") or from the conditional censoring distribution as in the previous paragraph (\texttt{sim} = "cond").

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and \texttt{sim} is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of \texttt{Inf}, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of \texttt{Inf} and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.
When parallel = "snow" and cl is not supplied, library(survival) is run in each of the worker processes.

Value

An object of class "boot" containing the following components:

- \( t0 \) The value of statistic when applied to the original data.
- \( t \) A matrix of bootstrap replicates of the values of statistic.
- \( R \) The number of bootstrap replicates performed.
- \( sim \) The simulation type used. This will usually be the input value of sim unless that was "model" but cox was not supplied, in which case it will be "ordinary".
- \( data \) The data used for the bootstrap. This will generally be the input value of data unless sim = "weird", in which case it will just be the columns containing the times and the censoring indicators.
- \( seed \) The value of .Random.seed when censboot started work.
- \( statistic \) The input value of statistic.
- \( strata \) The strata used in the resampling. When sim = "ordinary" this will be a vector which stratifies the observations, when sim = "weird" it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
- \( call \) The original call to censboot.

channing

### Channing House Data

**Description**

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

**Usage**

channing

**Format**

This data frame contains the following columns:

- **sex** A factor for the sex of each resident ("Male" or "Female").
- **entry** The residents age (in months) on entry to the centre
- **exit** The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
time: The length of time (in months) that the resident spent at Channing House.
(time=exit-entry)
cens: The indicator of right censoring. 1 indicates that the resident died at Channing House, 0
indicates that they left the house prior to July 1, 1975 or that they were still alive and living in
the centre at that date.

**Genetic Links to Left-handedness**

**Description**

The **claridge** data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain
genetic characteristic and handedness. The 37 subjects were women who had a son with mental
retardation due to inheriting a defective X-chromosome. For each such mother a genetic measure-
ment of their DNA was made. Larger values of this measurement are known to be linked to the
defective gene and it was hypothesized that larger values might also be linked to a progressive shift
away from right-handedness. Each woman also filled in a questionnaire regarding which hand they
used for various tasks. From these questionnaires a measure of hand preference was found for each
mother. The scale of this measure goes from 1, indicating someone who always favours their right
hand, to 8, indicating someone who always favours their left hand. Between these two extremes are
people who favour one hand for some tasks and the other for other tasks.

**Usage**

**claridge**

**Format**

This data frame contains the following columns:

dnan: The genetic measurement on each woman’s DNA.
hand: The measure of left-handedness on an integer scale from 1 to 8.

**Source**

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experi-
mental Psychology, University of Oxford.

c.o.transfer

Carbon Monoxide Transfer

Description

The c.o.transfer data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

Usage

c.o.transfer
This data frame contains the following columns:

- **entry** Carbon monoxide transfer factor on entry to hospital.
- **week** Carbon monoxide transfer one week after admittance to hospital.

The data were obtained from

---

**coal**  
*Dates of Coal Mining Disasters*

The coal data frame has 191 rows and 1 columns. This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

**Usage**

coal

**Format**

This data frame contains the following column:

- **date** The date of the disaster. The integer part of date gives the year. The day is represented as the fraction of the year that had elapsed on that day.

The data were obtained from

Description

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

Usage

control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL, 
        t = NULL, bias.adj = FALSE, alpha = NULL, ...)

Arguments

boot.out A bootstrap output object returned from boot. The bootstrap replicates must have been generated using the usual nonparametric bootstrap.
L The empirical influence values for the statistic of interest. If L is not supplied then empinf is called to calculate them from boot.out.
distn If present this must be the output from smooth.spline giving the distribution function of the linear approximation. This is used only if bias.adj is FALSE. Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by saddle.distn.
index The index of the variable of interest in the output of boot.out$statistic.
t0 The observed value of the statistic of interest on the original data set boot.out$data. This argument is used only if bias.adj is FALSE. The input value is ignored if t is not also supplied. The default value is is boot.out$t0[index].
t The bootstrap replicate values of the statistic of interest. This argument is used only if bias.adj is FALSE. The input is ignored if t0 is not supplied also. The default value is boot.out$t[,index].
bias.adj A logical variable which if TRUE specifies that the adjusted bias estimate using post-simulation balance is all that is required. If bias.adj is FALSE (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.
alpha The alpha levels for the required quantiles if bias.adj is FALSE.
... Any additional arguments that boot.out$statistic requires. These are passed unchanged every time boot.out$statistic is called. boot.out$statistic is called once if bias.adj is TRUE, otherwise it may be called by empinf for empirical influence calculations if L is not supplied.

Details

If bias.adj is FALSE then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation \( T^* = \hat{T} + \hat{T} - T \), moment estimates can be found. For quantile estimation the distribution of the linear approximation to \( t \) is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of \( t \) and hence to estimate the bootstrap quantiles of \( t \).
Value

If bias.adj is TRUE then the returned value is the adjusted bias estimate.
If bias. adj is FALSE then the returned value is a list with the following components

- **L**: The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by empinf.
- **tL**: The linear approximations to the bootstrap replicates \( t \) of the statistic of interest.
- **bias**: The control estimate of bias using the linear approximation to \( t \) as a control variate.
- **var**: The control estimate of variance using the linear approximation to \( t \) as a control variate.
- **k3**: The control estimate of the third cumulant using the linear approximation to \( t \) as a control variate.
- **quantiles**: A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to \( t \) as a control variate.
- **distn**: An output object from smooth.spline describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to \( t \). If distn was supplied on input then this is the same as the input otherwise it is calculated by a call to saddle.distn.

Examples

```r
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{ m <- mean(d$hours[i])
  n <- nrow(d)
  v <- (n-1)*var(d$hours[i])/n^2
  c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
  t = log(air.boot$t[, 2]))
```
**corr**  

**Correlation Coefficient**

**Description**

Calculates the weighted correlation given a data set and a set of weights.

**Usage**

```r
corr(d, w = rep(1, nrow(d))/nrow(d))
```

**Arguments**

- `d`: A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
- `w`: A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so `sum(w)` need not equal 1.

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between `d[,1]` and `d[,2]`.

**See Also**

`cor`

---

**cum3**  

**Calculate Third Order Cumulants**

**Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

```r
cum3(a, b = a, c = a, unbiased = TRUE)
```
Arguments

a  A vector of observations.
b  Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.
c  Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.

unbiased  A logical value indicating whether the unbiased estimator should be used.

Details

The unbiased estimator uses a multiplier of \(n/((n-1)*(n-2))\) where \(n\) is the sample size, if unbiased is FALSE then a multiplier of \(1/n\) is used. This is multiplied by \(\sum((a-\text{mean}(a))*(b-\text{mean}(b))*(c-\text{mean}(c)))\) to give the required estimate.

Value

The required estimate.

cv.glm

Cross-validation for Generalized Linear Models

Description

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

Usage

cv.glm(data, glmfit, cost, K)

Arguments

data  A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.
glmfit  An object of class "glm" containing the results of a generalized linear model fitted to data.
cost  A function of two vector arguments specifying the cost function for the cross-validation. The first argument to cost should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. cost must return a non-negative scalar value. The default is the average squared error function.
K  The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of K must be such that all groups are of approximately equal size. If the supplied value of K does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of K used. The default is to set K equal to the number of observations in data which gives the usual leave-one-out cross-validation.
The data is divided randomly into \( K \) groups. For each group the generalized linear model is fit to data omitting that group, then the function \( \text{cost} \) is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When \( K \) is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When \( K \) is less than the number of observations the \( K \) splits to be used are found by randomly partitioning the data into \( K \) groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in \( \text{delta} \) is the estimate adjusted by this method.

The returned value is a list with the following components.

- `call`: The original call to `cv.glm`.
- `K`: The value of \( K \) used for the \( K \)-fold cross validation.
- `delta`: A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.
- `seed`: The value of `.Random.seed` when `cv.glm` was called.

The value of `.Random.seed` is updated.

darwin  
*Darwin’s Plant Height Differences*

**Description**

The *darwin* data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

**Usage**

darwin

**Format**

This data frame contains the following column:

y  The difference in heights for the pairs of plants (in units of 0.125 inches).

### downs.bc

**Incidence of Down’s Syndrome in British Columbia**

**Description**

The `downs.bc` data frame has 30 rows and 3 columns.

Down’s syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down’s syndrome is highly dependent on the mother’s age and rises sharply after age 30. In the 1960’s a large scale study of the effect of maternal age on the incidence of Down’s syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

**Usage**

`downs.bc`

**Format**

This data frame contains the following columns:

- **age** The average age of all mothers in the age category.
- **m** The total number of live births to mothers in the age category.
- **r** The number of cases of Down’s syndrome.
Source
The data were obtained from

**ducks**

*Behavioral and Plumage Characteristics of Hybrid Ducks*

Description
The ducks data frame has 11 rows and 2 columns.
Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour.
The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

Usage
ducks

Format
This data frame contains the following columns:
- **plumage** The index of physical appearance based on the plumage of individual ducks.
- **behaviour** The index of behavioural characteristics of the ducks.

Source
The data were obtained from

References
**Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```r
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)
```

**Arguments**

- `y` A vector or matrix of data
- `tmin` The minimum value of the range over which the likelihood should be computed. This must be larger than min(y).
- `tmax` The maximum value of the range over which the likelihood should be computed. This must be smaller than max(y).
- `n.t` The number of points between `tmin` and `tmax` at which the value of the log-likelihood should be computed.
- `u` A function of the data and the parameter.

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package boot for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the boot package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen’s empirical likelihood home page at the URL [http://statistics.stanford.edu/~owen/empirical/](http://statistics.stanford.edu/~owen/empirical/).

**Value**

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

**Author(s)**

Angelo J. Canty

**References**

**Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

**Usage**

```r
empinf(boot.out = NULL, data = NULL, statistic = NULL,
       type = NULL, stype = NULL, index = 1, t = NULL,
       strata = rep(1, n), eps = 0.001, ...)
```

**Arguments**

- `boot.out` A bootstrap object created by the function `boot`. If type is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of data, statistic, stype, and strata are taken from the components of boot.out and any values passed to `empinf` directly are ignored.

- `data` A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if `boot.out` is not supplied. If boot.out is supplied then data is set to boot.out$data and any value supplied here is ignored.

- `statistic` The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of stype. Any other arguments that it takes must be supplied to `empinf` and will be passed to statistic unchanged. This is a required argument if `boot.out` is not supplied, otherwise its value is taken from `boot.out` and any value supplied here will be ignored.

- `type` The calculation type to be used for the empirical influence values. Possible values of type are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If t is supplied then the default value of type is "reg" and boot.out should be present so that its frequency array can be found. If t is not supplied then if stype is "w", the default value of type is "inf"; otherwise, if boot.out is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for type to be "reg" if boot.out is missing or to be "inf" if stype is not "w".

- `stype` A character variable giving the nature of the second argument to statistic. It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If boot.out is supplied the value of stype is set to boot.out$stype and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If type is "inf" then stype MUST be "w".
index

An integer giving the position of the variable of interest in the output of statistic.

t

A vector of length boot.out$R which gives the bootstrap replicates of the statistic of interest. t is used only when type is reg and it defaults to boot.out$t[,index].

strata

An integer vector or a factor specifying the strata for multi-sample problems. If boot.out is supplied the value of strata is set to boot.out$strata. Otherwise it is an optional argument which has default corresponding to the single sample situation.

eps

This argument is used only if type is "inf". In that case the value of epsilon to be used for numerical differentiation will be eps divided by the number of observations in data.

... Any other arguments that statistic takes. They will be passed unchanged to statistic every time that it is called.

Details

If type is "inf" then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. stype is "w"). If type is "jack" then the usual leave-one-out jackknife estimates of the empirical influence are returned. If type is "pos" then the positive (include-one-twice) jackknife values are used. If type is "reg" then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of statistic on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to boot.array. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call empinf when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

Value

A vector of the empirical influence values of statistic applied to data. The values will be in the same order as the observations in data.

Warning

All arguments to empinf must be passed using the name = value convention. If this is not followed then unpredictable errors can occur.

envelope

Confidence Envelopes for Curves

Description

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

Usage

envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))

Arguments

boot.out An object of class "boot" for which boot.out$t contains the replicates of the curve at a number of fixed points.

mat A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if boot.out is not supplied and is set to boot.out$t otherwise.
**level**

The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.

**index**

The numbers of the columns of `mat` which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

**Details**

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

**Value**

A list with the following components:

- **point**: A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.
- **overall**: A matrix similar to `point` but containing the envelope which controls the overall error.
- **k.pt**: The quantiles used for the pointwise envelope.
- **err.pt**: A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.
- **k.ov**: The quantiles used for the overall envelope.
- **err.ov**: A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.
- **err.nom**: A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

grav.gen <- function(dat, mle) rnorm(length(dat))
```
exp.tilt

Exponential Tilting

Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

Usage

exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL, strata = rep(1, length(L)))

Arguments

L
The empirical influence values for the statistic of interest based on the observed data. The length of L should be the same as the size of the original data set. Typically L will be calculated by a call to empinf.

theta
The value at which the tilted distribution is to be centred. This is not required if lambda is supplied but is needed otherwise.

t0
The current value of the statistic. The default is that the statistic equals 0.

lambda
The Lagrange multiplier(s). For each value of lambda a multinomial distribution is found with probabilities proportional to \(\exp(\lambda L[j])\). In general lambda is not known and so theta would be supplied, and the corresponding value of lambda found. If both lambda and theta are supplied then lambda is ignored and the multipliers for tilting to theta are found.

strata
A vector or factor of the same length as \L\ giving the strata for the observed data and the empirical influence values L.

Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean theta. The weights chosen to achieve this are given by \(p[j]\) proportional to \(\exp(\lambda L[j]/n)\), where \(n\) is the number of data points. lambda is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value theta. Thus lambda is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function nlmin. If this minimum is not equal to zero then the method fails.
Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions imp.prob or imp.quantile to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of smooth.f. The function tilt.boot uses exp.tilt or smooth.f to find the weights for a tilted bootstrap.

Value

A list with the following components:

- **p**: The tilted probabilities. There will be m distributions where m is the length of theta (or lambda if supplied). If m is 1 then p is a vector of length(L) probabilities. If m is greater than 1 then p is a matrix with m rows, each of which contain length(L) probabilities. In this case the vector p[i,] is the distribution tilted to theta[i]. p is in the form required by the argument weights of the function boot for importance resampling.

- **lambda**: The Lagrange multiplier used in the equation to determine the tilted probabilities. lambda is a vector of the same length as theta.

- **theta**: The values of theta to which the distributions have been tilted. In general this will be the input value of theta but if lambda was supplied then this is the vector of the corresponding theta values.

### fir

**Counts of Balsam-fir Seedlings**

**Description**

The `fir` data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

**Usage**

```r
fir
```

**Format**

This data frame contains the following columns:

- `count`: The number of seedlings in the quadrant.
- `row`: The row number of the quadrant.
- `col`: The quadrant number within the row.

**Source**

---

### freq.array

**Bootstrap Frequency Arrays**

**Description**

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

**Usage**

```r
freq.array(i.array)
```

**Arguments**

- `i.array`: This will be a matrix of integers between 1 and n, where n is the number of observations in a data set. The matrix will have n columns and R rows where R is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`. 
**Value**

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

glm.diag

Generalized Linear Model Diagnostics

Description

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

Usage

glm.diag(glmfit)

Arguments

glmfit glmfit is a glm.object - the result of a call to glm()

Value

Returns a list with the following components

res The vector of jackknife deviance residuals.
rd The vector of standardized deviance residuals.
rp The vector of standardized Pearson residuals.
cook The vector of approximate Cook statistics.
h The vector of leverages of the observations.
sd The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1.

Note

See the help for glm.diag.plots for an example of the use of glm.diag.

References

See Also

glm, glm.diag.plots, summary(glm)
glm.diag.plots  

Diagnostics plots for generalized linear models

Description

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

Usage

```r
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
               iden = FALSE, labels = NULL, ret = FALSE)
```

Arguments

- **glmfit**: `glm` object: the result of a call to `glm()`
- **glmdiag**: Diagnostics of `glmfit` obtained from a call to `glm.diag`. If it is not supplied then it is calculated.
- **subset**: Subset of data for which `glm` fitting performed: should be the same as the subset option used in the call to `glm()` which generated `glmfit`. Needed only if the `subset` option was used in the call to `glm`.
- **iden**: A logical argument. If TRUE then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke `identify()` on that plot. After exiting `identify()`, the user is again prompted, this loop continuing until the user responds to the prompt with 0. If `iden` is FALSE (default) the user cannot interact with the plots.
- **labels**: A vector of labels for use with `identify()` if `iden` is TRUE. If it is not supplied then the labels are derived from `glmfit`.
- **ret**: A logical argument indicating if `glmdiag` should be returned. The default is FALSE.

Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at \(8/(n-2p)\) where \(n\) is the number of observations and \(p\) is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at \(2p/(n-2p)\) and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.
Use of \texttt{idem=T} is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

**Value**

If \texttt{ret} is \texttt{TRUE} then the value of \texttt{glm.diag} is returned otherwise there is no returned value.

**Side Effects**

The current device is cleared and four plots are plotted by use of \texttt{split.screen(c(2,2))}. If \texttt{idem} is \texttt{TRUE}, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

**gravity**  
*Acceleration Due to Gravity*

**Description**

The \texttt{gravity} data frame has 81 rows and 2 columns.  
The \texttt{grav} data set has 26 rows and 2 columns.  
Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity, \( g \), at Washington. Each experiment produced a number of replicate estimates of \( g \) using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.  
The \texttt{gravity} data frame contains the data from all eight experiments. The \texttt{grav} data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.
hirose

Usage

gravity

Format

This data frame contains the following columns:

- **g**: The deviation of the estimate from 980.000 centimetres per second squared.
- **series**: A factor describing from which experiment the estimate was derived.

Importance Sampling Estimates

Description

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

Usage

\begin{verbatim}
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
             w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
         t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
             t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
\end{verbatim}

Arguments

- **boot.out**: A object of class "boot" generated by a call to boot or tilt.boot. Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights \(w\) are not supplied then \(boot.out\) is a required argument. It is also required if \(t\) is not supplied.
- **alpha**: The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.
- **index**: The index of the variable of interest in the output of \(boot.out$statistic\). This is not used if the argument \(t\) is supplied.
- **t0**: The values at which tail probability estimates are required. For each value \(t0[i]\) the function will estimate the bootstrap cdf evaluated at \(t0[i]\). If \(imp.prob\) is called without the argument \(t0\) then the bootstrap cdf evaluated at the observed value of the statistic is found.
- **t**: The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object \(boot.out\) but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in \(boot.out\)). Either \(boot.out\) or \(t\) must be supplied.
- **w**: The importance resampling weights for the bootstrap replicates. If they are not supplied then \(boot.out\) must be supplied, in which case the importance weights are calculated by a call to \(imp.weights\).
- **def**: A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if \(w\) is missing and it is passed unchanged to \(imp.weights\) to calculate \(w\).
- **q**: A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights \(w\) so this argument is ignored if \(w\) is supplied. If \(w\) is missing then \(q\) is passed as an argument to \(imp.weights\) and used to find \(w\).
Value

A list with the following components:

- **alpha**: The alpha levels used for the quantiles, if `imp.quantile` is used.
- **t0**: The values at which the tail probabilities are estimated, if `imp.prob` is used.
- **raw**: The raw importance resampling estimates. For `imp.moments` this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For `imp.prob`, `raw` is of the same length as `t0`, and for `imp.quantile` it is of the same length as `alpha`.
- **rat**: The ratio importance resampling estimates. In this method the weights \( w \) are rescaled to have average value one before they are used. The format of this vector is the same as `raw`.
- **reg**: The regression importance resampling estimates. In this method the weights which are used are derived from a regression of \( t^w \) on \( w \). This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as `raw`.

Examples

# Example 9.8 of Davison and Hinkley (1997) requires tilting the # resampling distribution of the studentized statistic to be centred # at the observed value of the test statistic, 1.84. In this example # we show how certain estimates can be found using resamples taken from # the tilted distribution.

```r
graw1 <- gravity[as.numeric(gravity[,2]) >= 7, ]
ggrav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
}
ggrav.z0 <- grav.fun(ggrav1, rep(1, 26), 0)
ggrav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w", strata = grav1[, 2], index = 3, orig = grav.z0[1])
ggrav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[, 2])
```
imp.weights <- boot(grav1, grav.fun, R = 199, stype = "w",
                   strata = grav1[, 2], weights = grav.tilt$p,
                   orig = grav.z0[1])
# Since the weights are needed for all calculations, we shall calculate
# them once only.
grav.w <- imp.weights(grav.tilt.boot)
grav.mom <- imp.moments(grav.tilt.boot, w = grav.w, index = 3)
grav.p <- imp.prob(grav.tilt.boot, w = grav.w, index = 3, t0 = grav.z0[3])
unlist(grav.p)
grav.q <- imp.quantile(grav.tilt.boot, w = grav.w, index = 3,
                         alpha = c(0.9, 0.95, 0.975, 0.99))
as.data.frame(grav.q)

imp.weights

Importance Sampling Weights

Description

This function calculates the importance sampling weight required to correct for simulation from a
distribution with probabilities p when estimates are required assuming that simulation was from an
alternative distribution with probabilities q.

Usage

imp.weights(boot.out, def = TRUE, q = NULL)

Arguments

boot.out A object of class "boot" generated by boot or tilt.boot. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.

def A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in boot.out were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.

q A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. q must have length equal to the number of observations in the boot.out$data and all elements of q must be positive.

Details

The importance sampling weight for a bootstrap replicate with frequency vector f is given by
prod((q/p)^f). This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities q even though, in fact, they came from the distribution p.
inv.logit

Value
A vector of importance weights of the same length as boot.out$t. These weights can then be used to reweight boot.out$t so that estimates can be found as if the simulations were from a distribution with probabilities q.

Note
See the example in the help for imp.moments for an example of using imp.weights.

References

See Also
boot.exp.tilt, imp.moments, smooth.f, tilt.boot

inv.logit

Inverse Logit Function

Description
Given a numeric object return the inverse logit of the values.

Usage
inv.logit(x)

Arguments
x A numeric object. Missing values (NAs) are allowed.

Details
The inverse logit is defined by \( \exp(x)/(1+\exp(x)) \). Values in x of -Inf or Inf return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

Value
An object of the same type as x containing the inverse logits of the input values.

See Also

islay  \textit{Jura Quartzite Azimuths on Islay}

\textbf{Description}

The islay data frame has 18 rows and 1 columns. Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

\textbf{Usage}

\texttt{islay}

\textbf{Format}

This data frame contains the following column:

\texttt{theta}  The angle of the azimuth in degrees East of North.

\textbf{Source}

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) \textit{A Handbook of Small Data Sets}, Chapman and Hall.

\textbf{References}

jack.after.boot  \textit{Jackknife-after-Bootstrap Plots}

\textbf{Description}

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

\textbf{Usage}

\texttt{jack.after.boot(boot.out, index = 1, t = NULL, L = NULL, useJ = TRUE, stinf = TRUE, alpha = NULL, main = "", ylab = NULL, ...)}
Arguments

boot.out  An object of class "boot" which would normally be created by a call to boot. It should represent a nonparametric bootstrap. For reliable results boot.out$R should be reasonably large.

index  The index of the statistic of interest in the output of boot.out$statistic.

t  A vector of length boot.out$R giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is boot.out$t[,index].

L  The empirical influence values for the statistic of interest. These are used only if useJ is FALSE. If they are not supplied and are needed, they are calculated by a call to empinf. If L is supplied then it is assumed that they are the infinitesimal jackknife values.

useJ  A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If FALSE the empirical influence values are used. The default is TRUE.

stinf  A logical variable indicating whether to standardize the jackknife values before plotting them. If TRUE then the jackknife values used are divided by their standard error.

alpha  The quantiles at which the plots are required. The default is c(0.05,0.1,0.16,0.5,0.84,0.9,0.95).

main  A character string giving the main title for the plot.

ylab  The label for the Y axis. If the default values of alpha are used and ylab is not supplied then a label indicating which percentiles are plotted is used. If alpha is supplied then the default label will not say which percentiles were used.

...  Any extra arguments required by boot.out$statistic. These are required only if useJ is FALSE and L is not supplied, in which case they are passed to empinf for use in calculation of the empirical influence values.

Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If useJ is TRUE then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If useJ is FALSE then empirical influence values are calculated by calling empinf.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

Value

There is no returned value but a plot is generated on the current graphics display.
Side Effects

A plot is created on the current graphics device.

# Example 3.24 of Davison and Hinkley (1997)

```r
frets.fun <- function(data, i) {
  pcorr <- function(x) {
    # Function to find the correlations and partial correlations between
    # the four measurements.
    v <- cor(x)
    v.d <- diag(var(x))
    iv <- solve(v)
    iv.d <- sqrt(diag(iv))
    iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
    q <- NULL
    n <- nrow(v)
    for (i in 1:(n-1))
      q <- rbind( q, c(v[i, 1:i], iv[i,(i+1):n]) )
    q <- rbind( q, v[n, ] )
    diag(q) <- round(diag(q))
    q
  }
  d <- data[i, ]
  v <- pcorr(d)
  c(v[1,], v[2,], v[3,], v[4,])
}

frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)
```

---

**k3.linear**  

Linear Skewness Estimate

**Description**

Estimates the skewness of a statistic from its empirical influence values.
Usage

k3.linear(L, strata = NULL)

Arguments

L Vector of the empirical influence values of a statistic. These will usually be calculated by a call to empinf.
strata A numeric vector or factor specifying which observations (and hence which components of L) come from which strata.

Value

The skewness estimate calculated from L.

References

See Also

empinf, linear.approx, var.linear

Examples

# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))

linear.approx

Linear Approximation of Bootstrap Replicates

Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

Usage

linear.approx(boot.out, L = NULL, index = 1, type = NULL, t0 = NULL, t = NULL, ...)

Arguments

boot.out An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function boot.
L A vector containing the empirical influence values for the statistic of interest. If it is not supplied then L is calculated through a call to empinf.
index The index of the variable of interest within the output of boot.out$statistic.
linear.approx

This gives the type of empirical influence values to be calculated. It is not used if \( L \) is supplied. The possible types of empirical influence values are described in the help for `empinf`.

The observed value of the statistic of interest. The input value is used only if one of \( t \) or \( L \) is also supplied. The default value is `boot.out$t0[index]`. If \( t0 \) is supplied but neither \( t \) nor \( L \) are supplied then \( t0 \) is set to `boot.out$t0[index]` and a warning is generated.

A vector of bootstrap replicates of the statistic of interest. If \( t0 \) is missing then \( t \) is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in \( L \)).

Any extra arguments required by `boot.out$statistic`. These are needed if \( L \) is not supplied as they are used by `empinf` to calculate empirical influence values.

The linear approximation to a bootstrap replicate with frequency vector \( f \) is given by \( t0 + \frac{\sum(L \ast f)}{n} \) in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

See Also

`boot`, `empinf`, `control`

Examples

# Using the city data let us look at the linear approximation to the # ratio statistic and its logarithm. We compare these with the # corresponding plots for the bigcity data

```r
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 499, stype = "w")
bigcity.boot <- boot(bigcity, ratio, R = 499, stype = "w")
opt <- par(pty = "s", mfrow = c(2, 2))

# The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t, city.lin1))
plot(city.boot$t, city.lin1, xlim = lim, ylim = lim,
     main = "Ratio; n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

# Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot, t0 = log(city.boot$t0),
```
lines.saddle.distn

Add a Saddlepoint Approximation to a Plot

Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

Usage

## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
       npts = 50, lty = 1, ...)

Arguments

x An object of class "saddle.distn" (see saddle.distn.object representing a saddlepoint approximation to a distribution.

dens A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.

h Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.

J When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list.

npts The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.
The line type to be used.

Any additional arguments to \( h \) and \( J \).

The function uses `smooth.spline` to produce the saddlepoint curve. When \( \text{dens=TRUE} \) the spline is on the log scale and when \( \text{dens=FALSE} \) it is on the probit scale.

\( \text{sad.d} \) is returned invisibly.

A line is added to the current plot.

`saddle.distn`

Examples

```r
# In this example we show how a plot such as that in Figure 9.9 of
# Davison and Hinkley (1997) may be produced. Note the large number of
# bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
  n <- length(d)
  (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata, vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t)))
exp.sp <- saddle.distn(A = exp.L/12, wdist = "m", t0 = exp.t0)
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1, t0 = exp.boot$t0)
```
logit

Logit of Proportions

Description
This function calculates the logit of proportions.

Usage
logit(p)

Arguments
p A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

Details
If any elements of p are outside the unit interval then an error message is generated. Values of p equal to 0 or 1 (to within machine precision) will return -Inf or Inf respectively. Any NAs in the input will also be NAs in the output.

Value
A numeric object of the same type as p containing the logits of the input values.

See Also
inv.logit, qlogis for which this is a wrapper.

manaus

Average Heights of the Rio Negro river at Manaus

Description
The manaus time series is of class "ts" and has 1080 observations on one variable.
The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.
The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.
Source

The data were kindly made available by Professors H. O’Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

**melanoma**

*Survival from Malignant Melanoma*

**Description**

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

**Usage**

`melanoma`

**Format**

This data frame contains the following columns:

- `time` Survival time in days since the operation, possibly censored.
- `status` The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.
- `sex` The patients sex; 1=male, 0=female.
- `age` Age in years at the time of the operation.
- `year` Year of operation.
- `thickness` Tumour thickness in mm.
- `ulcer` Indicator of ulceration; 1=present, 0=absent.

**Note**

This dataset is not related to the dataset in the `lattice` package with the same name.

**nitrofen**  *Toxicity of Nitrofen in Aquatic Systems*

**Description**

The nitrofen data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

**Usage**

nitrofen
nodal

Format

This data frame contains the following columns:

- **conc**: The nitrofen concentration in the solution (mug/litre).
- **brood1**: The number of live offspring in the first brood.
- **brood2**: The number of live offspring in the second brood.
- **brood3**: The number of live offspring in the third brood.
- **total**: The total number of live offspring in the first three broods.

Source

nodal

**Nodal Involvement in Prostate Cancer**

Description

The nodal data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

Usage

nodal

Format

This data frame contains the following columns:

- **m**: A column of ones.
- **r**: An indicator of nodal involvement.
- **aged**: The patients age dichotomized into less than 60 (0) and 60 or over (1).
- **stage**: A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.
grade Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

xray A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

acid The level of acid phosphatase in the blood serum.

Source

The data were obtained from

References

norm.ci

Normal Approximation Confidence Intervals

Description

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

Usage

```
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL, t0 = NULL, t = NULL, L = NULL, h = function(t) t, hdot = function(t) 1, hinv = function(t) t)
```

Arguments

- `boot.out`: A bootstrap output object returned from a call to `boot`. If `t0` is missing then `boot.out` is a required argument. It is also required if both `var.t0` and `t` are missing.
- `conf`: A scalar or vector containing the confidence level(s) of the required interval(s).
- `index`: The index of the statistic of interest within the output of a call to `boot.out$statistic`. It is not used if `boot.out` is missing, in which case `t0` must be supplied.
- `var.t0`: The variance of the statistic of interest. If it is not supplied then `var(t)` is used.
- `t0`: The observed value of the statistic of interest. If it is missing then it is taken from `boot.out` which is required in that case.
- `t`: Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if `var.t0` is not supplied. The default value is `boot.out$t[, index]`.
- `L`: The empirical influence values for the statistic of interest. These are used to calculate `var.t0` if neither `var.t0` nor `boot.out` are supplied. If a transformation is supplied through `h` then the influence values must be for the untransformed statistic `t0`. 
norm.ci

A function defining a monotonic transformation, the intervals are calculated on the scale of h(t) and the inverse function hinv is applied to the resulting intervals. h must be a function of one variable only and must be vectorized. The default is the identity function.

hdot

A function of one argument returning the derivative of h. It is a required argument if h is supplied and is used for approximating the variance of h(t0). The default is the constant function 1.

hinv

A function, like h, which returns the inverse of h. It is used to transform the intervals calculated on the scale of h(t) back to the original scale. The default is the identity function. If h is supplied but hinv is not, then the intervals returned will be on the transformed scale.

Details

It is assumed that the statistic of interest has an approximately normal distribution with variance var.t0 and so a confidence interval of length 2*qnorm((1+conf)/2)*sqrt(var.t0) is found. If boot.out or t are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at 2*t0-mean(t). Otherwise the interval is centred at t0.

Value

If length(conf) is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

Note

This function is primarily designed to be called by boot.ci to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as t0 and var.t0 can be supplied. See the examples below.

Nuclear Power Station Construction Data

Description

The nuclear data frame has 32 rows and 11 columns. The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers’ subsidies may be hidden in the quoted capital costs.

Usage

nuclear

The data were obtained from

References

Description

The `paulsen` data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

Usage

`paulsen`

Format

This data frame contains the following column:

- `y` The current flowing into individual brain cells. The currents are measured in pico-amperes.

Source

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

plot.boot

Plots of the Output of a Bootstrap Simulation

Description

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

Usage

```r
## S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```
Arguments

- **x**: An object of class "boot" returned from one of the bootstrap generation functions.
- **index**: The index of the variable of interest within the output of `boot.out`. This is ignored if `t` and `t0` are supplied.
- **t0**: The original value of the statistic. This defaults to `boot.out$t0[index]` unless `t` is supplied when it defaults to NULL. In that case no vertical line is drawn on the histogram.
- **t**: The bootstrap replicates of the statistic. Usually this will take on its default value of `boot.out$t[,index]`, however it may be useful sometimes to supply a different set of values which are a function of `boot.out$t`.
- **jack**: A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.
- **qdist**: The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.
- **nclass**: An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to `ceiling(length(t)/25)`.
- **df**: If `qdist` is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.
- **...**: When `jack` is TRUE additional parameters to `jack.after.boot` can be supplied. See the help file for `jack.after.boot` for details of the possible parameters.

Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

Value

`boot.out` is returned invisibly.

Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

plot(frets.boot, index = 7, jack = TRUE, stinf = FALSE, useJ = FALSE)
### Poisons

**Animal Survival Times**

**Description**

The poisons data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

**Usage**

poisons

**Format**

This data frame contains the following columns:

- time: The survival time of the animal in units of 10 hours.
- poison: A factor with levels 1, 2 and 3 giving the type of poison used.
- treat: A factor with levels A, B, C and D giving the treatment.

print.boot  

Print a Summary of a Bootstrap Object

Description

This is a method for the function print() for objects of the class "boot" created by a call to boot, censboot, tilt.boot or tsboot.

Usage

## S3 method for class 'boot'
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)

Arguments

x  A bootstrap output object of class "boot" generated by one of the bootstrap functions.
digits  The number of digits to be printed in the summary statistics.
index  Indices indicating for which elements of the bootstrap output summary statistics are required.
...  further arguments passed to or from other methods.

Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If boot.out$t0 is missing (such as when it was created by a call to tsboot with orig.t = FALSE) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.
print.bootci

Value

The bootstrap object is returned invisibly.

See Also

boot, censboot, imp.moments, plot.boot, tilt.boot, tsboot

print.bootci

Print Bootstrap Confidence Intervals

Description

This is a method for the function print() to print objects of the class "bootci".

Usage

## S3 method for class 'bootci'
print(x, hinv = NULL, ...)

Arguments

x
The output from a call to boot.ci.

hinv
A transformation to be made to the interval end-points before they are printed.

...
further arguments passed to or from other methods.

Details

This function prints out the results from boot.ci in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to boot.ci or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

Warning: Intervals used Extreme Quantiles

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

Some intervals may be unstable

Value

The object ci.out is returned invisibly.

boot.ci
print.saddle.distn  Print Quantiles of Saddlepoint Approximations

Description
This is a method for the function print() to print objects of class "saddle.distn".

Usage
## S3 method for class 'saddle.distn'
print(x, ...)

Arguments
x  An object of class "saddle.distn" created by a call to saddle.distn.
... further arguments passed to or from other methods.

Details
The quantiles of the saddlepoint approximation to the distribution are printed along with the original
call and some other useful information.

Value
The input is returned invisibly.

See Also
lines.saddle.distn, saddle.distn

print.simplex  Print Solution to Linear Programming Problem

Description
This is a method for the function print() to print objects of class "simplex".

Usage
## S3 method for class 'simplex'
print(x, ...)

Arguments
x  An object of class "simplex" created by calling the function simplex to solve
a linear programming problem.
... further arguments passed to or from other methods.
Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

Value

x is returned silently.

See Also

simplex

remission

Cancer Remission and Cell Activity

Description

The remission data frame has 27 rows and 3 columns.

Usage

remission

Format

This data frame contains the following columns:

LI  A measure of cell activity.

m  The number of patients in each group (all values are actually 1 here).

r  The number of patients (out of m) who went into remission.

Source

The data were obtained from

References

This function calculates a saddlepoint approximation to the distribution of a linear combination of \( W \) at a particular point \( u \), where \( W \) is a vector of random variables. The distribution of \( W \) may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of \( W \) can be calculated for \( W \) having binary or Poisson distributions.

Usage

\[
\text{saddle}(A = \text{NULL}, u = \text{NULL}, \text{wdist} = "m", \text{type} = "simp", d = \text{NULL}, \\
d1 = 1, \text{init} = \text{rep}(0.1, d), \text{mu} = \text{rep}(0.5, n), \text{LR} = \text{FALSE}, \\
\text{strata} = \text{NULL}, \text{K.adj} = \text{NULL}, \text{K2} = \text{NULL})
\]

Arguments

- **A**: A vector or matrix of known coefficients of the linear combinations of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.
- **u**: The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.
- **wdist**: The distribution of \( W \). This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If \( K.\text{adj} \) and \( K2 \) are given \( \text{wdist} \) is set to "o".
- **type**: The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When \( \text{wdist} \) is "o" or "m", type is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.
- **d**: This specifies the dimension of the whole statistic. This argument is required only when \( \text{wdist} = "o" \) and defaults to 1 if not supplied in that case. For other distributions it is set to \( \text{ncol}(A) \).
- **d1**: When type is "cond" this is the dimension of the statistic of interest which must be less than \( \text{length}(u) \). Then the saddlepoint approximation to the conditional distribution of the first \( d1 \) linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of \( d1 \) is 1.
- **init**: Used if \( \text{wdist} \) is either "m" or "o", this gives initial values to \( \text{nlsim} \) which is used to solve the saddlepoint equation.
- **mu**: The values of the parameters of the distribution of \( W \) when \( \text{wdist} \) is "m", "p" or "b". \( \text{mu} \) must be of the same length as \( W \) (i.e. \( \text{nrow}(A) \)). The default is that all values of \( \text{mu} \) are equal and so the elements of \( W \) are identically distributed.
- **LR**: If TRUE then the Lugannani-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's \( r^* \).
- **strata**: The strata for stratified data.
The adjusted cumulant generating function used when \texttt{wdist} is "o". This is a function of a single parameter, \texttt{zeta}, which calculates \( K(zeta) - u zeta \), where \( K(zeta) \) is the cumulant generating function of \( W \).

This is a function of a single parameter \texttt{zeta} which returns the matrix of second derivatives of \( K(zeta) \) for use when \texttt{wdist} is "o". If \texttt{K.adj} is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if \texttt{K.adj} is not supplied.

\textbf{Details}

If \texttt{wdist} is "o" or "m", the saddlepoint equations are solved using \texttt{nlmin} to minimize \texttt{K.adj} with respect to its parameter \texttt{zeta}. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the \texttt{glm} must satisfy the equation \( t(A) y = u \) (\( t() \) being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to \texttt{simplex}. The covariate matrix for the \texttt{glm} is given by \( A \).

\textbf{Value}

A list consisting of the following components

- \texttt{spa}: The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.
- \texttt{zeta.hat}: The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.
- \texttt{zeta2.hat}: If \texttt{type} is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of \texttt{type}.

\textbf{References}

\textbf{See Also}

\texttt{saddle.distn}, \texttt{simplex}

\textbf{Examples}

# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

# Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
saddle.distn

Saddlepoint Distribution Approximations for Bootstrap Statistics

Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of $W$ where $W$ is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of $W$ must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function control to approximate the distribution of the linear approximation to a statistic.

Usage

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m", type = "simp", npts = 20, t = NULL, t0 = NULL, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE, strata = NULL, ...)

Arguments

A

This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point $t$ at which a saddlepoint is required. The most common reason for $A$ being a function would be if the statistic is not itself a linear combination of the $W$ but is the solution to a linear estimating equation.
If \( A \) is a function then \( u \) must also be a function returning a vector with length equal to the number of columns of the matrix returned by \( A \). Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If \( A \) is a matrix with more than one column (such as when \( \text{wdist} = "\text{cond}" \)) then \( u \) should be a vector with length one less than \( \text{ncol}(A) \). In this case \( u \) specifies the values of the conditioning variables. If \( A \) is a matrix with one column or a vector then \( u \) is not used.

**alpha**

The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.

**wdist**

The distribution of \( W \). Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).

**type**

The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If \( \text{wdist} \) is "m", type is set to "simp".

**npts**

The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.

**t**

A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in \( t \) as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If \( t \) is supplied then \( \text{npts} \) is set to \( \text{length}(t) \). When \( t \) is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range.

**t0**

If \( t \) is not supplied then a vector of length 2 should be passed as \( t0 \). The first component of \( t0 \) should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in \( t0[1] \).

**init**

When \( \text{wdist} \) is "m", this vector should contain the initial values to be passed to \( \text{nlmin} \) when it is called to solve the saddlepoint equations.

**mu**

The vector of parameter values for the distribution. The default is that the components of \( W \) are identically distributed.

**LR**

A logical flag. When \( \text{LR} \) is TRUE the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen’s \( r^* \).

**strata**

A vector giving the strata when the rows of \( A \) relate to stratified data. This is used only when \( \text{wdist} \) is "m".

### Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of \( \text{alpha} \). The lower endpoint is found by evaluating the saddlepoint at the points \( t0[1]-2\times t0[2], t0[1]-4\times t0[2], t0[1]-8\times t0[2] \) etc. until a point is found with a cdf approximation less than \( \min(\text{alpha})/10 \), then a bisection method is used to find the endpoint which has cdf approximation in the range \( (\min(\text{alpha})/1000, \min(\text{alpha})/10) \). Then a number of, equally spaced, points are chosen between the lower endpoint and \( t0[1] \) until
a total of \( \frac{npts}{2} \) approximations have been made. The remaining \( \frac{npts}{2} \) points are chosen to the right of \( t_0[1] \) in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of \( t_0[2] \) is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of \( t_0[2] \) will usually solve the problem.

**Value**

The returned value is an object of class "saddle.distn". See the help file for `saddle.distn.object` for a description of such an object.

**Examples**

```r
# The bootstrap distribution of the mean of the air-conditioning
# data: fails to find value on R (and probably on S too)
air.t0 <- c(mean(aircondit$hours), sqrt(var(aircondit$hours)/12))
## Not run: saddle.distn(A = aircondit$hours/12, t0 = air.t0)

# alternatively using the conditional poisson
saddle.distn(A = cbind(aircondit$hours/12, 1), u = 12, wdist = "p",
             type = "cond", t0 = air.t0)

# Distribution of the ratio of a sample of size 10 from the bigcity
# data, taken from Example 9.16 of Davison and Hinkley (1997).
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
bigcity.t0 <- c(mean(bigcity$x)/mean(bigcity$u), sqrt(city.v))
Afn <- function(t, data) cbind(data$x - t*data$u, 1)
ufn <- function(t, data) c(0,10)
saddle.distn(A = Afn, u = ufn, wdist = "b", type = "cond",
             t0 = bigcity.t0, data = bigcity)
```
# From Example 9.16 of Davison and Hinkley (1997) again, we find the
# conditional distribution of the ratio given the sum of city$u.
Afn <- function(t, data) cbind(data$x-t*data$u, data$u, 1)
ufn <- function(t, data) c(0, sum(data$u), 10)

city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.v))
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0, 
data = city)

---

### saddle.distn.object

**Saddlepoint Distribution Approximation Objects**

#### Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

#### Generation

This class of objects is returned from calls to the function `saddle.distn`.

#### Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

#### Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

- **quantiles** A matrix with 2 columns. The first column contains the probabilities alpha and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

- **points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of t which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When type is "simp", there is only one of those. When type is "cond" there are 2*d-1 where d is the number of columns in A or the output of A(t,...{}). The first d of these correspond to the numerator and the remainder correspond to the denominator.

- **distn** An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

- **call** The original call to `saddle.distn` which generated the object.

- **LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

**Description**

The salinity data frame has 28 rows and 4 columns. Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

`salinity`

**Format**

This data frame contains the following columns:

- **sal**: The average salinity of the water over two weeks.
- **lag**: The average salinity of the water lagged two weeks. Since only spring is used, the value of lag is not always equal to the previous value of sal.
- **trend**: A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.
- **dis**: The amount of river discharge during the two weeks for which sal is the average salinity.

**Source**

The data were obtained from

**References**

---

**simplex**

*Simplex Method for Linear Programming Problems*

**Description**

This function will optimize the linear function `a%*%x` subject to the constraints `A1%*%x <= b1`, `A2%*%x >= b2`, `A3%*%x = b3` and `x >= 0`. Either maximization or minimization is possible but the default is minimization.
### Usage

```r
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
        b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

### Arguments

- **a**: A vector of length \( n \) which gives the coefficients of the objective function.
- **A1**: An \( m_1 \) by \( n \) matrix of coefficients for the \( \leq \) type of constraints.
- **b1**: A vector of length \( m_1 \) giving the right hand side of the \( \leq \) constraints. This argument is required if \( A1 \) is given and ignored otherwise. All values in \( b1 \) must be non-negative.
- **A2**: An \( m_2 \) by \( n \) matrix of coefficients for the \( \geq \) type of constraints.
- **b2**: A vector of length \( m_2 \) giving the right hand side of the \( \geq \) constraints. This argument is required if \( A2 \) is given and ignored otherwise. All values in \( b2 \) must be non-negative. Note that the constraints \( x \geq 0 \) are included automatically and so should not be repeated here.
- **A3**: An \( m_3 \) by \( n \) matrix of coefficients for the equality constraints.
- **b3**: A vector of length \( m_3 \) giving the right hand side of equality constraints. This argument is required if \( A3 \) is given and ignored otherwise. All values in \( b3 \) must be non-negative.
- **maxi**: A logical flag which specifies minimization if FALSE (default) and maximization otherwise. If maxi is TRUE then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
- **n.iter**: The maximum number of iterations to be conducted in each phase of the simplex method. The default is \( n + 2 \times (m_1 + m_2 + m_3) \).
- **eps**: The floating point tolerance to be used in tests of equality.

### Details

The method employed by this function is the two phase tableau simplex method. If there are \( \geq \) or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each \( \geq \) or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the \( \leq \) form, the origin is a feasible solution and so the first stage can be omitted.

### Value

An object of class "simplex": see `simplex.object`.

### Note

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form \( x[i] \geq b2[i] \) they should be omitted by setting \( x[i] = x[i] - b2[i] \), changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.
simplex.object

simplex.object  Linear Programming Solution Objects

Description

Class of objects that result from solving a linear programming problem using simplex.

Generation

This class of objects is returned from calls to the function simplex.

Methods

The class "saddle.distn" has a method for the function print.

Structure

Objects of class "simplex" are implemented as a list with the following components.

soln  The values of x which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

solved  This indicates whether the problem was solved. A value of -1 indicates that no feasible solution could be found. A value of 0 that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of 1 indicates that an optimal solution has been found.

value  The value of the objective function at soln.

val.aux  This is NULL if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

obj  The original coefficients of the objective function.

a  The objective function coefficients re-expressed such that the basic variables have coefficient zero.

a.aux  This is NULL if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.
The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions $m_1 + m_2 + m_3$ by $n + m_1 + m_2$, where the final $m_1 + m_2$ columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional $m_1 + m_2 + m_3$ columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between $n+1$ and $n+m_1$ correspond to slack variables, those between $n+m_1+1$ and $n+m_2$ correspond to surplus variables and those greater than $n+m_2$ are artificial variables. Indices greater than $n+m_2$ should occur only if solved is $-1$ as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the $m_1$ slack variables which arise when the "$\leq$" constraints are re-expressed as the equalities $A_1 x + \text{slack} = b_1$.

**surplus** The final values of the $m_2$ surplus variables which arise when the "$\leq$" constraints are re-expressed as the equalities $A_2 x - \text{surplus} = b_2$.

**artificial** This is NULL if a feasible solution can be found. If no solution can be found then this contains the values of the $m_1 + m_2 + m_3$ artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

**smooth.f**

### Smooth Distributions on Data Points

#### Description
This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, theta, of the statistic of interest. The method results in distributions which vary smoothly with theta.

#### Usage

```r
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index], width = 0.5)
```

#### Arguments

- **theta**: The required value for the statistic of interest. If `theta` is a vector, a separate distribution will be found for each element of `theta`.
- **boot.out**: A bootstrap output object returned by a call to `boot`. index
- **index**: The index of the variable of interest in the output of `boot.out$statistic`. This argument is ignored if `t` is supplied. Index must be a scalar.
- **t**: The bootstrap values of the statistic of interest. This must be a vector of length `boot.out$R` and the values must be in the same order as the bootstrap replicates in `boot.out`.
- **width**: The standardized width for the kernel smoothing. The smoothing uses a value of `width*s` for epsilon, where `s` is the bootstrap estimate of the standard error of the statistic of interest. `width` should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If `width` is too large then the distribution becomes closer to uniform.
Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of \( t \) weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value \( \theta \) but it will typically have a value which is close to \( \theta \). The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

Value

If \( \text{length}(\theta) \) is 1 then a vector with the same length as the data set \( \text{boot.out$data} \) is returned. The value in position 1 is the probability to be given to the data point in position 1 so that the distribution has parameter value approximately equal to \( \theta \). If \( \text{length}(\theta) \) is bigger than 1 then the returned value is a matrix with \( \text{length}(\theta) \) rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of \( \theta \).

\texttt{boot, exp.tilt, tilt.boot}

Examples

# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling # distribution of the studentized statistic to be centred at the observed # value of the test statistic 1.84. In the book exponential tilting was used # but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1],
  weights = grav.sm)

# Estimated p-values can be found from these as follows
mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

---

### sunspot

**Annual Mean Sunspot Numbers**

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by k(f+10g) where g is the number of sunspot groups observed, f is the total number of spots within the groups and k is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

### survival

**Survival of Rats after Radiation Doses**

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

**Usage**

survival
Format

This data frame contains the following columns:

dose  The dose of radiation administered (rads).
surv  The survival rate of the batches expressed as a percentage.

**tau**

*Tau Particle Decay Modes*

Description

The `tau` data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970’s by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

Usage

tau

Format

This data frame contains the following columns:

rate  The decay rate expressed as a percentage.
decay  The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

**tilt.boot**

*Non-parametric Tilted Bootstrap*

**Description**

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

**Usage**

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i", strata = rep(1, n), L = NULL, theta = NULL, alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5, index = 1, ...)
```

**Arguments**

- **data**
  The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.

- **statistic**
  A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be `data` and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to `tilt.boot` and will be passed unchanged to statistic each time it is called.

- **R**
  The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of `R` are the number of simulations to be performed resampling from each reweighted distribution. The first value of `R` must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus `length(R)` should always equal `1 + length(theta)`.

- **sim**
  This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.

- **stype**
  A character string indicating the type of second argument expected by statistic. The possible values that stype can take are "i" (indices), "w" (weights) and "f" (frequencies).

- **strata**
  An integer vector or factor representing the strata for multi-sample problems.
tilt.boot

L The empirical influence values for the statistic of interest. They are used only for exponential tilting when tilt is TRUE. If tilt is TRUE and they are not supplied then tilt.boot uses empinf to calculate them.

theta The required parameter value(s) for the tilted distribution(s). There should be one value of theta for each of the non-uniform distributions. If \( R[1] \) is 0 theta is a required argument. Otherwise theta values can be estimated from the initial uniform bootstrap and the values in alpha.

alpha The alpha level to which tilting is required. This parameter is ignored if \( R[1] \) is 0 or if theta is supplied, otherwise it is used to find the values of theta as quantiles of the initial uniform bootstrap. In this case \( R[1] \) should be large enough that \( \min(c(alpha,1-alpha))*R[1] > 5 \), if this is not the case then a warning is generated to the effect that the theta are extreme values and so the tilted output may be unreliable.

tilt A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing (smooth.f) is used. If tilt is FALSE then \( R[1] \) must be positive. In fact in this case the value of \( R[1] \) should be fairly large (in the region of 500 or more).

width This argument is used only if tilt is FALSE, in which case it is passed unchanged to smooth.f as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See smooth.f for more details.

index The index of the statistic of interest in the output from statistic. By default the first element of the output of statistic is used.

... Any additional arguments required by statistic. These are passed unchanged to statistic each time it is called.

Value

An object of class "boot" with the following components

t0 The observed value of the statistic on the original data.
t The values of the bootstrap replicates of the statistic. There will be \( \text{sum}(R) \) of these, the first \( R[1] \) corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).
R The input vector of the number of bootstrap replicates.
data The original data as supplied.
statistic The statistic function as supplied.
sim The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".
stype The type of statistic supplied, it is the same as the input value stype.
call A copy of the original call to tilt.boot.
strata The strata as supplied.
weights The matrix of weights used. If \( R[1] \) is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If \( R[1] \) equals 0 then the uniform weights are omitted and only the tilted weights are output.
theta The values of theta used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and alpha.

tsboot

Bootstrapping of Time Series

Description

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

Usage

```r
tsboot(tseries, statistic, R, l = NULL, sim = "model", endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE, ran.gen, ran.args = NULL, parallel = c("no", "multicore", "snow"), ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

Arguments

- **tseries**
  A univariate or multivariate time series.

- **statistic**
  A function which when applied to `tseries` returns a vector containing the statistic(s) of interest. Each time `statistic` is called it is passed a time series of length `n.sim` which is of the same class as the original `tseries`. Any other arguments which `statistic` takes must remain constant for each bootstrap replicate and should be supplied through the `...` argument to `tsboot`.

- **R**
  A positive integer giving the number of bootstrap replicates required.

- **sim**
  The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of `l`), "geom" (block resampling with block lengths having a geometric distribution with mean `l`) or "scramble" (phase scrambling).

- **l**
  If `sim` is "fixed" then `l` is the fixed block length used in generating the replicate time series. If `sim` is "geom" then `l` is the mean of the geometric distribution used to generate the block lengths. `l` should be a positive integer less than the length of `tseries`. This argument is not required when `sim` is "model" but it is required for all other simulation types.

- **endcorr**
  A logical variable indicating whether end corrections are to be applied when `sim` is "fixed". When `sim` is "geom", `endcorr` is automatically set to TRUE; `endcorr` is not used when `sim` is "model" or "scramble".

- **n.sim**
  The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which `n.sim` is larger than the original length is if `tseries` is a residual time series from fitting some model to the original time series. In this case, `n.sim` would usually be the length of the original time series.

- **orig.t**
  A logical variable which indicates whether `statistic` should be applied to `tseries` itself as well as the bootstrap replicate series. If `statistic` is expecting a longer time series than `tseries` or if applying `statistic` to `tseries` will not yield any useful information then `orig.t` should be set to FALSE.
This is a function of three arguments. The first argument is a time series. If sim is "model" then it will always be tseries that is passed. For other simulation types it is the result of selecting n.sim observations from tseries by some scheme and converting the result back into a time series of the same form as tseries (although of length n.sim). The second argument to ran.gen is always the value n.sim, and the third argument is ran.args, which is used to supply any other objects needed by ran.gen. If sim is "model" then the generation of the replicate time series will be done in ran.gen (for example through use of arima.sim). For the other simulation types ran.gen is used for 'post-blackening'. The default is that the function simply returns the time series passed to it.

This will be supplied to ran.gen each time it is called. If ran.gen needs any extra arguments then they should be supplied as components of ran.args. Multiple arguments may be passed by making ran.args a list. If ran.args is NULL then it should not be used within ran.gen but note that ran.gen must still have its third argument.

A logical argument indicating whether normal margins should be used for phase scrambling. If norm is FALSE then margins corresponding to the exact empirical margins are used.

Extra named arguments to statistic may be supplied here. Beware of partial matching to the arguments of tsboot listed above.

See the help for boot.

Details

If sim is "fixed" then each replicate time series is found by taking blocks of length l, from the original time series and putting them end-to-end until a new series of length n.sim is created. When sim is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean l. Post-blackening can be carried out on these replicate time series by including the function ran.gen in the call to tsboot and having tseries as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function boot with the argument sim = "parametric".

Value

An object of class "boot" with the following components.

- t0: If orig.t is TRUE then t0 is the result of statistic(tseries,...{}) otherwise it is NULL.
- t: The results of applying statistic to the replicate time series.
- R: The value of R as supplied to tsboot.
- tseries: The original time series.
- statistic: The function statistic as supplied.
The simulation type used in generating the replicates.

endcorr

The value of endcorr used. The value is meaningful only when sim is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if sim is "geom".

n.sim

The value of n.sim used.

l

The value of l used for block based resampling. This will be NULL if block based resampling was not used.

ran.gen

The ran.gen function used for generating the series or for ‘post-blackening’.

ran.args

The extra arguments passed to ran.gen.

call

The original call to tsboot.

boot, arima.sim

Examples

lynx.fun <- function(tsb) {
  ar.fit <- ar(tsb, order.max = 25)
  c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their
# data, we set orig.t to FALSE since the function applied to the residual
# time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)
lynx.sim <- function(res, n.sim, ran.args) {
  # random generation of replicate series using arima.sim
  rg1 <- function(n, res) sample(res, n, replace = TRUE)
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, 
    rand.gen = rg1, res = as.vector(res)))
}
lynx.3 <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114, 
orig.t = FALSE, ran.gen = lynx.sim, 
ran.args = list(ts = log(lynx), model = lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed", 
n.sim = 114, orig.t = FALSE, ran.gen = lynx.black, 
ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom", 
n.sim = 114, orig.t = FALSE, ran.gen = lynx.black, 
ran.args = list(ts = log(lynx), model = lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

---

tuna  

### Tuna Sighting Data

**Description**

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

**Usage**

tuna

**Format**

This data frame contains the following column:

- **y** The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.
**urine**

**Source**

The data were obtained from

**References**

---

<table>
<thead>
<tr>
<th>urine</th>
<th>Urine Analysis Data</th>
</tr>
</thead>
</table>

**Description**

The urine data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

`urine`

**Format**

This data frame contains the following columns:

- `r` Indicator of the presence of calcium oxalate crystals.
- `gravity` The specific gravity of the urine.
- `ph` The pH reading of the urine.
- `osmo` The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.
- `cond` The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.
- `urea` The urea concentration in millimoles per litre.
- `calc` The calcium concentration in millimoles per litre.

Description

Estimates the variance of a statistic from its empirical influence values.

Usage

\texttt{var.linear(L, strata = NULL)}

Arguments

- \texttt{L} Vector of the empirical influence values of a statistic. These will usually be calculated by a call to \texttt{empinf}.
- \texttt{strata} A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

Value

The variance estimate calculated from \texttt{L}.

References

See Also

diff, empinf, linear.approx, k3.linear

Examples

\begin{verbatim}
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))
\end{verbatim}

Description

\texttt{wool} is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

Chapter 19

The class package

\begin{verbatim}
batchSOM

\textit{Self-Organizing Maps: Batch Algorithm}
\end{verbatim}

Description
Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage
\begin{verbatim}
batchSOM(data, grid = somgrid(), radii, init)
\end{verbatim}

Arguments
\begin{itemize}
\item \texttt{data} \hspace{1cm} a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
\item \texttt{grid} \hspace{1cm} A grid for the representatives: see \texttt{somgrid}.
\item \texttt{radii} \hspace{1cm} the radii of the neighbourhood to be used for each pass: one pass is run for each element of \texttt{radii}.
\item \texttt{init} \hspace{1cm} the initial representatives. If missing, chosen (without replacement) randomly from \texttt{data}.
\end{itemize}

Details
The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

Value
An object of class "SOM" with components
\begin{itemize}
\item \texttt{grid} \hspace{1cm} the grid, an object of class "somgrid".
\item \texttt{codes} \hspace{1cm} a matrix of representatives.
\end{itemize}

circles = rep(0.4, 48), inches = FALSE, add = TRUE)
text(crabs.som$grid$pts[bins, 1] + rnorm(400, 0, 0.1),
as.character(crabs.grp))
```

condense

Condense training set for k-NN classifier

Description

Condense training set for k-NN classifier

Usage

```r
condense(train, class, store, trace = TRUE)
```

Arguments

- `train` : matrix for training set
- `class` : vector of classifications for test set
- `store` : initial store set. Default one randomly chosen element of the set.
- `trace` : logical. Trace iterations?

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

Index vector of cases to be retained (the final store set).

### Examples

```r
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep, , drop=FALSE], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2, , drop=FALSE], test, cl[keep2])
```

### knn

**k-Nearest Neighbour Classification**

#### Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

#### Usage

```r
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

#### Arguments

- `train` matrix or data frame of training set cases.
- `test` matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
- `cl` factor of true classifications of training set
- `k` number of neighbours considered.
- `l` minimum vote for definite decision, otherwise doubt. (More precisely, less than k-l dissenting votes are allowed, even if k is increased by ties.)
- `prob` If this is true, the proportion of the votes for the winning class are returned as attribute `prob`.
- `use.all` controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.
Value

Factor of classifications of test set. doubt will be returned as NA.

Examples

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)

knn.cv

k-Nearest Neighbour Cross-Validatory Classification

Description

k-nearest neighbour cross-validatory classification from training set.

Usage

knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)

Arguments

train
matrix or data frame of training set cases.
cl
factor of true classifications of training set
k
number of neighbours considered.
l
minimum vote for definite decision, otherwise doubt. (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)
prob
If this is true, the proportion of the votes for the winning class are returned as attribute prob.
use.all
controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

Details

This uses leave-one-out cross validation. For each row of the training set train, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.
Value

Factor of classifications of training set. doubt will be returned as NA.

**LVQ1**

*Learning Vector Quantization 1*

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

- **x**: a matrix or data frame of examples
- **cl**: a vector or factor of classifications for the examples
- **codebk**: a codebook
- **niter**: number of iterations
- **alpha**: constant for training

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**References**

**See Also**

Examples

```r
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
c1 <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
cd <- lvqinit(train, c1, 10)
.lvqtest(cd, train)
cd0 <- olvq1(train, c1, cd)
.lvqtest(cd0, train)
cd1 <- lvq1(train, c1, cd0)
.lvqtest(cd1, train)
```

LVQ2

Learning Vector Quantization 2.1

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03, win = 0.3)
```

Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training
- `win`: a tolerance for the closeness of the two nearest vectors.

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

References

Learn Vector Quantization 3

Description

Moves examples in a codebook to better represent the training set.

Usage

```
fvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
    win = 0.3, epsilon = 0.1)
```

Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training
- `win`: a tolerance for the closeness of the two nearest vectors.
- `epsilon`: proportion of move for correct vectors

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

 lvqtest(cd3, train)

lvqinit

Initialize a LVQ Codebook

Description

Construct an initial codebook for LVQ methods.

Usage

lvqinit(x, cl, size, prior, k = 5)

Arguments

x a matrix or data frame of training examples, n by p.
cl the classifications for the training examples. A vector or factor of length n.
size the size of the codebook. Defaults to \( \min(\text{round}(0.4*ng*(ng-1 + p/2),0),n) \)
where ng is the number of classes.
prior Probabilities to represent classes in the codebook. Default proportions in the training set.
k k used for k-NN test of correct classification. Default is 5.

Details

Selects size examples from the training set without replacement with proportions proportional to the prior or the original proportions.

Value

A codebook, represented as a list with components x and cl giving the examples and classes.

### `lvqtest`

*Classify Test Set from LVQ Codebook*

**Description**

Classify a test set by 1-NN from a specified LVQ codebook.

**Usage**

`lvqtest(codebk, test)`

**Arguments**

- `codebk`: codebook object returned by other LVQ software
- `test`: matrix of test examples

**Details**

Uses 1-NN to classify each test example against the codebook.

**Value**

Factor of classification for each row of `x`

**References**

multiedit

Multiedit for k-NN Classifier

Description

Multiedit for k-NN classifier

Usage

multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)

Arguments

x        matrix of training set.
class    vector of classification of training set.
k        number of neighbours used in k-NN.
V        divide training set into V parts.
I        number of null passes before quitting.
trace    logical for statistics at each pass.

Value

Index vector of cases to be retained.

```

olvg1

`olvg1`  
*Optimized Learning Vector Quantization 1*

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
olvg1(x, c1, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

Arguments

- `x`: a matrix or data frame of examples
- `c1`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

Value

A codebook, represented as a list with components `x` and `c1` giving the examples and classes.

References

lvqtest(cd, train)
cd1 <- olvq1(train, cl, cd)
lvqtest(cd1, train)
```

reduce.nn

Reduce Training Set for a k-NN Classifier

Description

Reduce training set for a k-NN classifier. Used after `condense`.

Usage

```r
reduce.nn(train, ind, class)
```

Arguments

- `train`: matrix for training set
- `ind`: Initial list of members of the training set (from `condense`).
- `class`: vector of classifications for test set

Details

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

Value

Index vector of cases to be retained.

References

knn(train[keep2,], test, cl[keep2])
```

SOM  
Self-Organizing Maps: Online Algorithm

Description

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

```r
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

Arguments

data  
a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.

grid  
A grid for the representatives: see `somgrid`.

rlen  
the number of updates: used only in the defaults for alpha and radii.

alpha  
the amount of change: one update is done for each element of alpha. Default is to decline linearly from 0.05 to 0 over rlen updates.

radii  
the radii of the neighbourhood to be used for each update: must be the same length as alpha. Default is to decline linearly from 4 to 1 over rlen updates.

init  
the initial representatives. If missing, chosen (without replacement) randomly from data.

Details

alpha and radii can also be lists, in which case each component is used in turn, allowing two- or more phase training.

Value

An object of class "SOM" with components

grid  
the grid, an object of class "somgrid".

codes  
a matrix of representatives.
References

See Also

somgrid, batchSOM

Examples

```r
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[-(rep(1:4, rep(50,4)))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training
crabs.som2 <- SOM(lcrabs, gr,
  alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
  radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)
```

---

**somgrid**

*Plot SOM Fits*

Description

Plotting functions for SOM results.

Usage

```r
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))
```

## S3 method for class 'somgrid'
plot(x, type = "p", ...)

## S3 method for class 'SOM'
plot(x, ...)

Arguments

- `xdim`, `ydim` dimensions of the grid
- `topo` the topology of the grid.
- `x` an object inheriting from class "somgrid" or "SOM".
- `type`, `...` graphical parameters.
Details

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a stars plot of the representative at each grid point.

Value

For somgrid, an object of class "somgrid", a list with components

pts a two-column matrix giving locations for the grid points.
xdim, ydim, topo

as in the arguments to somgrid.

batchSOM, SOM
Chapter 20

The cluster package

agnes

Agglomerative Nesting (Hierarchical Clustering)

Description

Computes agglomerative hierarchical clustering of the dataset.

Usage

agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
       stand = FALSE, method = "average", par.method,
       keep.diss = n < 100, keep.data = !diss, trace.lev = 0)

Arguments

x
data matrix or data frame, or dissimilarity matrix, depending on the value of the
diss argument.

In case of a matrix or data frame, each row corresponds to an observation, and
each column corresponds to a variable. All variables must be numeric. Missing
values (NAs) are allowed.

In case of a dissimilarity matrix, x is typically the output of daisy or dist.
Also a vector with length n*(n-1)/2 is allowed (where n is the number of ob-
servations), and will be interpreted in the same way as the output of the above-
mentioned functions. Missing values (NAs) are not allowed.

diss

logical flag: if TRUE (default for dist or dissimilarity objects), then x is
assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix of
observations by variables.

metric

character string specifying the metric to be used for calculating dissimilarities
between observations. The currently available options are "euclidean" and
"manhattan". Euclidean distances are root sum-of-squares of differences, and
manhattan distances are the sum of absolute differences. If x is already a dis-
similarity matrix, then this argument will be ignored.

stand

logical flag: if TRUE, then the measurements in x are standardized before cal-
culating the dissimilarities. Measurements are standardized for each variable
(column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

**method** character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-group arithmetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the \texttt{par.method} argument, and "gaverage" a generalized "average" aka “flexible UPGMA” method also using the Lance-Williams formula and \texttt{par.method}.

The default is "average".

**par.method** If \texttt{method} is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.

**keep.diss, keep.data** logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

**trace.lev** integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

**Details**

\texttt{agnes} is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as \texttt{hclust}, \texttt{agnes} has the following features: (a) it yields the agglomerative coefficient (see \texttt{agnes.object}) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see \texttt{plot.agnes}).

The \texttt{agnes}-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two nearest clusters are combined to form one larger cluster.

For \texttt{method}="average", the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In \texttt{method}="single", we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When \texttt{method}="complete", we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The \texttt{method} = "flexible" allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters \( C_1 \) and \( C_2 \) are agglomerated into a new cluster, the dissimilarity between their union and another cluster \( Q \) is given by

\[
D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,
\]

where the four coefficients \((\alpha_1, \alpha_2, \beta, \gamma)\) are specified by the vector \texttt{par.method}, either directly as vector of length 4, or (more conveniently) if \texttt{par.method} is of length 1, say = \( \alpha \), \texttt{par.method} is extended to give the “Flexible Strategy” (K&R(1990), p.236 f) with Lance-Williams coefficients \((\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)\).

Also, if \texttt{length(par.method) == 3,} \( \gamma = 0 \) is set.
Care and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. Since `cluster` version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The `weighted average` (method="weighted") is the same as method="flexible",par.method = 0.5. Further, method="single" is equivalent to method="flexible",par.method = c(.5,.5,0,-.5), and method="complete" is equivalent to method="flexible",par.method = c(.5,.5,0,.5).

The method = "gaverage" is a generalization of "average", aka “flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with $\alpha_1$ and $\alpha_2$ not constant, but proportional to the sizes $n_1$ and $n_2$ of the clusters $C_1$ and $C_2$ respectively, i.e,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where $\alpha'_1$, $\alpha'_2$ are determined from `par.method`, either directly as $(\alpha_1, \alpha_2, \beta, \gamma)$ or $(\alpha_1, \alpha_2, \beta)$ with $\gamma = 0$, or (less flexibly, but more conveniently) as follows:

Belbin et al proposed “flexible beta”, i.e. the user would only specify $\beta$ (as `par.method`), sensibly in

$$-1 \leq \beta < 1,$$

and $\beta$ determines $\alpha'_1$ and $\alpha'_2$ as

$$\alpha'_j = 1 - \beta,$$

and $\gamma = 0$.

This $\beta$ may be specified by `par.method` (as length 1 vector), and if `par.method` is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a $\beta$ value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that method = "gaverage",par.method = 0 (or par.method = c(1,1,0,0)) is equivalent to the agnes() default method "average".

Value

an object of class "agnes" (which extends "twins") representing the clustering. See `agnes.object` for details, and methods applicable.

BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

Hierarchical methods like agnes, diana, and mona construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

Partitioning methods like pam, clara, and fanny require that the number of clusters be given by the user.

Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

#### Examples

```r
data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
agn1
plot(agn1)

op <- par(mfrow=c(2,2))
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
plot(agn2)
## alpha = 0.625 => beta = -1/4 is "recommended" by some
agnS <- agnes(votes.repub, method = "flexible", par.meth = 0.625)
plot(agnS)
par(op)

## "show" equivalence of three "flexible" special cases
d.vr <- daisy(votes.repub)
a.wgt <- agnes(d.vr, method = "weighted")
a.sing <- agnes(d.vr, method = "single")
a.comp <- agnes(d.vr, method = "complete")
iC <- -(6:7) # not using 'call' and 'method' for comparisons
stopifnot(
  all.equal(a.wgt [iC], agnes(d.vr, method="flexible", par.method = 0.5)[iC]) ,
  all.equal(a.sing[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0,-.5))[iC]),
  all.equal(a.comp[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0,.5))[iC])

## Exploring the dendrogram structure
(d2 <- as.dendrogram(agn2)) # two main branches
d2[[1]] # the first branch
d2[[2]][[1]]# the 2nd one { 8 + 42 = 50 }
d2[[1]][[1]][[1]]# first sub-branch of branch 1 .. and shorter form
identical(d2[[c(1,1)]],
  d2[[1]][[1]]))
## a "textual picture" of the dendrogram :
str(d2)

data(agriculture)

## Plot similar to Figure 7 in ref
## Not run: plot(agnes(agriculture), ask = TRUE)

data(animals)
aa.a <- agnes(animals) # default method = "average"
aa.ga <- agnes(animals, method = "gaverage")
```
agne.object

## Show how "gaverage" is a "generalized average":
aa.ga.0 <- agnes(animals, method = "gaverage", par.method = 0)
stopifnot(all.equal(aa.ga.0[iC], aa.a[iC]))

---

agne.object

### Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

### Value

A legitimate agnes object is a list with the following components:

- **order**: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- **order.lab**: a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- **height**: a vector with the distances between merging clusters at the successive stages.
- **ac**: the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation i, denote by m(i) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The ac is the average of all 1 - m(i). It can also be seen as the average width (or the percentage filled) of the banner plot. Because ac grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
- **merge**: an (n-1) by 2 matrix, where n is the number of observations. Row i of merge describes the merging of clusters at step i of the clustering. If a number j in the row is negative, then the single observation |j| is merged at this stage. If j is positive, then the merger is with the cluster formed at stage j of the algorithm.
- **diss**: an object of class "dissimilarity" (see dissimilarity.object), representing the total dissimilarity matrix of the dataset.
- **data**: a matrix containing the original or standardized measurements, depending on the stand option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.

### GENERATION

This class of objects is returned from agnes.
METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.
In addition, `cutree(x, *)` can be used to “cut” the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for agnes objects. After applying `as.hclust()`, all its methods are available, of course.

See Also

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`, `cutree`.

Examples

data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

## cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))

agriculture  European Union Agricultural Workforces

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

data(agriculture)

Format

A data frame with 12 observations on 2 variables:

```
[, 1] x  numeric  per capita GNP
[, 2] y  numeric  percentage in agriculture
```

The row names of the data frame indicate the countries.
**Details**

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

**Source**

**References**

see those in agnes.

**See Also**

agnes, daisy, diana.

**Examples**

data(animals)

```r
## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(animals, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(animals, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(animals), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(animals), ask = TRUE)
```

<table>
<thead>
<tr>
<th>animals</th>
<th>Attributes of Animals</th>
</tr>
</thead>
</table>

**Description**

This data set considers 6 binary attributes for 20 animals.

**Usage**

data(animals)
Format

A data frame with 20 observations on 6 variables:

<table>
<thead>
<tr>
<th></th>
<th>war</th>
<th>warm-blooded</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>fly</td>
<td>can fly</td>
</tr>
<tr>
<td>3</td>
<td>ver</td>
<td>vertebrate</td>
</tr>
<tr>
<td>4</td>
<td>end</td>
<td>endangered</td>
</tr>
<tr>
<td>5</td>
<td>gro</td>
<td>live in groups</td>
</tr>
<tr>
<td>6</td>
<td>hai</td>
<td>have hair</td>
</tr>
</tbody>
</table>

All variables are encoded as 1 = ‘no’, 2 = ‘yes’.

Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

Source

References

see Struyf, Hubert & Rousseeuw (1996), in agnes.

Examples

```r
data(animals)
apply(animals, 2, table) # simple overview

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

Description

Draws a “banner”, i.e. basically a horizontal barplot visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.
**Usage**

```r
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
    main=NULL, sub=NULL, xlab = "Height", adj = 0,
    col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
    rev.xax = !fromLeft, xax.pretty = TRUE,
    labels = NULL, nmax.lab = 35, max.strlen = 5,
    yax.do = axes && length(x$order) <= nmax.lab,
    yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)```

**Arguments**

- `x` a list with components `order`, `order.lab` and `height` when `w`, the next argument is not specified.
- `w` non-negative numeric vector of bar widths.
- `fromLeft` logical, indicating if the banner is from the left or not.
- `main`, `sub` main and sub titles, see `title`.
- `xlab` x axis label (with ‘correct’ default e.g. for `plot.agnes`)
- `adj` passed to `title(main,sub)` for string adjustment.
- `col` vector of length 2, for two horizontal segments.
- `border` color for bar border; now defaults to background (no border).
- `axes` logical indicating if axes (and labels) should be drawn at all.
- `frame.plot` logical indicating the banner should be framed; mainly used when `border = 0` (as per default).
- `rev.xax` logical indicating if the x axis should be reversed (as in `plot.diana`).
- `xax.pretty` logical or integer indicating if `pretty()` should be used for the x axis.
- `labels` labels to use on y-axis; the default is constructed from x.
- `nmax.lab` integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- `max.strlen` positive integer giving the length to which strings are truncated in banner plot labeling.
- `yax.do` logical indicating if a y axis and banner labels should be drawn.
- `yaxRight` logical indicating if the y axis is on the right or left.
- `y.mar` positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.
- `...` graphical parameters (see `par`) may also be supplied as arguments to this function.

**Note**

This is mainly a utility called from `plot.agnes`, `plot.diana` and `plot.mona`.

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).
Examples

```r
data( agriculture )
bannerplot( agnes( agriculture ), main = "Bannerplot")
```

---

**chorSub**  
*Subset of C-horizon of Kola Data*

### Description

This is a small rounded subset of the C-horizon data *chorizon* from package *mvoutlier*.

### Usage

```r
data(chorSub)
```

### Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

### Details

This data set was produced from *chorizon* via these statements:

```r
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110])[190:250,])
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", ",", colnames(chorSub))
```

### Source

### See Also

*chorizon* in package *mvoutlier* and other Kola data in the same package.

### Examples

```r
data(chorSub)
summary(chorSub)
pairs(chorSub, gap = .1)# some outliers
```
Description

Computes a "clara" object, a list representing a clustering of the data into k clusters.

Usage

```r
clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
stand = FALSE, samples = 5,
sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)
```

Arguments

- **x**: data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
- **k**: integer, the number of clusters. It is required that 0 < k < n where n is the number of observations (i.e., n = nrow(x)).
- **metric**: character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", and "jaccard". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
- **stand**: logical, indicating if the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation.
- **samples**: integer, say N, the number of samples to be drawn from the dataset. The default, N = 5, is rather small for historical (and now back compatibility) reasons and we recommend to set samples an order of magnitude larger.
- **sampsize**: integer, say j, the number of observations in each sample. sampsize should be higher than the number of clusters (k) and at most the number of observations (n = nrow(x)). While computational effort is proportional to j^2, see note below, it may still be advisable to set j = sampsize to a larger value than the (historical) default.
- **trace**: integer indicating a trace level for diagnostic output during the algorithm.
- **medoids.x**: logical indicating if the medoids should be returned, identically to some rows of the input data x. If FALSE, keep.data must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (i.e. med component), and the algorithm saves space by needing one copy less of x.
- **keep.data**: logical indicating if the (scaled if stand is true) data should be kept in the result. Setting this to FALSE saves memory (and hence time), but disables clusplot()ing of the result. Use medoids.x = FALSE to save even more memory.
clara

logical indicating if R’s random number generator should be used instead of the primitive clara()-builtin one. If true, this also means that each call to clara() returns a different result – though only slightly different in good situations.

pamLike

logical indicating if the “swap” phase (see pam, in C code) should use the same algorithm as pam(). Note that from Kaufman and Rousseeuw’s description this should have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, pamLike = FALSE has been chosen to remain back compatible rather than “PAM compatible”.

correct.d

logical or integer indicating that—only in the case of NAs present in x—the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016. Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies correct.d.

Details

clara is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as pam, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (sampsize) such that the time and storage requirements become linear in n rather than quadratic.

Each sub-dataset is partitioned into k clusters using the same algorithm as in pam. Once k representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until sampsize has been reached.

Value

an object of class "clara" representing the clustering. See clara.object for details.

Note

By default, the random sampling is implemented with a very simple scheme (with period 2\(^{16} = 65536\)) inside the Fortran code, independently of R’s random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting rngR = TRUE which uses R’s random number generators. Then, clara() results are made reproducible typically by using set.seed() before calling clara.

The storage requirement of clara computation (for small k) is about \(O(n \times p) + O(j^2)\) where \(j = \text{sampsize}\), and \((n, p) = \text{dim}(x)\). The CPU computing time (again assuming small k) is about \(O(n \times p \times j^2 \times \text{N})\), where \(\text{N} = \text{samples}\). For “small” datasets, the function pam can be used directly. What can be considered small, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “small (say with fewer than 200 observations)”; as of 2006, you can use pam with several thousand observations.
Author(s)

Kaufman and Rousseeuw (see agnes), originally. Metric "jaccard": Kamil Kozlowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from trace on, and most R documentation and all tests by Martin Maechler.

See Also

agnes for background and references; clara.object, pam, partition.object, plot.partition.

Examples

## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
      cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
          clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

## 'xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:

nSim <- 100
nCl <- 3 # = no.classes
set.seed(421)# (reproducibility)
c1 <- matrix(NA,nrow(xclara), nSim)
for(i in 1:nSim)
c1[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tc1 <- apply(c1,1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
tab0 <- tc1[,iDoubt, drop=FALSE]
dimnames(tab0) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
t(t(tab0)) # how many times in which clusters
}
Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from `clara`.

Value

A legitimate `clara` object is a list with the following components:

- **sample**: labels or case numbers of the observations in the best sample, that is, the sample used by the `clara` algorithm for the final partition.
- **medoids**: the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from `clara(*,medoids.x=FALSE)`. Use the following `i.med` in that case.
- **i.med**: the indices of the medoids above: `medoids <- x[i.med,]` where `x` is the original data matrix in `clara(x,*)`.
- **clustering**: the clustering vector, see `partition.object`.
- **objective**: the objective function for the final clustering of the entire dataset.
- **clusinfo**: matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster’s medoid, divided by the minimal dissimilarity between the cluster’s medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
- **diss**: dissimilarity (maybe NULL), see `partition.object`.
- **silinfo**: list with silhouette width information for the best sample, see `partition.object`.
- **call**: generating call, see `partition.object`.
- **data**: matrix, possibly standardized, or NULL, see `partition.object`.

Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a `clara` object.

See Also

`clara`, `dissimilarity.object`, `partition.object`, `plot.partition`. 
clusGap() calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters \( k \), it compares \( \log(W(k)) \) with \( E^* \log(W(k)) \) where the latter is defined via bootstrapping, i.e., simulating from a reference \( (H_0) \) distribution, a uniform distribution on the hypercube determined by the ranges of \( x \), after first centering, and then \( \text{svd} \) (aka ‘PCA’)-rotating them when (as by default) \( \text{spaceH0} = \text{“scaledPCA”} \).

maxSE(f, SE.f) determines the location of the maximum of \( f \), taking a “1-SE rule” into account for the *SE* methods. The default method “firstSEmax” looks for the smallest \( k \) such that its value \( f(k) \) is not more than 1 standard error away from the first local maximum. This is similar but not the same as "Tibs2001SEmax", Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

Usage

clusGap(x, FUNcluster, K.max, B = 100, d.power = 1, spaceH0 = c("scaledPCA", "original"), verbose = interactive(), ...)

maxSE(f, SE.f, method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax", "firstmax", "globalmax"), SE.factor = 1)

## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

## S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]), main = NULL, do.arrows = TRUE, arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)

Arguments

- **x**: numeric matrix or data.frame.
- **FUNcluster**: a function which accepts as first argument a (data) matrix like \( x \), second argument, say \( k, k \geq 2 \), the number of clusters desired, and returns a list with a component named (or shortened to) cluster which is a vector of length \( n = \text{nrow}(x) \) of integers in \( 1:k \) determining the clustering or grouping of the \( n \) observations.
- **K.max**: the maximum number of clusters to consider, must be at least two.
- **B**: integer, number of Monte Carlo (“bootstrap”) samples.
- **d.power**: a positive integer specifying the power \( p \) which is applied to the euclidean distances (dist) before they are summed up to give \( W(k) \). The default, \( d.\text{power} = 1 \), corresponds to the “historical” R implementation, whereas \( d.\text{power} = 2 \) corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.
clusGap

spaceH0

a character string specifying the space of the $H_0$ distribution (of no cluster). Both "scaledPCA" and "original" use a uniform distribution in a hyper cube and had been mentioned in the reference; "original" been added after a proposal (including code) by Juan Gonzalez.

verbose

integer or logical, determining if "progress" output should be printed. The default prints one bit per bootstrap sample.

... (for clusGap():) optionally further arguments for FUNcluster(), see kmeans example below.

f

numeric vector of ‘function values’, of length $K$, whose ("1 SE respected") maximum we want.

SE.f

numeric vector of length $K$ of standard errors of $f$.

method

character string indicating how the “optimal” number of clusters, ̂$k$, is computed from the gap statistics (and their standard deviations), or more generally how the location ̂$k$ of the maximum of $f_k$ should be determined.

"globalmax": simply corresponds to the global maximum, i.e., is which.max(f)

"firstmax": gives the location of the first local maximum.

"Tibs2001SEmax": uses the criterion, Tibshirani et al (2001) proposed: “the smallest $k$ such that $f(k) \geq f(k+1) - s_{k+1}$”. Note that this chooses $k = 1$ when all standard deviations are larger than the differences $f(k+1) - f(k)$.

"firstSEmax": location of the first $f()$ value which is not smaller than the first local maximum minus SE.factor * SE.f[], i.e, within an “f S.E.” range of that maximum (see also SE.factor). This, the default, has been proposed by Martin Maechler in 2012, when adding clusGap() to the cluster package, after having seen the "globalSEmax" proposal (in code) and read the "Tibs2001SEmax" proposal.

"globalSEmax": (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first $f()$ value which is not smaller than the global maximum minus SE.factor * SE.f[], i.e, within an “f S.E.” range of that maximum (see also SE.factor).

See the examples for a comparison in a simple case.

SE.factor

[When method contains "SE"] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an SE.factor $f$, the “f S.E.”-rule is used, more generally.

type, xlab, ylab, main

arguments with the same meaning as in plot.default(), with different default.

do.arrows

logical indicating if (1 SE-)"error bars" should be drawn, via arrows().

arrowArgs

a list of arguments passed to arrows(); the default, notably angle and code, provide a style matching usual error bars.

Details

The main result <res>$Tab[, "gap"] of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see set.seed()). On the other hand, in our experience, using B = 500 gives quite precise results such that the gap plot is basically unchanged after an another run.
Value

clusGap(...) returns an object of S3 class "clusGap", basically a list with components

Tab
a matrix with K.max rows and 4 columns, named "logW", "E.logW", "gap", and
"SE.sim", where gap = E.logW -logW, and SE.sim corresponds to the standard
error of gap, SE.sim[k]=s_k, where s_k := \sqrt{1 + 1/Bsd^2(gap_j)}, and sd^2() is
the standard deviation of the simulated ("bootstrapped") gap values.

call
the clusGap(...) call.

spaceH0 the spaceH0 argument (match.arg()ed).
n number of observations, i.e., nrow(x).
B input B
FUnUncluster input function FUnUncluster

Author(s)

This function is originally based on the functions gap of (Bioconductor) package SAGx by Per
Broberg, gapStat() from former package SLmisc by Matthias Kohl and ideas from gap() and its
methods of package lga by Justin Harrington.
The current implementation is by Martin Maechler.
The implementation of spaceH0 = "original" is based on code proposed by Juan Gonzalez.

Examples

### --- maxSE() methods ---------------------------------------------

(mets <- eval(formals(maxSE)$method))
fk <- c(2,3,5,4,7,8,5,4)
sk <- c(1,1,2,1,1,3,1,1)/2

## use plot.clusGap():
plot(structure(class="clusGap", list(Tab = cbind(gap=fk, SE.sim=sk))))

## Note that 'firstmax' and 'globalmax' are always at 3 and 6 :
sapply(c(1/4, 1,2,4), function(SEf) sapply(mets, function(M) maxSE(fk, sk, method = M, SE.factor = SEf)))

### --- clusGap() ---------------------------------------------------
## ridiculously nicely separated clusters in 3 D:

```r
x <- rbind(matrix(rnorm(150, sd = 0.1), ncol = 3),
           matrix(rnorm(150, mean = 1, sd = 0.1), ncol = 3),
           matrix(rnorm(150, mean = 2, sd = 0.1), ncol = 3),
           matrix(rnorm(150, mean = 3, sd = 0.1), ncol = 3))
```

## Slightly faster way to use pam (see below)

```r
pam1 <- function(x,k) list(cluster = pam(x,k, cluster.only=TRUE))
```

## We do not recommend using hier.clustering here, but if you want, 
## there is factoextra::hcut () or a cheap version of it 

```r
hclusCut <- function(x, k, d.meth = "euclidean", ...)
  list(cluster = cutree(hclust(dist(x, method=d.meth), ...), k=k))
```

## You can manually set it before running this:  doExtras <- TRUE # or FALSE 

```r
if(!(exists("doExtras") && is.logical(doExtras)))
doExtras <- cluster:::doExtras()
```

```r
if(doExtras) {
  ## Note we use B = 60 in the following examples to keep them "speedy".
  ## ---- rather keep the default B = 500 for your analysis!

  ## note we can pass 'nstart = 20' to kmeans():
  gskmn <- clusGap(x, FUN = kmeans, n.start = 20, K.max = 8, B = 60)
  gskmn #-> its print() method
  plot(gskmn, main = "clusGap(. , FUN = kmeans, n.start=20, B= 60")

  set.seed(12); system.time(
    gsPam0 <- clusGap(x, FUN = pam, K.max = 8, B = 60)
  )
  set.seed(12); system.time(
    gsPam1 <- clusGap(x, FUN = pam1, K.max = 8, B = 60)
  )

  ## and show that it gives the "same":
  not.eq <- c("call", "FUNcluster"); n <- names(gsPam0)
  eq <- n[!(n %in% not.eq)]
  stopifnot(identical(gsPam1[eq], gsPam0[eq]))

  print(gsPam1, method="globalSEmax")
  print(gsPam1, method="globalmax")

  print(gsHc <- clusGap(x, FUN = hclusCut, K.max = 8, B = 60))
}
```

```r
gs.pam.RU <- clusGap(ruspini, FUN = pam1, K.max = 8, B = 60)
```

```r
plot(gs.pam.RU, main = "Gap statistic for the 'ruspini' data")
mtext("k = 4 is best .. and k = 5 pretty close")
```

## This takes a minute..

## No clustering ==> k = 1 ("one cluster") should be optimal:

```r
Z <- matrix(rnorm(256*3), 256,3)
gsP.Z <- clusGap(Z, FUN = pam1, K.max = 8, B = 200)
```

```r
plot(gsP.Z, main = "clusGap(<iid_rnorm_p=3>) ==> k = 1 cluster is optimal")
gsP.Z
```
clusplot

Bivariate Cluster Plot (of a Partitioning Object)

Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

Usage

clusplot(x, ...)

## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)

Arguments

- **x**: an R object, here, specifically an object of class "partition", e.g. created by one of the functions pam, clara, or fanny.
- **main**: title for the plot; when NULL (by default), a title is constructed, using x$call.
- **dist**: when x does not have a diss nor a data component, e.g., for pam(dist(*),keep.diss=FALSE), dist must specify the dissimilarity for the clusplot.
- **...**: optional arguments passed to methods, notably the clusplot.default method (except for the diss one) may also be supplied to this function. Many graphical parameters (see par) may also be supplied as arguments here.

Details

The clusplot.partition() method relies on clusplot.default.

If the clustering algorithms pam, fanny and clara are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with pam or fanny, the dissimilarity matrix will be given as input to clusplot. When the clustering algorithm clara was applied to a data matrix with NAs then clusplot will replace the missing values as described in clusplot.default, because a dissimilarity matrix is not available.

Value

For the partition (and default) method: An invisible list with components Distances and Shading, as for clusplot.default, see there.

Side Effects

a 2-dimensional clusplot is created on the current graphics device.

See Also

clusplot.default for references; partition.object, pam, pam.object, clara, clara.object, fanny, fanny.object, par.
Examples

```r
## For more, see ?clusplot.default

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

cclusplot.default  Bivariate Cluster Plot (clusplot) Default Method

Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

Usage

```r
## Default S3 method:
clusplot(x, clus, diss = FALSE,
s.x.2d = mkCheckX(x, diss), stand = FALSE,
lines = 2, shade = FALSE, color = FALSE,
labels= 0, plotchar = TRUE,
col.p = "dark green", col.txt = col.p,
col.clus = if(color) c(2, 4, 6, 3) else 5,
cex = 1, cex.txt = cex,
span = TRUE,
add = FALSE,
xlim = NULL, ylim = NULL,
main = paste("CLUSPLOT("#, deparse(substitute(x)),""),
sub = paste("These two components explain",
 round(100 * var.dec, digits = 2), "% of the point variability."),
xlab = "Component 1", ylab = "Component 2",
verbose = getOption("verbose"),
...)```

Arguments

- `x` matrix or data frame, or dissimilarity matrix, depending on the value of the diss argument.
  In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NA) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.
  In case of a dissimilarity matrix, x is the output of daisy or dist or a symmetric matrix. Also, a vector of length \( n \times (n - 1)/2 \) is allowed (where \( n \) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NA) are not allowed.
clusplot.default

clus
a vector of length n representing a clustering of x. For each observation the
vector lists the number or name of the cluster to which it has been assigned.
clus is often the clustering component of the output of pam, fanny or clara.

diss
logical indicating if x will be considered as a dissimilarity matrix or a matrix of
observations by variables (see x argument above).

s.x.2d
a list with components named x (a n × 2 matrix; typically something like
principal components of original data), labs and var.dec.

stand
logical flag: if true, then the representations of the n observations in the 2-
dimensional plot are standardized.

lines
integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses.
The distance between two ellipses E1 and E2 is measured along the line
connecting the centers m1 and m2 of the two ellipses.
In case E1 and E2 overlap on the line through m1 and m2, no line is drawn.
Otherwise, the result depends on the value of lines: If
lines = 0, no distance lines will appear on the plot;
lines = 1, the line segment between m1 and m2 is drawn;
lines = 2, a line segment between the boundaries of E1 and E2 is drawn (along
the line connecting m1 and m2).

shade
logical flag: if TRUE, then the ellipses are shaded in relation to their density.
The density is the number of points in the cluster divided by the area of the
ellipse.

color
logical flag: if TRUE, then the ellipses are colored with respect to their density.
With increasing density, the colors are light blue, light green, red and purple. To
see these colors on the graphics device, an appropriate color scheme should be
selected (we recommend a white background).

labels
integer code, currently one of 0,1,2,3,4 and 5. If
labels= 0, no labels are placed in the plot;
labels= 1, points and ellipses can be identified in the plot (see identify);
labels= 2, all points and ellipses are labelled in the plot;
labels= 3, only the points are labelled in the plot;
labels= 4, only the ellipses are labelled in the plot.
labels= 5, the ellipses are labelled in the plot, and points can be identified.
The levels of the vector clus are taken as labels for the clusters. The labels
of the points are the rownames of x if x is matrix like. Otherwise (diss =
TRUE), x is a vector, point labels can be attached to x as a "Labels" attribute
(attr(x,"Labels")), as is done for the output of daisy.
A possible names attribute of clus will not be taken into account.

plotchar
logical flag: if TRUE, then the plotting symbols differ for points belonging to
different clusters.

span
logical flag: if TRUE, then each cluster is represented by the ellipse with small-
est area containing all its points. (This is a special case of the minimum volume
elipsoid.)
If FALSE, the ellipse is based on the mean and covariance matrix of the same
points. While this is faster to compute, it often yields a much larger ellipse.
There are also some special cases: When a cluster consists of only one point, a
tiny circle is drawn around it. When the points of a cluster fall on a straight line,
span=FALSE draws a narrow ellipse around it and span=TRUE gives the exact
line segment.
clusplot.default

add logical indicating if ellipses (and labels if labels is true) should be added to an already existing plot. If false, neither a title or sub title, see sub, is written.

col.p color code(s) used for the observation points.

col.txt color code(s) used for the labels (if labels >= 2).

col.clus color code for the ellipses (and their labels); only one if color is false (as per default).

cex, cex.txt character expansion (size), for the point symbols and point labels, respectively.

xlim, ylim numeric vectors of length 2, giving the x- and y- ranges as in plot.default.

main main title for the plot; by default, one is constructed.

sub sub title for the plot; by default, one is constructed.

xlab, ylab x- and y- axis labels for the plot, with defaults.

verbose a logical indicating, if there should be extra diagnostic output; mainly for ‘de-bugging’.

... Further graphical parameters may also be supplied, see par.

Details
clusplot uses function calls princomp(*, cor = (ncol(x) > 2)) or cmdscale(*, add=TRUE), respectively, depending on diss being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.
Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

Value
An invisible list with components:

Distances When lines is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in [i,j] is the distance between ellipse i and ellipse j. If lines = 0, then the value of this component is NA.

Shading A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, y[i] and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put shading = y/z *37 + 3.

Side Effects
a visual display of the clustering is plotted on the current graphics device.

Note
When we have 4 or fewer clusters, then the color=TRUE gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function pam to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. col.clus specifies the colors used.
The col.p and col.txt arguments, added for R, are recycled to have length the number of observations. If col.p has more than one value, using color = TRUE can be confusing because of a mix of point and ellipse colors.

c coef.hclust

---

**Agglomerative / Divisive Coefficient for 'hclust' Objects**

**Description**

Computes the “agglomerative coefficient” (aka “divisive coefficient” for diana), measuring the clustering structure of the dataset.

For each observation i, denote by \(m(i)\) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all \(1 - m(i)\). It can also be seen as the average width (or the percentage filled) of the banner plot.

c coefHier() directly interfaces to the underlying C code, and “proves” that only object$heights is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

**Usage**

```
c coefHier(object)
c coef.hclust(object, ...)
```

S3 method for class 'hclust'

```
c coef(object, ...)
```

S3 method for class 'twins'

```
c coef(object, ...)
```

**Arguments**

- **object**
  
an object of class "hclust" or "twins", i.e., typically the result of hclust(), agnes(), or diana().
  
  Since coef.hclust only uses object$heights, and object$merge, object can be any list-like object with appropriate merge and heights components.
  
  For coefHier, even only object$heights is needed.

- **...**
  
currently unused potential further arguments

**Value**

a number specifying the agglomerative (or divisive for diana objects) coefficient as defined by Kaufman and Rousseeuw, see agnes.object $ ac or diana.object $ dc.
Examples

```r
data(agriculture)
aa <- agnes( agriculture)
coef(aa)  # really just extracts aa$ac
coef(as.hclust(aa))  # recomputes
coefHier(aa)  # ditto
```

---

daisy

**Dissimilarity Matrix Calculation**

Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower's formula is used, see 'Details' below.

Usage

```r
daisy(x, metric = c("euclidean", "manhattan", "gower"),
   stand = FALSE, type = list(), weights = rep.int(1, p),
   warnBin = warnType, warnAsym = warnType, warnConst = warnType,
   warnType = TRUE)
```

Arguments

- **x**: numeric matrix or data frame, of dimension \(n \times p\), say. Dissimilarities will be computed between the rows of \(x\). Columns of mode numeric (i.e. all columns when \(x\) is a matrix) will be recognized as interval scaled variables, columns of class factor will be recognized as nominal variables, and columns of class ordered will be recognized as ordinal variables. Other variable types should be specified with the `type` argument. Missing values (NAs) are allowed.
- **metric**: character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. "Gower's distance" is chosen by metric "gower" or automatically if some columns of \(x\) are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section.
- **stand**: logical flag: if TRUE, then the measurements in \(x\) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If not all columns of \(x\) are numeric, `stand` will be ignored and Gower's standardization (based on the range) will be applied in any case, see argument `metric`, above, and the details section.
type list for specifying some (or all) of the types of the variables (columns) in \( x \). The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and "symm" (symmetric binary variables). Each component’s value is a vector, containing the names or the numbers of the corresponding columns of \( x \). Variables not mentioned in the type list are interpreted as usual (see argument \( x \)).

weights an optional numeric vector of length \( p = \text{ncol}(x) \); to be used in "case 2" (mixed variables, or \( \text{metric} = \text{"gower"} \), specifying a weight for each variable \( (x[,k]) \) instead of 1 in Gower’s original formula.

warnBin, warnAsym, warnConst logicals indicating if the corresponding type checking warnings should be signalled (when found).

warnType logical indicating if all the type checking warnings should be active or not.

Details

The original version of \textit{daisy} is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to \textit{dist} whose input must be numeric variables, the main feature of \textit{daisy} is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If \( x \) contains any columns of these data-types, both arguments \text{metric} and \text{stand} will be ignored and Gower’s coefficient will be used as the metric. This can also be activated for purely numeric data by \text{metric} = \text{"gower"}. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range \([0, 1]\), exactly.

Note that setting the type to \text{symm} (symmetric binary) gives the same dissimilarities as using \text{nominal} (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that \textit{daisy} signals a warning when 2-valued numerical variables do not have an explicit type specified, because the reference authors recommend to consider using "asymm"; the warning may be silenced by \text{warnBin} = \text{FALSE}.

In the \textit{daisy} algorithm, missing values in a row of \( x \) are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and \text{metric} is not "gower"), the metric is "euclidean", and \( n_g \) is the number of columns in which neither row \( i \) and \( j \) have NAs, then the dissimilarity \( d(i,j) \) returned is \( \sqrt{p/n_g} \ (p = \text{ncol}(x)) \) times the Euclidean distance between the two vectors of length \( n_g \) shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is \( p/n_g \). If \( n_g = 0 \), the dissimilarity is NA.

2. When some variables have a type other than interval scaled, or if \text{metric} = "gower" is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

\[
    d_{ij} = \frac{\sum_{k=1}^{p} w_k \delta^{(k)}_{ij} d^{(k)}_{ij}}{\sum_{k=1}^{p} w_k \delta^{(k)}_{ij}}.
\]

In other words, \( d_{ij} \) is a weighted mean of \( d^{(k)}_{ij} \) with weights \( w_k \delta^{(k)}_{ij} \), where \( w_k = \text{weights}[k] \), \( \delta^{(k)}_{ij} \) is 0 or 1, and \( d^{(k)}_{ij} \) the \( k \)-th variable contribution to the total distance, is a distance between \( x[i,k] \) and \( x[j,k] \), see below.
The 0-1 weight \( \delta_{ij}^{(k)} \) becomes zero when the variable \( x[,k] \) is missing in either or both rows (i and j), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution \( d_{ij}^{(k)} \) of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that “standard scoring” is applied to ordinal variables, i.e., they are replaced by their integer codes \( 1:K \). Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions \( d_{ij}^{(k)} \) are in \([0, 1]\), the dissimilarity \( d_{ij} \) will remain in this range. If all weights \( w_k \delta_{ij}^{(k)} \) are zero, the dissimilarity is set to \texttt{NA}.

\section*{Value}

an object of class "dissimilarity" containing the dissimilarities among the rows of \( x \). This is typically the input for the functions \texttt{pam}, \texttt{fanny}, \texttt{agnes} or \texttt{diana}. For more details, see \texttt{dissimilarity.object}.

\section*{Background}

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

\section*{Author(s)}

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version. Martin Maechler improved the \texttt{NA} handling and type specification checking, and extended functionality to \texttt{metric = "gower"} and the optional \texttt{weights} argument.

\section*{Examples}

```r
data(agriculture)
## Example 1 in ref:
## Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy(agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
## compare with
as.matrix(daisy(agriculture, metric = "gower"))
data(flower)
```
Diana

Divisive ANalysis Clustering

Description

Computes a divisive hierarchical clustering of the dataset returning an object of class diana.

Usage

diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE, stop.at.k = FALSE, keep.diss = n < 100, keep.data = !diss, trace.lev = 0)

Arguments

x

data matrix or data frame, or dissimilarity matrix or object, depending on the value of the diss argument.

In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.

In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

diss

logical flag: if TRUE (default for dist or dissimilarity objects), then x will be considered as a dissimilarity matrix. If FALSE, then x will be considered as a matrix of observations by variables.

metric

character string specifying the metric to be used for calculating dissimilarities between observations.

The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.

stand

logical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

stop.at.k

logical or integer, FALSE by default. Otherwise must be integer, say k, in \{1, 2, ..., n\}, specifying that the diana algorithm should stop early.

Non-default NOT YET IMPLEMENTED.

## Example 2 in ref

summary(dfl1 <- daisy(flower, type = list(asymm = 3)))
summary(dfl2 <- daisy(flower, type = list(asymm = c(1, 3), ordratio = 7)))

## this failed earlier:

summary(dfl3 <- daisy(flower,
  type = list(asymm = c("V1", "V3"), symm= 2,
  ordratio= 7, logratio= 8)))
keep.diss, keep.data  
logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

trace.lev  
integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

diana is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, diana provides (a) the divisive coefficient (see diana.object) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see plot.diana).

The diana-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all n observations. Clusters are divided until each cluster contains only a single observation.

At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

Value

an object of class "diana" representing the clustering; this class has methods for the following generic functions: print, summary, plot.

Further, the class "diana" inherits from "twins". Therefore, the generic function pltree can be used on a diana object, and as.hclust and as.dendrogram methods are available.

A legitimate diana object is a list with the following components:

order  a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
order.lab  a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
height  a vector with the diameters of the clusters prior to splitting.
dc  the divisive coefficient, measuring the clustering structure of the dataset. For each observation i, denote by \( d(i) \) the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The dc is the average of all \( 1 - d(i) \). It can also be seen as the average width (or the percentage filled) of the banner plot. Because dc grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
merge  an (n-1) by 2 matrix, where n is the number of observations. Row i of merge describes the split at step n-i of the clustering. If a number j in row r is negative, then the single observation \(|j|\) is split off at stage n-r. If j is positive, then the cluster that will be splitted at stage n-j (described by row j), is split off at stage n-r.
an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.

data
a matrix containing the original or standardized measurements, depending on the stand option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.

See Also
agnes also for background and references; cutree (and as.hclust) for grouping extraction; daisy, dist, plot.diana, twins.object.

Examples
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2)## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}
data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)

Dissimilarity Matrix Object

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called do, and n the number of observations, i.e., n <- attr(do,"Size"), then for i < j <= n, the dissimilarity between (row) i and j is do[n*(i-1) -i*(i-1)/2 + j-i]. The length of the vector is n * (n - 1)/2, i.e., of order n².

"dissimilarity" objects also inherit from class dist and can use dist methods, in particular, as.matrix, such that d_{ij} from above is just as.matrix(do)[i,j].

The object has the following attributes:

Size the number of observations in the dataset.
**ellipsoidhull**

the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".

Labels

optionally, contains the labels, if any, of the observations of the dataset.

NA.message

optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.

Types

when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54):

A Asymmetric binary
S Symmetric binary
N Nominal (factor)
O Ordinal (ordered factor)
I Interval scaled (numeric)
T raTio to be log transformed (positive numeric)
.

**GENERATION**

daisy returns this class of objects. Also the functions pam, clara, fanny, agnes, and diana return a dissimilarity object, as one component of their return objects.

**METHODS**

The "dissimilarity" class has methods for the following generic functions: print, summary.

**See Also**

daisy, dist, pam, clara, fanny, agnes, diana.

---

ellipsoidhull

*Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set*

**Description**

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

**Usage**

```r
ellipsoidhull(x, tol=0.01, maxit=5000, 
ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
```

### S3 method for class 'ellipsoid'

```r
print(x, digits = max(1, getOption("digits") - 2), ...)
```
Arguments

**x**
the \( n \times p \)-dimensional points as numeric \( n \times p \) matrix.

**tol**
convergence tolerance for Titterington's algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increas maxit as well.

**maxit**
integer giving the maximal number of iteration steps for the algorithm.

**ret.wt, ret.sqdist, ret.pr**
logicals indicating if additional information should be returned; \( \text{ret.wt} \) specifying the weights, \( \text{ret.sqdist} \) the squared distances and \( \text{ret.pr} \) the final probabilities in the algorithms.

**digits,**
the usual arguments to \text{print} methods.

Details

The "spanning ellipsoid" algorithm is said to stem from Titterington(1976), in Pison et al (1999) who use it for \text{clusplot.default}.

The problem can be seen as a special case of the "Min.Vol." ellipsoid of which a more more flexible and general implementation is \text{cov.mve} in the \text{MASS} package.

Value

an object of class "ellipsoid", basically a list with several components, comprising at least

**cov**
\( p \times p \) covariance matrix description the ellipsoid.

**loc**
\( p \)-dimensional location of the ellipsoid center.

**d2**
average squared radius. Further, \( d_2 = t_2 \), where \( t \) is "the value of a t-statistic on the ellipse boundary" (from \text{ellipse} in the \text{ellipse} package), and hence, more usefully, \( d_2 = qchisq(alpha, df = p) \), where alpha is the confidence level for \( p \)-variate normally distributed data with location and covariance \( \text{loc} \) and \( \text{cov} \) to lie inside the ellipsoid.

**wt**
the vector of weights iff \( \text{ret.wt} \) was true.

**sqdist**
the vector of squared distances iff \( \text{ret.sqdist} \) was true.

**prob**
the vector of algorithm probabilities iff \( \text{ret.pr} \) was true.

**it**
number of iterations used.

**tol, maxit**
just the input argument, see above.

**eps**
the achieved tolerance which is the maximal squared radius minus \( p \).

**ierr**
error code as from the algorithm; \( 0 \) means \text{ok}.

**conv**
logical indicating if the converged. This is defined as \( \text{it} < \text{maxit} \&\& \text{ierr} == 0 \).

Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original code.

References

See Also

predict.ellipsoid which is also the predict method for ellipsoid objects.
volume.ellipsoid for an example of 'manual' ellipsoid object construction;
further ellipsee from package ellipse and ellipsePoints from package sfsmisc.
chull for the convex hull, clusplot which makes use of this; cov.mve.

Examples

x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy. <- ellipsoidhull(xy)
exy. # >> calling print.ellipsoid()

plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy.), col="blue")
points(rbind(exy.$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
## --> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii],3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
      col="blue", bg = adjustcolor("blue",0.25))

fanny

Fuzzy Analysis Clustering

Description

Computes a fuzzy clustering of the data into k clusters.

Usage

fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)

Arguments

x data matrix or data frame, or dissimilarity matrix, depending on the value of the
diss argument.
In case of a matrix or data frame, each row corresponds to an observation, and
each column corresponds to a variable. All variables must be numeric. Missing
values (NA) are allowed.
In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also
a vector of length n*(n-1)/2 is allowed (where n is the number of observations),
and will be interpreted in the same way as the output of the above-mentioned
functions. Missing values (NA) are not allowed.
k integer giving the desired number of clusters. It is required that $0 < k < n/2$ where $n$ is the number of observations.

diss logical flag: if TRUE (default for dist or dissimilarity objects), then $x$ is assumed to be a dissimilarity matrix. If FALSE, then $x$ is treated as a matrix of observations by variables.

memb.exp number $r$ strictly larger than 1 specifying the membership exponent used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.

metric character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the squared euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.

If $x$ is already a dissimilarity matrix, then this argument will be ignored.

stand logical; if true, the measurements in $x$ are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.

iniMem.p numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.

cluster.only logical; if true, no silhouette information will be computed and returned, see details.

keep.diss, keep.data logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation time.

maxit, tol maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults maxit = 500 and tol = 1e-15 used to be hardwired inside the algorithm.

trace.lev integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by $u_{iv}$ the membership of observation $i$ to cluster $v$.

The memberships are nonnegative, and for a fixed observation $i$ they sum to 1. The particular method fanny stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in daisy) and has been extended by Martin Maechler to allow user specified memb.exp, iniMem.p, maxit, tol, etc.

Fanny aims to minimize the objective function

$$
\sum_{v=1}^{k} \sum_{i=1}^{n} \sum_{j=1}^{n} u_{iv}^{r} u_{jv}^{r} d(i, j) \\
2 \sum_{j=1}^{n} u_{jv}^{r}
$$
where \( n \) is the number of observations, \( k \) is the number of clusters, \( r \) is the membership exponent \( \text{memb.exp} \) and \( d(i,j) \) is the dissimilarity between observations \( i \) and \( j \).

Note that \( r \to 1 \) gives increasingly crisper clusterings whereas \( r \to \infty \) leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default, \( r = 2 \) can lead to complete fuzzyness, i.e., memberships \( u_{iv} \equiv 1/k \). In that case a warning is signalled and the user is advised to choose a smaller \( \text{memb.exp} \) (\( = r \)).

Compared to other fuzzy clustering methods, \textit{fanny} has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see \texttt{plot.partition}).

### Value

an object of class "\texttt{fanny}" representing the clustering. See \texttt{fanny.object} for details.

### See Also

\texttt{agnes} for background and references; \texttt{fanny.object, partition.object, plot.partition, daisy, dist}.

### Examples

```r
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
          cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
          cbind(rnorm( 3,3.2,0.5), rnorm( 3,3.2,0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crisper' for obs. 26:28
(fanny(x, 2, memb.exp = 3)) # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

### fanny.object

\textit{Fuzzy Analysis (FANNY) Object}

\textbf{Description}

The objects of class "\texttt{fanny}" represent a fuzzy clustering of a dataset.
A legitimate fanny object is a list with the following components:

- **membership**: matrix containing the memberships for each pair consisting of an observation and a cluster.
- **memb.exp**: the membership exponent used in the fitting criterion.
- **coeff**: Dunn’s partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all squared membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1. The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$, and ranges between 0 and 1. A low value of Dunn’s coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
- **clustering**: the clustering vector of the nearest crisp clustering, see partition.object.
- **k.crisp**: integer ($\leq k$) giving the number of crisp clusters; can be less than $k$, where it’s recommended to decrease memb.exp.
- **objective**: named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.
- **convergence**: named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).
- **diss**: an object of class "dissimilarity", see partition.object.
- **call**: generating call, see partition.object.
- **silinfo**: list with silhouette information of the nearest crisp clustering, see partition.object.
- **data**: matrix, possibly standardized, or NULL, see partition.object.

**GENERATION**

These objects are returned from fanny.

**METHODS**

The "fanny" class has methods for the following generic functions: print, summary.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

**See Also**

fanny, print.fanny, dissimilarity.object, partition.object, plot.partition.
Description

8 characteristics for 18 popular flowers.

Usage

data(flower)

Format

A data frame with 18 observations on 8 variables:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>. &quot;V1&quot;</td>
<td>factor winters</td>
</tr>
<tr>
<td>. &quot;V2&quot;</td>
<td>factor shadow</td>
</tr>
<tr>
<td>. &quot;V3&quot;</td>
<td>factor tubers</td>
</tr>
<tr>
<td>. &quot;V4&quot;</td>
<td>factor color</td>
</tr>
<tr>
<td>. &quot;V5&quot;</td>
<td>ordered soil</td>
</tr>
<tr>
<td>. &quot;V6&quot;</td>
<td>ordered preference</td>
</tr>
<tr>
<td>. &quot;V7&quot;</td>
<td>numeric height</td>
</tr>
<tr>
<td>. &quot;V8&quot;</td>
<td>numeric distance</td>
</tr>
</tbody>
</table>

- **V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.
- **V2** shadow, is binary and shows whether the plant needs to stand in the shadow.
- **V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.
- **V4** color, is nominal and specifies the flower’s color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).
- **V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.
- **V6** preference, is ordinal and gives someone’s preference ranking going from 1 to 18.
- **V7** height, is interval scaled, the plant’s height in centimeters.
- **V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

References

Struyf, Hubert and Rousseeuw (1996), see agnes.

Examples

daisy(flower, type = list(asymm = c(1, 3), ordratio = 7))
lower.to.upper.tri.inds

Permute Indices for Triangular Matrices

Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

Usage

lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)

Arguments

n integer larger than 1.

Value

integer vector containing a permutation of 1:N where \( N = n(n - 1)/2 \).

See Also

upper.tri, lower.tri with a related purpose.

Examples

m5 <- matrix(NA,5,5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m
stopifnot(lower.to.upper.tri.inds(2) == 1,
lower.to.upper.tri.inds(3) == 1:3,
upper.to.lower.tri.inds(3) == 1:3,
sort(upper.to.lower.tri.inds(5)) == 1:10,
sort(lower.to.upper.tri.inds(6)) == 1:15)

mona

MONothetic Analysis Clustering of Binary Variables

Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

Usage

mona(x, trace.lev = 0)
Arguments

\( x \)

A data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (\( \text{NAs} \)) is allowed. Every observation must have at least one value different from \( \text{NA} \). No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical is not allowed.

\( \text{trace.lev} \)

A logical or integer indicating if (and how much) the algorithm should produce progress output.

Details

**mona** is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including **agnes** and **diana**) are “polythetic”, i.e., they use all variables together.

The **mona**-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables. At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be split. The association between variables \( f \) and \( g \) is given by \( a(f,g) \times d(f,g) - b(f,g) \times c(f,g) \), where \( a(f,g) \), \( b(f,g) \), \( c(f,g) \), and \( d(f,g) \) are the numbers in the contingency table of \( f \) and \( g \). [That is, \( a(f,g) \) (resp. \( d(f,g) \)) is the number of observations for which \( f \) and \( g \) both have value 0 (resp. value 1); \( b(f,g) \) (resp. \( c(f,g) \)) is the number of observations for which \( f \) has value 0 (resp. 1) and \( g \) has value 1 (resp. 0).] The total association of a variable \( f \) is the sum of its associations to all variables.

Value

An object of class “**mona**” representing the clustering. See **mona.object** for details.

Missing Values (\( \text{NAs} \))

The **mona**-algorithm requires “pure” 0-1 values. However, **mona**(\( x \)) allows \( x \) to contain (not too many) \( \text{NAs} \). In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable \( f \) has missing values, the variable \( g \) with the largest absolute association to \( f \) is looked up. When the association between \( f \) and \( g \) is positive, any missing value of \( f \) is replaced by the value of \( g \) for the same observation. If the association between \( f \) and \( g \) is negative, then any missing value of \( f \) is replaced by the value of 1-\( g \) for the same observation.

Note

In **cluster** versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one variable, i.e., \( \text{ncol}(x) = 1 \), which currently signals an error (because the algorithm now in C, haes not correctly taken account of this special case).

See Also

**agnes** for background and references; **mona.object**, **plot.mona**.
Examples

```r
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

## One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniN2 <- within(animals, aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3)
ani.idNA <- within(animals, end[!is.na(end)] <- 1)

try( mona(ani.NA) ) ## error: .. object with all values missing
try( mona(aniNA) ) ## error: .. more than half missing values
try( mona(aniN2) ) ## error: all have at least one missing
try( mona(ani.non2) ) ## error: all must be binary
try( mona(ani.idNA) ) ## error: ditto
```

mona.object

---

**Description**

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from `mona`.

**Value**

A legitimate `mona` object is a list with the following components:

- `data`: matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
- `order`: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- `order.lab`: a vector similar to `order`, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- `variable`: vector of length n-1 where n is the number of observations, specifying the variables used to separate the observations of `order`.
- `step`: vector of length n-1 where n is the number of observations, specifying the separation steps at which the observations of `order` are separated.

**METHODS**

The "mona" class has methods for the following generic functions: `print, summary, plot`.

**See Also**

`mona` for examples etc, `plot.mona`. 

Partitioning Around Medoids

Description

Partitioning (clustering) of the data into \( k \) clusters “around medoids”, a more robust version of K-means.

Usage

```r
pam(x, k, diss = inherits(x, "dist"),
    metric = c("euclidean", "manhattan"),
    medoids = NULL, stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only,
    pamonce = FALSE, trace.lev = 0)
```

Arguments

- **x**
  - data matrix or data frame, or dissimilarity matrix or object, depending on the value of the `diss` argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (`NA`s) are allowed—as long as every pair of observations has at least one case not missing.
  - In case of a dissimilarity matrix, `x` is typically the output of `daisy` or `dist`. Also a vector of length \( n(n-1)/2 \) is allowed (where \( n \) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (`NA`s) are not allowed.

- **k**
  - positive integer specifying the number of clusters, less than the number of observations.

- **diss**
  - logical flag: if TRUE (default for `dist` or dissimilarity objects), then `x` will be considered as a dissimilarity matrix. If FALSE, then `x` will be considered as a matrix of observations by variables.

- **metric**
  - character string specifying the metric to be used for calculating dissimilarities between observations.
  - The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If `x` is already a dissimilarity matrix, then this argument will be ignored.

- **medoids**
  - NULL (default) or length-\( k \) vector of integer indices (in \( 1:n \)) specifying initial medoids instead of using the ‘build’ algorithm.

- **stand**
  - logical; if true, the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If `x` is already a dissimilarity matrix, then this argument will be ignored.

- **cluster.only**
  - logical; if true, only the clustering will be computed and returned, see details.
do.swap logical indicating if the swap phase should happen. The default, TRUE, corresponds to the original algorithm. On the other hand, the swap phase is much more computer intensive than the build one for large \( n \), so can be skipped by do.swap = FALSE.

keep.diss, keep.data logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

pamonce logical or integer in 0:5 specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019) see below.

trace.lev integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

The basic pam algorithm is fully described in chapter 2 of Kaufman and Rousseeuw (1990). Compared to the k-means approach in \texttt{kmeans}, the function \texttt{pam} has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see \texttt{plot.partition}) (d) it allows to select the number of clusters using \( \text{mean(silhouette(pr)[,"sil_width"]}) \) on the result \( pr \leftarrow \text{pam(\.\.\.)} \), or directly its component \( pr\$sinfo\$avg.width \), see also \texttt{pam.object}.

When \texttt{cluster.only} is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e., \( \text{pam}(x,k,\text{cluster.only=TRUE}) \) is the same as \( \text{pam}(x,k)\$clustering \) but computed more efficiently.

The \texttt{pam}-algorithm is based on the search for \( k \) representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of \( k \) medoids, \( k \) clusters are constructed by assigning each observation to the nearest medoid. The goal is to find \( k \) representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when \texttt{medoids} are not specified, the algorithm first looks for a good initial set of medoids (this is called the build phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid that will decrease the objective (this is called the swap phase).

When the \texttt{medoids} are specified, their order does not matter; in general, the algorithms have been designed to not depend on the order of the observations.

The \texttt{pamonce} option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.

The default FALSE (or integer 0) corresponds to the original “swap” algorithm, whereas \texttt{pamonce = 1} (or TRUE), corresponds to the first proposal .... and \texttt{pamonce = 2} additionally implements the second proposal as well.

The key ideas of FastPAM (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

\texttt{pamonce = 3}: reduces the runtime by a factor of \( \text{O}(k) \) by exploiting that points cannot be closest to all current medoids at the same time.

\texttt{pamonce = 4}: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.
pam

pamonce = 5: adds minor optimizations copied from the pamonce = 2 approach, and is expected to be the fastest variant.

Value

an object of class "pam" representing the clustering. See ?pam.object for details.

Note

For large datasets, pam may need too much memory or too much computation time since both are \( O(n^2) \). Then, clara() is preferable, see its documentation.

There is hard limit currently, \( n \leq 65536 \), at \( 2^{16} \) because for larger \( n \), \( n(n-1)/2 \) is larger than the maximal integer (\(.Machine\$integer.max = 2^{31} - 1\)).

Author(s)

Kaufman and Rousseau's orginal Fortran code was translated to C and augmented in several ways, e.g. to allow cluster.only=TRUE or do.swap=FALSE, by Martin Maechler. Matthias Studer, Univ.Geneva provided the pamonce (1 and 2) implementation.

Examples

```r
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx # Medoids: '7' and '25' ...
summary(pamx)
plot(pamx)

## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))
## no _build_ *and* no _swap_ phase: just cluster all obs. around (1, 16):
p2.s <- pam(x, 2, medoids = c(1,16), do.swap = FALSE)
p2.s

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)
```

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

### Description

The objects of class "pam" represent a partitioning of a dataset into clusters.

### Value

A legitimate pam object is a list with the following components:

- **medoids**: the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a matrix with in each row the coordinates of one medoid.
- **id.med**: integer vector of indices giving the medoid observation numbers.
- **clustering**: the clustering vector, see *partition.object*.
- **objective**: the objective function after the first and second step of the pam algorithm.
- **isolation**: vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated.
  
  A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.

- **clusinfo**: matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).
- **silinfo**: list with silhouette width information, see *partition.object*.
- **diss**: dissimilarity (maybe NULL), see *partition.object*.
- **call**: generating call, see *partition.object*.
- **data**: (possibly standardized) see *partition.object*.

### Generation

These objects are returned from pam.

### Methods

The "pam" class has methods for the following generic functions: print, summary.
INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a `pam` object.

See Also

`pam, dissimilarity.object, partition.object, plot.partition`.

Examples

```r
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50, mean=5), rnorm(30, mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k)$silinfo$avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")
plot(1:20, asw, type= "h", main = "pam() clustering assessment",
     xlab= "k ( # clusters)", ylab= "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

partition.object

**Partitioning Object**

Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

Value

a "partition" object is a list with the following (and typically more) components:

- **clustering**: the clustering vector. An integer vector of length `n`, the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.
- **call**: the matched `call` generating the object.
- **silinfo**: a list with all `silhouette` information, only available when the number of clusters is non-trivial, i.e., `1 < k < n` and then has the following components, see `silhouette`:
  - **widths**: an (n x 3) matrix, as returned by `silhouette()`, with for each observation `i` the cluster to which `i` belongs, as well as the neighbor cluster of `i` (the cluster, not containing `i`, for which the average dissimilarity between its observations and `i` is minimal), and the silhouette width `s(i)` of the observation.
  - **clus.avg.widths**: the average silhouette width per cluster.
  - **avg.width**: the average silhouette width for the dataset, i.e., simply the average of `s(i)` over all observations `i`. 

---

**partition.object** 2575
This information is also needed to construct a silhouette plot of the clustering, see `plot.partition`.
Note that `avg.width` can be maximized over different clusterings (e.g. with varying number of clusters) to choose an optimal clustering.

- **objective**: value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
- **diss**: an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for `clara`).
- **data**: a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

### GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

### METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

### INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".
See `pam.object`, `clara.object` and `fanny.object` for details.

### See Also

`pam`, `clara`, `fanny`.

---

**plantTraits**

*Plant Species Traits Data*

**Description**

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

**Usage**

`data(plantTraits)`

**Format**

A data frame with 136 observations on the following 31 variables.

- **pdias**: Diaspore mass (mg)
- **longindex**: Seed bank longevity
- **durflow**: Seed bank longevity
- **height**: Plant height, an ordered factor with levels `1 < 2 < ... < 8`.
- **begflow**: Time of first flowering, an ordered factor with levels `1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9`
mycor  Mycorrhizas, an ordered factor with levels \(0\)never < 1 sometimes < always
vegaer  aerial vegetative propagation, an ordered factor with levels \(0\)never < 1 present but limited < important.
vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.
autopoll selfing pollination, an ordered factor with levels \(0\)never < 1rare < 2 often < the rule
insects insect pollination, an ordered factor with 5 levels \(0 < ... < 4.
wind wind pollination, an ordered factor with 5 levels \(0 < ... < 4.
lign a binary factor with levels \(0:1\), indicating if plant is woody.
piq a binary factor indicating if plant is thorny.
ros a binary factor indicating if plant is rosette.
semiros semi-rosette plant, a binary factor (\(0: no; 1: yes\)).
leafy lefy plant, a binary factor.
suman summer annual, a binary factor.
winan winter annual, a binary factor.
monocarp monocarpic perennial, a binary factor.
polycarp polycarpic perennial, a binary factor.
seasae seasonal aestival leaves, a binary factor.
seashiv seasonal hibernal leaves, a binary factor.
seasver seasonal vernal leaves, a binary factor.
everalw leaves always evergreen, a binary factor.
everparti leaves partially evergreen, a binary factor.
elaio fruits with an elaiosome (dispersed by ants), a binary factor.
endozoo endozoochorous fruits, a binary factor.
epizo epizoocchorous fruits, a binary factor.
aquat aquatic dispersal fruits, a binary factor.
windgl wind dispersed fruits, a binary factor.
unsp unspecialized mechanism of seed dispersal, a binary factor.

Details
Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occured.

Source
Examples

```r
data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
daib <- daisy(plantTraits,
              type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(daib, method="ward")
plot(agn.trts, which.plots = 2, cex = 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
_cmdsdaib <- cmdscale(daib, k=6)
plot(_cmdsdaib[, 1:2], asp = 1, col = cutree6)
```

Description

Creates plots for visualizing an agnes object.

Usage

```r
## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

Arguments

- `x` an object of class "agnes", typically created by `agnes(.)`.
- `ask` logical; if true and `which.plots` is NULL, plot.agnes operates in interactive mode, via `menu`.
- `which.plots` integer vector or NULL (default), the latter producing both plots. Otherwise, `which.plots` must contain integers of 1 for a `banner` plot or 2 for a dendrogram or "clustering tree".
- `main, sub` main and sub title for the plot, with convenient defaults. See documentation for these arguments in `plot.default`.
- `adj` for label adjustment in `bannerplot()`.
- `nmax.lab` integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- `max.strlen` positive integer giving the length to which strings are truncated in banner plot labeling.
- `xax.pretty` logical or integer indicating if `pretty(x, ..., n = xax.pretty)` should be used for the x axis. `xax.pretty = FALSE` is for back compatibility.
- `...` graphical parameters (see `par`) may also be supplied and are passed to `bannerplot()` or `pltree()` (see `pltree.twins`), respectively.
Details

When ask = TRUE, rather than producing each plot sequentially, plot.agnes displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask = TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the agnes algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call bannerplot and pltree(), i.e., its method pltree.twins, respectively.

directly with corresponding arguments, e.g., xlab or ylab.

Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner
Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

For the dendrogram, more flexibility than via pltree() is provided by dg <- as.dendrogram(x) and plotting dg via plot.dendrogram.

References

See Also

agnes and agnes.object; bannerplot, pltree.twins, and par.

Examples

# Can also pass 'labels' to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "g"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150)# bannerplot labels are mess

plot.diana

Plots of a Divisive Hierarchical Clustering

Description

Creates plots for visualizing a diana object.

Usage

## S3 method for class 'diana'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)

Arguments

x
an object of class "diana", typically created by diana(.).

ask
logical; if true and which.plots is NULL, plot.diana operates in interactive mode, via menu.

which.plots
integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".

main, sub
main and sub title for the plot, each with a convenient default. See documentation for these arguments in plot.default.

adj
for label adjustment in bannerplot().

nmax.lab
integer indicating the number of labels which is considered too large for single-name labelling the banner plot.

max.strlen
positive integer giving the length to which strings are truncated in banner plot labeling.

xax.pretty
logical or integer indicating if pretty(*, n = xax.pretty) should be used for the x axis. xax.pretty = FALSE is for back compatibility.

... graphical parameters (see par) may also be supplied and are passed to bannerplot() or pltree(), respectively.

Details

When ask = TRUE, rather than producing each plot sequentially, plot.diana displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask= TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the diana algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.
**Side Effects**

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

- Banner
- Clustering tree

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

**References**

see those in `plot.agnes`.

**See Also**

`diana, diana.object, twins.object, par`.

**Examples**

```r
example(diana)# -> dv <- diana(....)
plot(dv, which = 1, nmax.lab = 100)
## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0,0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

---

**plot.mona**

*Banner of Monothetic Divisive Hierarchical Clusterings*

**Description**

Creates the banner of a `mona` object.

**Usage**

```r
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse(x$call)),
     sub = NULL, xlab = "Separation step",
     col = c(2,0), axes = TRUE, adj = 0,
     nmax.lab = 35, max.strlen = 5, ...)
```
Arguments

- **x**: an object of class "mona", typically created by `mona(.)`.
- **main,sub**: main and sub titles for the plot, with convenient defaults. See documentation in `plot.default`.
- **xlab**: x axis label, see `title`.
- **col,adj**: graphical parameters passed to `bannerplot()`.
- **axes**: logical, indicating if (labeled) axes should be drawn.
- **nmax.lab**: integer indicating the number of labels which is considered too large for labeling.
- **max.strlen**: positive integer giving the length to which strings are truncated in labeling.
- **...**: further graphical arguments are passed to `bannerplot()` and `text`.

Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

Side Effects

A banner is plotted on the current graphics device.

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

References

see those in `plot.agnes`.

See Also

- `mona`, `mona.object`, `par`.

---

**plot.partition**  
*Plot of a Partition of the Data Set*

Description

Creates plots for visualizing a partition object.
plot.partition

Usage

## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
stand = FALSE, lines = 2,
shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)

Arguments

x  an object of class "partition", typically created by the functions pam, clara, or fanny.
ask  logical; if true and which.plots is NULL, plot.partition operates in interactive mode, via menu.
which.plots  integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a clusplot or 2 for silhouette.
nmax.lab  integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
max.strlen  positive integer giving the length to which strings are truncated in silhouette plot labeling.
data  numeric matrix with the scaled data; per default taken from the partition object x, but can be specified explicitly.
dist  when x does not have a diss component as for pam(*,keep.diss=FALSE), dist must be the dissimilarity if a clusplot is desired.
stand,lines,shade,color,labels,plotchar,span,xlim,ylim,main, ...
All optional arguments available for the clusplot.default function (except for the diss one) and graphical parameters (see par) may also be supplied as arguments to this function.

Details

When ask= TRUE, rather than producing each plot sequentially, plot.partition displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call par (ask= TRUE) before invoking the plot command.
The clusplot of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see clusplot.partition for more details).
The silhouette plot of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation i, a bar is drawn, representing its silhouette width s(i), see silhouette for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large s(i) (almost 1) are very well clustered, a small s(i) (around 0) means that the observation lies between two clusters, and observations with a negative s(i) are probably placed in the wrong cluster.
A clustering can be performed for several values of k (the number of clusters). Finally, choose the value of k with the largest overall average silhouette width.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:
Clusplot
Silhouette plot
Note

In the silhouette plot, observation labels are only printed when the number of observations is less than nmax.lab (40, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters. For more flexibility, use plot(silhouette(x),...), see plot.silhouette.

References

Further, the references in plot.agnes.

See Also

partition.object, clusplot.partition, clusplot.default, pam, pam.object, clara, clara.object, fanny, fanny.object, par.

Examples

```r
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))
## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

pltree

Plots Clustering Tree of a Hierarchical Clustering

Description

pltree() Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the twins method draws the tree of a twins object, i.e., hierarchical clustering, typically resulting from agnes() or diana().

Usage

```r
pltree(x, ...) # S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
       labels = NULL, ylab = "Height", ...)
```
Arguments

- `x`: in general, an R object for which a `pltree` method is defined; specifically, an object of class "twins", typically created by either `agnes()` or `diana()`.
- `main`: main title with a sensible default.
- `labels`: labels to use; the default is constructed from `x`.
- `ylab`: label for y-axis.
- `...`: graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x),...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

Value

A NULL value is returned.

See Also

- `agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

Examples

```r
# Load data
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0,2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
     nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
     main = deparse(agn$call))
par(op)
```

Description

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.
Usage

data(pluton)

Format

This data frame contains the following columns:

- **Pu238** the percentages of $^{238}$Pu, always less than 2 percent.
- **Pu239** the percentages of $^{239}$Pu, typically between 60 and 80 percent (from neutron capture of Uranium, $^{238}$U).
- **Pu240** percentage of the plutonium 240 isotope.
- **Pu241** percentage of the plutonium 241 isotope.

Details

Note that the percentage of plutonium-242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

Source

Available as 'pluton.dat' from the archive of the University of Antwerpen, 
'....../datasets/clusplot-examples.tar.gz'. no longer available.

References

Examples

data(pluton)

    hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
    pu5 <- pluton
    pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
    pairs(pu5)

predict.ellipsoid

Predict Method for Ellipsoid Objects

Description

Compute points on the ellipsoid boundary, mostly for drawing.

Usage

    predict.ellipsoid(object, n.out=201, ...)
    ## S3 method for class 'ellipsoid'
    predict(object, n.out=201, ...)
    ellipsoidPoints(A, d2, loc, n.half = 201)
Arguments

- **object**: an object of class ellipsoid, typically from `ellipsoidHull()`: alternatively any list-like object with proper components, see details below.
- **n.out, n.half**: half the number of points to create.
- **A, d2, loc**: arguments of the auxiliary `ellipsoidPoints`, see below.
- **...**: passed to and from methods.

Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for ellipsoid objects, see `ellipsoidHull`. The class of `object` is not checked; it must solely have valid components `loc` (length `p`), the `p × p` matrix `cov` (corresponding to `A`) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*,p)` quantile.

Unfortunately, this is only implemented for `p = 2`, currently; contributions for `p ≥ 3` are very welcome.

Value

A numeric matrix of dimension `2*n.out` times `p`.

See Also

- `ellipsoidHull`
- `volume.ellipsoid`

Examples

```r
## see also example(ellipsoidHull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)"

mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x,y)
C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}
```
Usage

## S3 method for class 'agnes'
print(x, ...)

Arguments

x  
an agnes object.

...  
potential further arguments (required by generic).

See Also

summary.agnes producing more output; agnes, agnes.object, print, print.default.

---

print.clara  
Print Method for CLARA Objects

Description

Prints the best sample, medoids, clustering vector and objective function of clara object. This is a method for the function print() for objects inheriting from class clara.

Usage

## S3 method for class 'clara'
print(x, ...)

Arguments

x  
a clara object.

...  
potential further arguments (require by generic).

See Also

summary.clara producing more output; clara, clara.object, print, print.default.

---

print.diana  
Print Method for DIANA Objects

Description

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object. This is a method for the function print() for objects inheriting from class diana.

Usage

## S3 method for class 'diana'
print(x, ...)

Arguments

\[ x \] a diana object.

\[ \ldots \] potential further arguments (require by generic).

See Also

diana, diana.object, print.default.

print.dissimilarity  
*Print and Summary Methods for Dissimilarity Objects*

Description

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions print() and summary() for dissimilarity objects. See print, print.default, or summary for the general behavior of these.

Usage

```r
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)

## S3 method for class 'dissimilarity'
summary(object,
         digits = max(3, getOption("digits") - 2), ...)

## S3 method for class 'summary.dissimilarity'
print(x, ...)```

Arguments

\[ x, \text{object} \] a dissimilarity object or a summary.dissimilarity one for print.summary.dissimilarity().

\[ \text{digits} \] the number of digits to use, see print.default.

\[ \text{diag, upper, justify, right} \] optional arguments specifying how the triangular dissimilarity matrix is printed; see print.dist.

\[ \ldots \] potential further arguments (require by generic).

See Also
daisy, dissimilarity.object, print.default, print.dist.

Examples

```r
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20,5)))
sd # -> print.summary.dissimilarity(.)
str(sd)```
print.mona

Print and Summary Methods for FANNY Objects

Description

Prints the objective function, membership coefficients and clustering vector of fanny object. This is a method for the function print() for objects inheriting from class Fanny.

Usage

## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)

Arguments

x, object a fanny object.
digits number of significant digits for printing. see print.default.
... potential further arguments (required by generic).

See Also

fanny, fanny.object, print, print.default.

print.mona

Print Method for MONA Objects

Description

Prints the ordering of objects, separation steps, and used variables of a mona object. This is a method for the function print() for objects inheriting from class mona.

Usage

## S3 method for class 'mona'
print(x, ...)

Arguments

x a mona object.
... potential further arguments (require by generic).

See Also

mona, mona.object, print, print.default.
**Description**

Prints the medoids, clustering vector and objective function of pam object. This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```r
## S3 method for class 'pam'
print(x, ...)  
```

**Arguments**

- `x` a pam object.
- `...` potential further arguments (require by generic).

**See Also**

`pam`, `pam.object`, `print`, `print.default`

---

**ruspini**

**Ruspini Data**

**Description**

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

**Usage**

```r
data(ruspini)  
```

**Format**

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

**Source**

**References**

see those in `agnes`. 
Examples

data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))

silhouette

Compute or Extract Silhouette Information from Clustering

Description

Compute silhouette information according to a given clustering in k clusters.

Usage

silhouette(x, ...)

## Default S3 method:
silhouette(x, dist, dmatrix, ...)

## S3 method for class 'partition'
silhouette(x, ...)

## S3 method for class 'clara'
silhouette(x, full = FALSE, ...)

sortSilhouette(object, ...)

## S3 method for class 'silhouette'
summary(object, FUN = mean, ...)

plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width \text{* } s[i]"),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

Arguments

x an object of appropriate class; for the default method an integer vector with k different integer cluster codes or a list with such an $x$clustering component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$.

dist a dissimilarity object inheriting from class dist or coercible to one. If not specified, dmatrix must be.

dmatrix a symmetric dissimilarity matrix ($n \times n$), specified instead of dist, which can be more efficient.

full logical specifying if a full silhouette should be computed for clara object. Note that this requires $O(n^2)$ memory, since the full dissimilarity (see daisy) is needed internally.

object an object of class silhouette.

... further arguments passed to and from methods.
### Function: silhouette

#### Arguments:
- **FUN**: function used to summarize silhouette widths.
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
- **max.strlen**: positive integer giving the length to which strings are truncated in silhouette plot labeling.
- **main, sub, xlab**: arguments to `title`; have a sensible non-NULL default here.
- **col, border, cex.names**: arguments passed to `barplot`; note that the default used to be `col = heat.colors(n), border = par("fg")` instead. `col` can also be a color vector of length `k` for clusterwise coloring, see also `do.col.sort`.
- **do.col.sort**: logical indicating if the colors `col` should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.
- **do.n.k**: logical indicating if `n` and `k` “title text” should be written.
- **do.clus.stat**: logical indicating if cluster size and averages should be written right to the silhouettes.

#### Details
For each observation `i`, the silhouette width `s(i)` is defined as follows:

Put `a(i) = average dissimilarity between i and all other points of the cluster to which i belongs (if i is the only observation in its cluster, `s(i) := 0 without further calculations). For all other clusters `C, put `d(i, C) = average dissimilarity of i to all observations of C. The smallest of these `d(i, C) is `b(i) := min_C d(i, C), and can be seen as the dissimilarity between i and its “neighbor” cluster, i.e., the nearest one to which it does not belong. Finally,

\[
s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}
\]

*silhouette.default()* is now based on C code donated by Romain Francois (the R version being still available as `cluster:::silhouette.default.R`).

Observations with a large `s(i)` (almost 1) are very well clustered, a small `s(i)` (around 0) means that the observation lies between two clusters, and observations with a negative `s(i)` are probably placed in the wrong cluster.

#### Value

*silhouette()* returns an object, `sil`, of class `silhouette` which is an `n x 3` matrix with attributes. For each observation `i`, `sil[i,]` contains the cluster to which `i` belongs as well as the neighbor cluster of `i` (the cluster, not containing `i`, for which the average dissimilarity between its observations and `i` is minimal), and the silhouette width `s(i)` of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

*summary(sil)* returns an object of class `summary.silhouette`, a list with components

- **si.summary**: numerical `summary` of the individual silhouette widths `s(i)`.
- **clus.avg.widths**: numeric (rank 1) array of clusterwise `means` of silhouette widths where `mean = FUN` is used.
- **avg.width**: the total mean `FUN(s)` where `s` are the individual silhouette widths.
- **clus.sizes**: `table` of the `k` cluster sizes.
- **call**: if available, the `call` creating `sil`.
Ordered: logical identical to attr(sil, "Ordered"), see below.

sortSilhouette(sil) orders the rows of sil as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width \( s(i) \). attr(sil, "Ordered") is a logical indicating if sil is ordered as by sortSilhouette(). In that case, rownames(sil) will contain case labels or numbers, and attr(sil, "iOrd") the ordering index vector.

Note

While silhouette() is intrinsic to the partition clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from silhouette.default() with cutree() and distance as input.

By default, for clara() partitions, the silhouette is just for the best random subset used. Use full = TRUE to compute (and later possibly plot) the full silhouette.

References

chapter 2 of Kaufman and Rousseeuw (1990), see the references in plot.agnes.

See Also

partition.object, plot.partition.

Examples

data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0,3,0),
        mgp= c(1.6,.8,0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
  mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
         outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

  # the same with cluster-wise colours:
  c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
  for(k in 2:6)
    plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE,
         col = c6[1:k])
par(op)

  # clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xc1k <- xclara[ sample(nrow(xclara), size = 1000) ,] ) # rownames == indices
cl3 <- clara(xc1k, 3)
plot(silhouette(cl3))  # only of the “best” subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE)  # this is the same as
s.full <- silhouette(cl3$clustering, daisy(xc1k))
stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
## color dependent on original “3 groups of each 1000”: % __FIXME ??__
plot(sf, col = 2+ as.integer(names(cl3$clustering) ) %/ 1000,
     main =”plot(silhouette(clara(.), full = TRUE))”)

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn’t too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

### sizeDiss

#### Sample Size of Dissimilarity Like Object

**Description**

Returns the number of observations (sample size) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of \( f(n) = \frac{n(n-1)}{2} \).

**Usage**

`sizeDiss(d)`

**Arguments**

- `d` any R object with length (typically) \( n(n-1)/2 \).

**Value**

- a number; \( n \) if length(d) == n(n-1)/2, `NA` otherwise.

**See Also**

- `dissimilarity.object` and also `as.dist` for class dissimilarity and dist objects which have a `Size` attribute.

**Examples**

```r
sizeDiss(1:10)# 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA
n <- 1:100
stopifnot(n == sapply( n*(n-1)/2, function(n) sizeDiss(logical(n))))
```
summary.agnes  Summary Method for 'agnes' Objects

Description

Returns (and prints) a summary list for an agnes object. Printing gives more output than the corresponding print.agnes method.

Usage

```r
## S3 method for class 'agnes'
summary(object, ...)
## S3 method for class 'summary.agnes'
print(x, ...)
```

Arguments

- `x, object` a agnes object.
- `...` potential further arguments (require by generic).

See Also

agnes, agnes.object.

Examples

```r
data(agriculture)
summary(agnes(agriculture))
```

summary.clara  Summary Method for 'clara' Objects

Description

Returns (and prints) a summary list for a clara object. Printing gives more output than the corresponding print.clara method.

Usage

```r
## S3 method for class 'clara'
summary(object, ...)
## S3 method for class 'summary.clara'
print(x, ...)
```

Arguments

- `x, object` a clara object.
- `...` potential further arguments (require by generic).
See Also

clara.object

Examples

## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0, 4), rnorm(400, 0, 4)),
          cbind(rnorm(400,10,8), rnorm(400,40,5)),
          cbind(rnorm(400,30,4), rnorm(400, 0, 4)),
          cbind(rnorm(400,40,4), rnorm(400,20,2)),
          cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
## Mis'classification' table:

table(rep(1:5, rep(400,5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))
plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)

summary.diana

Summary Method for 'diana' Objects

Description

Returns (and prints) a summary list for a diana object.

Usage

## S3 method for class 'diana'
summary(object, ...)

## S3 method for class 'summary.diana'
print(x, ...)

Arguments

x, object a diana object.

... potential further arguments (require by generic).

See Also

diana, diana.object.
summary.mona  Summary Method for 'mona' Objects

Description

Returns (and prints) a summary list for a mona object.

Usage

## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)

Arguments

x, object  a mona object.
...
potential further arguments (require by generic).

See Also

mona, mona.object.

summary.pam  Summary Method for PAM Objects

Description

Summarize a pam object and return an object of class summary.pam. There’s a print method for the latter.

Usage

## S3 method for class 'pam'
summary(object, ...)
## S3 method for class 'summary.pam'
print(x, ...)

Arguments

x, object  a pam object.
...
potential further arguments (require by generic).

See Also

pam, pam.object.
Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

Value

See agnes.object and diana.object for details.

GENERATION

This class of objects is returned from agnes or diana.

METHODS

The "twins" class has a method for the following generic function: pltree.

INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

See Also

agnes, diana.

volume.ellipsoid Compute the Volume (of an Ellipsoid)

Description

Compute the volume of geometric R object. This is a generic function and has a method for ellipsoid objects (typically resulting from ellipsoidhull()).

Usage

volume(object, ...)  
## S3 method for class 'ellipsoid'  
volume(object, log = FALSE, ...)

Arguments

object  
an R object the volume of which is wanted; for the ellipsoid method, an object of that class (see ellipsoidhull or the example below).

log  
logical indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.

...  
potential further arguments of methods, e.g. log.
Value

a number, the volume $V$ (or $\log(V)$ if $\log = \text{TRUE}$) of the given object.

Author(s)

Martin Maechler (2002, extracting from former clusplot code); Keefe Murphy (2019) provided code for dimensions $d > 2$.

See Also

ellipsoidhull for spanning ellipsoid computation.

Examples

```r
## example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
  class = "ellipsoid")
volume(myEl)# i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100,5)
e5 <- ellipsoidhull(d5)
```

votes.repub

Votes for Republican Candidate in Presidential Elections

Description

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

Usage

data(votes.repub)

Source

Data from 1964 to 1976 is from R. M. Scammon, American Votes 12, Congressional Quarterly.
Description

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

Usage

data(xclara)

Format

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the \( x \) and \( y \) coordinates of the points, respectively.

Note

Our version of the xclara is slightly more rounded than the one from \texttt{read.table("xclara.dat")} and the relative difference measured by \texttt{all.equal} is \( 1.15 \times 10^{-7} \) for V1 and \( 1.17 \times 10^{-7} \) for V2 which suggests that our version has been the result of a \texttt{options(digits = 7)} formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. \texttt{pam(*, 3)} gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices \{1 : 900\}, \{901 : 2050\}, and \{2051 : 3000\}, see the example.

Source

Sample data set accompanying the reference below (file ‘xclara.dat’ in side ‘clus_examples.tar.gz’).

References

Examples

```r
## Visualization: Assuming groups are defined as \{1:1000\}, \{1001:2000\}, \{2001:3000\)
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535) ## PAM’s medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3) ## takes ~2 seconds
px$clustering ; iCl <- split(seq_along(px$clustering), px$clustering)
boxplot(iCl, range = 0.7, horizontal=TRUE,
main = "Indices of the 3 clusters of pam(xclara, 3)")
```

```
## Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
## We see 3 + 2 + 2 = 7 clear “outlier”s or “wrong group” observations:
with(bxCl, rbind(out, group))
## out  1038 1451 1610  30 327 562 770
```
## group 1 1 1 2 2 3 3
## Apart from these, what are the robust ranges of indices? -- Robust range:
t(iR <- bxCl$stats[c(1,5),])
## 1 900
## 901 2050
## 2051 3000
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
Chapter 21

The codetools package

---

**checkUsage**

*Check R Code for Possible Problems*

**Description**

Check R code for possible problems.

**Usage**

```r
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
            suppressLocal = FALSE, suppressParamAssigns = !all,
            suppressParamUnused = !all, suppressFundefMismatch = FALSE,
            suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
            skipWith = FALSE, suppressUndefined = !all,
            suppressPartialMatchArgs = TRUE)

checkUsageEnv(env, ...)

checkUsagePackage(pack, ...)
```

**Arguments**

- **fun** closure.
- **name** character; name of closure.
- **env** environment containing closures to check.
- **pack** character naming package to check.
- **...** options to be passed to checkUsage.
- **report** function to use to report possible problems.
- **all** logical; report all possible problems if TRUE.
- **suppressLocal** suppress all local variable warnings.
- **suppressParamAssigns** suppress warnings about assignments to formal parameters.
- **suppressParamUnused** suppress warnings about unused formal parameters.
- **suppressFundefMismatch** suppress warnings about mismatches between function definitions.
- **suppressLocalUnused** suppress warnings about unused local variables.
- **suppressNoLocalFun** suppress warnings about functions without local variables.
- **skipWith** suppress warnings about unused formal parameters.
- **suppressUndefined** suppress warnings about undefined symbols.
- **suppressPartialMatchArgs** suppress warnings about partial matches in argument names.
suppressFundefMismatch
  suppress warnings about multiple local function definitions with different formal
  argument lists
suppressLocalUnused
  suppress warnings about unused local variables
suppressNoLocalFun
  suppress warnings about using local variables as functions with no apparent
  local function definition
skipWith
  logical; if true, do no examine code portion of with expressions.
suppressUndefined
  suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
  suppress warnings about partial argument matching

Details
checkUsage checks a single R closure. Options control which possible problems to report. The
default settings are moderately verbose. A first pass might use suppressLocal=TRUE to suppress
all information related to local variable usage. The suppressXYZ values can either be scalar logicals
or character vectors; then they are character vectors they only suppress problem reports for the
variables with names in the vector.
checkUsageEnv and checkUsagePackage are convenience functions that apply checkUsage to all
closures in an environment or a package. checkUsagePackage requires that the package be loaded.
If the package has a name space then the internal name space frame is checked.

Author(s)
  Luke Tierney

Examples
  checkUsage(checkUsage)
  checkUsagePackage("codetools", all=TRUE)
  ## Not run: checkUsagePackage("base", suppressLocal=TRUE)

Description
  These functions provide some tools for analysing R code. Mainly intended to support the other
tools in this package and byte code compilation.

Usage
  collectLocals(e, collect)
  collectUsage(fun, name = "<anonymous>", ...)
  constantFold(e, env = NULL, fail = NULL)
  findFuncLocals(formals, body)
  findLocals(e, envir = .BaseEnv)
  findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal, startCollectLocals, finishCollectLocals, warn, signal)
walkCode(e, w = makeCodeWalker())

Arguments

e R expression.
elist list of R expressions.
v R object.
fun closure.
formals formal arguments of a closure.
body body of a closure.
name character.
env character.
envir environment.
w code walker.

findGlobals  

Find Global Functions and Variables Used by a Closure

Description

Finds global functions and variables used by a closure.

Usage

findGlobals(fun, merge = TRUE)

Arguments

fun  
function object; usually a closure.

merge  
logical

Details

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of assign and rm).

Value

Character vector if merge is true; otherwise, a list with functions and variables character vector components. Character vectors are of length zero For non-closures.

Author(s)

Luke Tierney

Examples

findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)

showTree  

Print Lisp-Style Representation of R Expression

Description

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

Usage

showTree(e, write = cat)

Arguments

e  
R expression.

write  
function of one argument to write the result.
showTree

Author(s)

Luke Tierney

Examples

showTree(quote(-3))
showTree(quote("x"<-1))
showTree(quote("f"(x)))
showTree
Chapter 22

The foreign package

lookup.xport  
Lookup Information on a SAS XPORT Format Library

Description
Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

Usage
lookup.xport(file)

Arguments
file  
character variable with the name of the file to read. The file must be in SAS XPORT format.

Value
A list with one component for each dataset in the XPORT format library.

Author(s)
Saikat DebRoy

References

See Also
read.xport
Examples

```r
## Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

## End(Not run)
```

read.arff  
**Read Data from ARFF Files**

Description

Reads data from Weka Attribute-Relation File Format (ARFF) files.

Usage

```r
read.arff(file)
```

Arguments

- `file`  
a character string with the name of the ARFF file to read from, or a `connection` which will be opened if necessary, and if so closed at the end of the function call.

Value

A data frame containing the data from the ARFF file.

References

See Also

`write.arff`; functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

read.dbf  
**Read a DBF File**

Description

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

Usage

```r
read.dbf(file, as.is = FALSE)
```
Arguments

- `file`: name of input file
- `as.is`: should character vectors not be converted to factors?

Details

DBF is the extension used for files written for the `XBASE` family of database languages, covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products (http://www.clicketyclick.dk/databases/xbase/format/). Most of these follow the file structure used by Ashton-Tate’s dBase II, III or 4 (later owned by Borland).

read.dbf is based on C code from http://shapelib.maptools.org/ which implements the `XBASE` specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates); all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that it is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names(unique=TRUE)`.

There is an attribute "data_type" giving the single-character dBase types for each field.

Note

Not to be able to read a particular ‘DBF’ file is not a bug: this is a convenience function especially for shapefiles.

Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

Examples

```r
x <- read.dbf(system.file("files/sids.dbf", package="foreign")[[1]])
str(x)
summary(x)
```
**read.dta**

*Read Stata Binary Files*

**Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```r
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
          missing.type = FALSE,
          convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

- `file` a filename or URL as a character string.
- `convert.dates` Convert Stata dates to `Date` class, and date-times to `POSIXct` class?
- `convert.factors` Use Stata value labels to create factors? (Version 6.0 or later).
- `missing.type` For version 8 or later, store information about different types of missing data?
- `convert.underscore` Convert "_" in Stata variable names to "." in R names?
- `warn.missing.labels` Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes ‘http:’, ‘ftp:’ or ‘https:’) the URL is first downloaded to a temporary file and then read. (‘https:’ is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R’s `Date` class, and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata’s date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If `missing.type` is `TRUE` a separate list is created with the same variable names as the loaded data. For string variables the list value is `NULL`. For other variables the value is `NA` where the observation is not missing and 0–26 when the observation is missing. This is attached as the “missing” attribute of the returned value.

The default file format for Stata 13, `format-115`, is substantially different from those for Stata 5–12.
Value

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113'), 10 (Stata 10 and 11, 'format-114'), and 12 (Stata 12, 'format-115').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

Author(s)

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

References

Stata Users Manual (versions 5 & 6), Programming manual (version 7), or online help (version 8 and later) describe the format of the files. Or directly at http://www.stata.com/help.cgi?dta_114 and http://www.stata.com/help.cgi?dta_113, but note that these have been changed since first published.

See Also

Different approaches are available in package memisc (see its help for Stata.file), function read_dta in package haven and package readstata13.

write.dta, attributes, Date, factor

Examples

write.dta(swiss,swissfile <- tempfile())
read.dta(swissfile)
Arguments

file       A filename, URL, or connection.
read.deleted   Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.
guess.broken.dates
   Attempt to convert dates with 0 or 2 digit year information (see ‘Details’).
thisyear      A 4-digit year to use for dates with no year. Defaults to the current year.
lower.case.names
   Convert variable names to lowercase?

Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit
years are always converted to Date class. With the guess.broken.dates option the function will
attempt to convert two-digit years using the operating system’s default method (see Date) and will
use the current year or the thisyear argument for dates with no year information.

If read.deleted is TRUE the "deleted" attribute of the data frame indicates the deleted records.

Value

A data frame.

Note

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be
readable with the RODBC package.

read.mtp          Read a Minitab Portable Worksheet

Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

Usage

read.mtp(file)
read.octave

Arguments

file character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

Note

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

Examples

## Not run:
read.mtp("ex1-10.mtp")
## End(Not run)

---

read.octave Read Octave Text Data Files

Description

Read a file in Octave text data format into a list.

Usage

read.octave(file)

Arguments

file a character string with the name of the file to read.

Details

This function is used to read in files in Octave text data format, as created by save -text in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and N-d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and NULL is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave’s load and save (as text) facilities as an intermediary step.
**read.spss**

**Value**

A list with one named component for each variable in the file.

**Author(s)**

Stephen Eglen <stephen@gnu.org> and Kurt Hornik

**References**

http://www.octave.org/

**read.spss**  
*Read an SPSS Data File*

**Description**

`read.spss` reads a file stored by the SPSS `save` or `export` commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

**Usage**

```r
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,  
max.value.labels = Inf, trim.factor.names = FALSE,  
trim_values = TRUE, reencode = NA, use.missings = to.data.frame,  
sub = ".", add.undeclared.levels = c("sort", "append", "no"),  
duplicated.value.labels = c("append", "condense"),  
duplicated.value.labels.infix = "_duplicated_", ...)  
```

**Arguments**

- `file` character string: the name of the file or URL to read.
- `use.value.labels` logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching label are returned as NA).
- `to.data.frame` logical: return a data frame?
- `max.value.labels` logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.
- `trim.factor.names` logical: trim trailing spaces from factor levels?
- `trim_values` logical: should values and value labels have trailing spaces ignored when matching for `use.value.labels = TRUE`?
- `reencode` logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in UTF-8 or latin-1 locales, only. Alternatively a character string specifying an encoding to assume for the file.
- `use.missings` logical: should information on user-defined missing values be used to set the corresponding values to NA?
sub character string: If not NA it is used by iconv to replace any non-convertible bytes in character/factor input. Default is ".". For back compatibility with foreign versions <= 0.8-68 use sub=NA.

add.undeclared.levels character: specify how to handle variables with at least one value label and further non-missing values that have no value label (like a factor levels in R). For "sort" (the default) it adds undeclared factor levels to the already declared levels (and labels) and sort them according to level, for "append" it appends undeclared factor levels to declared levels (and labels) without sorting, and for "no" this does not convert to factor in case of numeric SPSS levels (not labels), and still converts to factor if the SPSS levels are characters and to.data.frame=TRUE. For back compatibility with foreign versions <= 0.8-68 use add.undeclared.levels="no" (not recommended as this may convert some values with missing corresponding value labels to NA).

duplicated.value.labels character: what to do with duplicated value labels for different levels. For "append" (the default), the first original value label is kept while further duplicated labels are renamed to paste0(label,duplicated.value.labels.infix,level), for "condense", all levels with identical labels are condensed into exactly the first of these levels in R. Back compatibility with foreign versions <= 0.8-68 is not given as R versions >= 3.4.0 no longer support duplicated factor labels.

duplicated.value.labels.infix character: the infix used for labels of factor levels with duplicated value labels in SPSS (default ".duplicated_") if duplicated.value.labels="append".

Details

This uses modified code from the PSPP project (http://www.gnu.org/software/pspp/ for reading the SPSS formats.

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is supported where supported by download.file with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting max.value.labels you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels.

If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument trim.values=TRUE causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for sub for ways to remove trailing spaces in character data.

URL http://msdn.microsoft.com/en-us/library/ms776446(VS.85).aspx provides a list of translations from Windows codepage numbers to encoding names that iconv is likely to know about and so suitable values for reencode. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 or latin-1 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see iconvlist).
### Value

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute "codepage" to the result.

There may be attributes "label.table" and "variable.labels". Attribute "label.table" is a named list of value labels with one element per variable, either NULL or a named character vector. Attribute "variable.labels" is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute "Missings". This is a named list with one list element per variable. Each element has an element type, a length-one character vector giving the type of missingness, and may also have an element value with the values corresponding to missingness. This is a complex subject (where the R and C source code for read.spss is the main documentation), but the simplest cases are types "one", "two" and "three" with a corresponding number of (real or string) values whose labels can be found from the "label.table" attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also [http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html](http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html)

### Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3,...

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 and latin-1 locales: see argument reencode.

### Author(s)

Saikat DebRoy and the R-core team

### See Also

A different interface also based on the PSPP codebase is available in package [memisc](http): see its help for `spss.system.file`.

### Examples

```r
(sav <- system.file("files", "electric.sav", package = "foreign"))
dat <- read.spss(file=sav)
str(dat)  # list structure with attributes

dat <- read.spss(file=sav, to.data.frame=TRUE)
str(dat)  # now a data.frame

### Now we use an example file that is not very well structured and
### hence may need some special treatment with appropriate argument settings.
### Expect lots of warnings as value labels (corresponding to R factor labels) are uncomplete,
### and an unsupported long string variable is present in the data
(sav <- system.file("files", "testdata.sav", package = "foreign"))
```
### Examples for add.undeclared.levels:

```r
## add.undeclared.levels = "sort" (default):
x.sort <- read.spss(file=sav, to.data.frame = TRUE)
## add.undeclared.levels = "append":
x.append <- read.spss(file=sav, to.data.frame = TRUE,
                 add.undeclared.levels = "append")
## add.undeclared.levels = "no":
x.no <- read.spss(file=sav, to.data.frame = TRUE,
                 add.undeclared.levels = "no")

levels(x.sort$factor_n_undeclared)
levels(x.append$factor_n_undeclared)
str(x.no$factor_n_undeclared)
```

### Examples for duplicated.value.labels:

```r
## duplicated.value.labels = "append" (default)
x.append <- read.spss(file=sav, to.data.frame=TRUE)
## duplicated.value.labels = "condense"
x.condense <- read.spss(file=sav, to.data.frame=TRUE,
                duplicated.value.labels = "condense")

levels(x.append$factor_n_duplicated)
levels(x.condense$factor_n_duplicated)

as.numeric(x.append$factor_n_duplicated)
as.numeric(x.condense$factor_n_duplicated)
```

### Long Strings (>255 chars) are imported in consecutive separate variables

```r
## Long Strings (>255 chars) are imported in consecutive separate variables
## (see warning about subtype 14):
x <- read.spss(file=sav, to.data.frame=TRUE, stringsAsFactors=FALSE)

cat.long.string <- function(x, w=70) cat(paste(strwrap(x, width=w), "\n"))

## first part: x$string_500:
cat.long.string(x$string_500)
## second part: x$STRIN0:
cat.long.string(x$STRIN0)
## complete long string:
long.string <- apply(x[,c("string_500", "STRIN0")], 1, paste, collapse="")
cat.long.string(long.string)
```

---

**read.ssd**

*Obtain a Data Frame from a SAS Permanent Dataset, via read.xport*

**Description**

Generates a SAS program to convert the ssd contents to SAS transport format and then uses read.xport to obtain a data frame.

**Usage**

```r
read.ssd(libname, sectionnames,
          tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```
Arguments

libname character string defining the SAS library (usually a directory reference)

sectionnames character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended.

tmpXport character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.

tmpProgLoc character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.

tsascmd character string giving full path to SAS executable.

Details

Creates a SAS program and runs it.

Error handling is primitive.

Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

Note

This requires SAS to be available. If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as .csv, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

Examples

## if there were some files on the web we could get a real
## runnable example
## Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"
R> baseline <- read.ssd("trialdata", "baseline")
read.systat

Obtain a Data Frame from a Systat File

Description
read.systat reads a rectangular data file stored by the Systat SAVE command as (legacy) *.sys or more recently *.syd files.

Usage
read.systat(file, to.data.frame = TRUE)

Arguments
file
character variable with the name of the file to read
to.data.frame
return a data frame (otherwise a list)

Details
The function only reads those Systat files that are rectangular data files (mtype = 1), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when to.data.frame is FALSE, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

Value
A data frame (or list) with one component for each variable in the saved data set.

Author(s)
Roger Bivand
References

Examples

```r
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[[1]])
str(iris.s)
summary(iris.s)
```

Description

Reads a file as a SAS XPORT format library and returns a list of data.frames.

Usage

```r
read.xport(file, ...)
```

Arguments

- `file` character variable with the name of the file to read. The file must be in SAS XPORT format.
- `...` passed to `as.data.frame` when creating the data frames.

Value

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by ._, .A to .Z by SAS) are mapped to `NA`.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or '"': these are not treated as `NA` missing values.

`lookup.xport`
S3 read functions

Examples

## Not run: ## no XPORT file is installed
read.xport("test.xpt")

## End(Not run)

S3 read functions

Read an S3 Binary or data.dump File

Description

Reads binary data files or data.dump files that were produced in S version 3.

Usage

data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)

Arguments

file the filename of the S-PLUS data.dump or binary file.
print whether to print the name of each object as read from the file.
verbose whether to print the name of every subitem within each object.
env environment within which to create the restored object(s).

Details

read.S can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.
data.restore can read a similar range of files produced by data.dump and for newer versions of S-PLUS, those from data.dump(.....,oldStyle=TRUE).

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

Value

For read.S, an R version of the S3 object.
For data.restore, the name of the file.

Author(s)

Duncan Murdoch
### Examples

```r
## if you have an S-PLUS _Data file containing 'myobj'
## Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)

## End(Not run)
```

---

**write.arff**

**Write Data into ARFF Files**

### Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

### Usage

```r
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

### Arguments

- **x**: the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.
- **file**: either a character string naming a file, or a connection. "" indicates output to the standard output connection.
- **eol**: the character(s) to print at the end of each line (row).
- **relation**: The name of the relation to be written in the file.

### Details

```
relation will be passed through make.names before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have X prepended.
However, the references say that ARFF files are ASCII files, and that encoding is not enforced.
```

### References

### See Also

- `read.arff`; functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

### Examples

```r
write.arff(iris, file = "")
```
**write.dbf**  

Write a DBF File

**Description**

The function tries to write a data frame to a DBF file.

**Usage**

```r
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

**Arguments**

- `dataframe` a data frame object.
- `file` a file name to be written to.
- `factor2char` logical, default `TRUE`, convert factor columns to character: otherwise they are written as the internal integer codes.
- `max_nchar` The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

**Details**

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical","numeric","integer","character","factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

**Value**

Invisible NULL.

**Note**

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric","integer","character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0,-1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

Write Files in Stata Binary Format

Description

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be drop-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

Usage

write.dta(dataframe, file, version = 7L,
convert.dates = TRUE, tz = "GMT",
convert.factors = c("labels", "string", "numeric", "codes"))

Arguments

dataframe a data frame.
file character string giving filename.
version integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10.
convert.dates logical: convert Date and POSIXct objects: see section ‘Dates’.
tz timezone for date conversion.
convert.factors how to handle factors.
Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The abbreviate function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata 'value labels' for the factor levels. With convert.factors = "string", the factor levels are written as strings (the name of the value label is taken from the "val.labels" attribute if it exists or the variable name otherwise). With convert.factors = "numeric" the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, convert.factors = "codes" writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the "label.table" attribute contains value labels with names not already attached to a variable (not the variable name or name from "val.labels") then these will be written out as well.

If the "datalabel" attribute contains a string, it is written out as the dataset label otherwise the dataset label is "Written by R.".

If the "expansion.table" attribute exists expansion fields are written. This attribute should contain a list where each element is character vector of length three. The first vector element contains the name of a variable or "_dta" (meaning the dataset). The second element contains the character name. The third contains the associated data.

If the "val.labels" attribute contains a character vector with a string label for each value then this is written as the value labels. Otherwise the variable names are used.

If the "var.labels" attribute contains a character vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

For Stata 8 or later use the default version = 7 – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn’t have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

Value

NULL

Dates

Unless disabled by argument convert.dates = FALSE, R date and date-time objects (POSIXt classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

format xdate %td;
It is possible to pass objects of class POSIXct to Stata to be treated as one of its versions of date-times. Stata uses the number of milliseconds since 1960-01-01, either excluding (format %tc) or counting (format %tC) leap seconds. So either an object of class POSIXct can be passed to Stata with convert.dates = FALSE and converted in Stata, or 31569200 should be added and then multiplied by 1000 before passing to write.dta and assigning format %tc. Stata’s comments on the first route are at http://www.stata.com/manuals13/ddatetime.pdf, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

Examples

write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)

write.foreign
Write Text Files and Code to Read Them

Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

Usage

write.foreign(df, datafile, codefile,
            package = c("SPSS", "Stata", "SAS"), ...)

Arguments

df A data frame
datafile Name of file for data output
codefile Name of file for code output
package Name of package
... Other arguments for the individual writeForeign functions
Details

The work for this function is done by \texttt{foreign::writeForeignStata}, \texttt{foreign::writeForeignSAS} and \texttt{foreign::writeForeignSPSS}. To add support for another package, e.g. Systat, create a function \texttt{writeForeignSystat} with the same first three arguments as \texttt{write.foreign}. This will be called from \texttt{write.foreign} when \texttt{package="Systat"}. Numeric variables and factors are supported for all packages: dates and times (\texttt{Date}, \texttt{dates}, \texttt{date}, and \texttt{POSIXt} classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For \texttt{package="SAS"} there are optional arguments \texttt{dataname = "rdata"} taking a string that will be the SAS data set name, \texttt{validvarname} taking either \texttt{"V6"} or \texttt{"V7"}, and \texttt{libpath = NULL} taking a string that will be the directory where the target SAS dataset will be written when the generated SAS code been run.

For \texttt{package="SPSS"} there is an optional argument \texttt{maxchars = 32L} taking an integer that causes the variable names (not variable labels) to be abbreviated to not more than \texttt{maxchars} chars. For compatibility with SPSS version 12 and before, change this to \texttt{maxchars = 8L}. In single byte locales with SPSS versions 13 or later, this can be set to \texttt{maxchars = 64L}.

For \texttt{package="SPSS"}, as a side effect, the decimal indicator is always set by \texttt{SET DECIMAL=DOT}, which may override user settings of the indicator or its default derived from the current locale.

Value

Invisible \texttt{NULL}.

datafile <- tempfile()
codefile <- tempfile()
write.foreign(esoph, datafile, codefile, package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)

## End(Not run)
```
Chapter 23

The lattice package

Description

The lattice add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland's 1993 book *Visualizing Data*. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several 'high-level' generic functions (listed below in the “See Also” section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`, which also includes a discussion of the important topics of *conditioning* and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see `trellis.device`.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the `print.trellis` help page. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including `locator`-like functionality) are described in the `trellis.focus` help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading
the PDF reference manual available at https://cran.r-project.org/package=lattice. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer’s ‘Use R’ series; see the “References” section below.

Note

High-level lattice functions like xyplot are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then print-ed or plot-ed to create the actual plot. Due to R’s automatic printing rule, it is usually not necessary to explicitly carry out the second step, and lattice functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often source) or in other contexts where automatic printing is suppressed (e.g., for or while loops). In such situations, an explicit call to print or plot is required.

The lattice package is based on the Grid graphics engine and requires the grid add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing par() settings usually has no effect on Lattice plots; lattice provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

Bell Lab’s Trellis Page contains several documents outlining the use of Trellis graphics; these provide a holistic introduction to the Trellis paradigm: http://web.archive.org/web/20081020164041/http://cm.bell-labs.com/cm/ms/departments/sia/project/trellis/display.writing.html

See Also

The following is a list of high-level functions in the lattice package and their default displays. In all cases, the actual display is produced by the so-called “panel” function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as “panel.” followed by the name of the corresponding high-level function; i.e., the default panel function for xyplot is panel.xyplot, the one for histogram is panel.histogram, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

Univariate:

barchart: Bar plots.
bwplot: Box-and-whisker plots.
densityplot: Kernel density estimates.
dotplot: Cleveland dot plots.
histogram: Histograms.
qqmath: Theoretical quantile plots.
stripplot: One-dimensional scatterplots.

Bivariate:

qq: Quantile plots for comparing two distributions.
xyp: Scatterplots and time-series plots (and potentially a lot more).

Trivariate:

levelplot: Level plots (similar to image plots).
contourplot: Contour plots.
cloud: Three-dimensional scatter plots.
wireframe: Three-dimensional surface plots (similar to persp plots).

Hypervariate:

eplom: Scatterplot matrices.
paral: Parallel coordinate plots.

Miscellaneous:

rfs: Residual and fitted value plots (also see oneway).
tmd: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in panel.functions. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives lines, points, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like llines or panel.lines and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the latticeExtra package.

Common Bivariate Trellis Plots

Description
This help page documents several commonly used high-level Lattice functions. xyplot produces bivariate scatterplots or time-series plots, bwplot produces box-and-whisker plots, dotplot produces Cleveland dot plots, barchart produces bar plots, and stripplot produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

Usage
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

    subscripts = !is.null(groups),
    subset = TRUE)

Arguments

x

All high-level function in lattice are generic. x is the object on which method dispatch is carried out.

For the "formula" methods, x must be a formula describing the primary vari-
ables (used for the per-panel display) and the optional conditioning variables
(which define the subsets plotted in different panels) to be used in the plot. Con-
ditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form \( y \sim x \mid g_1 \times g_2 \times \ldots \) (or equivalently, \( y \sim x \mid g_1 + g_2 + \ldots \)), indicating that plots of \( y \) (on the y-axis) versus \( x \) (on the x-axis) should be produced conditional on the variables \( g_1, g_2, \ldots \). Here \( x \) and \( y \) are the primary variables, and \( g_1, g_2, \ldots \) are the conditioning variables. The conditioning variables may be omitted to give a formula of the form \( y \sim x \), in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., \( \sqrt{} \), \( \log() \), etc. See the data argument below for rules regarding evaluation of the terms in the formula.

With the exception of xyplot, the functions documented here may also be sup-
pplied a formula of the form \( \sim x \mid g_1 \times g_2 \times \ldots \). In that case, \( y \) defaults to \( \text{names}(x) \) if \( x \) is named, and a factor with a single level otherwise.

Cases where \( x \) is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning vari-
bles in the formula. For barchart and dotplot, non-trivial methods exist for
tables and arrays, documented at barchart.table.

The conditioning variables \( g_1, g_2, \ldots \) must be either factors or shingles. Shin-
gles provide a way of using numeric variables for conditioning; see the help
page of shingle for details. Like factors, they have a "levels" attribute, which
is used in producing the conditional plots. If necessary, numeric conditioning
variables are converted to shingles using the shingle function; however, using
equal.count may be more appropriate in many cases. Character variables are
coerced to factors.

**Extended formula interface:** As a useful extension of the interface described
above, the primary variable terms (both the LHS \( y \) and RHS \( x \)) may consist of
multiple terms separated by a '+' sign, e.g., \( y_1 + y_2 \sim x \mid a \times b \). This formula
would be taken to mean that the user wants to plot both \( y_1 \sim x \mid a \times b \) and \( y_2 \sim x \mid a \times b \), but with the \( y_1 \sim x \) and \( y_2 \sim x \) superposed in each panel. The two
groups will be distinguished by different graphical parameters. This is essen-
tially what the groups argument (see below) would produce, if \( y_1 \) and \( y_2 \) were
concatenated to produce a longer vector, with the groups argument being an
indicator of which rows come from which variable. In fact, this is exactly what
is done internally using the reshape function. This feature cannot be used in
conjunction with the groups argument.

To interpret \( y_1 + y_2 \) as a sum, one can either set allow.multiple=FALSE or use
I(y1+y2).

A variation on this feature is when the outer argument is set to TRUE. In that
case, the plots are not superposed in each panel, but instead separated into dif-
fferent panels (as if a new conditioning variable had been added).

**Primary variables:** The \( x \) and \( y \) variables should both be numeric in xyplot,
and an attempt is made to coerce them if not. However, if either is a factor, the
levels of that factor are used as axis labels. In the other four functions docu-
mented here, exactly one of \( x \) and \( y \) should be numeric, and the other a factor
or shingle. Which of these will happen is determined by the horizontal argument —
if horizontal=TRUE, then \( y \) will be coerced to be a factor or shingle,
otherwise \( x \). The default value of horizontal is FALSE if \( x \) is a factor or shin-
gle, TRUE otherwise. (The functionality provided by horizontal=FALSE is not S-compatible.)
Note that the x argument used to be called formula in earlier versions (when the high-level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

data
For the formula methods, a data frame (or more precisely, anything that is a valid envir argument in eval, e.g., a list or an environment) containing values for any variables in the formula, as well as groups and subset if applicable. If not found in data, or if data is unspecified, the variables are looked for in the environment of the formula. For other methods (where x is not a formula), data is usually ignored, often with a warning if it is explicitly specified.

allow.multiple
Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to TRUE whenever sensible.

outer
Logical flag controlling what happens with formulas using the extended interface described above (see the entry for x for details). Defaults to FALSE, except when groups is explicitly specified or grouping does not make sense for the default panel function.

box.ratio
Applicable to barchart and bwplot. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the box.width argument in the respective default panel functions.

horizontal
Logical flag applicable to bwplot, dotplot, barchart, and stripplot. Determines which of x and y is to be a factor or shingle (y if TRUE, x otherwise). Defaults to FALSE if x is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of scales in this case may be abbreviate = TRUE, in which case long labels which would usually overlap will be abbreviated. scales could also contain a minlength argument in this case, which would be passed to the abbreviate function.

Common arguments: The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

panel
Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding x and y variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the panel argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “panel.” followed by the name of the corresponding high-level function (e.g., panel.xyplot, panel.barchart, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named x and y, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as xyplot) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a . . . argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.
Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the \(x\) and \(y\) arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, \texttt{panel.grid}, \texttt{panel.loess}, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, \texttt{lines} can be replaced by \texttt{l1ines} (or equivalently, \texttt{panel.lines}). Note that traditional graphics functions like \texttt{lines} will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the \texttt{groups} argument is not \texttt{NULL}. In that case, the panel function should also accept arguments named \texttt{groups} and \texttt{subscripts} (see below for details). A useful panel function predefined for use in such cases is \texttt{panel.superpose}, which can be combined with different \texttt{panel.groups} functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the \texttt{groups} argument, including the default ones for \texttt{xyplot}, \texttt{barchart}, \texttt{dotplot}, and \texttt{stripplot}.

Even when \texttt{groups} is not present, the panel function can have \texttt{subscripts} as a formal argument. In either case, the \texttt{subscripts} argument passed to the panel function are the indices of the \(x\) and \(y\) data for that panel in the original data, BEFORE taking into account the effect of the \texttt{subset} argument. Note that \texttt{groups} remains unaffected by any subsetting operations, so \texttt{groups[subscripts]} gives the values of \texttt{groups} that correspond to the data in that panel.

This interpretation of \texttt{subscripts} does not hold when the extended formula interface is in use (i.e., when \texttt{allow.multiple} is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function \texttt{latticeParseFormula}), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, \texttt{subscripts} needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of \texttt{subset}, in which case \texttt{subscripts} may have no relationship with corresponding rows in the original data frame.

One can also use functions called \texttt{panel.number} and \texttt{packet.number}, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using \texttt{trellis.focus} etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using \texttt{perm.cond} and \texttt{index.cond} respectively), in which case \texttt{packet.number} gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

\texttt{panel.xyplot} has an argument called \texttt{type} which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to \texttt{xyplot} directly). In the event that a \texttt{groups} variable is used, \texttt{panel.xyplot}
calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

**aspect**
This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are "fill" (the default) which tries to make the panels as big as possible to fill the available space; "xy", which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a prepanel function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default prepanel function are used. Not all default prepanel functions produce sensible banking calculations.

**groups**
A variable or expression to be evaluated in `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified. See entries for key, auto.key and `simpleKey` for how to draw a key.

**auto.key**
A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns = 2)` will create a legend split into two columns (columns is documented in the entry for `key`).

More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (text) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified.

Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The `par.settings` argument, possibly in conjunction with `simpleTheme`, may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using key (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the
A function that takes the same arguments as the panel function and returns a list, possibly containing components named xlim, ylim, dx, and dy (and less frequently, xat and yat). The return value of a user-supplied prepanel function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The xlim and ylim components are similar to the high level xlim and ylim arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the xlim and ylim arguments are not explicitly specified (possibly as components in scales) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the prepanel function. This happens globally if the relation component of scales is "same", and on a per-panel basis otherwise.

The dx and dy components are used for banking computations in case aspect is specified as "xy". See documentation of banking for details.

If xlim or ylim is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first n integers, where n is the length of xlim or ylim, as the case may be. The elements of the character vector are used as the default labels for these n integers. Thus, to make this information consistent between panels, the xlim or ylim values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component xat or yat may be returned by the prepanel function, which should be a subset of 1:n, indicating which of the n values (levels) are actually represented in the panel. This is useful when calculating the limits with relation="free" or relation="sliced" in scales.

The prepanel function is responsible for providing a meaningful return value when the x, y (etc.) variables are zero-length vectors. When nothing else is appropriate, values of NA should be returned for the xlim and ylim components.

A logical flag or function. If FALSE, strips are not drawn. Otherwise, strips are drawn using the strip function, which defaults to strip.default. See documentation of strip.default to see the arguments that are available to the strip function. This description also applies to the strip.left argument (see ... below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for x in the formula defining the plot. Can be specified as NULL to omit the label altogether. Finer control is possible, as described in the entry for main, with the modification that if the label component is omitted from the list, it is replaced by the default xlab.

Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for y in the formula defining the plot. Finer control is possible, see entries for main and xlab.

Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in name=value form, and may also contain two other lists called x and y of the same form (described below). Components of x and y affect the respective axes only, while those in scales affect both. When parameters are specified in both lists, the values in x or y are used. Note that certain high-level functions have defaults that are specific to a particular
axis (e.g., bwplot has alternating=FALSE for the categorical axis only); these can only be overridden by an entry in the corresponding component of scales. As a special exception, scales (or its x and y components) can also be a character string, in which case it is interpreted as the relation component.

The possible components are:

relation A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For relation="same", the same limits, usually large enough to encompass all the data, are used for all the panels. For relation="free", limits for each panel is determined by just the points in that panel. Behavior for relation="sliced" is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the prepanel function, which can be overridden by xlim, ylim or scales$scales (except when relation="sliced", in which case explicitly specified limits are ignored with a warning). When relation is "free", xlim or ylim can be a list, in which case it is treated as if its components were the limit values obtained from the prepanel calculations for each panel (after being replicated if necessary).

tick.number An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see xlim.

draw A logical flag, defaulting to TRUE, that determines whether to draw the axis (i.e., tick marks and labels) at all.

alternating Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, alternating can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers
• 0: do not draw tick labels
• 1: bottom/left
• 2: top/right
• 3: both.

alternating applies only when relation="same". The default is TRUE, or equivalently, c(1,2)

limits Same as xlim and ylim.

at The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

labels Vector of labels (characters or expressions) to go along with at. Can also be a list like at.

cex A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.

font, fontface, fontfamily Specifies the font to be used for axis labels.

lineheight Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for cloud.)

tck Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.

col Color of tick marks and labels.
rot  Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.

abbreviate  A logical flag, indicating whether to abbreviate the labels using the abbreviate function. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength  Argument passed to abbreviate if abbreviate=TRUE.

log  Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x = list(log = 2)) is equivalent to y ~ log2(x).

See entry for equispaced.log below for details on how to control axis labeling.

equispaced.log  A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to TRUE.

Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If equispaced.log is FALSE, the choice made is similar to how log scales are annotated in traditional graphics. If TRUE, tick mark locations are chosen as ‘pretty’ equispaced values in the transformed scale, and labeled in the form "base^loc", where base is the base of the logarithm transformation, and loc are the locations in the transformed scale.

See also xscale.components.logpower in the latticeExtra package.

format  The format to use for POSIXct variables. See strftime for description of valid values.

axs  A character string, "r" (default) or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

subscripts  A logical flag specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified, or if the panel function accepts an argument named subscripts. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using panel.identify.

subset  An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If subscripts is TRUE, the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the drop.unused.levels argument.

xlim  Normally a numeric vector (or a DateTime object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of x. The latter form is interpreted as a range containing c(1, length(xlim)), with the character vector determining labels at tick positions 1:length(xlim).

xlim could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaning-
ful only when scales$s$relation is "free", in which case these are treated as if they were the corresponding limit components returned by prepanel calculations.

**ylim**

Similar to **xlim**, applied to the y-axis.

**drop.unused.levels**

A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an interaction is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components cond and data, both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by lattice.getOption("drop.unused.levels"), which is initially set to TRUE for both components. Note that this argument does not control dropping of levels of the groups argument.

**default.scales**

A list giving the default values of scales for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.

**default.prepanel**

A function or character string giving the name of a function that serves as the (component-wise) fallback prepanel function when the prepanel argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of `lattice.options`.

**lattice.options**

A list that could be supplied to `lattice.options`. These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the `par.settings` argument described below for a similar treatment of graphical settings.

... Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel function being used.

The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high-level functions, but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as “panel.” followed by the name of the high-level function; for example, the default panel function for bwplot is `panel.bwplot`. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

**as.table**:

A logical flag that controls the order in which panels should be displayed: if FALSE (the default), panels are drawn left to right, bottom to top (as in a graph); if TRUE, left to right, top to bottom (as in a table).
between: A list with components x and y (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). x and y are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different between values for different pages.

key: A list that defines a legend to be drawn on the plot. This list is used as an argument to the draw.key function, which produces a "grob" (grid object) eventually plotted by the print method for "trellis" objects. The structure of the legend is constrained in the ways described below. Although such a list can be and often is created explicitly, it is also possible to generate such a list using the simpleKey function; the latter is more convenient but less flexible. The auto.key argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by key, use the legend argument.

The position of the key can be controlled in either of two possible ways. If a component called space is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of space, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components x, y and corner. x and y determine the location of the corner of the key given by corner, which is usually one of c(0,0), c(1,0), c(1,1) and c(0,1), which denote the corners of the unit square. Fractional values are also allowed, in which case x and y determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

x and y should be numbers between 0 and 1, giving coordinates with respect to the "display area". Depending on the value of the "legend.bbox" option (see lattice.getOption), this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel"). The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for rep below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in key and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- cex=1 (text, lines, points)
- col="black" (text, rectangles, lines, points)
- alpha=1 (text, rectangles, lines, points)
- fill="transparent" (lines, points)
- lty=1 (lines)
• lwd=1 (lines, points)
• font=1 (text, points)
• fontface (text, points)
• fontfamily (text, points)
• pch=8 (lines, points)
• adj=0 (text)
• type="l" (lines)
• size=5 (rectangles, lines)
• height=1 (rectangles)
• lineheight=1 (text)
• angle=0 (rectangles, but ignored)
• density=-1 (rectangles, but ignored)

In addition, the component border can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, border controls the border of the entire key (see below). angle and density are unimplemented. size determines the width of columns of rectangles and lines in character widths. type is relevant for lines; "1" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. height gives heights of rectangles as a fraction of the default.

Other possible components of key are:

reverse.rows Logical flag, defaulting to FALSE. If TRUE, all components are reversed after being replicated (the details of which may depend on the value of rep). This is useful in certain situations, e.g., with a grouped barchart with stack = TRUE with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless reverse.rows = TRUE. Note that in this case, unless all columns have the same number or rows, they will no longer be aligned.

between Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

title String or expression giving a title for the key.

rep Logical flag, defaults to TRUE. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying rep=FALSE, in which case the length of each column will be determined by components of that column alone.

cex.title Zoom factor for the title.

lines.title The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.

padding.text The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently \(0.2 \times "\text{lines}"\). This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

background Background color for the legend. Defaults to the global background color.
alpha.background  An alpha transparency value between 0 and 1 for the background.

border  Either a color for the border, or a logical flag. In the latter case, the border color is black if border is TRUE, and no border is drawn if it is FALSE (the default).

transparent=FALSE  Logical flag, whether legend should have a transparent background.

just  A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See grid.layout for more precise details.

columns  The number of column-blocks (drawn side by side) the legend is to be divided into.

between.columns  Space between column blocks, in addition to between.

divide  Number of point symbols to divide each line when type is "b" or "o" in lines.

legend:  The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.

If used, legend must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the space component of key. If key (or colorkey for levelplot and wireframe) is specified, their space component must not conflict with the name of any component of legend.

Each component of legend must have a component called fun. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called args. For components named "inside", there can be additional components called x, y and corner, which work in the same way as for key.

page:  A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

xlab.top, ylab.right:  Labels for the x-axis on top, and y-axis on the right.

Similar to xlab and ylab, but less commonly used.

main:  Typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL.

main (as well as xlab, ylab and sub) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in plotmath. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for ylab). This feature can be used to provide column or row labels rather than a single axis label. When main (etc.) is a list, the actual label should be specified as the label component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (xlab and ylab usually have defaults, but main and sub do not). Further named arguments are passed on to textGrob; this can include arguments controlling positioning like just and rot as well as graphical parameters such as col and font (see gpar for a full list).

main, sub, xlab, ylab, xlab.top, and ylab.right can also be arbitrary "grob"s (grid graphical objects).
sub: Character string or expression (or a list of "grob") for a subtitle to be placed at the bottom of each page. See entry for main for finer control options.

par.strip.text: A list of parameters to control the appearance of strip text. Notable components are col, cex, font, and lines. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "\n"-s) or if the default height seems too small or too large. Additionally, the lineheight component can control the space between multiple lines. The labels can be abbreviated when shown by specifying abbreviate = TRUE, in which case the components minlength and dot (passed along to the abbreviate function) can be specified to control the details of how this is done.

layout: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. layout determines this arrangement. layout is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is c(0,n), where n is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via par("din")). If NA is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels. The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.

skip: A logical vector (default FALSE), replicated to be as long as the number of panels (spanning all pages). For elements that are TRUE, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

strip.left: strip.left can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for strip for detailed usage.

xlab.default, ylab.default: Fallback default for xlab and ylab when they are not specified. If NULL, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

xscale.components, yscale.components: Functions that determine axis annotation for the x and y axes respectively. See documentation for xscale.components.default, the default values of these arguments, to learn more.

axis: Function responsible for drawing axis annotation. See documentation for
axis.default, the default value of this argument, to learn more.

perm.cond: An integer vector, a permutation of 1:n, where n is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. perm.cond can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using perm.cond as the perm argument does in aperm.

index.cond: Whereas perm.cond permutes the dimensions of the multidimensional array of panels, index.cond can be used to subset (or reorder) margins of that array. index.cond can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. index.cond can be used to choose a 'subset' (in the R sense) of these levels, which is then used as the display order for that variable. If index.cond is a list, it has to be as long as the number of conditioning variables, and the i-th component has to be a valid indexing vector for levels(g_i), where g_i is the i-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the subset and drop.unused.levels arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to TRUE.

Note that the components of index.cond are interpreted in the order of the conditioning variables in the original call, and is not affected by perm.cond. Another possibility is to specify index.cond as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a ... argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use perm.cond and index.cond to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the update.trellis method, both can be set to NULL, which reverts these back to their defaults.

par.settings: A list that could be supplied to trellis.par.set. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the lattice.options argument described above for a similar treatment of non-graphical options.

plot.args: A list containing possible arguments to plot.trellis, which will be used by the plot or print methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.
Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the `formula` method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the `formula` (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables $g_1, g_2, \ldots$, a separate "packet" is produced, consisting of the points $(x, y)$ for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for `index.cond` above).

The coordinate system used by `lattice` by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. Default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with $g_1$ varying fastest, followed by $g_2$, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

Value

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The `update` method can be used to subsequently update components of the object, and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Note

Most of the arguments documented here are also applicable for the other high-level functions in the `lattice` package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

**B_01_xyplot.ts**

**Time series plotting methods**

**Description**

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

**Usage**

## S3 method for class 'ts'
xyplot(x, data = NULL,
screens = if (superpose) 1 else colnames(x),
...
superpose = FALSE,
cut = FALSE,
type = "l",
col = NULL,
lty = NULL,
lwd = NULL,
pch = NULL,
cex = NULL,
fill = NULL,
auto.key = superpose,
panel = if (superpose) "panel.superpose"
   else "panel.superpose.plain",
par.settings = list(),
layout = NULL, as.table = TRUE,
xlab = "Time", ylab = NULL,
default.scales = list(y = list(relation =
if (missing(cut)) "free" else "same")))

Arguments

x an object of class ts, which may be multi-variate, i.e. have a matrix structure
with multiple columns.
data not used, and must be left as NULL.
... additional arguments passed to xyplot, which may pass them on to
panel.xyplot.
screens factor (or coerced to factor) whose levels specify which panel each series is to
be plotted in. screens = c(1,2,1) would plot series 1, 2 and 3 in panels 1, 2
and 1. May also be a named list, see Details below.
superpose overlays all series in one panel (via screens = 1) and uses grouped style settings
(from trellis.par.get("superpose.line"), etc). Note that this is just a
convenience argument: its only action is to change the default values of other
arguments.
cut defines a cut-and-stack plot. cut can be a list of arguments to the function
equal.count, i.e. number (number of intervals to divide into) and overlap (the
fraction of overlap between cuts, default 0.5). If cut is numeric this is passed as
the number argument.
cut = TRUE tries to choose an appropriate number of cuts (up to a maximum of
6), using banking, and assuming a square plot region. This should have the
effect of minimising wasted space when aspect = "xy".
type, col, lty, lwd, pch, cex, fill
graphical arguments, which are processed and eventually passed to
panel.xyplot. These arguments can also be vectors or (named) lists, see De-
tails for more information.
auto.key a logical, or a list describing how to draw a key. See the auto.key entry in
xyplot. The default here is to draw lines, not points, and any specified style
arguments should show up automatically.
panel the panel function. It is recommended to leave this alone, but one can pass a
panel.groups argument which is handled by panel.superpose for each series.
par.settings  style settings beyond the standard col, lty, lwd, etc; see trellis.par.set and simpleTheme.

layout  numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.

as.table  to draw panels from top to bottom. The order is determined by the order of columns in x.

xlab, ylab  X axis and Y axis labels; see xyplot. Note in particular that ylab may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but **NOTE** in this case the vector should be reversed OR the argument as.table set to FALSE.

default.scales  scales specification. The default is set to have "free" Y axis scales unless cut is given. Note, users should pass the scales argument rather than default.scales.

**Details**

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., list(A = c(1,2), c(3,4)) in which c(3,4) is the default value and c(1,2) the value only for series A. The screens argument can be specified in a similar way.

Some examples are given below.

**Value**

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <felix@nfrac.org>. The first two authors developed xyplot.ts in their zoo package, including the screens approach. The third author developed a different xyplot.ts for cut-and-stack plots in the latticeExtra package. The final author fused these together.

**References**

**See Also**

xyplot, panel.xyplot, plot.ts, ts, xyplot.zoo in the zoo package.

**Examples**

```r
xyplot(ts(c(1:10,10:1)))

### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy", strip = FALSE, strip.left = TRUE, cut = list(number = 4, overlap = 0.05))
```
### A multivariate example; first juxtaposed, then superposed

```r
genes <- cbind(gene1 = rep(1:4, 5), gene2 = rep(1:4, each = 5))

xyplot(genes, scales = list(y = "same"))

xyplot(genes, superpose = TRUE, aspect = "xy", lwd = 2,
       type = c("l","g"), ylim = c(0, max(genes)))
```

### Examples using screens (these two are identical)

```r
xyplot(genes, screens = c(rep("Continental", 3), "UK"))

xyplot(genes, screens = list(FTSE = "UK", "Continental"))
```

### Automatic group styles

```r
xyplot(genes, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)

xyplot(genes, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE, xlim = extendrange(1996:1998),
       par.settings = standard.theme(color = FALSE))
```

### Specifying styles for series by name

```r
xyplot(genes, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)

xyplot(genes, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
       auto.key = TRUE)
```

### Example with simpler data, few data points

```r
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))

xyplot(z, screens = 1)

xyplot(z, screens = list(a = "primary (a)", "other (b & c)") ,
       type = list(a = c("p", "h"), b = c("p", "s"), "o"),
       pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

### table methods for barchart and dotplot

#### Description

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

#### Usage

```r
## S3 method for class 'table'
barchart(x, data, groups = TRUE,
         origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
barchart(x, data, ...)  
```

## S3 method for class 'matrix'
barchart(x, data, ...)
## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)

### Arguments

- **x**: A table, array or matrix object.
- **data**: Should not be specified. If specified, will be ignored with a warning.
- **groups**: A logical flag, indicating whether to use the last dimension as a grouping variable in the display.
- **origin, stack**: Arguments to `panel.barchart`. The defaults for the table method are different.
- **horizontal**: Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
- **...**: Other arguments, passed to the underlying formula method.

### Details

The first dimension is used as the variable on the categorical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument beforehand using `t` or `aperm`). For more flexibility, use the formula method after converting the table to a data frame using the relevant `as.data.frame` method.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Author(s)

         auto.key = list(title = "Survived"))
```
Histograms and Kernel Density Plots

Description

Draw Histograms and Kernel Density Plots, possibly conditioned on other variables.

Usage

```r
histogram(x, data, ...)  
densityplot(x, data, ...)  
```

## S3 method for class 'formula'

```r
histogram(x,  
data,  
allow.multiple, outer = TRUE,  
auto.key = FALSE,  
aspect = "fill",  
panel = lattice.getOption("panel.histogram"),  
prepanel, scales, strip, groups,  
xlab, xlim, ylab, ylim,  
type = c("percent", "count", "density"),  
nint = if (is.factor(x)) nlevels(x)  
else round(log2(length(x)) + 1),  
endpoints = extend.limits(range(as.numeric(x),  
                                 finite = TRUE), prop = 0.04),  
breaks,  
equal.widths = TRUE,  
drop.unused.levels =  
  lattice.getOption("drop.unused.levels"),  
...,  
lattice.options = NULL,  
default.scales = list(),  
default.prepanel =  
  lattice.getOption("prepanel.default.histogram"),  
subscripts,  
subset)
```

## S3 method for class 'numeric'

```r
histogram(x, data = NULL, xlab, ...)  
```

## S3 method for class 'factor'

```r
histogram(x, data = NULL, xlab, ...)  
```

## S3 method for class 'formula'

```r
densityplot(x,  
data,  
allow.multiple = is.null(groups) || outer,  
outer = !is.null(groups),  
auto.key = FALSE,  
aspect = "fill",  
panel = lattice.getOption("panel.densityplot"),  
prepanel, scales, strip, groups, weights,  
...)
```
## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

**Arguments**

- **x**: The object on which method dispatch is carried out.
  - For the formula method, x can be a formula of the form ~ x | g1 * g2 * ...., indicating that histograms or kernel density estimates of the x variable should be produced conditioned on the levels of the (optional) variables g1, g2, .... x should be numeric (or possibly a factor in the case of histogram), and each of g1, g2, .... should be either factors or shingles.
  - As a special case, the right hand side of the formula can contain more than one term separated by '+' signs (e.g., ~ x1 + x2 | g1 * g2). What happens in this case is described in the documentation for `xyplot`. Note that in either form, all the terms in the formula must have the same length after evaluation.
  - For the numeric and factor methods, x is the variable whose histogram or Kernel density estimate is drawn. Conditioning is not allowed in these cases.

- **data**: For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see `xyplot` for details). data should not be specified for the other methods, and is ignored with a warning if it is.

- **type**: A character string indicating the type of histogram that is to be drawn. "percent" and "count" give relative frequency and frequency histograms respectively, and can be misleading when breakpoints are not equally spaced. "density" produces a density histogram.
  - type defaults to "density" when the breakpoints are unequally spaced, and when breaks is NULL or a function, and to "percent" otherwise.

- **nint**: An integer specifying the number of histogram bins, applicable only when breaks is unspecified or NULL in the call. Ignored when the variable being plotted is a factor.

- **endpoints**: A numeric vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when breaks is unspecified and the variable being plotted is not a factor. In do.breaks, this specifies the interval that is to be divided up.

- **breaks**: Usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density.
When `breaks` is unspecified, the value of `lattice.getOption("histogram.breaks")` is first checked. If this value is NULL, then the default is to use
\[
\text{breaks} = \text{seq_len}(1 + n\text{levels}(x)) - 0.5
\]
when `x` is a factor, and
\[
\text{breaks} = \text{do.breaks}(\text{endpoints}, n\text{int})
\]
otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not NULL, or if `breaks` is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the `breaks` argument in `hist`. In particular, this allows specification of `breaks` as an integer giving the number of bins (similar to `nint`), as a character string denoting a method, or as a function.

When specified explicitly, a special value of `breaks` is NULL, in which case the number of bins is determined by `nint` and then breakpoints are chosen according to the value of `equal.widths`.

`equal.widths` A logical flag, relevant only when `breaks=NULL`. If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints).

`n` Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to `density`.

`panel` A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions `panel.histogram` and `panel.densityplot` are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

default.prepanel
  Fallback prepanel function. See xyplot.

weights
  numeric vector of weights for the density calculations, evaluated in the non-standard manner used for groups and terms in the formula, if any. If this is specified, it is subsetted using subscripts inside the panel function to match it to the corresponding x values.
  At the time of writing, weights do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).

bw, adjust, width
  Arguments controlling bandwidth. Passed on as arguments to density.

kernel, window
  The choice of kernel. Passed on as arguments to density.

give.Rkern
  Logical flag, passed on as argument to density. This argument is made available only for ease of implementation, and will produce an error if TRUE.

from, to, cut
  Controls range over which density is evaluated. Passed on as arguments to density.

na.rm
  Logical flag specifying whether NA values should be ignored. Passed on as argument to density, but unlike in density, the default is TRUE.

...
  Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

histogram draws Conditional Histograms, and densityplot draws Conditional Kernel Density Plots. The default panel function uses the density function to compute the density estimate, and all arguments accepted by density can be specified in the call to densityplot to control the output. See documentation of density for details.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

do.breaks is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

The form of the arguments accepted by the default panel function panel.histogram is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside histogram and passes only the breakpoints and the heights to the panel function, lattice simply passes along the original variable x along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

---

**Q-Q Plot with Theoretical Distribution**

Description

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

Usage

```r
qqmath(x, data, ...)
```

## S3 method for class 'formula'
```r
qqmath(x, data,
  allow.multiple = is.null(groups) || outer,
  outer = !is.null(groups),
  distribution = qnorm,
  f.value = NULL,
  auto.key = FALSE,
  aspect = "fill",
  panel = lattice.getOption("panel.qqmath"),
  prepanel = NULL,
  scales, strip, groups,
  xlab, xlim, ylab, ylim,
  drop.unused.levels = lattice.getOption("drop.unused.levels"),
```
...,
lattice.options = NULL,
default.scales = list(),
default.prepanel = lattice.getOption("prepanel.default.qqmath"),
subscripts,
subset)
## S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)

Arguments

- **x**: The object on which method dispatch is carried out. For the "formula" method, x should be a formula of the form ~ x | g1 * g2 * ...., where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.
- **data**: For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see `xyplot` for details). data should not be specified for the other methods, and is ignored with a warning if it is.
- **distribution**: A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are `qnorm`, `qunif`, etc. Distributions with other required arguments need to be provided as user-defined functions (see example with `qt`).
- **f.value**: An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function `ppoints`, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the `quantile` function for the sample, and the function specified as the distribution argument for the theoretical distribution. f.value defaults to `NULL`, which has the effect of using `ppoints` for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for `qqnorm`, but different from the S-PLUS default of `f.value=ppoints`.
   For large x, this argument can be used to restrict the number of points plotted. See also the `tails.n` argument in `panel.qqmath`.
- **panel**: A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function `panel.qqmath` is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.
- **allow.multiple**, **outer**
- **auto.key**
- **aspect**
- **prepanel**
- **scales**
- **strip**
- **groups**
- **xlab**, **ylab**
qqmath produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of qqmath is different from the corresponding S-PLUS function, but is similar to qqnorm. See the entry for f.value for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not qqmath itself. In fact, both the arguments distribution and f.value are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for panel.qqmath for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value
An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Examples
```r
norm(100), distribution = function(p) qt(p, df = 10))
qqmath(~ height | voice.part, aspect = "xy", data = singer,
   prepanel = prepanel.qqmathline,
   panel = function(x, ...) {
     panel.qqmathline(x, ...)
     panel.qqmath(x, ...)
   })
vp.comb <-
  factor(sapply(strsplit(as.character(singer$voice.part), split = " ",
    "[", 1),
    levels = c("Bass", "Tenor", "Alto", "Soprano"))
```
vp.group <-
  factor(sapply(strsplit(as.character(singer$voice.part), split = " ")
  , "[", 2))
qqmath(~ height | vp.comb, data = singer,
  groups = vp.group, auto.key = list(space = "right"),
  aspect = "xy",
  prepanel = prepanel.qqmathline,
  panel = function(x, ...) {
    panel.qqmathline(x, ...)
    panel.qqmath(x, ...)
  })

Quantile-Quantile Plots of Two Samples

Description
Quantile-Quantile plots for comparing two Distributions

Usage
qq(x, data, ...)

## S3 method for class 'formula'
qq(x, data, aspect = "fill",
  panel = lattice.getOption("panel.qq"),
  prepanel, scales, strip,
  groups, xlab, xlim, ylab, ylim, f.value = NULL,
  drop.unused.levels = lattice.getOption("drop.unused.levels"),
  ...,
  lattice.options = NULL,
  qtype = 7,
  default.scales = list(),
  default.prepanel = lattice.getOption("prepanel.default.qq"),
  subscripts,
  subset)

Arguments
x The object on which method dispatch is carried out.
For the "formula" method, x should be a formula of the form y ~ x | g1 * g2 * ...
, where x should be a numeric variable, and y a factor, shingle, character, or
numeric variable, with the restriction that there must be exactly two levels of y,
which divide the values of x into two groups. Quantiles for these groups will be
plotted against each other along the two axes.

data For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see xyplot for details).

f.value An optional numeric vector of probabilities, quantiles corresponding to which
should be plotted. This can also be a function of a single integer (representing
sample size) that returns such a numeric vector. A typical value for this argument
is the function ppoints, which is also the S-PLUS default. If specified, the
probabilities generated by this function is used for the plotted quantiles, through the quantile function.

\[ f \text{-} \text{value} \text{ defaults to \texttt{NULL}, which is equivalent to} \]

\[ f \text{-} \text{value} = \text{function}(n) \text{ ppoints}(n, \ a = 1) \]

This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for \texttt{qqplot} but different from the default behaviour of \texttt{qq} in S-PLUS.

For large \( x \), this argument can be used to restrict the number of quantiles plotted.

\textbf{panel}

A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function \texttt{panel.qq} is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

\textbf{qtype}

The type argument for \texttt{quantile}.

\textbf{aspect}

See \texttt{xyplot}.

\textbf{prepanel}

See \texttt{xyplot}.

\textbf{scales}

See \texttt{xyplot}.

\textbf{strip}

See \texttt{xyplot}.

\textbf{groups}

See \texttt{xyplot}.

\textbf{xlab, ylab}

See \texttt{xyplot}.

\textbf{xlim, ylim}

See \texttt{xyplot}.

\textbf{drop.unused.levels}

See \texttt{xyplot}.

\textbf{lattice.options}

See \texttt{xyplot}.

\textbf{default.scales}

See \texttt{xyplot}.

\textbf{subscripts}

See \texttt{xyplot}.

\textbf{subset}

See \texttt{xyplot}.

\textbf{default.prepanel}

Fallback prepanel function. See \texttt{xyplot}.

\textbf{...}

Further arguments. See corresponding entry in \texttt{xyplot} for non-trivial details.

\textbf{Details}

\texttt{qq} produces Q-Q plots of two samples. The default behaviour of \texttt{qq} is different from the corresponding S-PLUS function. See the entry for \texttt{f.value} for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for \texttt{xyplot}, which should be consulted to learn more detailed usage.

\textbf{Value}

An object of class "Trellis". The \texttt{update} method can be used to update components of the object and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.

## S3 method for class 'array'
contourplot(x, data = NULL, ...)

**Arguments**

- x
  for the formula method, a formula of the form z ~ x * y | g1 * g2 * ..., where z is a numeric response, and x, y are numeric values evaluated on a rectangular grid. g1, g2, ... are optional conditional variables, and must be either factors or shingles if present.
  Calculations are based on the assumption that all x and y values are evaluated
on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the x and y values need not be equally spaced.

Both levelplot and wireframe have methods for matrix, array, and table objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used in filled.contour and image. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the dimnames may be duplicated; this is handled by calling make.unique to make the names unique (although the original labels are used for the x- and y-axes).

data

For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.

row.values, column.values

Optional vectors of values that define the grid when x is a matrix. row.values and column.values must have the same lengths as nrow(x) and ncol(x) respectively. By default, row and column numbers.

panel

panel function used to create the display, as described in xyplot

aspect

For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is aspect="fill", as described in xyplot.

at

A numeric vector giving breakpoints along the range of z. Contours (if any) will be drawn at these heights, and the regions in between would be colored using col.regions. In the latter case, values outside the range of at will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a zlim argument might have been used for. However, this also means that when supplying at explicitly, one has to be careful to include values outside the range of z to ensure that all the data are shown.

at can have length one only if region=FALSE.

col.regions

color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in col.regions, the colors are recycled. The actual color assignment is performed by level.colors, which is documented separately.

alpha.regions

numeric, specifying alpha transparency (works only on some devices)

colorkey

logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components:

space: location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".

x, y: location, currently unused

col: A color ramp specification, as in the col.regions argument in level.colors

at: numeric vector specifying where the colors change. must be of length 1 more than the col vector.

tri.lower, tri.upper: Logical or numeric controlling whether the first and last intervals should be triangular instead of rectangular. With the default value (NA), this happens only if the corresponding extreme at values are -Inf or Inf respectively, and the triangles occupy 5% of the total length.
of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5\% when specified as TRUE.

**labels**: a character vector for labelling the at values, or more commonly, a list describing characteristics of the labels. This list may include components `labels`, `at`, `cex`, `col`, `rot`, `font`, `fontface` and `fontfamily`.

**tick.number**: The approximate number of ticks desired.

**tck**: A (scalar) multiplier for tick lengths.

**corner**: Interacts with x, y; currently unimplemented

**width**: The width of the key

**height**: The length of key as a fraction of the appropriate side of plot.

**raster**: A logical flag indicating whether the colorkey should be rendered as a raster image using `grid.raster`. See also `panel.levelplot.raster`.

**interpolate**: Logical flag, passed to `rasterGrob` when `raster=TRUE`.

**axis.line**: A list giving graphical parameters for the color key boundary and tick marks. Defaults to `trellis.par.get("axis.line")`.

**axis.text**: A list giving graphical parameters for the tick mark labels on the color key. Defaults to `trellis.par.get("axis.text")`.

**contour**: A logical flag, indicating whether to draw contour lines.

**cuts**: The number of levels the range of z would be divided into.

**labels**: Typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for `panel.levelplot`, to which this argument is passed on unchanged. That help page also documents the `label.style` argument, which affects how the labels are rendered.

**pretty**: A logical flag, indicating whether to use pretty cut locations and labels.

**region**: A logical flag, indicating whether regions between contour lines should be filled as in a level plot.

**allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset**

These arguments are described in the help page for `xyplot`.

**default.prepanel**

Fallback prepanel function. See `xyplot`.

... Further arguments may be supplied. Some are processed by `levelplot` or `contourplot`, and those that are unrecognized are passed on to the panel function.

**useRaster**

A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to TRUE changes the default panel function from `panel.levelplot` to `panel.levelplot.raster`, and sets the default value of `colorkey$raster` to TRUE.

Note that `panel.levelplot.raster` provides only a subset of the features of `panel.levelplot`, but setting `useRaster=TRUE` will not check whether any of the additional features have been requested.

Not all devices support raster images. For devices that appear to lack support, `useRaster=TRUE` will be ignored with a warning.

**Details**

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.
Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
at,
drape = FALSE,
pretty = FALSE,
drop.unused.levels,
....,
lattice.options = NULL,
default.scales =
  list(distance = c(1, 1, 1),
        arrows = TRUE,
        axs = axs.default),
default.prepanel = lattice.getOption("prepanel.default.cloud"),
colorkey,
col.regions,
alpha.regions,
cuts = 70,
subset = TRUE,
axs.default = "r")

## S3 method for class 'formula'
wireframe(x, 
  data, 
  panel = lattice.getOption("panel.wireframe"), 
  default.prepanel = lattice.getOption("prepanel.default.wireframe"), 
  ...) 

## S3 method for class 'matrix'
cloud(x, data = NULL, type = "h", 
      zlab = deparse(substitute(x)), aspect, ..., 
      xlim, ylim, row.values, column.values) 

## S3 method for class 'table'
cloud(x, data = NULL, groups = FALSE, 
      zlab = deparse(substitute(x)), 
      type = "h", ...) 

## S3 method for class 'matrix'
wireframe(x, data = NULL, 
      zlab = deparse(substitute(x)), aspect, ..., 
      xlim, ylim, row.values, column.values)

Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula of the form z ~ x * y | g1 * g2 * ...., 
where z is a numeric response, and x, y are numeric values. g1, g2, .... if present, 
are conditioning variables used for conditioning, and must be either factors or shingles. 
In the case of wireframe, calculations are based on the assumption that the x and y values are 
evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.

For wireframe, x, y and z may also be matrices (of the same dimension), in which case 
they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.

Missing values are allowed, either as NA values in the z vector, or missing rows 
in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in z are.

Both wireframe and cloud have methods for matrix objects, in which case 
x provides the z vector described above, while its rows and columns are 
interpreted as the x and y vectors respectively. This is similar to the form used in persp.

data

for the "formula" methods, an optional data frame in which variables in the 
formula (as well as groups and subset, if any) are to be evaluated. data should 
not be specified except when using the "formula" method.

row.values, column.values

Optional vectors of values that define the grid when x is a matrix. row.values 
and column.values must have the same lengths as nrow(x) and ncol(x) respectively. By default, row and column numbers.
dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.

- **type**: type of display in `cloud` (see `panel.3dscatter` for details). Defaults to "h" for the matrix method.

- **aspect, panel.aspect**: Unlike other high level functions, aspect is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the aspect argument in determining the aspect ratio of the panel (see `xyplot` for details) is played by `panel.aspect`, except that it can only be a numeric value.

  For the matrix methods, the default y/x aspect is \( \frac{\text{ncol}(x)}{\text{nrow}(x)} \) and the z/x aspect is the smaller of the y/x aspect and 1.

- **panel**: panel function used to create the display. See `panel.cloud` for (non-trivial) details.

- **default.prepanel**: Fallback prepanel function. See `xyplot`.

- **scales**: a list describing the scales. As with other high level functions (see `xyplot` for details), this list can contain parameters in name=value form. It can also contain components with the special names x, y and z, which can be similar lists with axis-specific values overriding the ones specified in `scales`.

  The most common use for this argument is to set `arrows=FALSE`, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by `draw=FALSE`. Another special component is `distance`, which specifies the relative distance of the axis label from the bounding box. If specified as a component of `scales` (as opposed to one of `scales$x`, etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the x, y and z labels respectively.

  Other components that work in the `scales` argument of `xyplot` etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)

  Note, however, that for these functions `scales` cannot contain information that is specific to particular panels. If you really need that, consider using the `scales.3d` argument of `panel.cloud`.

- **axs.default**: Unlike 2-D display functions, `cloud` does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in `wireframe`, which uses the same code. `axs.default` is intended to provide a different default for `cloud`. However, this feature has not yet been implemented.

- **zlab**: Specifies a label describing the z variable in ways similar to `xlab` and `ylab` (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if `zlab` (and `xlab` and `ylab`) is a list, it can contain a component called `rot`, controlling the rotation for the label.

- **zlim**: limits for the z-axis. Similar to `xlim` and `ylim` in other high level functions.

- **drape**: logical, whether the wireframe is to be draped in color. If `TRUE`, the height of a facet is used to determine its color in a manner similar to the coloring scheme used in `levelplot`. Otherwise, the background color is used to color the facets. This argument is ignored if `shade = TRUE` (see `panel.3dwire`).
at, col.regions, alpha.regions

these arguments are analogous to those in levelplot. if drape=TRUE, at gives the vector of cutpoints where the colors change, and col.regions the vector of colors to be used in that case. alpha.regions determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for col.regions and alpha.regions is derived from the Trellis setting "regions"

cuts

if at is unspecified, the approximate number of cutpoints if drape=TRUE

pretty

whether automatic choice of cutpoints should be prettified

colorkey

logical indicating whether a color key should be drawn alongside, or a list describing such a key. See levelplot for details.

Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the [-0.5, 0.5] cube (even smaller for non-default values of aspect). The viewing direction is given by a sequence of rotations specified by the screen argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of 1/distance from the origin. If perspective=FALSE, distance is set to 0 (i.e., the viewing point is at an infinite distance).

cloud draws a 3-D Scatter Plot, while wireframe draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by wireframe using the groups argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying groups with cloud results in a panel.superpose-like effect (via panel.3dscatter).

wireframe can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for panel.3dwire. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to cloud and wireframe directly.

For single panel plots, wireframe can also plot parametrized 3-D surfaces (i.e., functions of the form $f(u,v) = (x(u,v), y(u,v), z(u,v))$, where values of $(u,v)$ lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling wireframe with a formula $x$ of the form $z\sim x*y$, where $x$, $y$ and $z$ are all matrices of the same dimension, representing the values of $x(u,v)$, $y(u,v)$ and $z(u,v)$ evaluated on a discrete rectangular grid (the actual values of $(u,v)$ are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the $z$ values, but the distances of $(x,y,z)$ from the origin.

Note that this feature does not work with groups, subscripts, subset, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are 'behind' the points doesn't work in some extreme situations. Also, panel.cloud tries to figure out the optimal location of the arrows
and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the scp argument in `cloud`

These additional high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value
An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Note
There is a known problem with grouped `wireframe` displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

## S3 method for class 'matrix'
parallelplot(x, data = NULL, ..., groups = NULL, subset = TRUE)

## S3 method for class 'data.frame'
parallelplot(x, data = NULL, ..., groups = NULL, subset = TRUE)

Arguments

**x**

The object on which method dispatch is carried out.

For the "formula" method, a formula describing the structure of the plot, which should be of the form \(~ x \mid g_1 \ast g_2 \ast \ldots\), where \(x\) is a data frame or matrix. Each of \(g_1, g_2, \ldots\) must be either factors or shingles. The conditioning variables \(g_1, g_2, \ldots\) may be omitted.

For the `data.frame` methods, a data frame.

**data**

For the formula methods, an optional data frame in which variables in the for-
mula (as well as groups and subset, if any) are to be evaluated.

aspect
to avoid confusion between panels and subpanels, the default is to show the panels of a splom plot with space between them.

panel
For parallelplot, this has the usual interpretation, i.e., a function that creates the display within each panel. For splom, the terminology is slightly complicated. The role played by the panel function in most other high-level functions is played here by the superpanel function, which is responsible for the display for each conditional data subset. panel is simply an argument to the default superpanel function panel.pairs, and is passed on to it unchanged. It is used there to create each pairwise display. See panel.pairs for more useful options.

superpanel
a numeric value or a list, meant to be a less functional substitute for the scales argument in xyplot etc. This argument is passed to the superpanel function, and is handled by the default superpanel function panel.pairs. The help page for the latter documents this argument in more detail.

varnames
A character or expression vector or giving names to be used for the variables in x. By default, the column names of x.

horizontal.axis
logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).

auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset
See xyplot

... Further arguments. See corresponding entry in xyplot for non-trivial details.

Details
splom produces Scatter Plot Matrices. The role usually played by panel is taken over by superpanel, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both x- and y-limits from 0.5 to ncol(z) + 0.5. The only built-in option currently available is panel.pairs, which calls a further panel function for each pair (i,j) of variables in z inside a rectangle of unit width and height centered at c(i,j) (see panel.pairs for details).

Many of the finer customizations usually done via arguments to high level function like xyplot are instead done by panel.pairs for splom. These include control of axis limits, tick locations and prepanel calculations. If you are trying to fine-tune your splom plot, definitely look at the panel.pairs help page. The scales argument is usually not very useful in splom, and trying to change it may have undesired effects.

parallelplot draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value
An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Examples

```r
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
    panel = panel.superpose,
    key = list(title = "Three Varieties of Iris",
                columns = 3,
                points = list(pch = super.sym$pch[1:3],
                              col = super.sym$col[1:3]),
                text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3] | Species, data = iris,
    layout=c(2,2), pscales = 0,
    varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
    page = function(...) {
       ltext(x = seq(.6, .8, length.out = 4),
             y = seq(.9, .6, length.out = 4),
             labels = c("Three", "Varieties", "of", "Iris"),
             cex = 2)
    })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
            horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

Description

tmd Creates Tukey Mean-Difference Plots from a trellis object returned by xyplot, qq or qqmath. The prepanel and panel functions are used as appropriate. The formula method for tmd is provided for convenience, and simply calls tmd on the object created by calling xyplot on that formula.

Usage

tmd(object, ...)

## S3 method for class 'trellis'
tmd(object, 
    xlab = "mean",
    ylab = "difference",
    panel, 
    prepanel, 
    ...
)

prepanel.tmd.qqmath(x,
f.value = NULL,
distribution = qnorm,
qtype = 7,
groups = NULL,
subscripts, ...)
panel.tmd.qqmath(x,
  f.value = NULL,
distribution = qnorm,
qtype = 7,
groups = NULL,
subscripts, ...,
  identifier = "tmd")
panel.tmd.default(x, y, groups = NULL, ...,
  identifier = "tmd")
prepanel.tmd.default(x, y, ...)

Arguments

object An object of class "trellis" returned by xyplot, qq or qqmath.
xlab x label
ylab y label
panel panel function to be used. See details below.
prepanel prepanel function. See details below.
f.value, distribution, qtype see panel.qqmath.
groups, subscripts see xyplot.
x, y data as passed to panel functions in original call.
... other arguments
identifier A character string that is prepended to the names of grobs that are created by
  this panel function.

Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows:
the new coordinates are given by x=(x+y)/2 and y=y-x, which are then plotted. The default panel
function(s) add a reference line at y=0 as well.

tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such,
it only uses the arguments supplied to the panel function in the original call, and completely ignores
what the original panel function might have done with this data. tmd uses these panel arguments to
set up its own scales (using its prepanel argument) and display (using panel1). It is thus important
to provide suitable prepanel and panel functions to tmd depending on the original call.

Such functions currently exist for xyplot, qq (the ones with default in their name) and qqmath, as
listed in the usage section above. These assume the default displays for the corresponding high-level
call. If unspecified, the prepanel and panel arguments default to suitable choices.

tmd uses the update method for "trellis" objects, which processes all extra arguments supplied to tmd.
Value
An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

---

Residual and Fit Spread Plots

Description
Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

Usage
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL, 
    distribution = qunif, 
    panel, prepanel, strip, ...)

Arguments
- **model**: a fitted model object with methods fitted.values and residuals. Can be the value returned by oneway
- **layout**: default layout is c(2,1)
- **xlab**: defaults to "f.value"
- **distribution**: the distribution function to be used for qqmath
- **ylab**, **panel**, **prepanel**, **strip**
  - See xyplot
  - ... other arguments, passed on to qqmath.

Value
An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

B_11_oneway

Fit One-way Model

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using rfs

Usage

oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))

Arguments

formula formula of the form y ~ x where y is the numeric response and x is the grouping factor
data data frame in which the model is to be evaluated
location function or numeric giving the location statistic to be used for centering the observations, e.g. median, 0 (to avoid centering).
spread function or numeric giving the spread statistic to be used for scaling the observations, e.g. sd, 1 (to avoid scaling).

Value

A list with components

location vector of locations for each group.
spread vector of spreads for each group.
fitted.values vector of locations for each observation.
residuals residuals (y - fitted.values).
scaled.residuals residuals scaled by spread for their group

rfs, Lattice
C_01_trellis.device  Initializing Trellis Displays

Description

Initialization of a display device with appropriate graphical parameters.

Usage

trellis.device(device = getOption("device"),
    color = !(dev.name == "postscript"),
    theme = lattice.getOption("default.theme"),
    new = TRUE,
    retain = FALSE,
    ...
)
standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()

Arguments

device  function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see Devices), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.

color logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to trellis.par.set (and by arguments supplied directly in high level calls for some settings).

theme list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying lattice.options(default.theme = "col.whitebg"). For back-compatibility, this is initially (when lattice is loaded) set to getOption(lattice.theme).

If theme is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use .Device inside the function to ascertain what device has been opened.

new logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.

retain logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).
name

... additional parameters to be passed to the device function, most commonly file for non-screen devices, as well as height, width, etc. See the help file for individual devices for admissible arguments.

Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to \texttt{par} for standard R graphics and. together with \texttt{lattice.options}, mostly supplants it (\texttt{par} settings are mostly ignored by Lattice). Unlike \texttt{par}, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). \texttt{standard.theme} and \texttt{col.whitebg} produce predefined settings (a.k.a. themes), while \texttt{trellis.device} provides a high level interface to control which “theme” will be in effect when a new device is opened. \texttt{trellis.device} is called automatically when a “trellis” object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call \texttt{trellis.device} explicitly.

The \texttt{standard.theme} function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting \texttt{standard.theme} as the default theme argument, e.g. by putting \texttt{lattice.options(default.theme = "standard.theme")} in a startup script (see the entry for \texttt{theme} above for details).

Value

\texttt{standard.theme} returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in \texttt{trellis.device}, and can also be used as the \texttt{theme} argument to \texttt{trellis.par.set}, or even as \texttt{theme} in \texttt{trellis.device} to use the defaults for another device. \texttt{canonical.theme} is an alias for \texttt{standard.theme}.

\texttt{col.whitebg} returns a similar (but smaller) list that is suitable as the \texttt{theme} argument to \texttt{trellis.device} and \texttt{trellis.par.set}. It contains settings values which provide colors suitable for plotting on a white background. Note that the name \texttt{col.whitebg} is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

Note

Earlier versions of \texttt{trellis.device} had a \texttt{bg} argument to set the background color, but this is no longer supported. If supplied, the \texttt{bg} argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the \texttt{theme} argument instead.

Devices for valid choices of device on your platform.
trellis.par.get and trellis.par.set can be used to query and modify the settings after a
device has been initialized. The par.settings argument to high level functions, described in
xyplot, can be used to attach transient settings to a "trellis" object.

Graphical Parameters for Trellis Displays

Description

Functions used to query, display and modify graphical parameters for fine control of Trellis displays.
Modifications are made to the settings for the currently active device only.

Usage

trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)

Arguments

name A character string giving the name of a component. If unspecified in
trellis.par.get(), the return value is a named list containing all the current
settings (this can be used to get the valid values for name).
value a list giving the desired value of the component. Components that are already
defined as part of the current settings but are not mentioned in value will remain
unchanged.
theme a list describing how to change the settings, similar to what is returned by
trellis.par.get(). This is purely for convenience, allowing multiple calls
to trellis.par.set to be condensed into one. The name of each component
must be a valid name as described above, with the corresponding value a valid
value as described above.

As in trellis.device, theme can also be a function that produces such a list
when called. The function name can be supplied as a quoted string.

... Multiple settings can be specified in name = value form. Equivalent to calling
with theme = list(...) 
warn A logical flag, indicating whether a warning should be issued when
trellis.par.get is called when no graphics device is open.
strict Usually a logical flag, indicating whether the value should be interpreted
strictly. Usually, assignment of value to the corresponding named component
is fuzzy in the sense that sub-components that are absent from value but not
currently NULL are retained. By specifying strict = TRUE, such values will be
removed.

An even stricter interpretation is allowed by specifying strict as a numeric
value larger than 1. In that case, top-level components not specified in the call
will also be removed. This is primarily for internal use.
optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like x11 and windows, one for black and white plots (mostly useful for postscript) and one for color printers (color postcript, pdf).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a postscript device will not alter the x11 settings, which will remain in effect whenever an x11 device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the name component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```r
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```r
trellis.par.set(list(add.line = list(col = "red")))
and
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I’m not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.
grid.pars  Grid graphical parameters that are in effect globally unless overridden by specific settings.

fontsize  A list of two components (each a numeric scalar), text and points, for text and symbols respectively.

clip  A list of two components (each a character string, either "on" or "off"), panel and strip.

axis.components

layout.heights

layout.widths

Note

In some ways, trellis.par.get and trellis.par.set together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system does have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see `gpar` for a list of valid parameter names).

Examples

```r
show.settings()

tp <- trellis.par.get()

unusual <- c("grid.pars", "fontsize", "clip", "axis.components", "layout.heights", "layout.widths")

for (u in unusual) tp[[u]] <- NULL

names.tp <- lapply(tp, names)

unames <- sort(unique(unlist(names.tp)))

ans <- matrix(0, nrow = length(names.tp), ncol = length(unames))

rownames(ans) <- names(names.tp)

colnames(ans) <- unames

for (i in seq(along = names.tp))
    ans[i, ] <- as.numeric(unames %in% names.tp[[i]])

ans <- ans[, order(-colSums(ans))]

ans[ans == 0] <- NA

levelplot(t(ans), colorkey = FALSE,
    scales = list(x = list(rot = 90)),
    panel = function(x, y, z, ...) {
        panel.abline(v = unique(as.numeric(x)),
            h = unique(as.numeric(y)),
            col = "darkgrey")
        panel.xyplot(x, y, pch = 16 * z, ...)}
```
C_03_simpleTheme

Function to generate a simple theme

Description

Simple interface to generate a list appropriate as a theme, typically used as the par.settings argument in a high level call

Usage

simpleTheme(col, alpha,
  cex, pch, lty, lwd, font, fill, border,
  col.points, col.line,
  alpha.points, alpha.line)

Arguments

col, col.points, col.line
  A color specification. col is used for components "plot.symbol", "plot.line", "plot.polygon", "superpose.symbol", "superpose.line", and "superpose.polygon". col.points overrides col, but is used only for "plot.symbol" and "superpose.symbol". Similarly, col.line overrides col for "plot.line" and "superpose.line". The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

alpha, alpha.points, alpha.line
  A numeric alpha transparency specification. The same rules as col, etc., apply.

cex, pch, font
  Parameters for points. Applicable for components plot.symbol (for which only the first component is used) and superpose.symbol (for which the arguments can be vectors).

lty, lwd
  Parameters for lines. Applicable for components plot.line (for which only the first component is used) and superpose.line (for which the arguments can be vectors).

fill
  fill color, applicable for components plot.symbol, plot.polygon, superpose.symbol, and superpose.polygon.

border
  border color, applicable for components plot.polygon and superpose.polygon.

Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see trellis.device for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the auto.key argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the par.settings argument, which is usually tedious to
construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in simple name=value form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

**Value**

A list that would work as the theme argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

**See Also**

trellis.device, xyplot, Lattice

**Examples**

```r
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
        auto.key = list(space = "right"),
        par.settings = simpleTheme(pch = 16),
        xlab = "Barley Yield (bushels/acre) ",
        aspect=0.5, layout = c(1,6))
```

---

**Description**

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

**Usage**

```r
lattice.options(...)
lattice.getOption(name)
```

**Arguments**

- `name` character giving the name of a setting
- `...` new options can be defined, or existing ones modified, using one or more arguments of the form `name = value` or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.
Details

These functions are modeled on options and `getOption`, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

panel.error A function, or NULL. If the former, every call to the panel function will be wrapped inside `tryCatch` with the specified function as an error handler. The default is to use the panel.error function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to NULL, errors in panel functions will not be caught using `tryCatch`.

save.object Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to TRUE.

layout.widths, layout.heights Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the `grid` function unit (x, units, and optionally data).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using `trellis.par.set`.

drop.unused.levels A list of two components named cond and data, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See `xyplot` for more details. Note that this does not control dropping of levels of the 'groups' argument.

legend.bbox A character string, either "full" or "panel". This determines the interpretation of x and y when space="inside" in key (determining the legend; see `xyplot`): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

default.args A list giving default values for various standard arguments: as.table, aspect, between, skip, strip, xscale.components, yscale.components, and axis.

highlight.gpar A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

banking The banking function. See `banking`.

axis.padding List with components named "numeric" and "factor", both scalar numbers.

Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

skip.boundary.labels Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

interaction.sep The separator for creating interactions with the extended formula interface (see `xyplot`).

axis.units List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for `xyplot`. The options for the others have similarly patterned names.

Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

options, trellis.device, trellis.par.get, Lattice

Examples

names(lattice.options())
str(lattice.getOption("layout.widths"), max.level = 2)

Description

The print and plot methods produce a graph from a "trellis" object. The print method is necessary for automatic plotting. plot method is essentially an alias, provided for convenience. The summary method gives a textual summary of the object. dim and dimnames describe the cross-tabulation induced by conditioning. panel.error is the default handler used when an error occurs while executing the panel function.

Usage

## S3 method for class 'trellis'
plot(x, position, split,
more = FALSE, newpage = TRUE,
packet.panel = packet.panel.default,
draw.in = NULL,
panel.height = lattice.getOption("layout.heights")$panel,
panel.width = lattice.getOption("layout.widths")$panel,
save.object = lattice.getOption("save.object"),
panel.error = lattice.getOption("panel.error"),
prefix,
...)
## S3 method for class 'trellis'
print(x, ...)

## S3 method for class 'trellis'
summary(object, ...)

## S3 method for class 'trellis'
dim(x)
## S3 method for class 'trellis'
dimnames(x)

panel.error(e)
Arguments

\text{Arguments}

\begin{itemize}
\item \textit{x, object} an object of class "trellis"
\item \textit{position} a vector of 4 numbers, typically \texttt{c(xmin, ymin, xmax, ymax)} that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of \textit{x} is to be positioned. The coordinate system for this rectangle is [0-1] in both the \textit{x} and \textit{y} directions.
\item \textit{split} a vector of 4 integers, \texttt{c(x,y,nx,ny)}, that says to position the current plot at the \textit{x,y} position in a regular array of \textit{nx} by \textit{ny} plots. (Note: this has origin at top left)
\item \textit{more} A logical specifying whether more plots will follow on this page.
\item \textit{newpage} A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).
\item \textit{packet.panel} a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function \texttt{packet.panel.default}, whose help page details the arguments supplied to whichever function is specified as the \textit{packet.panel} argument.
\item \textit{draw.in} An optional (grid) viewport (used as the \texttt{name} argument in \texttt{downViewport}) in which the plot is to be drawn. If specified, the \texttt{newpage} argument is ignored. This feature is not well-tested.
\item \textit{panel.width, panel.height} lists with 2 components, that should be valid \texttt{x} and \texttt{units} arguments to \texttt{unit()} (the \texttt{data} argument cannot be specified currently, but can be considered for addition if needed). The resulting \texttt{unit} object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.
\item \textit{save.object} logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel’s data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the \texttt{update} method on the current plot, even if it was not assigned to a variable explicitly. For more details, see \texttt{trellis.focus}.
\item \textit{panel.error} a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using \texttt{tryCatch}) and supplied as the only argument to \texttt{panel.error}. The default behaviour (implemented as the \texttt{panel.error} function) is to print the corresponding error message in the panel and continue. To stop execution on error, use \texttt{panel.error = stop}.
\end{itemize}
Normal error recovery and debugging tools are unhelpful when \texttt{tryCatch} is used. \texttt{tryCatch} can be completely bypassed by setting \texttt{panel.error} to \texttt{NULL}.

\begin{description}
\item[prefix] A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently ":").
\item[e] an error condition caught by \texttt{tryCatch}
\item[...\hspace{1cm}] extra arguments, ignored by the \texttt{print} method. All arguments to the \texttt{plot} method are passed on to the \texttt{print} method.
\end{description}

\section*{Details}
This is the default print method for objects of class "trellis", produced by calls to functions like \texttt{xyplot}, \texttt{bwplot} etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments \texttt{split} and \texttt{position}.

When \texttt{newpage = FALSE}, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The \texttt{draw.in} argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in \texttt{x} (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see \texttt{trellis.focus}.

\section*{Note}
Unlike S-PLUS, trying to position a multipage display (using \texttt{position} and/or \texttt{split}) will mess things up.

\section*{Examples}
\begin{verbatim}
p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab = "Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))
\end{verbatim}
## Combining split and position:
print(p1, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p2, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport

## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
      layout = c(3, 2),
      panel = function(x, y, ...)
      {
        panel.xyplot(x, y, ...)
        fm <- lm(y ~ poly(x, panel.number()))
        llines(x, predict(fm))
      })

## Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:
")
ltext(grid::grid.locator(), lab = "linear")

## End(Not run)

grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")

grid::seekViewport(trellis.vpname("panel", 2, 1))
grid::grid.text("quadratic")

grid::seekViewport(trellis.vpname("panel", 3, 1))
grid::grid.text("cubic")

grid::seekViewport(trellis.vpname("panel", 1, 2))
grid::grid.text("degree 4")

grid::seekViewport(trellis.vpname("panel", 2, 2))
grid::grid.text("degree 5")

grid::seekViewport(trellis.vpname("panel", 3, 2))
grid::grid.text("degree 6")

---

C_06_update.trellis  Retrieve and Update Trellis Object

### Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

### Usage

```r
## S3 method for class 'trellis'
update(object,
```
Arguments

- **object, x**: The object to be updated, of class "trellis".
- **i, j**: Indices to be used. Names are not currently allowed.
- **drop**: Logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
- **prefix**: A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot.
Defaults to the value appropriate for the last "trellis" object printed. See \texttt{trellis.focus}.

Details

All high level lattice functions such as \texttt{xyplot} produce an object of (S3) class "trellis", which is usually displayed by its \texttt{print} method. However, the object itself can be manipulated and modified to a large extent using the update method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the update method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the \texttt{formula,data,groups,subscripts} and \texttt{subset}). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by \texttt{update}, but the ones listed above should work. The purpose of these arguments are described in the help page for \texttt{xyplot}. Any other argument is added to the list of arguments to be passed to the \texttt{panel} function. Because of their somewhat special nature, updates to objects produced by \texttt{cloud} and \texttt{wireframe} do not work very well yet.

The "[" method is a convenient shortcut for updating \texttt{index.cond}. The \texttt{t} method is a convenient shortcut for updating \texttt{perm.cond} in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching (‘transposing’) their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, \texttt{trellis.last.object} can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate \texttt{prefix} argument. If \texttt{trellis.last.object} is called with arguments, these are used to update the retrieved object before returning it.

Value

An object of class \texttt{trellis}, by default plotted by \texttt{print.trellis}. \texttt{trellis.last.object} returns \texttt{NULL} is no saved object is available.

Examples

\begin{verbatim}
spots <- by(sunspots, gl(235, 12, labels = 1749:1983), mean)
old.options <- lattice.options(save.object = TRUE)
xyplot(spots ~ 1749:1983, xlab = "", type = "l",
    scales = list(x = list(alternating = 2)),
    main = "Average Yearly Sunspots")
update(trellis.last.object(), aspect = "xy")
trellis.last.object(xlab = "Year")
lattice.options(old.options)
\end{verbatim}
Description

Functions to handle shingles

Usage

shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel'
as.character(x, ...)

## S3 method for class 'shingleLevel'
print(x, ...)

## S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)

Arguments

x       numeric variable or R object, shingle in plot.shingle and x[]. An object (list of intervals) of class "shingleLevel" in print.shingleLevel
object   shingle object to be summarized
showValues logical, whether to print the numeric part. If FALSE, only the intervals are printed
intervals numeric vector or matrix with 2 columns
subset   logical vector
drop     whether redundant shingle levels are to be dropped
panel, xlab, ylab standard Trellis arguments (see xyplot )
...      other arguments, passed down as appropriate. For example, extra arguments to equal.count are passed on to co.intervals. Graphical parameters can be passed as arguments to the plot method.
Details

A shingle is a data structure used in Trellis, and is a generalization of factors to 'continuous' variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the 'levels' of the shingle. The levels and nlevels functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of levels() applied to a shingle. For use in labelling, the as.character method can be used to convert levels of a shingle to character strings.

equal.count converts x to a shingle using the equal count algorithm. This is essentially a wrapper around co.intervals. All arguments are passed to co.intervals.

shingle creates a shingle using the given intervals. If intervals is a vector, these are used to form 0 length intervals.

as.shingle returns shingle(x) if x is not a shingle.

is.shingle tests whether x is a shingle.

plot.shingle displays the ranges of shingles via rectangles. print.shingle and summary.shingle describe the shingle object.

Value

x$intervals for levels.shingle(x), logical for is.shingle, an object of class "trellis" for plot (printed by default by print.trellis), and an object of class "shingle" for the others.

Examples

z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))
Arguments

key A list determining the key. See documentation for levelplot, in particular the section describing the colorkey argument, for details.
draw A scalar logical, indicating whether the grob is to be drawn.
vp The viewport in which to draw the grob, if applicable.

Value

A grid frame object (that inherits from "grob")

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

xyplot

Description

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

Usage

draw.key(key, draw=FALSE, vp=NULL, ...)

Arguments

key A list determining the key. See documentation for xyplot, in particular the section describing the key argument, for details.
draw logical, whether the grob is to be drawn.
vp viewport
... ignored

Value

A Grid frame object (that inherits from ‘grob’).

See Also

xyplot
D_level.colors A function to compute false colors representing a numeric or categorical variable

Description
Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

Usage
level.colors(x, at, col.regions, colors = TRUE, ...)

Arguments
x A numeric or factor variable.
at A numeric variable of breakpoints defining intervals along the range of x.
col.regions A specification of the colors to be assigned to each interval defined by at. This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below.
colors logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by at) each value in x falls into is returned.
...
Extra arguments, ignored.

Details
If at has length n, then it defines n-1 intervals. Values of x outside the range of at are not assigned to an interval, and the return value is NA for such values.

Colors are chosen by assigning a color to each of the n-1 intervals. If col.regions is a palette function (such as topo.colors, or the result of calling colorRampPalette), it is called with n-1 as an argument to obtain the colors. Otherwise, if there are exactly n-1 colors in col.regions, these get assigned to the intervals. If there are fewer than n-1 colors, col.regions gets recycled. If there are more, a more or less equally spaced (along the length of col.regions) subset is chosen.

Value
A vector of the same length as x. Depending on the colors argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of x fall in.

Author(s)
Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also
levelplot, colorRampPalette.
Examples

depth.col <-
  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
    col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
  strip = strip.custom(var.name = "Stations"),
  colours = depth.col,
  panel = function(x, y, colours, subscripts, ...) {
    panel.xyplot(x, y, pch = 21, col = "transparent",
    fill = colours[subscripts], ...)
  })

D_make.groups

Grouped data from multiple vectors

Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

Usage

make.groups(...)

Arguments

... one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

Value

When all the input arguments are vectors, a data frame with two columns

data all the vectors supplied, concatenated

which factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of rbind applied to them, along with an additional which column as described above.

Lattice
Examples

```r
sim.dat <-
  make.groups(uniform = runif(200),
              exponential = rexp(175),
              lognormal = rlnorm(150),
              normal = rnorm(125))
qqmath(~ data | which, sim.dat, scales = list(y = "free"))
```

**D_simpleKey**

*Function to generate a simple key*

**Description**

Simple interface to generate a list appropriate for draw.key

**Usage**

```r
simpleKey(text, points = TRUE,
           rectangles = FALSE,
           lines = FALSE,
           col, cex, alpha, font, fontface, fontfamily,
           lineheight, ...)
```

**Arguments**

- `text` character or expression vector, to be used as labels for levels of the grouping variable
- `points` logical
- `rectangles` logical
- `lines` logical
- `col, cex, alpha, font, fontface, fontfamily, lineheight` Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in trellis.par.get("add.text")
- `...` further arguments added to the list, eventually passed to draw.key

**Details**

A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as xyplot. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. simpleKey is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The simpleKey function produces a suitable key argument using a simpler interface. The resulting list will use the text argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the text component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling simpleKey directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the auto.key argument is supplied in a high-level plot with
a groups argument. In that case, the text argument of simpleKey defaults to levels(groups),
and the defaults for the other arguments depend on the relevant high-level function. Note that these
defaults can be overridden by supplying auto.key as a list containing the replacement values.

Value

A list that would work as the key argument to xyplot, etc.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, draw.key, trellis.par.get, and xyplot, specifically the entry for auto.key.

---

**D_strip.default**

*Default Trellis Strip Function*

Description

strip.default is the function that draws the strips by default in Trellis plots. Users can write
their own strip functions, but most commonly this involves calling strip.default with a slightly
different arguments. strip.custom provides a convenient way to obtain new strip functions that
differ from strip.default only in the default values of certain arguments.

Usage

```r
strip.default(which.given,
  which.panel,
  var.name,
  factor.levels,
  shingle.intervals,
  strip.names = c(FALSE, TRUE),
  strip.levels = c(TRUE, FALSE),
  sep = " ",
  style = 1,
  horizontal = TRUE,
  bg = trellis.par.get("strip.background")$col[which.given],
  fg = trellis.par.get("strip.shingle")$col[which.given],
  par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

Arguments

- `which.given` integer index specifying which of the conditioning variables this strip corre-
sponds to.
- `which.panel` vector of integers as long as the number of conditioning variables. The contents
  are indices specifying the current levels of each of the conditioning variables
  (thus, this would be unique for each distinct packet). This is identical to the
  return value of `which.packet`, which is a more accurate name.
**variant**

vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of `strip.names` and `style` (see below). By default, the names are shown for shingles, but not for factors.

**factor.levels**

vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with `which.given`. Whether these levels are shown on the strip depends on the values of `strip.levels` and `style` (see below). `factor.levels` may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in `par.strip.text` (see `xyplot`).

**shingle.intervals**

if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by `levels(shingle)`). Otherwise, it should be `NULL`.

**strip.names**

a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when `style` is not one of 1 and 3.

**strip.levels**

a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.

**sep**

character or expression, serving as a separator if the name and level are both to be shown.

**style**

integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when `shingle.intervals` is non-null).

The best way to find out what effect the value of `style` has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for `style = 2`, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.

Note that unlike S-PLUS, the default value of `style` is 1. `strip.names` and `strip.levels` have no effect if `style` is not 1 or 3.

**horizontal**

logical, specifying whether the labels etc should be horizontal. `horizontal=FALSE` is useful for strips on the left of panels using `strip.left=TRUE`.

**par.strip.text**

list with parameters controlling the text on each strip, with components `col`, `cex`, `font`, etc.

**bg**

strip background color.

**fg**

strip foreground color.
arguments to be passed on to strip.default, overriding whatever value it would have normally assumed

Details
default strip function for trellis functions. Useful mostly because of the style argument — non-default styles are often more informative, especially when the names of the levels of the factor \( x \) are small. Traditional use is as \( \text{strip} = \text{function}(\ldots) \text{strip.default}(\ldots, \text{style} = 2, \ldots) \), though this can be simplified by the use of strip.custom.

Value
strip.default is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. strip.custom returns a function that is similar to strip.default, but with different defaults for the arguments specified in the call.

Examples
## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris, 
   \text{strip} = \text{function}(\ldots, \text{style}) \text{strip.default}(\ldots, \text{style} = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris, 
   \text{strip} = \text{strip.custom}(\text{style} = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris, 
   \text{strip} = \text{FALSE},
   \text{strip.left} = \text{stripcustom}(\text{style} = 4, \text{horizontal} = \text{FALSE}))

D_trellis.object

A Trellis Plot Object

Description
This class of objects is returned by high level lattice functions, and is usually plotted by default by its \texttt{print} method.

Details
A trellis object, as returned by high level lattice functions like \texttt{xyplot}, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: \texttt{as.table}, \texttt{layout}, \texttt{page}, \texttt{panel}, \texttt{prepanel}, \texttt{main}, \texttt{sub}, \texttt{par.strip.text}, \texttt{strip}, \texttt{skip}, \texttt{xlab ylab}, \texttt{par.settings}, \texttt{lattice.options} and \texttt{plot.args}. Some other typical components are:
formula  the Trellis formula used in the call
index.cond  list with index for each of the conditioning variables
perm.cond  permutation of the order of the conditioning variables
aspect.fill  logical, whether aspect is "fill"
aspect.ratio  numeric, aspect ratio to be used if aspect.fill is FALSE
call  call that generated the object.
condlevels  list with levels of the conditioning variables
legend  list describing the legend(s) to be drawn
panel.args  a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.
panel.args.common  a list containing the arguments common to all the panel functions in name=value form
x.scales  list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"
y.scales  list describing y-scale, similar to x.scales
x.between  numeric vector of interpanel x-space
y.between  numeric vector of interpanel y-space
x.limits  numeric vector of length 2 or list, giving x-axis limits
y.limits  similar to x.limits
packet.sizes  array recording the number of observations in each packet

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

*Lattice, xyplot, print.trellis*

---

**Description**

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.
Usage

panel.identify(x, y = NULL,
    subscripts = seq_along(x),
    labels = subscripts,
    n = length(x), offset = 0.5,
    threshold = 18, ## in points, roughly 0.25 inches
    panel.args = trellis.panelArgs(),
    ...
)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,

trellis.unfocus()
trellis.panelArgs(x, packet.number)
Arguments

x, y, z  variables defining the contents of the panel. In the case of trellis.plotArgs, a "trellis" object.

n  the number of points to identify by default (overridden by a right click)

subscripts  an optional vector of integer indices associated with each point. See details below.

text  an optional vector of labels associated with each point. Defaults to subscripts

typical panel arguments of panel.qqmath. These will usually be obtained from panel.args

offset  the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The offset specifies (in "char" units) how far from the identified point the labels should be printed.

threshold  threshold in grid's "points" units. Points further than these from the mouse click position are not considered

panel.args  list that contains components names x (and usually y), to be used if x is missing. Typically, when called after trellis.focus, this would appropriately be the arguments passed to that panel.

typical arguments as passed to panel.cloud. These are required to recompute the relevant three-dimensional projections in panel.identify.cloud.

panel.3d.identify  the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to panel.identify is used.

name  A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. trellis.vpname and trellis.focus deal with viewport names only, and only accept the values explicitly listed above. trellis.grobname is meant to create names for grobs, and can currently accept any value.

If name, as well as column and row is missing in a call to trellis.focus, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.

When name is "panel", "strip", or "strip.left", column and row must also be specified. When name is "legend", side must also be specified.

column, row  integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with as.table=TRUE

guess  logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to trellis.focus.

side  character string, relevant only for legends (i.e., when name="legend"), indicating their position. Partial specification is allowed, as long as it is unambiguous.

clip.off  logical, whether clipping should be off. relevant when name is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting clip.off=FALSE does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.
type  A character string specifying whether the grob is specific to a particular panel or strip. 
When type is "panel", "strip", or "strip.left", information about the panel is added to the grob name.

group An integer specifying whether the grob is specific to a particular group within the plot. 
When group is greater than zero, information about the group is added to the grob name.

which.given, which.panel integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables. 
When which.panel has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.

prefix A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. 
This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the prefix argument in print.trellis. 
Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last. 
For switchFocus, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.

highlight logical, whether the viewport being assigned focus should be highlighted. For trellis.focus, the default is TRUE in interactive mode, and trellis.switchFocus by default preserves the setting currently active.

packet.number integer, which panel to get data from. See packet.number for details on how this is calculated

verbose whether details will be printed

... For panel.identify.qqmath, extra parameters are passed on to panel.identify. For panel.identify, extra arguments are treated as graphical parameters and are used for labelling. For trellis.focus and trellis.switchFocus, these are used (in combination with lattice.options) for highlighting the chosen viewport if so requested. 
Graphical parameters can be supplied for panel.link.splom.

Details

panel.identify is similar to identify. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. 
Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to trellis.focus first is necessary.

panel.link.splom is meant for use with splom, and requires a panel to be chosen using trellis.focus before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. panel.brush.splom is a (misnamed) alias for panel.link.splom, retained for back-compatibility.

panel.identify.qqmath is a specialized wrapper meant for use with the display produced by qqmath. panel.identify.qqmath is a specialized wrapper meant for use with the display produced by cloud. It would be unusual to call them except in a context where default panel function arguments are available through trellis.panelArgs (see below).
One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the subscripts that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the ‘current’ viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```r
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in `xyplot`) and not the position in the layout, because a layout determines the panel only after the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

### Value

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos = TRUE` is not yet implemented, but can be considered for addition if requested.
trellis.panelArgs returns a named list of arguments that were available to the panel function for the chosen panel.

trellis.vpname and trellis.grobname return character strings.

trellis.focus has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components col and row giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is NULL. If click was outside a panel, both col and row are set to 0.

Note

The viewports created by lattice are accessible to the user through trellis.focus as described above. Functions from the grid package can also be used directly. For example, current.vpTree can be used to inspect the current viewport tree and seekViewport or downViewport can be used to navigate to these viewports. For such usage, trellis.vpname and trellis.grobname provides a portable way to access the appropriate viewports and grobs by name.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of panel.identify.qqmath and support for focusing on panels interactively.

**F_1_panel.barchart**

*Default Panel Function for barchart*

**Description**

Default panel function for barchart.

**Usage**

```r
panel.barchart(x, y, box.ratio = 1, box.width,
```
horizontal = TRUE,
origin = NULL, reference = TRUE,
stack = FALSE,
groups = NULL,
col = if (is.null(groups)) plot.polygon$col
else superpose.polygon$col,
border = if (is.null(groups)) plot.polygon$border
else superpose.polygon$border,
lty = if (is.null(groups)) plot.polygon$lty
else superpose.polygon$lty,
lwd = if (is.null(groups)) plot.polygon$lwd
else superpose.polygon$lwd,
..., identifier = "barchart")

Arguments

x  Extent of Bars. By default, bars start at left of panel, unless origin is specified, in which case they start there.
y  Horizontal location of bars. Possibly a factor.
box.ratio  Ratio of bar width to inter-bar space.
box.width  Thickness of bars in absolute units; overrides box.ratio. Useful for specifying thickness when the categorical variable is not a factor, as use of box.ratio alone cannot achieve a thickness greater than 1.
horizontal  Logical flag. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
origin  The origin for the bars. For grouped displays with stack = TRUE, this argument is ignored and the origin set to 0. Otherwise, defaults to NULL, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, origin = 0 is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
reference  Logical, whether a reference line is to be drawn at the origin.
stack  logical, relevant when groups is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.
groups  Optional grouping variable.
col, border, lty, lwd  Graphical parameters for the bars. By default, the trellis parameter plot.polygon is used if there is no grouping variable, otherwise superpose.polygon is used. col gives the fill color, border the border color, and lty and lwd the line type and width of the borders.
...  Extra arguments will be accepted but ignored.
identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level barchart call directly.
Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

barchart

Examples
barchart(yield ~ variety | site, data = barley,
groups = year, layout = c(1,6), origin = 0,
ylab = "Barley Yield (bushels/acre)",
scales = list(x = list(abbreviate = TRUE,
minlength = 5)))

Description
This is the default panel function for bwplot.

Usage
panel.bwplot(x, y, box.ratio = 1,
box.width = box.ratio / (1 + box.ratio),
horizontal = TRUE,
pch, col, alpha, cex,
font, fontfamily, fontface,
fill, varwidth = FALSE,
notch = FALSE, notch.frac = 0.5,
..., levels.fos,
stats = boxplot.stats,
coef = 1.5,
do.out = TRUE,
identifier = "bwplot")

Arguments
x, y numeric vector or factor. Boxplots drawn for each unique value of y (x) if
horizontal is TRUE (FALSE)
box.ratio ratio of box thickness to inter box space
box.width thickness of box in absolute units; overrides box.ratio. Useful for specifying
thickness when the categorical variable is not a factor, as use of box.ratio
alone cannot achieve a thickness greater than 1.
horizontal logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of
x and y are switched. x is now the ‘factor’. Interpretation of other arguments
change accordingly. See documentation of bwplot for a fuller explanation.
pch, col, alpha, cex, font, fontfamily, fontface

graphical parameters controlling the dot. pch="|" is treated specially, by re-
placing the dot with a line (similar to boxplot)

fill
color to fill the boxplot

varwidth
logical. If TRUE, widths of boxplots are proportional to the number of points
used in creating it.

notch
if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of
two plots do not overlap this is ‘strong evidence’ that the two medians differ
(Chambers et al., 1983, p. 62). See boxplot.stats for the calculations used.

notch.frac
numeric in (0,1). When notch=TRUE, the fraction of the box width that the
notches should use.

stats
a function, defaulting to boxplot.stats, that accepts a numeric vector and re-
turns a list similar to the return value of boxplot.stats. The function must
accept arguments coef and do.out even if they do not use them (a ... argu-
ment is good enough). This function is used to determine the box and whisker
plot.

coeff, do.out
passed to stats

levels.fos
numeric values corresponding to positions of the factor or shingle variable. For
internal use.

... further arguments, ignored.

identifier
A character string that is prepended to the names of grobs that are created by
this panel function.

Details

Creates Box and Whisker plot of x for every level of y (or the other way round if
horizontal=FALSE). By default, the actual boxplot statistics are calculated using boxplot.stats.
Note that most arguments controlling the display can be supplied to the high-level bwplot call
directly.

Although the graphical parameters for the dot representing the median can be controlled by optional
arguments, many others can not. These parameters are obtained from the relevant settings parameters
"box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

F_1_panel.cloud  

Default Panel Function for cloud

Description

These are default panel functions controlling cloud and wireframe displays.

Usage

panel.cloud(x, y, subscripts, z,  
  groups = NULL,  
  perspective = TRUE,  
  distance = if (perspective) 0.2 else 0,  
  xlim, ylim, zlim,  
  panel.3d.cloud = "panel.3dscatter",  
  panel.3d.wireframe = "panel.3dwire",  
  screen = list(z = 40, x = -60),  
  R.mat = diag(4), aspect = c(1, 1),  
  par.box = NULL,  
  xlab, ylab, zlab,  
  xlab.default, ylab.default, zlab.default,  
  scales.3d,  
  proportion = 0.6,  
  wireframe = FALSE,  
  scpos,  
  ...,  
  at,  
  identifier = "cloud")

panel.wireframe(...)

panel.3dscatter(x, y, z, rot.mat, distance,  
  groups, type = "p",  
  xlim, ylim, zlim,  
  xlim.scaled, ylim.scaled, zlim.scaled,  
  zero.scaled,  
  col, col.point, col.line,  
  lty, lwd, cex, pch,  
  cross, ..., .scale = FALSE, subscripts,  
  identifier = "3dscatter")

panel.3dwire(x, y, z, rot.mat = diag(4), distance,  
  shade = FALSE,  
  shade.colors.palette = trellis.par.get("shade.colors")$palette,  
  light.source = c(0, 0, 1000),  
  xlim, ylim, zlim,  
  xlim.scaled,
ylim.scaled,
zlim.scaled,
col = if (shade) "transparent" else "black",
lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygon$col,
polynum = 100,
....,
.scale = FALSE,
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha,
identifier = "3dwire")

Arguments

x, y, z numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For panel.cloud these are essentially the same as the data passed to the high level plot (except if formula was a matrix, the appropriate x and y vectors are generated). By the time they are passed to panel.3dscatter and panel.3dwire, they have been appropriately subsetted (using subscripts) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).

Further, for panel.3dwire, x and y are shorter than z and represent the sorted locations defining a rectangular grid. Also in this case, z may be a matrix if the display is grouped, with each column representing one surface.

In panel.cloud (called from wireframe) and panel.3dwire, x, y and z could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

subscripts index specifying which points to draw. The same x, y and z values (representing the whole data) are passed to panel.cloud for each panel. subscripts specifies the subset of rows to be used for the particular panel.

groups specification of a grouping variable, passed down from the high level functions.

perspective logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting distance to 0

distance numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / distance. This is described in a little more detail in the documentation for cloud

screen A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.

R.mat initial rotation matrix in homogeneous coordinates, to be applied to the data before screen rotates the view further.

par.box graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter box.3d.
xlim, ylim, zlim
limits for the respective axes. As with other lattice functions, these could each
be a numeric 2-vector or a character vector indicating levels of a factor.

panel.3d.cloud, panel.3d.wireframe
functions that draw the data-driven part of the plot (as opposed to the bounding
box and scales) in cloud and wireframe. This function is called after the ‘back’
of the bounding box is drawn, but before the ‘front’ is drawn.

Any user-defined custom display would probably want to change these func-
tions. The intention is to pass as much information to this function as might be
useful (not all of which are used by the defaults). In particular, these functions
can expect arguments called xlim, ylim, zlim which give the bounding box
ranges in the original data scale and xlim.scaled, ylim.scaled, zlim.scaled
which give the bounding box ranges in the transformed scale. More arguments
can be considered on request.

aspect
aspect as in cloud

xlab, ylab, zlab
Labels, have to be lists. Typically the user will not manipulate these, but instead
control this via arguments to cloud directly.

xlab.default for internal use
ylab.default for internal use
zlab.default for internal use

scales.3d list defining the scales
proportion numeric scalar, gives the length of arrows as a proportion of the sides
scpos A list with three components x, y and z (each a scalar integer), describing which
of the 12 sides of the cube the scales should be drawn. The defaults should be
OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See com-
ments in the source code of panel.cloud to see the details of this enumeration.)

wireframe logical, indicating whether this is a wireframe plot
drape logical, whether the facets will be colored by height, in a manner similar to
levelplot. This is ignored if shade=TRUE.

at, col.regions, alpha.regions
deals with specification of colors when drape = TRUE in wireframe. at can
be a numeric vector, col.regions a vector of colors, and alpha.regions a
numeric scalar controlling transparency. The resulting behaviour is similar to
levelplot, at giving the breakpoints along the z-axis where colors change,
and the other two determining the colors of the facets that fall in between.

rot.mat 4x4 transformation matrix in homogeneous coordinates. This gives the rotation
matrix combining the screen and R.mat arguments to panel.cloud
type Character vector, specifying type of cloud plot. Can include one or more of "p",
"l", "h" or "b". "p" and "l" mean ‘points’ and ‘lines’ respectively, and "b"
means ‘both’. "h" stands for ‘histogram’, and causes a line to be drawn from
each point to the X-Y plane (i.e., the plane representing z = 0), or the lower (or
upper) bounding box face, whichever is closer.

xlim.scaled, ylim.scaled, zlim.scaled
axis limits (after being scaled to the bounding box)

zero.scaled z-axis location (after being scaled to the bounding box) of the X-Y plane in the
original data scale, to which lines will be dropped (if within range) from each
point when type = "h"
cross logical, defaults to TRUE if pch = "+". panel.3dscatter can represent each point by a 3d ‘cross’ of sorts (it’s much easier to understand looking at an example than from a description). This is different from the usual pch argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used. This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.

shade logical, indicating whether the surface is to be colored using an illumination model with a single light source.

shade.colors.palette a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits. All three numbers should be between 0 and 1. The shade.colors.palette function should return a valid color. The default function is obtained from the trellis settings.

light.source a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube.

col.num quadrilateral faces are drawn in batches of col.num at a time. Drawing too few at a time increases the total number of calls to the underlying grid.polygon function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.

col.groups colors for different groups

col, col.point, col.line, lty, lwd, cex, pch, alpha

Graphical parameters. Some other arguments (such as lty for line width) may also be passed through the ... argument.

... other parameters, passed down when appropriate

.scale Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting .scale=TRUE may be helpful for calls to panel.3dscatter and panel.3dwire in user-supplied panel functions.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

These functions together are responsible for the content drawn inside each panel in cloud and wireframe. panel.wireframe is a wrapper to panel.cloud, which does the actual work.

panel.cloud is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether wireframe is TRUE, it calls either panel.3d.wireframe or panel.3d.cloud, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For cloud, the data is unstructured, and x, y and z are all passed to the panel.3d.cloud
function. For wireframe, on the other hand, \(x\) and \(y\) are increasing vectors with unique values, defining a rectangular grid. \(z\) must be a matrix with \(\text{length}(x) \times \text{length}(y)\) rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a type argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors.

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

**F_1_panel.densityplot**  
*Default Panel Function for densityplot*

**Description**

This is the default panel function for `densityplot`.

**Usage**

```r
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,  
groups = NULL, weights = NULL,  
jitter.amount, type, ...,  
identifier = "density")
```

**Arguments**

- **x**: data points for which density is to be estimated
- **darg**: list of arguments to be passed to the `density` function. Typically, this should be a list with zero or more of the following components: `bw`, `adjust`, `kernel`, `window`, `width`, `give.Rkern`, `n`, `from`, `to`, `cut`, `na.rm` (see `density` for details)
- **plot.points**: logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case `panel.rug` is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points.
ref logical, whether to draw x-axis
groups an optional grouping variable. If present, \texttt{panel.superpose} will be used instead to display each subgroup
weights numeric vector of weights for the density calculations. If this is specified, the \texttt{...} part must also include a \texttt{subscripts} argument that matches the weights to \texttt{x}.
jitter.amount when \texttt{plot.points=\textquote{\texttt{jitter}}}”, the value to use as the \texttt{amount} argument to \texttt{jitter}.
type type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a \texttt{type} argument, if specified, from affecting the density curve.
... extra graphical parameters. Note that additional arguments to \texttt{panel.rug} cannot be passed on through \texttt{panel.densityplot}.
identifier A character string that is prepended to the names of grobs that are created by this panel function.

Author(s) Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

\begin{verbatim}
F_1_panel.dotplot

Default Panel Function for dotplot

Description

Default panel function for dotplot.

Usage

\texttt{panel.dotplot(x, y, horizontal = TRUE, pch, col, lty, lwd, col.line, levels.fos, groups = NULL, \ldots, identifier = \textquote{\texttt{dotplot}})}

Arguments

\begin{verbatim}
x, y \hspace{0.5cm} \texttt{variables to be plotted in the panel. Typically y is the ‘factor'}}
horizontal \hspace{0.5cm} \texttt{logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of \texttt{bwplot} for a fuller explanation. pch, col, lty, lwd, col.line \hspace{0.5cm} \texttt{graphical parameters}}
levels.fos \hspace{0.5cm} \texttt{locations where reference lines will be drawn}
\end{verbatim}
\end{verbatim}
groups grouping variable (affects graphical parameters)

... extra parameters, passed to panel.xyplot which is responsible for drawing the foreground points (panel.dotplot only draws the background reference lines).

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates (possibly grouped) Dotplot of x against y or vice versa

dotplot

Description

This is the default panel function for histogram.

Usage

panel.histogram(x, 
breaks, 
equal.widths = TRUE, 
type = "density", 
nint = round(log2(length(x)) + 1), 
alpha, col, border, lty, lwd, 
..., 
identifier = "histogram")

Arguments

x The data points for which the histogram is to be drawn
breaks The breakpoints for the histogram
equal.widths logical used when breaks==NULL
type Type of histogram, possible values being "percent", "density" and "count"
nint Number of bins for the histogram
alpha, col, border, lty, lwd graphical parameters for bars; defaults are obtained from the plotpolygon settings.
... other arguments, passed to hist when deemed appropriate
identifier A character string that is prepended to the names of grobs that are created by this panel function.

histogram

Panel Functions for levelplot and contourplot

Description
These are the default panel functions for levelplot and contourplot. Also documented is an alternative raster-based panel function for use with levelplot.

Usage
panel.levelplot(x, y, z,
subscripts,
at = pretty(z),
shrink,
labels,
label.style = c("mixed", "flat", "align"),
contour = FALSE,
region = TRUE,
col = add.line$col,
lty = add.line$lty,
lwd = add.line$lwd,
border = "transparent",
border.lty = 1,
border.lwd = 0.1,
...,
col.regions = regions$col,
alpha.regions = regions$alpha,
identifier = "levelplot")

panel.contourplot(...)
Arguments

x, y, z  Variables defining the plot.
subscripts  Integer vector indicating what subset of x, y and z to draw.
at  Numeric vector giving breakpoints along the range of z. See levelplot for details.
shrink  Either a numeric vector of length 2 (meant to work as both x and y components),
or a list with components x and y which are numeric vectors of length 2. This
allows the rectangles to be scaled proportional to the z-value. The specification
can be made separately for widths (x) and heights (y). The elements of the length
2 numeric vector gives the minimum and maximum proportion of shrinkage
(corresponding to min and max of z).
labels  Either a logical scalar indicating whether the labels are to be drawn, or a char-
acter or expression vector giving the labels associated with the at values. Alternatively, labels can be a list with the following components:
  labels: a character or expression vector giving the labels. This can be omitted,
in which case the defaults will be used.
col, cex, alpha: graphical parameters for label texts
fontfamily, fontface, font: font used for the labels
label.style  Controls how label positions and rotation are determined. A value of "flat"
causes the label to be positioned where the contour is flattest, and the label is
not rotated. A value of "align" causes the label to be drawn as far from the
boundaries as possible, and the label is rotated to align with the contour at that
point. The default is to mix these approaches, preferring the flattest location
unless it is too close to the boundaries.
contour  A logical flag, specifying whether contour lines should be drawn.
region  A logical flag, specifying whether inter-contour regions should be filled with
appropriately colored rectangles.
col, lty, lwd  Graphical parameters for contour lines.
border  Border color for rectangles used when region=TRUE.
border.lty, border.lwd  Graphical parameters for the border
...  Extra parameters.
col.regions  A vector of colors, or a function to produce a vector of colors, to be used if
region=TRUE. Each interval defined by at is assigned a color, so the number of
colors actually used is one less than the length of at. See level.colors for
details on how the color assignment is done.
alpha.regions  numeric scalar controlling transparency of facets
interpolate  logical, passed to grid.raster.
identifier  A character string that is prepended to the names of grobs that are created by
this panel function.

Details

The same panel function is used for both levelplot and contourplot (which differ only in default
values of some arguments). panel.contourplot is a simple wrapper to panel.levelplot.
When contour=TRUE, the contourLines function is used to calculate the contour lines.
panel.levelplot.raster is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through grid.raster). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using panel.levelplot.raster, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see levelplot for details.

suppressWarnings(plot(levelplot(rnorm(10) ~ 1:10 + sort(runif(10)),
  panel = panel.levelplot.raster,
  interpolate = TRUE)))
levelplot(volcano, panel = panel.levelplot.raster)
levelplot(volcano, panel = panel.levelplot.raster,
  col.regions = topo.colors, cuts = 30, interpolate = TRUE)

F_1_panel.pairs

Default Superpanel Function for splom

Description
This is the default superpanel function for splom.

Usage
panel.pairs(z,
  panel = lattice.getOption("panel.splom"),
  lower.panel = panel,
  upper.panel = panel,
  diag.panel = "diag.panel.splom",
  as.matrix = FALSE,
  groups = NULL,
  panel.subscripts,
  subscripts,
  pscales = 5,
  prepanel.limits = scale.limits,
  varnames = colnames(z),
  varname.col, varname.cex, varname.font,
  varname.fontfamily, varname.fontface,
F_1_panel.pairs

axis.text.col, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface, axis.text.lineheight, axis.line.col, axis.line.lty, axis.line.lwd, axis.line.alpha, axis.line.tck, ...

diag.panel.splom(x = NULL, varname = NULL, limits, at = NULL, labels = NULL, draw = TRUE, tick.number = 5, varname.col, varname.cex, varname.lineheight, varname.font, varname.fontfamily, varname.fontface, axis.text.col, axis.text.alpha, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface, axis.text.lineheight, axis.line.col, axis.line.alpha, axis.line.lty, axis.line.lwd, axis.line.tck, ...

Arguments

z The data frame used for the plot.
panel, lower.panel, upper.panel

The panel function used to display each pair of variables. If specified, lower.panel and upper.panel are used for panels below and above the diagonal respectively.

In addition to extra arguments not recognized by panel.pairs, the list of arguments passed to the panel function also includes arguments named i and j, with values indicating the row and column of the scatterplot matrix being plotted.
diag.panel

The panel function used for the diagonals. See arguments to diag.panel.splom to know what arguments this function is passed when called. Use diag.panel=NULL to suppress plotting on the diagonal panels.
as.matrix

logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to pairs). This is in essence the same functionality as provided by as.table for the panel layout.
groups

Grouping variable, if any
panel.subscripts

logical specifying whether the panel function accepts an argument named subscripts.
subscripts

The indices of the rows of z that are to be displayed in this (super)panel.
pscales

Controls axis labels, passed down from splom. If pscales is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If pscales is a list, it should have one component for each column in z, each of which itself a list with the following valid components:

at: a numeric vector specifying tick locations
labels: character vector labels to go with at
limits: numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)
These are specifications on a per-variable basis, and used on all four sides in the
diagonal cells used for labelling. Factor variables are labelled with the factor
names. Use pscales=0 to suppress the axes entirely.

prepanel.limits
A function to calculate suitable axis limits given a single argument x containing
a data vector. The return value of the function should be similar to the xlim
or ylim argument documented in xyplot; that is, it should be a numeric or
DateTime vector of length 2 defining a range, or a character vector representing
levels of a factor.

Most high-level lattice plots (such as xyplot) use the prepanel function for
deciding on axis limits from data. This function serves a similar function by
calculating the per-variable limits. These limits can be overridden by the corre-
sponding limits component in the pscales list.

x
data vector corresponding to that row / column (which will be the same for
diagonal 'panels').

varname
ticknumber
draw
labels
varnames
varname.col
varname.cex
varname.lineheight
varname.font, varname.fontfamily, varname.fontface
axis.text.col
axis.text.cex
axis.text.font, axis.text.fontfamily, axis.text.fontface
axis.text.lineheight
axis.text.alpha
axis.line.col
axis.line.lty
axis.line.lwd
axis.line.alpha
axis.line.tck

Further arguments, passed on to panel, lower.panel, upper.panel, and
diag.panel from panel.pairs. Currently ignored by diag.panel.splom.
Details

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

`splom`

Examples

```r
Cmat <- outer(1:6, 1:6, 
  function(i, j) rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE, 
  panel = function(x, y, i, j, ...) {
    panel.fill(Cmat[i,j])
    panel.text(.5,.5, paste("(",i","",j,")",sep=""))
  })
```

Description

This is the default panel function for `parallel`.

Usage

```r
panel.parallel(x, y, z, subscripts, 
  groups = NULL, 
  col, lwd, lty, alpha, 
  common.scale = FALSE, 
  lower, 
  upper, 
  ..., 
  horizontal.axis = TRUE, 
  identifier = "parallel")
```

Arguments

- `x, y` dummy variables, ignored.
- `z` The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.
- `subscripts` The indices of the rows of `z` that are to be displayed in this panel.
- `groups` An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of `z` in the same group share parameters).
col, lwd, lty, alpha

graphical parameters (defaults to the settings for superpose.line). If groups is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame z.

common.scale

logical, whether a common scale should be used columns of z. Defaults to FALSE, in which case the horizontal range for each column is different (as determined by lower and upper).

lower, upper

numeric vectors replicated to be as long as the number of columns in z. Determines the lower and upper bounds to be used for scaling the corresponding columns of z after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.

... other arguments (ignored)

horizontal.axis

logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).

identifier

A character string that is prepended to the names of grobs that are created by this panel function.

Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for `parallel`

**F_1_panel.qqmath**

Default Panel Function for qqmath

Description

This is the default panel function for qqmath.

Usage

```r
panel.qqmath(x, f.value = NULL,
             distribution = qnorm,
             qtype = 7,
             groups = NULL, ...,
             tails.n = 0,
             identifier = "qqmath")
```
Arguments

- **x**: vector (typically numeric, coerced if not) of data values to be used in the panel.
- **f.value**, **distribution**: Defines how quantiles are calculated. See `qqmath` for details.
- **qtype**: The type argument to be used in `quantile` functions.
- **groups**: An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.
- **...**: Further arguments, often graphical parameters, eventually passed on to `panel.xyplot`. Arguments `grid` and `abline` of `panel.xyplot` may be particularly useful.
- **tails.n**: number of data points to represent exactly on each tail of the distribution. This reproduces the effect of `f.value = NULL` for the extreme data values, while approximating the remaining data. It has no effect if `f.value = NULL`. If `tails.n` is given, `qtype` is forced to be 1.
- **identifier**: A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

`qqmath`

Examples

```r
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "*", distribution = qnorm,
    grid = TRUE, abline = c(0, 1),
    xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
    panel = function(..., f.value) {
        switch(panel.number(),
            panel.qqmath(..., f.value = NULL),
            panel.qqmath(..., f.value = ppoints(100)),
            panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
    }, layout = c(3, 1))[c(1,1,1)]
```
Description

This is the default panel function for stripplot. Also see panel.superpose.

Usage

```r
panel.stripplot(x, y, jitter.data = FALSE,
    factor = 0.5, amount = NULL,
    horizontal = TRUE, groups = NULL,
    ..., 
    identifier = "stripplot")
```

Arguments

- `x, y`: coordinates of points to be plotted
- `jitter.data`: whether points should be jittered to avoid overplotting. The actual jittering is performed inside `panel.xyplot`, using its `jitter.x` or `jitter.y` argument (depending on the value of `horizontal`).
- `factor, amount`: amount of jittering, see `jitter`
- `horizontal`: logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of `x` and `y` are switched. `x` is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- `groups`: optional grouping variable
- `...`: additional arguments, passed on to `panel.xyplot`
- `identifier`: A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates stripplot (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`).

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

- `stripplot`, `jitter`
Description

This is the default panel function for xyplot. Also see panel.superpose. The default panel functions for splom and qq are essentially the same function.

Usage

panel.xyplot(x, y, type = "p",
             groups = NULL,
             pch, col, col.line, col.symbol,
             font, fontfamily, fontface,
             lty, cex, fill, lwd,
             horizontal = FALSE, ..., 
             grid = FALSE, abline = NULL,
             jitter.x = FALSE, jitter.y = FALSE,
             factor = 0.5, amount = NULL,
             identifier = "xyplot")
panel.splom(..., identifier = "splom")
panel.qq(..., identifier = "qq")

Arguments

x, y     variables to be plotted in the scatterplot
type     character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth", and "spline". If type has more than one element, an attempt is made to combine the effect of each of the components.
          The behaviour if any of the first six are included in type is similar to the effect of type in plot (type "b" is actually the same as "o"). "r" adds a linear regression line (same as panel.lmline, except for default graphical parameters). "smooth" adds a loess fit (same as panel.loess). "spline" adds a cubic smoothing spline fit (same as panel.spline). "g" adds a reference grid using panel.grid in the background (but using the grid argument is now the preferred way to do so). "a" has the effect of calling panel.average, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of horizontal.
          Type "s" (and "S") sorts the values along one of the axes (depending on horizontal); this is unlike the behavior in plot. For the latter behavior, use type = "s" with panel = panel.points.
          See example(xyplot) and demo(lattice) for examples.
groups   an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup
col, col.line, col.symbol
default colours are obtained from plot.symbol and plot.line using trellis.par.get.
font, fontface, fontfamily
font used when pch is a character
pch, lty, cex, lwd, fill
other graphical parameters. fill serves the purpose of bg in points for certain
values of pch

horizontal
A logical flag controlling the orientation for certain type’s, e.g., “h”, “s”, ans
“S”.

... Extra arguments, if any, for panel.xyplot. In most cases panel.xyplot igno-
res these. For types “r” and “smooth”, these are passed on to panel.lmline
and panel.loess respectively.

grid
A logical flag, character string, or list specifying whether and how a background
grid should be drawn. This provides the same functionality as type=”g”, but is
the preferred alternative as the effect type=”g” is conceptually different from
that of other type values (which are all data-dependent). Using the grid argu-
ment also allows more flexibility.

Most generally, grid can be a list of arguments to be supplied to panel.grid,
which is called with those arguments. Three shortcuts are available:

TRUE: roughly equivalent to list(h = -1,v = -1)

“h”: roughly equivalent to list(h = -1,v = 0)

“v”: roughly equivalent to list(h = 0,v = -1)

No grid is drawn if grid = FALSE.

abline
A numeric vector or list, specifying arguments arguments for panel.abline,
which is called with those arguments. If specified as a (possibly named) numeric
vector, abline is coerced to a list. This allows arguments of the form abline =
c(0,1), which adds the diagonal line, or abline = c(h = 0,v = 0), which adds
the x- and y-axes to the plot. Use the list form for finer control; e.g., abline =
list(h = 0,v = 0,col = “grey”).

For more flexibility, use panel.abline directly.

jitter.x, jitter.y
logical, whether the data should be jittered before being plotted.

factor, amount controls amount of jittering.

identifier A character string that is prepended to the names of grobs that are created by
this panel function.

Details

Creates scatterplot of x and y, with various modifications possible via the type argument. panel.qq
draws a 45 degree line before calling panel.xyplot.

Note that most of the arguments controlling the display can be supplied directly to the high-level
(e.g. xyplot) call.

            type <- types[panel.number()]
            grid::grid.text(label = sprintf("%s", type),
                            x = 0.5, y = 0.5)
            grid::grid.rect()
        },
        scales = list(alternating = c(0, 2), tck = c(0, 0.7), draw = FALSE),
        par.settings =
        list(layout.widths = list(strip.left = c(1, 0, 0, 0, 0)),
             panel = function(...) {
                 type <- types[panel.number()]
                 horizontal <- horiz[panel.number()]
                 panel.xyplot(...,
                               type = type,
                               horizontal = horizontal)
             })[rep(1, length(types))]

F_2_llines

Replacements of traditional graphics functions

Description

These functions are intended to replace common low level traditional graphics functions, primarily
for use in panel functions. The originals can not be used (at least not easily) because lattice panel
functions need to use grid graphics. Low level drawing functions in grid can be used directly as
well, and is often more flexible. These functions are provided for convenience and portability.

Usage

lplot.xy(xy, type, pch, lty, col, cex, lwd,
         font, fontfamily, fontface,
         col.line, col.symbol, alpha, fill,
         origin = 0, ..., identifier, name.type)

llines(x, ...)
lpoints(x, ...)
llines(x, y = NULL, type = "l", 
   col, alpha, lty, lwd, ..., identifier, name.type)
## Default S3 method:
llpoints(x, y = NULL, type = "p", col, pch, alpha, fill, 
   font, fontfamily, fontface, cex, ..., identifier, name.type)
## Default S3 method:
lltext(x, y = NULL, labels = seq_along(x), 
   col, alpha, cex, srt = 0, 
   lineheight, font, fontfamily, fontface, 
   adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)
llsegments(x0, y0, x1, y1, x2, y2, 
   col, alpha, lty, lwd, 
   font, fontface, ..., identifier, name.type)
llrect(xleft, ybottom, xright, ytop, 
   x = (xleft + xright) / 2, 
   y = (ybottom + ytop) / 2, 
   width = xright - xleft, 
   height = ytop - ybottom, 
   col = "transparent", 
   border = "black", 
   lty = 1, lwd = 1, alpha = 1, 
   just = "center", 
   hjust = NULL, vjust = NULL, 
   font, fontface, 
   ..., identifier, name.type)
llarrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL, 
   angle = 30, code = 2, length = 0.25, unit = "inches", 
   ends = switch(code, "first", "last", "both"), 
   type = "open", 
   col = add.line$col, 
   alpha = add.line$alpha, 
   lty = add.line$lty, 
   lwd = add.line$lwd, 
   fill = NULL, 
   font, fontface, 
   ..., identifier, name.type)
lpolygon(x, y = NULL, 
   border = "black", col = "transparent", fill = NULL, 
   font, fontface, ..., identifier, name.type)

panel.lines(...) 
panel.points(...) 
panel.segments(...) 
panel.text(...) 
panel.rect(...) 
panel.arrows(...) 
panel.polygon(...)
Arguments

x, y, x0, y0, x1, y1, x2, y2, xy

locations. x2 and y2 are available for S compatibility.

length, unit
determines extent of arrow head. length specifies the length in terms of unit, which can be any valid grid unit as long as it doesn’t need a data argument. unit defaults to inches, which is the only option in the base version of the function, arrows.

angle, code, type, labels, srt, adj, pos, offset
arguments controlling behaviour. See respective base functions for details. For l arrows and panel.larrows, type is either "open" or "closed", indicating the type of arrowhead.

ends
serves the same function as code, using descriptive names rather than integer codes. If specified, this overrides code

col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, col.symbol, border

graphical parameters. fill applies to points when pch is in 21:25 and specifies the fill color, similar to the bg argument in the base graphics function points. For devices that support alpha-transparency, a numeric argument alpha between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0.

fill, font and fontface are included in lrect, larrows, lpolygon, and lsegments only to ensure that they are not passed down (as gpar does not like them).

origin
for type="h" or type="H", the value to which lines drop down.

xleft, ybottom, xright, ytop
see rect

width, height, just, hjust, vjust
finer control over rectangles, see grid.rect

... extra arguments, passed on to lower level functions as appropriate.

identifier
A character string that is prepended to the name of the grob that is created.

name.type
A character value indicating whether the name of the grob should have panel or strip information added to it. Typically either "panel", "strip", "strip.left", or "" (for no extra information).

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions panel.* are essentially identical to the l* versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

Note

There is a new type="H" option wherever appropriate, which is similar to type="h", but with horizontal lines.

Useful Panel Function Components

Description

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

Usage

panel.abline(a = NULL, b = 0,
h = NULL, v = NULL,
reg = NULL, coef = NULL,
col, col.line, lty, lwd, alpha, type,
..., reference = FALSE,
identifier = "abline")

panel.refline(...)

panel.curve(expr, from, to, n = 101,
curve.type = "l",
col, lty, lwd, type,
..., identifier = "curve")

panel.rug(x = NULL, y = NULL,
regular = TRUE,
start = if (regular) 0 else 0.97,
end = if (regular) 0.03 else 1,
x.units = rep("npc", 2),
y.units = rep("npc", 2),
col, col.line, lty, lwd, alpha,
..., identifier = "rug")

panel.average(x, y, fun = mean, horizontal = TRUE,
lwd, lty, col, col.line, type,
..., identifier = "linejoin")

panel.linejoin(x, y, fun = mean, horizontal = TRUE,
lwd, lty, col, col.line, type,
..., identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")

See Also

points, lines, rect, text, segments, arrows, Lattice
```
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
                 n = 50, col, col.line, lwd, lty, type,
                 ..., identifier = "mathdensity")
```

**Arguments**

- **x, y** Variables defining the contents of the panel. In `panel.grid` these are optional and are used only to choose an appropriate method of `pretty`.

- **a, b** Coefficients of the line to be added by `panel.abline`. `a` can be a vector of length 2, representing the coefficients of the line to be added, in which case `b` should be missing. `a` can also be an appropriate ‘regression’ object, i.e., an object which has a `coef` method that returns a length 2 numeric vector. The corresponding line will be plotted. The `reg` argument overrides `a` if specified.

- **coef** Coefficients of the line to be added as a vector of length 2.

- **reg** A (linear) regression object, with a `coef` method that gives the coefficients of the corresponding regression line.

- **h, v** For `panel.abline`, these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For `panel.grid`, these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. `h=-1` and `v=-1` are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using `pretty`, which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). `h` and `v` can be negative numbers other than `-1`, in which case `-h` and `-v` (as appropriate) is supplied as the `n` argument to `pretty`.

If `x` and/or `y` are specified in `panel.grid`, they will be used to select an appropriate method for `pretty`. This is particularly useful while plotting date-time objects.

- **reference** A logical flag determining whether the default graphical parameters for `panel.abline` should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The `panel.refline` function is a wrapper around `panel.abline` that calls it with `reference = TRUE`.

- **expr** An expression considered as a function of `x`, or a function, to be plotted as a curve.

- **n** The number of points to use for drawing the curve.

- **from, to** optional lower and upper x-limits of curve. If missing, limits of current panel are used.

- **curve.type** Type of curve ("p" for points, etc), passed to `llines`.

- **regular** A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).

- **start, end** endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of `regular`, and cover 3% of the panel width and height.
Character vectors, replicated to be of length two. Specifies the (grid) units associated with start and end above. x.units and y.units are for the rug on the x-axis and y-axis respectively (and thus are associated with start and end values on the y and x scales respectively).

col, col.line, lty, lwd, alpha, border
Graphical parameters.

type
Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified type argument (perhaps meant for another function) does not affect the display.

fun
The function that will be applied to the subset of x values (or y if horizontal is FALSE) determined by the unique values of y (x).

horizontal
A logical flag. If FALSE, the plot is ‘transposed’ in the sense that the roles of x and y are switched; x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.

dmath
A vectorized function that produces density values given a numeric vector named x, e.g., dnorm.

args
A list giving additional arguments to be passed to dmath.

... Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by col, col.line, and col.symbol, the last two overriding the first for lines and points respectively.

identifier
A character string that is prepended to the names of grobs that are created by this panel function.

Details

panel.abline adds a line of the form y = a + b * x, or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. panel.refline is similar, but uses the “reference.line” settings for the defaults.

panel.grid draws a reference grid.

panel.curve adds a curve, similar to what curve does with add = TRUE. Graphical parameters for the curve are obtained from the “add.line” setting.

panel.average treats one of x and y as a factor (according to the value of horizontal), calculates fun applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with panel.xyplot, and more commonly with panel.superpose to produce interaction plots.

panel.linejoin is an alias for panel.average. It is retained for back-compatibility, and may go away in future.

panel.mathdensity plots a (usually theoretical) probability density function. This can be useful in conjunction with histogram and densityplot to visually assess goodness of fit (note, however, that qqmath is more suitable for this).

panel.rug adds a rug representation of the (marginal) data to the panel, much like rug.

panel.lmline(x,y) is equivalent to panel.abline(lm(y ~ x)).

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>
F_2_panel.loess

Panel Function to Add a LOESS Smooth

Description
A predefined panel function that can be used to add a LOESS smooth based on the provided data.

Usage
panel.loess(x, y, span = 2/3, degree = 1,
            family = c("symmetric", "gaussian"),
            evaluation = 50,
            lwd, lty, col, col.line, type,
            horizontal = FALSE,
            ..., identifier = "loess")

Arguments
x, y Variables defining the data to be used.
lwd, lty, col, col.line Graphical parameters for the added line. col.line overrides col.

Examples
## Interaction Plot
bwplot(yield ~ site, barley, groups = year,
       panel = function(x, y, groups, subscripts, ...) {
         panel.grid(h = -1, v = 0)
         panel.stripplot(x, y, ..., jitter.data = TRUE,
                         groups = groups, subscripts = subscripts)
         panel.superpose(x, y, ..., panel.groups = panel.average,
                         groups = groups, subscripts = subscripts)
       },
       auto.key =
       list(points = FALSE, lines = TRUE, columns = 2))

## Superposing a fitted normal density on a Histogram
histogram(~ height | voice.part, data = singer, layout = c(2, 4),
          type = "density", border = "transparent", col.line = "grey60",
          xlab = "Height (inches)",
          ylab = "Density Histogram\n with Normal Fit",
          panel = function(x, ...) {
            panel.histogram(x, ...)
            panel.mathdensity(dmath = dnorm,
                              args = list(mean=mean(x),sd=sd(x)), ...)
          })

See Also
Lattice, panel.axis, panel.identify identify, trellis.par.set.
type
Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.

span, degree, family, evaluation
Arguments to \texttt{loess.smooth}, for which \texttt{panel.loess} is essentially a wrapper.

horizontal
A logical flag controlling which variable is to be treated as the predictor (by default \(x\)) and which as the response (by default \(y\)). If \texttt{TRUE}, the plot is ‘transposed’ in the sense that \(y\) becomes the predictor and \(x\) the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in \texttt{bwplot}).

... Extra arguments, passed on to \texttt{panel.lines}.

identifier
A character string that is prepended to the names of grobs that are created by this panel function.

\textbf{Value}

The object returned by \texttt{loess.smooth}.

\textbf{Author(s)}

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

\textbf{See Also}

\texttt{Lattice}, \texttt{loess.smooth}, \texttt{prepanel.loess}

\textbf{F_2_panel.qqmathline}

Useful panel function with qqmath

\textbf{Description}

Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

\textbf{Usage}

\begin{verbatim}
panel.qqmathline(x, y = x, 
distribution = qnorm, 
probs = c(0.25, 0.75), 
qtype = 7, 
groups = NULL, 
..., 
identifier = "qqmathline")
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
\item \textbf{x} \hspace{1cm} The original sample, possibly reduced to a fewer number of quantiles, as determined by the \texttt{f.value} argument to \texttt{qqmath}
\item \textbf{y} \hspace{1cm} an alias for \texttt{x} for backwards compatibility
\item \textbf{distribution} \hspace{1cm} quantile function for reference theoretical distribution.
\end{itemize}
F_2_panel.smoothScatter

numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.

qtype

the type of quantile computation used in quantile

groups

optional grouping variable. If non-null, a line will be drawn for each group.

other arguments.

A character string that is prepended to the names of grobs that are created by this panel function.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

prepanel.qqmathline, qqmath, quantile

Lattice panel function analogous to smoothScatter

Description

This function allows the user to place smoothScatter plots in lattice graphics.

Usage

panel.smoothScatter(x, y = NULL, 
nbin = 64, cuts = 255, 
bandwidth, 
colramp, 
nrpoints = 100, 
transformation = function(x) x^0.25, 
pch = ".", 
cex = 1, col="black", 
range.x, 
..., 
raster = FALSE, 
subscripts, 
identifier = "smoothScatter")

Arguments

x Numeric vector containing x-values or n by 2 matrix containing x and y values.
y Numeric vector containing y-values (optional). The length of x must be the same as that of y.
nbin Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.
cuts number of cuts defining the color gradient
bandwidth Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function `bkde2D`.

colramp Function accepting an integer n as an argument and returning n colors.

nrpoints Numeric vector of length 1 giving number of points to be superimposed on the density image. The first nrpoints points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose nrpoints = Inf.

transformation Function that maps the density scale to the color scale.

pch, cex graphical parameters for the nrpoints “outlying” points shown in the display

range.x see `bkde2D` for details.

col points color parameter

... Further arguments that are passed on to `panel.levelplot`.

raster logical; if TRUE, `panel.levelplot.raster` is used, making potentially smaller output files.

subscripts ignored, but necessary for handling of ...in certain situations. Likely to be removed in future.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

This replicates the display part of the smoothScatter function by replacing standard graphics calls by grid-compatible ones.

**Value**

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

**Author(s)**

Deepayan Sarkar <deepayan.sarkar@r-project.org>

**Examples**

```r
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xysplot(V1 ~ V2 + V3, ddf, outer = TRUE,
        panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```
Panel Function to Add a Spline Smooth

Description

A predefined panel function that can be used to add a spline smooth based on the provided data.

Usage

```r
panel.spline(x, y, npoints = 101,
    lwd = plot.line$lwd,
    lty = plot.line$lty, 
    col, col.line = plot.line$col, 
    type, 
    horizontal = FALSE, ..., 
    keep.data = FALSE, 
    identifier = "spline")
```

Arguments

- **x, y** Variables defining the data to be used.
- **npoints** The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.
- **lwd, lty, col, col.line** Graphical parameters for the added line. `col.line` overrides `col`.
- **type** Ignored. The argument is present only to make sure that an explicitly specified `type` argument (perhaps meant for another function) does not affect the display.
- **horizontal** A logical flag controlling which variable is to be treated as the predictor (by default `x`) and which as the response (by default `y`). If `TRUE`, the plot is ‘transposed’ in the sense that `y` becomes the predictor and `x` the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in `bwplot`).
- **keep.data** Passed on to `smooth.spline`. The default here (FALSE) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to `TRUE` if the return value of `panel.spline`, which is the fitted model as returned by `smooth.spline`, is to be used for subsequent computations.
- **...** Extra arguments, passed on to `smooth.spline` and `panel.lines` as appropriate.
- **identifier** A character string that is prepended to the names of grobs that are created by this panel function.

Value

The fitted model as returned by `smooth.spline`.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>
See Also

Lattice, smooth.spline, prepanel.spline

### Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The x (and y where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

### Usage

```r
panel.superpose(x, y = NULL, subscripts, groups,
    panel.groups = "panel.xyplot",
    ..., 
    col, col.line, col.symbol,
    pch, cex, fill, font,
    fontface, fontfamily,
    lty, lwd, alpha,
    type = "p", grid = FALSE,
    distribute.type = FALSE)
```

```r
panel.superpose.2(..., distribute.type = TRUE)
```

```r
panel.superpose.plain(...,
    col, col.line, col.symbol,
    pch, cex, fill, font,
    fontface, fontfamily,
    lty, lwd, alpha)
```

### Arguments

- **x, y** Coordinates of the points to be displayed. Usually numeric.
- **panel.groups** The panel function to be used for each subgroup of points. Defaults to `panel.xyplot`. To be able to distinguish between different levels of the originating group inside `panel.groups`, it will be supplied two special arguments called `group.number` and `group.value` which will hold the numeric code and factor level corresponding to the current level of groups. No special care needs to be taken when writing a `panel.groups` function if this feature is not used.
- **subscripts** An integer vector of subscripts giving indices of the x and y values in the original data source. See the corresponding entry in `xyplot` for details.
- **groups** A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of groups. The default graphical parameters are obtained from the "superpose.symbol" and "superpose.line" settings using `trellis.par.get` wherever appropriate.
type  Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the panel.groups function, which must know what to do with it. By default, panel.groups is \texttt{panel.xyplot}, whose help page describes the admissible values.

The functions panel.superpose and panel.superpose.2 differ only in the default value of distribute.type, which controls the way the type argument is interpreted. If distribute.type = FALSE, then the interpretation is the same as for panel.xyplot for each of the unique groups. In other words, if type is a vector, all the individual components are honoured concurrently. If distribute.type = TRUE, type is replicated to be as long as the number of unique values in groups, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying type as a list, each component being the desired type vector for the corresponding group.

If distribute.type = FALSE, any occurrence of "g" in type causes a grid to be drawn, and all such occurrences are removed before type is passed on to panel.groups.

grid Logical flag specifying whether a background reference grid should be drawn. See \texttt{panel.xyplot} for details.

col  A vector color specification. See Details.

col.line  A vector color specification. See Details.

col.symbol  A vector color specification. See Details.

pch  A vector plotting character specification. See Details.

cex  A vector size factor specification. See Details.

fill  A vector fill color specification. See Details.

font, fontface, fontfamily  A vector color specification. See Details.

lty  A vector color specification. See Details.

lwd  A vector color specification. See Details.

alpha  A vector alpha-transparency specification. See Details.

...  Extra arguments. Passed down to panel.superpose from panel.superpose.2, and to panel.groups from panel.superpose.

distribute.type  logical controlling interpretation of the type argument.

Details

\texttt{panel.superpose} divides up the x (and optionally y) variable(s) by the unique values of groups[subscripts], and plots each subset with different graphical parameters. The graphical parameters (col.symbol, pch, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When panel.groups is called for the i-th level of groups, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the panel.groups function. With the default panel.groups, the col argument is overridden by col.line and col.symbol for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, col will still be supplied as an argument to panel.groups functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the
"superpose.line" and "superpose.symbol" settings as appropriate. The alpha parameter takes it default from the "superpose.line" setting.

`panel.superpose` and `panel.superpose.2` differ essentially in how type is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in S, which is the same as that of `panel.superpose.2`.

`panel.superpose.plain` is the same as `panel.superpose`, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in `xyplot.ts`.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org> (panel.superpose.2 originally contributed by Neil Klepeis)

See Also

Different functions when used as panel.groups gives different types of plots, for example `panel.xyplot`, `panel.dotplot` and `panel.average` (This can be used to produce interaction plots).

See `Lattice` for an overview of the package, and `xyplot` for common arguments (in particular, the discussion of the extended formula interface and the groups argument).

---

**F_2_panel.violin**

Panel Function to create Violin Plots

Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

Usage

```r
panel.violin(x, y, box.ratio = 1, box.width, horizontal = TRUE,
             alpha, border, lty, lwd, col,
             varwidth = FALSE,
             bw, adjust, kernel, window,
             width, n = 50, from, to, cut,
             na.rm, ..., 
             identifier = "violin")
```

Arguments

- `x, y` numeric vector or factor. Violin plots are drawn for each unique value of `y` (`x`) if `horizontal` is TRUE (FALSE)
- `box.ratio` ratio of the thickness of each violin and inter violin space
- `box.width` thickness of the violins in absolute units; overrides `box.ratio`. Useful for specifying thickness when the categorical variable is not a factor, as use of `box.ratio` alone cannot achieve a thickness greater than 1.
**horizontal** logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of \(x\) and \(y\) are switched. \(x\) is now the ‘factor’. See documentation of \texttt{bwplot} for a fuller explanation.

**alpha**, **border**, **lty**, **lwd**, **col**

graphical parameters controlling the violin. Defaults are taken from the "plot.polygon" settings.

**varwidth** logical. If FALSE, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by box.ratio). If TRUE, densities across violins will have comparable scale.

**bw**, **adjust**, **kernel**, **window**, **width**, **n**, **from**, **to**, **cut**, **na.rm**

arguments to \texttt{density}, passed on as appropriate

**...** arguments passed on to \texttt{density}.

**identifier** A character string that is prepended to the names of grobs that are created by this panel function.

### Details

Creates Violin plot of \(x\) for every level of \(y\). Note that most arguments controlling the display can be supplied to the high-level (typically \texttt{bwplot}) call directly.

**Default Prepanel Functions**

### Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.
Usage

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)  
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)  
prepanel.default.qq(x, y, ...)  
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)  
prepanel.default.cloud(perspective, distance,  
    xlim, ylim, zlim,  
    screen = list(z = 40, x = -60),  
    R.mat = diag(4),  
    aspect = c(1, 1), panel.aspect = 1,  
    ..., zoom = 0.8)  
prepanel.default.levelplot(x, y, subscripts, ...)  
prepanel.default.qqmath(x, f.value, distribution, qtype,  
    groups, subscripts, ..., tails.n = 0)  
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)  
prepanel.default.parallel(x, y, z, ..., horizontal.axis)  
prepanel.default.splom(z, ...)

Arguments

x, y             x and y values, numeric or factor  
horizontal       logical, applicable when one of the variables is to be treated as categorical (factor or shingle).  
horizontal.axis  logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).  
nlevels          number of levels of such a categorical variable.  
origin, stack    for barcharts or the type="h" plot type  
breaks, equal.widths, type, nint  
                 details of histogram calculations. type has a different meaning in prepanel.default.xyplot (see panel.xyplot)  
                 groups, subscripts  
                 See xyplot. Whenever appropriate, calculations are done separately for each group and then combined.  
weights          numeric vector of weights for the density calculations. If this is specified, it is subsetted by subscripts to match it to x.  
perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom  
                 see panel.cloud  
f.value, distribution, tails.n  
                 see panel.qqmath  
darg             list of arguments passed to density  
z                see panel.parallel and panel.pairs  
qtype             type of quantile  
                 ... other arguments, usually ignored

Value

A list with components xlim, ylim, dx and dy, and possibly xat and yat, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for xyplot.
Useful Prepanel Function for Lattice

These are predefined prepanel functions available in Lattice.

Usage

prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
                   probs = c(0.25, 0.75), qtype = 7,
                   groups, subscripts,
                   ...)
prepanel.loess(x, y, span, degree, family, evaluation,
              horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
              horizontal = FALSE, ..., 
              keep.data = FALSE)

Arguments

x, y x and y values, numeric or factor
distribution quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in qqmath.
qtype type of quantile
probs numeric vector of length two, representing probabilities. If used with aspect="xy", the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible.
span, degree, family, evaluation
Arguments controlling the underlying loess smooth.
horizontal, npoints
See documentation for corresponding panel function.
keep.data Ignored. Present to capture argument of the same name in smooth.spline.
groups, subscripts
See xyplot. Whenever appropriate, calculations are done separately for each group and then combined.
... Other arguments. These are passed on to other functions if appropriate (in particular, smooth.spline), and ignored otherwise.
Details

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, prepanel.lmline computes the dx and dy such that it reflects the slope of the linear regression line; for prepanel.qqmathline, this is the slope of the line passing through the quantile pairs specified by probs. For prepanel.loess and prepanel.spline, dx and dy reflect the piecewise slopes of the nonlinear smooth.

Value

usually a list with components xlim, ylim, dx and dy, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under `xyplot`. There are also several prepanel functions that serve as the default for high level functions, see `prepanel.default.xyplot`

G_axis.default       Default axis annotation utilities

Description

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the axis argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

Usage

```r
xscale.components.default(lim,
    packet.number = 0,
    packet.list = NULL,
    top = TRUE,
    ...
)
yscale.components.default(lim,
    packet.number = 0,
    packet.list = NULL,
    right = TRUE,
    ...
)
axis.default(side = c("top", "bottom", "left", "right"),
    scales, components, as.table,
    labels = c("default", "yes", "no"),
    ticks = c("default", "yes", "no"),
```

Arguments

lim the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.

packet.number which packet (counted according to the packet order, described in \texttt{print.trellis}) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.

packet.list list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)

top, right the value of the top and right components of the result, as appropriate. See below for interpretation.

side on which side the axis is to be drawn. The usual partial matching rules apply.

scales the appropriate component of the scales argument supplied to the high level function, suitably standardized.

components list, similar to those produced by \texttt{xscale.components.default} and \texttt{yscale.components.default}.

as.table the as.table argument in the high level function.

labels whether labels are to be drawn. By default, the rules determined by scales are used.

ticks whether labels are to be drawn. By default, the rules determined by scales are used.

\ldots many other arguments may be supplied, and are passed on to other internal functions.

prefix A character string identifying the plot being drawn (see \texttt{print.trellis}). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.

Details

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

Value

\texttt{xscale.components.default} and \texttt{yscale.components.default} return a list of the form suitable as the components argument of \texttt{axis.default}. Valid components in the return value of \texttt{xscale.components.default} are:

num.limit A numeric limit for the box.
A list with two elements, ticks and labels. ticks must be a list with components at and tck which give the location and lengths of tick marks. tck can be a vector, and will be recycled to be as long as at. labels must be a list with components at, labels, and check.overlap. at and labels give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. check.overlap is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.

This can be a logical flag; if TRUE, top is treated as being the same as bottom; if FALSE, axis annotation for the top axis is omitted. Alternatively, top can be a list like bottom.

Valid components in the return value of yscale.components.default are left and right. Their interpretations are analogous to (respectively) the bottom and top components described above.

<table>
<thead>
<tr>
<th>G_banking</th>
<th>Banking</th>
</tr>
</thead>
</table>

**Description**

Calculates banking slope
Usage

banking(dx, dy)

Arguments

dx, dy vector of consecutive x, y differences.

Details

banking is the banking function used when aspect = "xy" in high level Trellis functions. It is usually not very meaningful except with xyplot. It considers the absolute slopes (based on dx and dy) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs' website (see Lattice), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying lattice.options("banking").

G_latticeParseFormula  Parse Trellis formula

Description
this function is used by high level Lattice functions like xyplot to parse the formula argument and evaluate various components of the data.

Usage
latticeParseFormula(model, data, dimension = 2,
subset = TRUE, groups = NULL,
multiple, outer,
subscripts,
drop)

Arguments
model the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the dimension argument. The 2d formulas are of the form y ~ x| g1 * ... * gn, and the 3d formulas are of the form z ~ x * y | g1 * ... * gn. In the first form, y may be omitted. The conditioning variables g1,...,gn can be omitted in either case.
data the environment/dataset where the variables in the formula are evaluated.
dimension dimension of the model, see above
subset index for choosing a subset of the data frame
groups the grouping variable, if present
multiple, outer logicals, determining how a '+' in the y and x components of the formula are processed. See xyplot for details
subscripts logical, whether subscripts are to be calculated
drop logical or list, similar to the drop.unused.levels argument in xyplot, indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

Value
returns a list with several components, including left,right,left.name,right.name,condition for 2-D, and left,right.x,right.y,left.name,right.x.name,right.y.name,condition for 3-D. Other possible components are groups, subscr

G_packet.panel.default

Associating Packets with Panels

Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

Usage

packet.panel.default(layout, condlevels, page, row, column, skip, all.pages.skip = TRUE)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>layout</td>
<td>the layout argument in high level functions, suitably standardized.</td>
</tr>
<tr>
<td>condlevels</td>
<td>a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels</td>
</tr>
<tr>
<td>page, row, column</td>
<td>the location of the panel in the coordinate system of pages, rows and columns.</td>
</tr>
<tr>
<td>skip</td>
<td>the skip argument in high level functions</td>
</tr>
<tr>
<td>all.pages.skip</td>
<td>whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.</td>
</tr>
</tbody>
</table>

Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is p, then the i-th conditioning variable will have level condlevels[[i]][p[i]].

print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))
```

G_panel.axis

**Panel Function for Drawing Axis Ticks and Labels**

Description

panel.axis is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. current.panel.limits can be used to retrieve a panel’s x and y limits.

Usage

```r
panel.axis(side = c("bottom", "left", "top", "right"),
          at, labels = TRUE,
          draw.labels = TRUE,
          check.overlap = FALSE,
          outside = FALSE,
          ticks = TRUE,
          half = !outside,
          which.half,
          tck = as.numeric(ticks),
          rot = if (is.logical(labels)) 0 else c(90, 0),
          text.col, text.alpha, text.cex, text.font,
          text.fontfamily, text.fontface, text.lineheight,
          line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")
```
Arguments

side
A character string indicating which side axes are to be drawn on. Partial specification is allowed.

at
Numeric vector giving location of labels.

labels
The labels to go along with at. The labels can be a character vector or a vector of expressions. Alternatively, at can be a logical flag: If TRUE, the labels are derived from at, otherwise, labels are empty.

draw.labels
A logical indicating whether labels are to be drawn.

check.overlap
A logical, whether to check for overlapping of labels. This also has the effect of removing at values that are 'too close' to the limits.

outside
A logical flag, indicating whether to draw the labels outside the panel or inside. Note that outside=TRUE will only have a visible effect if clipping is disabled for the viewport (panel).

ticks
Logical flag, whether to draw the tickmarks.

half
Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in splom.

which.half
Character string, either "lower" or "upper", indicating which half is to be used for tick locations if half = TRUE. Defaults to whichever is suitable for splom.

tck
A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.

rot
Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.

text.col
Color for the axis label text. See gpar for more details on this and the other graphical parameters listed below.

text.alpha
Alpha-transparency value for the axis label text.

text.cex
Size multiplier for the axis label text.

text.font, text.fontfamily, text.fontface
Font for the axis label text.

text.lineheight
Line height for the axis label text.

line.col
Color for the axis label text.

line.lty
Color for the axis.

line.lwd
Color for the axis.

line.alpha
Alpha-transparency value for the axis.

unit
Which grid unit the values should be in.

Details

panel.axis can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in panel.pairs for splom, as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots 'after the fact' by adding axes.

Value

current.panel.limits returns a list with components xlim and ylim, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by unit, by default "native".
Accessing Auxiliary Information During Plotting

Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the panel, strip and axis functions. Note that this information is not available to the prepanel function, which is executed prior to the actual plotting.

Usage

```r
current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)

trellis.currentLayout(which = c("packet", "panel"), prefix)
```

Arguments

- `which`: whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).
- `prefix`: A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See `trellis.focus`.

Value

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel, see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.
Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls. You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

**G_Rows**

*Extract rows from a list*

**Description**

Convenience function to extract subset of a list. Usually used in creating keys.

**Usage**

```r
Rows(x, which)
```

**Arguments**

- `x`: list with each member a vector of the same length
- `which`: index for members of `x`

**Value**

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

Utility functions for 3-D plots

Description

These are (related to) the default panel functions for cloud and wireframe.

Usage

ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)

Arguments

x x can be a numeric matrix with 3 rows for ltransform3dto3d
screen list, as described in panel.cloud
R.mat 4x4 transformation matrix in homogeneous coordinates
dist controls transformation to account for perspective viewing

Details

ltransform3dMatrix and ltransform3dto3d are utility functions to help in computation of projections. These functions are used inside the panel functions for cloud and wireframe. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the screen argument in cloud and wireframe and a R.mat, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying R.mat followed by the rotations in screen. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

Description

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

Usage

barley

Format

A data frame with 120 observations on the following 4 variables.

yield  Yield (averaged across three blocks) in bushels/acre.

year  Factor with levels 1932, 1931

site  Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crockston", "Waseca"

Details

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crockston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

H_environmental

Atmospheric environmental conditions in New York City

Description

Usage

environmental

Format

A data frame with 111 observations on the following 4 variables.

- **ozone**  Average ozone concentration (of hourly measurements) of in parts per billion.
- **radiation**  Solar radiation (from 08:00 to 12:00) in langleys.
- **temperature**  Maximum daily emperature in degrees Fahrenheit.
- **wind**  Average wind speed (at 07:00 and 10:00) in miles per hour.

H_ethanol

Description

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

Usage

ethanol

Format

A data frame with 88 observations on the following 3 variables.

- **NOx**: Concentration of nitrogen oxides (NO and NO2) in micrograms/J.
- **C**: Compression ratio of the engine.
- **E**: Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**H_melanoma**

*Melanoma skin cancer incidence*

**Description**
These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**
melanoma
Format

A data frame with 37 observations on the following 2 variables.

- **year**: Years 1936 to 1972.
- **incidence**: Rate of melanoma cancer per 100,000 population.

Note

This dataset is not related to the `melanoma` dataset in the `boot` package with the same name. The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per million, but this is not consistent with data found at the National Cancer Institute (https://www.cancer.gov/).

USMortality
USRegionalMortality

Format

USRegionalMortality is a data frame with 400 observations on the following 6 variables.

Region  A factor specifying HHS Region. See details.
Status  A factor with levels Rural and Urban
Sex  A factor with levels Female and Male
Cause  Cause of death. A factor with levels Alzheimers, Cancer, Cerebrovascular diseases, Diabetes, Flu and pneumonia, Heart disease, Lower respiratory, Nephritis, Suicide, and Unintentional injuries
Rate  Age-adjusted death rate per 100,000 population
SE  Standard error for the rate

USMortality is a data frame with 40 observations, containing the same variables with the exception of Region.

Details

The region-wise data give estimated rates separately for each of 10 HHS regions. The location of the regional offices and their coverage area, available from https://www.hhs.gov/about/agencies/iea/regional-offices/index.html, is given below.

HHS Region 01 - Boston:  Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont
HHS Region 02 - New York:  New Jersey, New York, Puerto Rico, and the Virgin Islands
HHS Region 03 - Philadelphia:  Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia
HHS Region 04 - Atlanta:  Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee
HHS Region 05 - Chicago:  Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin
HHS Region 06 - Dallas:  Arkansas, Louisiana, New Mexico, Oklahoma, and Texas
HHS Region 07 - Kansas City:  Iowa, Kansas, Missouri, and Nebraska
HHS Region 08 - Denver:  Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming
HHS Region 09 - San Francisco:  Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and Republic of Palau
HHS Region 10 - Seattle:  Alaska, Idaho, Oregon, and Washington

References

Examples

```r
dotplot(reorder(Cause, Rate) ~ Rate | Status,
    data = USMortality, groups = Sex,
    par.settings = simpleTheme(pch = 16), auto.key = list(columns = 2),
    scales = list(x = list(log = TRUE, equispaced.log = FALSE)))

dotplot(reorder(Cause, Rate):Sex ~ Rate | Status,
    data = USRegionalMortality, groups = Sex,
    scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
```

Description

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

Usage

```r
lset(theme = col.whitebg())
```

Arguments

- **theme**
  - a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

The mgcv package

### anova.gam

**Approximate hypothesis tests related to GAM fits**

#### Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to `drop1` rather than `anova.lm` (i.e. it's like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table or GLRT test: this latter approach should not be used to test the significance of terms which can be penalized to zero. Models to be compared should be fitted to the same data using the same smoothing parameter selection method.

#### Usage

```r
## S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
       freq = FALSE)
## S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3),...)
```

#### Arguments

- **object,...** fitted model objects of class `gam` as produced by `gam()`.
- **x** an `anova.gam` object produced by a single model call to `anova.gam()`.
- **dispersion** a value for the dispersion parameter: not normally used.
- **test** what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp". Reset to "Chisq" for extended and general families unless NULL.
- **freq** whether to use frequentist or Bayesian approximations for parametric term p-values. See `summary.gam` for details.
- **digits** number of digits to use when printing output.
Details

If more than one fitted model is provided than `anova.glm` is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom (when possible this is a smoothing parameter uncertainty corrected version). For extended and general families this is set so that a GLRT test is used. The p-values resulting from the multi-model case are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to `anova.gam`, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notionall null model.

If only one model is provided then the significance of each model term is assessed using Wald like tests, conditional on the smoothing parameter estimates: see `summary.gam` and Wood (2013a,b) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but is available in package `RLRsim`).

In the single model case `print.anova.gam` is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the paraPen argument will not be good.

Value

In the multi-model case `anova.gam` produces output identical to `anova.glm`, which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from `summary.gam`

`print.anova.gam` simply produces tabulated output.

WARNING

If models 'a' and 'b' differ only in terms with no un-penalized components (such as random effects) then p-values from `anova(a,b)` are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using 'paraPen': use `freq=TRUE` to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to `drop1`, not `anova.lm`.

b1<gam(y ~ x0 + s(x1) + s(x2), data=dat)
anova(b,b1,test="F")
```

bam

Generalized additive models for very large datasets

Description

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM (the extended families listed in family.mgcv can also be used). The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like gam, except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data (see Wood, Goude and Shaw, 2015). The advantage of bam is much lower memory footprint than gam, but it can also be much faster, for large datasets. bam can also compute on a cluster set up by the parallel package.

An alternative fitting approach (Wood et al. 2017, Li and Wood, 2019) is provided by the discrete=TRUE method. In this case a method based on discretization of covariate values and C code level parallelization (controlled by the nthreads argument instead of the cluster argument) is used. This extends both the data set and model size that are practical.
Usage

bam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL, 
na.action=na.omit, offset=NULL, method="fREML", control=list(), 
select=FALSE, scale=0, gamma=1, knots=NULL, sp=NULL, min.sp=NULL, 
paraPen=NULL, chunk.size=10000, rho=0, AR.start=NULL, discrete=FALSE, 
cluster=NULL, nthreads=1, use.chol=FALSE, samfrac=1, 
coef=NULL, drop.unused.levels=TRUE, G=NULL, fit=TRUE, drop.intercept=NULL,...)

Arguments

formula A GAM formula (see formula.gam and also gam.models). This is exactly like 
the formula for a GLM except that smooth terms, s and te can be added to the 
right hand side to specify that the linear predictor depends on smooth functions 
of predictors (or linear functionals of these).

family This is a family object specifying the distribution and link to use in fitting 
etc. See glm and family for more details. The extended families listed in 
family.mgcv can also be used.

data A data frame or list containing the model response variable and covari-
ates required by the formula. By default the variables are taken from 
environment(formula): typically the environment from which gam is called.

weights prior weights on the contribution of the data to the log likelihood. Note that a 
weight of 2, for example, is equivalent to having made exactly the same obser-
vation twice. If you want to reweight the contributions of each datum without 
changing the overall magnitude of the log likelihood, then you should normalize 
the weights (e.g. weights <- weights/mean(weights)).

subset an optional vector specifying a subset of observations to be used in the fitting 
process.

na.action a function which indicates what should happen when the data contain ‘NA’s. 
The default is set by the ‘na.action‘ setting of ‘options‘, and is ‘na.fail‘ if that is 
unset. The “factory-fresh” default is ‘na.omit‘.

offset Can be used to supply a model offset for use in fitting. Note that this offset 
will always be completely ignored when predicting, unlike an offset included in 
formula (this used to conform to the behaviour of lm and glm).

method The smoothing parameter estimation method. “GCV.Cp” to use GCV for 
unknown scale parameter and Mallows’ Cp/UBRE/AIC for known scale. 
"GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML 
estimation, including of unknown scale, "P-REML" for REML estimation, but 
using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but us-
ing maximum likelihood in place of REML. Default "fREML" uses fast REML 
computation.

control A list of fit control parameters to replace defaults returned by gam.control. 
Any control parameters not supplied stay at their default values.

select Should selection penalties be added to the smooth effects, so that they can in 
principle be penalized out of the model? See gamma to increase penalization. Has 
the side effect that smooths no longer have a fixed effect component (improper 
prior from a Bayesian perspective) allowing REML comparison of models with 
the same fixed effect structure.

scale If this is positive then it is taken as the known scale parameter. Negative signals 
that the scale parameter is unknown. 0 signals that the scale parameter is 1 for
Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.

**gamma**  
Increase above 1 to force smoother fits. gamma is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so log(n)/2 is BIC like). n/gamma can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.

**knots**  
This is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See **tprs** for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

**sp**  
A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then length(sp) must correspond to the number of underlying smoothing parameters.

**min.sp**  
Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters full.sp, in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. length(min.sp) should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).

**paraPen**  
Optional list specifying any penalties to be applied to parametric model terms. **gam.models** explains more.

**chunk.size**  
The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to 4*p if chunk.size < 4*p where p is the number of coefficients.

**rho**  
An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in std.rsd if non zero. Also usable with other models when discrete=TRUE, in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.

**AR.start**  
Logical variable of same length as data, TRUE at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If NULL then there are no breaks in AR1 correlation.

**discrete**  
With method="FREML" it is possible to discretize covariates for storage and efficiency reasons. If discrete is TRUE, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins.

**cluster**  
Bam can compute the computationally dominant QR decomposition in parallel using parLapply from the parallel package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.

**nthreads**  
Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If NA set to max(1,length(cluster)). See details.

**gc.level**  
To keep the memory footprint down, it helps to call the garbage collector often, but this takes a substantial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between.
use.chol  By default bam uses a very stable QR update approach to obtaining the QR
decomposition of the model matrix. For well conditioned models an alternative
accumulates the crossproduct of the model matrix and then finds its Choleski
decomposition, at the end. This is somewhat more efficient, computationally.

samfrac  For very large sample size Generalized additive models the number of iterations
needed for the model fit can be reduced by first fitting a model to a random
sample of the data, and using the results to supply starting values. This initial fit
is run with sloppy convergence tolerances, so is typically very low cost. samfrac
is the sampling fraction to use. 0.1 is often reasonable.

doef  initial values for model coefficients

drop.unused.levels  by default unused levels are dropped from factors before fitting. For some
smooths involving factor variables you might want to turn this off. Only do
so if you know what you are doing.

G  if not NULL then this should be the object returned by a previous call to bam with
fit=FALSE. Causes all other arguments to be ignored except sp, chunk.size,
gamma,nthreads, cluster, rho, gc.level, samfrac, use.chol, method and
scale (if >0).

fit  if FALSE then the model is set up for fitting but not estimated, and an object is
returned, suitable for passing as the G argument to bam.

drop.intercept  Set to TRUE to force the model to really not have the a constant in the parametric
model part, even with factor variables present.

...  further arguments for passing on e.g. to gam.fit (such as mustart).

Details

When discrete=FALSE, bam operates by first setting up the basis characteristics for the smooths,
using a representative subsample of the data. Then the model matrix is constructed in blocks using
predict.gam. For each block the factor R, from the QR decomposition of the whole model matrix
is updated, along with Q'y. and the sum of squares of y. At the end of block processing, fitting takes
place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudo-
data, at each step of the PIRLS. Smoothness selection is performed on the working model at each
stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to
justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified
via the asymptotic multivariate normality of Q'z where z is the IRLS pseudodata.

For full method details see Wood, Goude and Shaw (2015).

Note that POI is not as stable as the default nested iteration used with gam, but that for very large,
information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an
expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost
any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are
typically much less costly in the multi-dimensional case.

If cluster is provided as a cluster set up using makeCluster (or makeForkCluster) from the
parallel package, then the rate limiting QR decomposition of the model matrix is performed in
parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine
it is usually best to set the cluster size to the number of physical cores, which is often less than what
is reported by detectCores. Using more than the number of physical cores can result in no speed
up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from
using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

When discrete=TRUE the covariate data are first discretized. Discretization takes place on a smooth by smooth basis, or in the case of tensor product smooths (or any smooth that can be represented as such, such as random effects), separately for each marginal smooth. The required spline bases are then evaluated at the discrete values, and stored, along with index vectors indicating which original observation they relate to. Fitting is by a version of performance oriented iteration/PQL using REML smoothing parameter selection on each iterative working model (as for the default method). The iteration is based on the derivatives of the REML score, without computing the score itself, allowing the expensive computations to be reduced to one parallel block Cholesky decomposition per iteration (plus two basic operations of equal cost, but easily parallelized). Unlike standard POI/PQL, only one step of the smoothing parameter update for the working model is taken at each step (rather than iterating to the optimal set of smoothing parameters for each working model). At each step a weighted model matrix crossproduct of the model matrix is required - this is efficiently computed from the pre-computed basis functions evaluated at the discretized covariate values. Efficient computation with tensor product terms means that some terms within a tensor product may be re-ordered for maximum efficiency. See Wood et al (2017) and Li and Wood (2019) for full details.

When discrete=TRUE parallel computation is controlled using the nthreads argument. For this method no cluster computation is used, and the parallel package is not required. Note that actual speed up from parallelization depends on the BLAS installed and your hardware. With the (R default) reference BLAS using several threads can make a substantial difference, but with a single threaded tuned BLAS, such as openblas, the effect is less marked (since cache use is typically optimized for one thread, and is then sub optimal for several). However the tuned BLAS is usually much faster than using the reference BLAS, however many threads you use. If you have a multi-threaded BLAS installed then you should leave nthreads at 1, since calling a multi-threaded BLAS from multiple threads usually slows things down: the only exception to this is that you might choose to form discrete matrix cross products (the main cost in the fitting routine) in a multi-threaded way, but use single threaded code for other computations: this can be achieved by e.g. nthreads=c(2,1), which would use 2 threads for discrete inner products, and 1 for most code calling BLAS. Not that the basic reason that multi-threaded performance is often disappointing is that most computers are heavily memory bandwidth limited, not flop rate limited. It is hard to get data to one core fast enough, let alone trying to get data simultaneously to several cores.

discrete=TRUE will often produce identical results to the methods without discretization, since covariates often only take a modest number of discrete values anyway, so no approximation at all is involved in the discretization process. Even when some approximation is involved, the differences are often very small as the algorithms discretize marginally whenever possible. For example each margin of a tensor product smooth is discretized separately, rather than discretizing onto a grid of covariate values (for an equivalent isotropic smooth we would have to discretize onto a grid). The marginal approach allows quite fine scale discretization and hence very low approximation error. Note that when using the smooth id mechanism to link smoothing parameters, the discrete method cannot force the linked bases to be identical, so some differences to the none discrete methods will be noticeable.

The extended families given in family.mgcv can also be used. The extra parameters of these are estimated by maximizing the penalized likelihood, rather than the restricted marginal likelihood as in gam. So estimates may differ slightly from those returned by gam. Estimation is accomplished by a Newton iteration to find the extra parameters (e.g. the theta parameter of the negative binomial or the degrees of freedom and scale of the scaled t) maximizing the log likelihood given the model coefficients at each iteration of the fitting procedure.
Value

An object of class "gam" as described in `gamObject`.

WARNINGS

The routine may be slower than optimal if the default "tp" basis is used.

Unless `discrete=TRUE`, you must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than ‘gam’ for the same dataset.

With `discrete=TRUE`, te terms are efficiently computed, but t2 are not.

**bam.update**

*Update a strictly additive bam model for new data.*

**Description**

Gaussian with identity link models fitted by `bam` can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

**Usage**

```r
bam.update(b, data, chunk.size=10000)
```

**Arguments**

- `b`: A `gam` object fitted by `bam` and representing a strictly additive model (i.e. gaussian errors, identity link).
- `data`: Extra data to augment the original data used to obtain `b`. Must include a `weights` column if the original fit was weighted and a `AR.start` column if `AR.start` was non NULL in original fit.
- `chunk.size`: size of subsets of data to process in one go when getting fitted values.

**Details**

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the same AR1 model for the residuals as that employed in the original model fit (see `rho` parameter of `bam`).
Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

**Value**

An object of class "gam" as described in `gamObject`.

**WARNINGS**

AIC computation does not currently take account of AR model, if used.

**bandchol**

**Choleski decomposition of a band diagonal matrix**

**Description**

Computes Choleski decomposition of a (symmetric positive definite) band-diagonal matrix, \(A\).

**Usage**

```r
bandchol(B)
```

**Arguments**

- **B**
  
  An \(n \times k\) matrix containing the diagonals of the matrix \(A\) to be decomposed. First row is leading diagonal, next is first sub-diagonal, etc. sub-diagonals are zero padded at the end. Alternatively gives \(A\) directly, i.e. a square matrix with \(2k-1\) non zero diagonals (those from the lower triangle are not accessed).

**Details**

Calls `dpbtrf` from LAPACK. The point of this is that it has \(O(k^2n)\) computational cost, rather than the \(O(n^3)\) required by dense matrix methods.

**Value**

Let \(R\) be the factor such that \(t(R) \%*\% R = A\). \(R\) is upper triangular and if the rows of \(B\) contained the diagonals of \(A\) on entry, then what is returned is an \(n \times k\) matrix containing the diagonals of \(R\), packed as \(B\) was packed on entry. If \(B\) was square on entry, then \(R\) is returned directly. See examples.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

```r
require(mgcv)
## simulate a banded diagonal matrix
n <- 7;set.seed(8)
A <- matrix(0,n,n)
sdiag(A) <- runif(n);sdiag(A,1) <- runif(n-1)
sdiag(A,2) <- runif(n-2)
A <- crossprod(A)

## full matrix form...
bandchol(A)
chol(A) ## for comparison

## compact storage form...
B <- matrix(0,3,n)
B[1,] <- sdiag(A);B[2,1:(n-1)] <- sdiag(A,1)
B[3,1:(n-2)] <- sdiag(A,2)
bandchol(B)
```

**betar**  
*GAM beta regression family*

**Description**

Family for use with *gam* or *bam*, implementing regression for beta distributed data on (0,1). A linear predictor controls the mean, $\mu$ of the beta distribution, while the variance is then $\mu(1 - \mu)/(1 + \phi)$, with parameter $\phi$ being estimated during fitting, alongside the smoothing parameters.

**Usage**

```r
betar(theta = NULL, link = "logit", eps=.Machine$double.eps*100)
```

**Arguments**

- `theta`  
  the extra parameter ($\phi$ above).

- `link`  
  The link function: one of "logit", "probit", "cloglog" and "cauchit".

- `eps`  
  the response variable will be truncated to the interval [eps, 1-eps] if there are values outside this range. This truncation is not entirely benign, but too small a value of eps will cause stability problems if there are zeroes or ones in the response.

**Details**

These models are useful for proportions data which can not be modelled as binomial. Note the assumption that data are in (0,1), despite the fact that for some parameter values 0 and 1 are perfectly legitimate observations. The restriction is needed to keep the log likelihood bounded for all parameter values. Any data exactly at 0 or 1 are reset to be just above 0 or just below 1 using the eps argument (in fact any observation <eps is reset to eps and any observation >1-eps is reset to 1-eps). Note the effect of this resetting. If $\mu \phi > 1$ then impossible 0s are replaced with highly improbable eps values. If the inequality is reversed then 0s with infinite probability density are replaced with eps values having high finite probability density. The equivalent condition for 1s is...
(1 − μ)φ > 1. Clearly all types of resetting are somewhat unsatisfactory, and care is needed if data contain 0s or 1s (often it makes sense to manually reset the 0s and 1s in a manner that somehow reflects the sampling setup).

**Value**

An object of class `extended.family`.

**WARNINGS**

Do read the details section if your data contain 0s and or 1s.

**Author(s)**

Natalya Pya (nat.pya@gmail.com) and Simon Wood (s.wood@r-project.org)

**Examples**

```r
library(mgcv)
## Simulate some beta data...
set.seed(3);n<400
dat <- gamSim(1,n=n)
mu <- binomial(linkinv(dat$f/4-2))
phi <- .5
a <- mu*phi;b <- phi - a;
dat$y <- rbeta(n,a,b)

bm <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=betar(link="logit"),data=dat)

bm
plot(bm,pages=1)
```

**blas.thread.test**

**BLAS thread safety**

**Description**

Most BLAS implementations are thread safe, but some versions of OpenBLAS, for example, are not. This routine is a diagnostic helper function, which you will never need if you don’t set `nthreads>1`, and even then are unlikely to need.

**Usage**

```r
blas.thread.test(n=1000,nt=4)
```

**Arguments**

- `n`: Number of iterations to run of parallel BLAS calling code.
- `nt`: Number of parallel threads to use
Details

While single threaded OpenBLAS 0.2.20 was thread safe, versions 0.3.0-0.3.6 are not, and from version 0.3.7 thread safety of the single threaded OpenBLAS requires making it with the option USE_LOCKING=1. The reference BLAS is thread safe, as are MKL and ATLAS. This routine repeatedly calls the BLAS from multi-threaded code and is sufficient to detect the problem in single threaded OpenBLAS 0.3.x.

A multi-threaded BLAS is often no faster than a single-threaded BLAS, while judicious use of threading in the code where the BLAS can still deliver a modest speed improvement. For this reason it is often better to use a single threaded BLAS and the codethreads options to bam or gam. For bam(.,.,discrete=TRUE) using several threads can be a substantial benefit, especially with the reference BLAS.

The MKL BLAS is multi-threaded by default. Under linux setting environment variable MKL_NUM_THREADS=1 before starting R gives single threaded operation.

Simon N. Wood <simon.wood@r-project.org>

Description

mgcv works largely because many people have reported bugs over the years. If you find something that looks like a bug, please report it, so that the package can be improved. mgcv does not have a large development budget, so it is a big help if bug reports follow the following guidelines.

The ideal report consists of an email to <simon.wood@r-project.org> with a subject line including mgcv somewhere, containing

1. The results of running sessionInfo in the R session where the problem occurs. This provides platform details, R and package version numbers, etc.
3. Short cut and paste-able code that produces the problem, including the code for loading/generating the data (using standard R functions like load, read.table etc).
4. Any required data files. If you send real data it will only be used for the purposes of debugging.

Of course if you have dug deeper and have an idea of what is causing the problem, that is also helpful to know, as is any suggested code fix. (Don't send a fixed package .tar.gz file, however - I can’t use this).

Author(s)

Simon N. Wood <simon.wood@r-project.org>
**choldrop**  
*Deletion and rank one Cholesky factor update*

**Description**

Given a Cholesky factor, $R$, of a matrix, $A$, choldrop finds the Cholesky factor of $A[-k,-k]$, where $k$ is an integer. cholup finds the factor of $A + uu^T$ (update) or $A - uu^T$ (downdate).

**Usage**

choldrop(R, k)
cholup(R, u, up)

**Arguments**

- `R` Cholesky factor of a matrix, $A$.
- `k` row and column of $A$ to drop.
- `u` vector defining rank one update.
- `up` if TRUE compute update, otherwise downdate.

**Details**

First consider choldrop. If $R$ is upper triangular then $t(R[-k],[-k])%*%R[-k] == A[-k,-k]$, but $R[-k]$ has elements on the first sub-diagonal, from its kth column onwards. To get from this to a triangular Cholesky factor of $A[-k,-k]$ we can apply a sequence of Givens rotations from the left to eliminate the sub-diagonal elements. The routine does this. If $R$ is a lower triangular factor then Givens rotations from the right are needed to remove the extra elements. If $n$ is the dimension of $R$ then the update has $O(n^2)$ computational cost.

cholup (which assumes $R$ is upper triangular) updates based on the observation that $R^T R + uu^T = [u, R^T]^T[0, R_1^T]^T$, where $R_1$ is the modified factor. $Q$ is constructed from a sequence of Givens rotations in order to zero the elements of $u$. Downdating is similar except that hyperbolic rotations have to be used in place of Givens rotations — see Golub and van Loan (2013, section 6.5.4) for details. Downdating only works if $A - uu^T$ is positive definite. Again the computational cost is $O(n^2)$.

Note that the updates are vector oriented, and are hence not susceptible to speed up by use of an optimized BLAS. The updates are set up to be relatively Cache friendly, in that in the upper triangular case successive Givens rotations are stored for sequential application column-wise, rather than being applied row-wise as soon as they are computed. Even so, the upper triangular update is slightly slower than the lower triangular update.

choose.k

Basis dimension choice for smooths

Description

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size, \( k \). When setting up models in the mgcv package, using s or te terms in a model formula, \( k \) must be chosen: the defaults are essentially arbitrary.

In practice \( k>1 \) (or \( k \)) sets the upper limit on the degrees of freedom associated with an \( s \) smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For te smooths the upper limit of the degrees of freedom is given by the product of the \( k \) values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the \( fx=TRUE \) option, in which case it is unpenalized.

So, exact choice of \( k \) is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

Examples

```r
require(mgcv)
set.seed(0)
n <- 6
A <- crossprod(matrix(runif(n*n),n,n))
R0 <- chol(A)
k <- 3
Rd <- choldrop(R0,k)
range(Rd-chol(A[-k,-k]))
Rd;chol(A[-k,-k])

## same but using lower triangular factor A = LL'
L <- t(R0)
Ld <- choldrop(L,k)
range(Ld-t(chol(A[-k,-k])))
Ld;t(chol(A[-k,-k]))

## Rank one update example
u <- runif(n)
R <- cholup(R0,u,TRUE)
Ru <- chol(A+u %*% t(u)) # direct for comparison
R;Ru
range(R-Ru)

## Downdate - just going back from R to R0
Rd <- cholup(R,u,FALSE)
R0;Rd
range(R-Ru)
```
As with all model assumptions, it is useful to be able to check the choice of k informally. If the effective degrees of freedom for a model term are estimated to be much less than k-1 then this is unlikely to be very worthwhile, but as the EDF approach k-1, checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased k to see if there is pattern in the residuals that could potentially be explained by increasing k. Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect k and refit the original model. If there are no statistically important changes as a result of doing this, then k was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when k is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

`gam.check` runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which k is too low. Grossly too small k will also be visible from partial residuals available with `plot.gam`.

One scenario that can cause confusion is this: a model is fitted with k=10 for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with k=20 and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with k=20 contains a larger subspace of functions with EDF 8.7 than did the function space with k=10: one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

b
## edf substantially up, -ve REML substantially down
Reduced version of Columbus OH crime data

Description

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

Usage

data(columb)
data(columb.polys)

Format

columb is a 49 row data frame with the following columns

   area  land area of district
   home.value  housing value in 1000USD.
   income  household income in 1000USD.
   crime  residential burglaries and auto thefts per 1000 households.
   open.space  measure of open space in district.
   district  code identifying district, and matching names(columb.polys).

columb.polys contains the polygons defining the areas in the format described below.

Details

The data frame columb relates to the districts whose boundaries are coded in columb.polys. columb.polys[i] is a 2 column matrix, containing the vertices of the polygons defining the boundary of the ith district. columb.polys[[2]] has an artificial hole inserted to illustrate how holes in districts can be specified. Different polygons defining the boundary of a district are separated by NA rows in columb.polys[[1]], and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). names(columb.polys) matches columb$district (order unimportant).

Source

The data are adapted from the columbus example in the spdep package, where the original source is given as:

concurvity

Examples

```r
## see ?mrf help files
```

### concurvity

GAM concurvity measures

#### Description

Produces summary measures of concurvity between `gam` components.

#### Usage

```r
concurvity(b, full=TRUE)
```

#### Arguments

- `b`: An object inheriting from class "gam".
- `full`: If `TRUE` then concurvity of each term with the whole of the rest of the model is considered. If `FALSE` then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered.

#### Details

Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term, \( f \), in the model can be decomposed into a part, \( g \), that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term's own space. If \( g \) makes up a large part of \( f \) then there is a concurvity problem. The indices used are all based on the square of \( \|g\|/\|f\| \), that is the ratio of the squared Euclidean norms of the vectors of \( f \) and \( g \) evaluated at the observed covariate values.

The three measures are as follows

- **worst**: This is the largest value that the square of \( \|g\|/\|f\| \) could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.
- **observed**: This just returns the value of the square of \( \|g\|/\|f\| \) according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.
- **estimate**: This is the squared F-norm of the basis for \( g \) divided by the F-norm of the basis for \( f \). It is a measure of the extent to which the \( f \) basis can be explained by the \( g \) basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.
**Value**

If `full=TRUE` a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If `full=FALSE` a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

**Examples**

```r
library(mgcv)
## simulate data with concurvity...
set.seed(8);n<-200
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
    (10 * x)^3 * (1 - x)^10
f2(x) <- sort(runif(n)) ## first covariate
## make covariate x a smooth function of t + noise...
x <- f2(x) + rnorm(n)*3
## simulate response dependent on t and x...
y <- sin(4*pi*t) + exp(x/20) + rnorm(n)*.3
## fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")
## assess concurvity between each term and 'rest of model'...
concurvity(b)
## ... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)
```

---

**cox.ph**  
**Additive Cox Proportional Hazard Model**

**Description**

The `cox.ph` family implements the Cox Proportional Hazards model with Peto’s correction for ties, optional stratification, and estimation by penalized partial likelihood maximization, for use with `gam`. In the model formula, event time is the response. Under stratification the response has two columns: time and a numeric index for stratum. The weights vector provides the censoring information (0 for censoring, 1 for event). `cox.ph` deals with the case in which each subject has one event/censoring time and one row of covariate values. When each subject has several time dependent covariates see `cox.pht`.

See example below for conditional logistic regression.
Usage

```r
cox.ph(link="identity")
```

Arguments

- **link**: currently (and possibly for ever) only "identity" supported.

Details

Used with `gam` to fit Cox Proportional Hazards models to survival data. The model formula will have event/censoring times on the left hand side and the linear predictor specification on the right hand side. Censoring information is provided by the `weights` argument to `gam`, with 1 indicating an event and 0 indicating censoring.

Stratification is possible, allowing for different baseline hazards in different strata. In that case the response has two columns: the first is event/censoring time and the second is a numeric stratum index. See below for an example.

Prediction from the fitted model object (using the `predict` method) with `type="response"` will predict on the survivor function scale. This requires evaluation times to be provided as well as covariates (see example). Also see example code below for extracting the cumulative baseline hazard/survival directly. The fitted.values stored in the model object are survival function estimates for each subject at their event/censoring time.

Deviance, martingale, score, or schoenfeld residuals can be extracted. See Klein and Moeschberger (2003) for descriptions. The score residuals are computed by strata. See the examples for simple PH assumption checks by plotting score residuals, and Klein and Moeschberger (2003, section 11.4) for details. Note that high correlation between terms can undermine these checks.

Estimation of model coefficients is by maximising the log-partial likelihood penalized by the smoothing penalties. See e.g. Hastie and Tibshirani, 1990, section 8.3. for the partial likelihood used (with Peto’s approximation for ties), but note that optimization of the partial likelihood does not follow Hastie and Tibshirani. See Klein and Moeschberger (2003) for estimation of residuals, the cumulative baseline hazard, survival function and associated standard errors (the survival standard error expression has a typo).

The percentage deviance explained reported for Cox PH models is based on the sum of squares of the deviance residuals, as the model deviance, and the sum of squares of the deviance residuals when the covariate effects are set to zero, as the null deviance. The same baseline hazard estimate is used for both.

This family deals efficiently with the case in which each subject has one event/censoring time and one row of covariate values. For studies in which there are multiple time varying covariate measures for each subject then the equivalent Poisson model should be fitted to suitable pseudodata using `bam(..., discrete=TRUE)`. See `cox.pht`
Value

An object inheriting from class `general.family`.

Additive Cox proportional hazard models with time varying covariates

Description

The `cox.ph` family only allows one set of covariate values per subject. If each subject has several
time varying covariate measurements then it is still possible to fit a proportional hazards regression
model, via an equivalent Poisson model. The recipe is provided by Whitehead (1980) and is equally valid in the smooth additive case. Its drawback is that the equivalent Poisson dataset can be quite large.

The trick is to generate an artificial Poisson observation for each subject in the risk set at each non-censored event time. The corresponding covariate values for each subject are whatever they are at the event time, while the Poisson response is zero for all subjects except those experiencing the event at that time (this corresponds to Peto’s correction for ties). The linear predictor for the model must include an intercept for each event time (the cumulative sum of the exponential of these is the Breslow estimate of the baseline hazard).

Below is some example code employing this trick for the pbcseq data from the survival package. It uses bam for fitting with the discrete=TRUE option for efficiency: there is some approximation involved in doing this, and the exact equivalent to what is done in cox.ph is rather obtained by using gam with method="REML" (taking some 14 times the computational time for the example below).

The function tdpois in the example code uses crude piecewise constant interpolation for the covariates, in which the covariate value at an event time is taken to be whatever it was the previous time that it was measured. Obviously more sophisticated interpolation schemes might be preferable.

Examples

require(mgcv);require(survival)

## First define functions for producing Poisson model data frame

app <- function(x,t,to) {
  ## wrapper to approx for calling from apply...
  y <- if (sum(!is.na(x))<1) rep(NA,length(to)) else
    approx(t,x,to,method="constant",rule=2)$y
  if (is.factor(x)) factor(levels(x)[y],levels=levels(x)) else y
} ## app

tdpois <- function(dat,event="z",et="futime",t="day",status="status1", id="id") {
  ## dat is data frame. id is patient id; et is event time; t is observation time; status is 1 for death 0 otherwise; ## event is name for Poisson response.
  if (event %in% names(dat)) warning("event name in use")
  require(utils) ## for progress bar
  te <- sort(unique(dat[[et]][dat[[status]]==1])) ## event times
  sid <- unique(dat[[id]])
  inter <- interactive()
  if (inter) prg <- txtProgressBar(min = 0, max = length(sid), initial = 0,
    char = ",",width = NA, title="Progress", style = 3)
  ## create dataframe for poisson model data
  dat[[event]] <- 0; start <- 1
dap <- dat[rep(1:length(sid),length(te)),]
  for (i in 1:length(sid)) { ## work through patients
    di <- dat[dat[[id]]==sid[i],] ## ith patient's data
    tr <- te[te <= di[[et]][1]] ## times required for this patient
    ## Now do the interpolation of covariates to event times...
    um <- data.frame(lapply(X=di,FUN=app,t=di[[t]],to=tr))
}

Evaluate cyclic B spline basis

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.
Usage

cSplineDes(x, knots, ord = 4, derivs=0)

Arguments

  x  covariate values for smooth.
  knots  The knot locations: the range of these must include all the data.
  ord  order of the basis. 4 is a cubic spline basis. Must be >1.
  derivs  order of derivative of the spline to evaluate, between 0 and ord-1. Recycled to length of x.

Details

  The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

Value

  A matrix with length(x) rows and length(knots)-1 columns.

Author(s)

  Simon N. Wood <simon.wood@r-project.org>

  ## create some x's and knots...
  n <- 200
  x <- 0:(n-1)/(n-1);k<- 0:5/5
  X <- cSplineDes(x,k)  ## cyclic spline design matrix
  ## plot evaluated basis functions...
  plot(x,X[,1],type="l"); for (i in 2:5) lines(x,X[,i],col=i)
  ## check that the ends match up....
  ee <- X[1,]-X[n,];ee
tol <- .Machine$double.eps^.75
  if (all.equal(ee,ee*0,tolerance=tol)!=TRUE)
    stop("cyclic spline ends don't match!")

  ## similar with uneven data spacing...
  x <- sort(runif(n)) + 1  ## sorting just makes end checking easy
  k <- seq(min(x),max(x),length=8)  ## create knots
  X <- cSplineDes(x,k)  ## get cyclic spline model matrix
  plot(x,X[,1],type="l"); for (i in 2:ncol(X)) lines(x,X[,i],col=i)
  ee <- X[1,]-X[n,];ee  ## do ends match??
tol <- .Machine$double.eps^.75
  if (all.equal(ee,ee*0,tolerance=tol)!=TRUE)
    stop("cyclic spline ends don't match!")
dDeta

Description

INTERNAL function. Distribution families provide derivatives of the deviance and link w.r.t. $\mu = \text{inv\_link}(\eta)$. This routine converts these to the required derivatives of the deviance w.r.t. $\eta$, the linear predictor.

Usage

dDeta(y, mu, wt, theta, fam, deriv = 0)

Arguments

- **y**: vector of observations.
- **mu**: if $\eta$ is the linear predictor, $\mu = \text{inv\_link}(\eta)$. In a traditional GAM $\mu = \text{E}(y)$.
- **wt**: vector of weights.
- **theta**: vector of family parameters that are not regression coefficients (e.g. scale parameters).
- **fam**: the family object.
- **deriv**: the order of derivative of the smoothing parameter score required.

Value

A list of derivatives.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

exclude.too.far

Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for vis.gam and plot.gam.

Usage

exclude.too.far(g1,g2,d1,d2,dist)
Arguments

g1 co-ordinates of grid relative to first axis.
g2 co-ordinates of grid relative to second axis.
d1 co-ordinates of data relative to first axis.
d2 co-ordinates of data relative to second axis.
dist how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and dist is a distance within this unit square.

Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in g1 and g2 lies exactly in the unit square (i.e. on [0,1] by [0,1]). These scalings are applied to g1, g2, d1 and d2. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than dist the corresponding entry in the returned array is set to TRUE (otherwise to FALSE). The distance calculations are performed in compiled code for speed without storage overheads.

Value

A logical array with TRUE indicating a node in the grid defined by g1, g2 that is 'too far' from any datum.

plot(gx[!tf],gy[!tf],pch=".");points(x,y,col=2)
**extract.lme.cov**  
*Extract the data covariance matrix from an lme object*

**Description**

This is a service routine for **gamm**. Extracts the estimated covariance matrix of the data from an **lme** object, allowing the user control about which levels of random effects to include in this calculation. **extract.lme.cov** forms the full matrix explicitly: **extract.lme.cov2** tries to be more economical than this.

**Usage**

```
extract.lme.cov(b, data = NULL, start.level = 1)
extract.lme.cov2(b, data = NULL, start.level = 1)
```

**Arguments**

- `b`  
  A fitted model object returned by a call to **lme**.
- `data`  
  The data frame/ model frame that was supplied to **lme**, but with any rows removed by the na action dropped. Uses the data stored in the model object if not supplied.
- `start.level`  
  The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.

**Details**

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extracts that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The **extract.lme.cov** calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. **extract.lme.cov2** is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

**gamm** uses **extract.lme.cov2**.

**extract.lme.cov** does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. **extract.lme.cov2** does deal with this situation.

**Value**

For **extract.lme.cov** an estimated covariance matrix.

For **extract.lme.cov2** a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

extract.lme.cov2(b)

Description
As well as the standard families documented in family (see also glm) which can be used with functions gam, bam and gamm, mgcv also supplies some extra families, most of which are currently only usable with gam, although some can also be used with bam. These are described here.

Details
The following families are in the exponential family given the value of a single parameter. They are usable with all modelling functions.

- **Tweedie** An exponential family distribution for which the variance of the response is given by the mean response to the power p. p is in (1,2) and must be supplied. Alternatively, see tw to estimate p (gam only).
- **negbin** The negative binomial. Alternatively see nb to estimate the theta parameter of the negative binomial (gam only).
The following families are for regression type models dependent on a single linear predictor, and with a log likelihood which is a sum of independent terms, each corresponding to a single response observation. Usable with \texttt{gam}, with smoothing parameter estimation by "REML" or "ML" (the latter does not integrate the unpenalized and parameteric effects out of the marginal likelihood optimized for the smoothing parameters). Also usable with \texttt{bam}.

- \texttt{ocat} for ordered categorical data.
- \texttt{tw} for Tweedie distributed data, when the power parameter relating the variance to the mean is to be estimated.
- \texttt{nb} for negative binomial data when the \texttt{theta} parameter is to be estimated.
- \texttt{betar} for proportions data on (0,1) when the binomial is not appropriate.
- \texttt{scat} scaled t for heavy tailed data that would otherwise be modelled as Gaussian.
- \texttt{zip} for zero inflated Poisson data, when the zero inflation rate depends simply on the Poisson mean.

The following families implement more general model classes. Usable only with \texttt{gam} and only with \texttt{REML} smoothing parameter estimation.

- \texttt{cox.ph} the Cox Proportional Hazards model for survival data.
- \texttt{gammals} a gamma location-scale model, where the mean and standard deviation are modelled with separate linear predictors.
- \texttt{gaulss} a Gaussian location-scale model where the mean and the standard deviation are both modelled using smooth linear predictors.
- \texttt{gevlss} a generalized extreme value (GEV) model where the location, scale and shape parameters are each modelled using a linear predictor.
- \texttt{gumbls} a Gumbel location-scale model (2 linear predictors).
- \texttt{shash} Sinh-arcsinh location scale and shape model family (4 linear predictors).
- \texttt{ziplss} a ‘two-stage’ zero inflated Poisson model, in which ‘potential-presence’ is modelled with one linear predictor, and Poisson mean abundance given potential presence is modelled with a second linear predictor.
- \texttt{mvn}: multivariate normal additive models.
- \texttt{multinom}: multinomial logistic regression, for unordered categorical responses.

**FFdes**  
*Level 5 fractional factorial designs*

### Description

Computes level 5 fractional factorial designs for up to 120 factors using the algorithm of Sanchez and Sanchez (2005), and optionally central composite designs.

### Usage

```r
FFdes(size=5, ccd=FALSE)
```

### Arguments

- `size`: number of factors up to 120.
- `ccd`: if `TRUE`, adds points along each axis at the same distance from the origin as the points in the fractional factorial design, to create the outer points of a central composite design. Add central points to complete.

### Details

Basically a translation of the code provided in the appendix of Sanchez and Sanchez (2005).

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

### References

### Examples

```r
require(mgcv)
plot(rbind(0,FFdes(2,TRUE)),xlab="x",ylab="y", col=c(2,1,1,1,4,4,4,4),pch=19,main="CCD")
FFdes(5)
FFdes(5,TRUE)
```

**fix.family.link**  
*Modify families for use in GAM fitting and checking*

### Description

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.
Usage

fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)

Arguments

fam A family.

Details

Consider the first 3 function first. Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions dvar, d2var, d3var, d2link, d3link, d4link and for RE/ML ls, then these functions simply return the family unmodified: this allows non-standard links to be used with gam when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then d4link and d3var can be dummy, as they are ignored. Similarly ls is only needed for RE/ML.

The dvar function is a function of a mean vector, mu, and returns a vector of corresponding first derivatives of the family variance function. The d2link function is also a function of a vector of mean values, mu: it returns a vector of second derivatives of the link, evaluated at mu. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a dvar and d2var, function if your family only requires links that occur in one of the standard families.

The second two functions are useful for investigating the distribution of residuals and are used by qq.gam. If possible the functions add quantile (qf) or random deviate (rd) generating functions to the family. If a family already has qf or rd functions then it is left unmodified. qf functions are only available for some families, and for quasi families neither type of function is available.

Value

A family object with extra component functions dvar, d2var, d2link, d3link, d4link, ls, and possibly qf and rd, depending on which functions are called. fix.family.var also adds a variable scale set to negative to indicate that family has a free scale parameter.

gam.fit3, qq.gam
**Description**

Identifies columns of a matrix $X_2$ which are linearly dependent on columns of a matrix $X_1$. Primarily of use in setting up identifiability constraints for nested GAMs.

**Usage**

```r
fixDependence(X1, X2, tol = .Machine$double.eps^.5, rank.def = 0, strict = FALSE)
```

**Arguments**

- **X1**: A matrix.
- **X2**: A matrix, the columns of which may be partially linearly dependent on the columns of $X_1$.
- **tol**: The tolerance to use when assessing linear dependence.
- **rank.def**: If the degree of rank deficiency in $X_2$, given $X_1$, is known, then it can be supplied here, and tol is then ignored. Unused unless positive and not greater than the number of columns in $X_2$.
- **strict**: if TRUE then only columns individually dependent on $X_1$ are detected, if FALSE then enough columns to make the reduced $X_2$ full rank and independent of $X_1$ are detected.

**Details**

The algorithm uses a simple approach based on QR decomposition: see Wood (2017, section 5.6.3) for details.

**Value**

A vector of the columns of $X_2$ which are linearly dependent on columns of $X_1$ (or which need to be deleted to achieve independence and full rank if strict==FALSE). NULL if the two matrices are independent.

Examples

```r
library(mgcv)
n<-20;c1<-4;c2<-7
X1<-matrix(runif(n*c1),n,c1)
X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
fixDependence(X1,X2,strict=TRUE)
```

**Description**

Description of `gam` formula (see Details), and how to extract it from a fitted `gam` object.

**Usage**

```r
## S3 method for class 'gam'
formula(x,...)
```

**Arguments**

- `x` fitted model objects of class `gam` (see `gamObject`) as produced by `gam()`.
- `...` un-used in this case

**Details**

`gam` will accept a formula or, with some families, a list of formulae. Other mgcv modelling functions will not accept a list. The list form provides a mechanism for specifying several linear predictors, and allows these to share terms: see below.

The formulae supplied to `gam` are exactly like those supplied to `glm` except that smooth terms, `s`, `te`, `ti` and `t2` can be added to the right hand side (and `.` is not supported in `gam` formulae).

Smooth terms are specified by expressions of the form:

```r
s(x1,x2,...,k=12,fx=FALSE,bs="tp",by=z,id=1)
```

where `x1`, `x2`, etc. are the covariates which the smooth is a function of, and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for `k`, but if not informal checking is easy: see `choose.k` and `gam.check`.

`fx` is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by `k` (almost always `k-1`). `bs` indicates the basis to use for the smooth: the built in options are described in `smooth.terms`, and user defined smooths can be added (see `user.defined.smooth`). If `bs` is not supplied then the default "tp" (tprs) basis is used. by can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x,by=z))` would specify a model `E(y) = f(x)z` where `f(·)` is a smooth function. The by option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for ‘varying coefficient models’: see `gam.models`. id is
used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:
\( \text{te}(x,z,bs=c("tp","tp"),m=c(2,3),k=c(5,10)) \)
which would specify a tensor product smooth of the two covariates \( x \) and \( z \) constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. te provides further information.

\( \text{ti} \) terms are a variant designed to be used as interaction terms when the main effects (and any lower order interactions) are present. \( \text{t2} \) produces tensor product smooths that are the natural low rank analogue of smoothing spline anova models.

\( \text{s} \), \( \text{te} \), \( \text{ti} \) and \( \text{t2} \) terms accept an \( \text{sp} \) argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If \( \text{sp} \) is supplied then it over-rides whatever is in the \( \text{sp} \) argument to \( \text{gam} \), if it is not supplied then it defaults to all negative, but does not over-ride the \( \text{sp} \) argument to \( \text{gam} \).

Formulae can involve nested or “overlapping” terms such as
\( y = s(x) + s(z) + s(x,z) \) or \( y = s(x,z) + s(z,v) \)
but nested models should really be set up using \( \text{ti} \) terms: see \( \text{gam.side} \) for further details and examples.

Smooth terms in a \( \text{gam} \) formula will accept matrix arguments as covariates (and corresponding by variable), in which case a ‘summation convention’ is invoked. Consider the example of \( s(X,Z,by=L) \) where \( X \), \( Z \) and \( L \) are n by m matrices. Let \( F \) be the n by m matrix that results from evaluating the smooth at the values in \( X \) and \( Z \). Then the contribution to the linear predictor from the term will be \( \text{rowSums}(F*L) \) (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see \( \text{linear.functional.terms} \) for more information and examples (including functional linear models/signal regression).

Note that \( \text{gam} \) allows any term in the model formula to be penalized (possibly by multiple penalties), via the \( \text{paraPen} \) argument. See \( \text{gam.models} \) for details and example code.

When several formulae are provided in a list, then they can be used to specify multiple linear predictors for families for which this makes sense (e.g. \( \text{mvn} \)). The first formula in the list must include a response variable, but later formulae need not (depending on the requirements of the family). Let the linear predictors be indexed, 1 to d where d is the number of linear predictors, and the indexing is in the order in which the formulae appear in the list. It is possible to supply extra formulae specifying that several linear predictors should share some terms. To do this a formula is supplied in which the response is replaced by numbers specifying the indices of the linear predictors which will share the terms specified on the r.h.s. For example 1+3 ~ s(x)+z-1 specifies that linear predictors 1 and 3 will share the terms \( s(x) \) and \( z \) (but we don’t want an extra intercept, as this would usually be unidentifiable). Note that it is possible that a linear predictor only includes shared terms: it must still have its own formula, but the r.h.s. would simply be -1 (e.g. \( y \sim -1 \) or \( -1 \)).

Value

Returns the model formula, \( x\$\text{formula} \). Provided so that anova methods print an appropriate description of the model.

WARNING

A \( \text{gam} \) formula should not refer to variables using e.g. \( \text{dat}["x"] \).

formXtViX

**Description**

This is a service routine for `gamm`. Given, \( V \), an estimated covariance matrix obtained using `extract.lme.cov2` this routine forms a matrix square root of \( X^T V^{-1} X \) as efficiently as possible, given the structure of \( V \) (usually sparse).

**Usage**

`formXtViX(V, X)`

**Arguments**

- \( V \) A data covariance matrix list returned from `extract.lme.cov2`
- \( X \) A model matrix.

**Details**

The covariance matrix returned by `extract.lme.cov2` may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix, \( R \) such that `crossprod(R)` gives \( X^T V^{-1} X \).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

fs.test  
*FELSPLINE test function*

Description

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

Usage

```r
fs.test(x,y,r0=.1,r=.5,l=3,b=1,exclude=TRUE)
fs.boundary(r0=.1,r=.5,l=3,n.theta=20)
```

Arguments

- `x, y` Points at which to evaluate the test function.
- `r0` The test domain is a sort of bent sausage. This is the radius of the inner bend.
- `r` The radius of the curve at the centre of the sausage.
- `l` The length of an arm of the sausage.
- `b` The rate at which the function increases per unit increase in distance along the centre line of the sausage.
- `exclude` Should exterior points be set to `NA`?
- `n.theta` How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve.

Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

Value

`fs.test` returns function evaluations, or NAs for points outside the boundary. `fs.boundary` returns a list of `x, y` points to be jointed up in order to define/draw the boundary.

Author(s)

Simon N. Wood <simon.wood@r-project.org>
References

Examples

```r
require(mgcv)
## plot the function, and its boundary...
fsb <- fs.boundary()
m<-300;n<-150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsb$x,fsb$y,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```

full.score  

GCV/UBRE score for use within nlm

Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters.

This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the the outer method is "nlm.fd" (see `gam` argument optimizer).

Usage

```r
full.score(sp,G,family,control,gamma,...)
```

Arguments

- `sp`  
The logs of the smoothing parameters
- `G`  
a list returned by `mgcv:::gam.setup`
- `family`  
The family object for the GAM.
- `control`  
a list returned be `gam.control`
- `gamma`  
the degrees of freedom inflation factor (usually 1).
- `...`  
other arguments, typically for passing on to `gam.fit`.

Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by `gam.fit`.

Author(s)

Simon N. Wood <simon.wood@r-project.org>
Generalized additive models with integrated smoothness estimation

Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM and a variety of other models estimated by a quadratically penalised likelihood type approach (see `family.mgcv`). The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Confidence/credible intervals are readily available for any quantity predicted using a fitted model.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate), and users can add smooths. Linear functionals of smooths can also be included in models. For an overview of the smooths available see `smooth.terms`. For more on specifying models see `gam.models`, `random.effects` and `linear.functional.terms`. For more on model selection see `gam.selection`. Do read `gam.check` and `choose.k`.

See `gam` from package `gam`, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see `bam`, for mixed GAM see `gamm` and `random.effects`.

Usage

```r
gam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL, na.action, offset=NULL, method="GCV.Cp", optimizer=c("outer","newton"), control=list(), scale=0, select=FALSE, knots=NULL, sp=NULL, min.sp=NULL, H=NULL, gamma=1, fit=TRUE, paraPen=NULL, G=NULL, in.out, drop.unused.levels=TRUE, drop.intercept=NULL, discrete=FALSE, ...)```

Arguments

- **formula**: A GAM formula, or a list of formulae (see `formula.gam` and also `gam.models`). These are exactly like the formula for a GLM except that smooth terms, `s`, `te`, `ti` and `t2`, can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).
- **family**: This is a family object specifying the distribution and link to use in fitting etc (see `glm` and `family`). See `family.mgcv` for a full list of what is available, which goes well beyond exponential family. Note that quasi families actually result in the use of extended quasi-likelihood if method is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6).
- **data**: A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`: typically the environment from which `gam` is called.
- **weights**: prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to re-weight the contributions of each datum without...
changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. \texttt{weights <- weights/mean(weights)}).

\textbf{subset} an optional vector specifying a subset of observations to be used in the fitting process.

\textbf{na.action} a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.

\textbf{offset} Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in \texttt{formula} (this used to conform to the behaviour of \texttt{lm} and \texttt{glm}).

\textbf{control} A list of fit control parameters to replace defaults returned by \texttt{gam.control}. Values not set assume default values.

\textbf{method} The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Beyond the exponential family "REML" is the default, and the only other option is "ML".

\textbf{optimizer} An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by method). "perf" (deprecated) for performance iteration. "outer" for the more stable direct approach. "outer" can use several alternative optimizers, specified in the second element of optimizer: "newton" (default), "bfgs", "optim", "nlm" and "nlm.fd" (the latter is based entirely on finite differenced derivatives and is very slow). "efs" for the extended Fellner Schall method of Wood and Fasiolo (2017).

\textbf{scale} If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.

\textbf{select} If this is \texttt{TRUE} then \texttt{gam} can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding smoothing parameter is estimated as zero then the extra penalty has no effect. Use \texttt{gamma} to increase level of penalization.

\textbf{knots} this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the \texttt{k} value supplied (note that the number of knots is not always just \texttt{k}). See \texttt{tprs} for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

\textbf{sp} A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then \texttt{length(sp)} must correspond to the number of underlying smoothing parameters.

\textbf{min.sp} Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters \texttt{full.sp}, in the returned object, will need to be added to what is supplied here to get the smoothing parameters.
Actually multiplying the penalties. `length(min.sp)` should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).

A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.

gamma
Increase this beyond 1 to produce smoother models. `gamma` multiplies the effective degrees of freedom in the GCV or UBRE/AIC. `coden/gamma` can be viewed as an effective sample size in the GCV score, and this also enables it to be used with REML/ML. Ignored with P-RE/ML or the efs optimizer.

fit
If this argument is TRUE then `gam` sets up the model and fits it, but if it is FALSE then the model is set up and an object G containing what would be required to fit is returned is returned. See argument G.

paraPen
optional list specifying any penalties to be applied to parametric model terms. `gam.models` explains more.

G
Usually NULL, but may contain the object returned by a previous call to `gam` with fit=FALSE, in which case all other arguments are ignored except for sp, gamma, in.out, scale, control, method optimizer and fit.

in.out
optional list for initializing outer iteration. If supplied then this must contain two elements: sp should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); scale is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the the initial value of the scale parameter, if this is to be estimated by RE/ML.

drop.unused.levels
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

drop.intercept
Set to TRUE to force the model to really not have the a constant in the parametric model part, even with factor variables present. Can be vector when formula is a list.

discrete
experimental option for setting up models for use with discrete methods employed in `bam`. Do not modify.

Details
A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

\[ \log(E(y_i)) = \alpha + f_1(x_{1i}) + f_2(x_{2i}) \]

where the (independent) response variables \( y_i \sim \text{Poi} \), and \( f_1 \) and \( f_2 \) are smooth functions of covariates \( x_1 \) and \( x_2 \). The log is an example of a link function. Note that to be identifiable the model requires constraints on the smooth functions. By default these are imposed automatically and require that the function sums to zero over the observed covariate values (the presence of a metric by variable is the only case which usually suppresses this).
If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex over-fitting estimates of $f_1$ and $f_2$. For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggliness’. To control the trade-off between penalizing wiggliness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The mgcv implementation of gam represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

gam in mgcv solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE ) criterion

$$D/n + 2sDoF/n - s$$

where $D$ is the deviance, $n$ the number of data, $s$ the scale parameter and $DoF$ the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when $s$ is known.

Alternatives are GACV, or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice. The main computational challenge solved by the mgcv package is to optimize the smoothness selection criteria efficiently and reliably.

Broadly gam works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (design matrix) and a set of penalty matrices for the smooth terms. The linear identifiability constraints are also obtained at this point. The model is fit using gam.fit, gam.fit3 or variants, which are modifications of glm.fit. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Re-weighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is possible in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS step a working penalized linear model is estimated, and the smoothing parameter estimation can be performed for each such working model. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. This option is available in bam and gamm but is deprecated for gam (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and gam.fit3 or one of its variants is used in place of gam.fit. gam uses the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see smooth.terms for an overview and smooth.construct for how to add smooth classes). The choice of the basis dimension ($k$ in the s, te, ti and t2 terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by $k-1$ or occasionally $k$). Of course the $k$ should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).
Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in `linear.functional.terms`. `link{family.mgcv}` details what is available beyond GLMs and the exponential family.

Details of the default underlying fitting methods are given in Wood (2011 and 2004). Some alternative methods are discussed in Wood (2000 and 2006).

`gam()` is not a clone of Trevor Hastie’s original (as supplied in S-PLUS or package `gam`). The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te`, `ti` or `t2` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. (vii) Models beyond the exponential family are available. See `gam` from package `gam`, for GAMs via the original Hastie and Tibshirani approach.

**Value**

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn’t actually fit it. Otherwise the function returns an object of class "gam" as described in `gamObject`.

**WARNINGS**

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See `choose.k` and `gam.check`.

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

gam.check

Some diagnostics for a fitted gam model

Description

Takes a fitted gam object produced by gam() and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate. Care should be taken in interpreting the results when applied to gam objects returned by gamm.

Usage

gam.check(b, old.style=FALSE,
          type=c("deviance","pearson","response"),
          k.sample=5000, k.rep=200,
          rep=0, level=.9, r1.col=2, rep.col="gray80", ...)

Arguments

b a fitted gam object as produced by gam().
old.style If you want old fashioned plots, exactly as in Wood, 2006, set to TRUE.
type type of residuals, see residuals.gam, used in all plots.
k.sample Above this k testing uses a random sub-sample of data.
k.rep how many re-shuffles to do to get p-value for k testing.
rep, level, r1.col, rep.col arguments passed to qq.gam() when old.style is false, see there.
... extra graphics parameters to pass to plotting functions.
Details

Checking a fitted `gam` is like checking a fitted `glm`, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. `choose.k` provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the k-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled `k.rep` times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `k.sample` data, the tests are based of `k.sample` randomly sampled data. Low p-values may indicate that the basis dimension, `k`, has been set too low, especially if the reported edf is close to `k'`, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect `k` and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low `k`. See `choose.k` for fuller discussion.

The QQ plot produced is usually created by a call to `qq.gam`, and plots deviance residuals against approximate theoretical quantiles of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using `qq.gam`. Note that residuals for models fitted to binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

Take care when interpreting results from applying this function to a model fitted using `gamm`. In this case the returned `gam` object is based on the working model used for estimation, and will treat all the random effects as part of the error. This means that the residuals extracted from the `gam` object are not standardized for the family used or for the random effects or correlation structure. Usually it is necessary to produce your own residual checks based on consideration of the model structure you have used.

Value

A vector of reference quantiles for the residual distribution, if these can be computed.
gam.control

Setting GAM fitting defaults

This is an internal function of package mgcv which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see `gam` arguments `method` and `optimizer`.

Usage

```r
 gam.control(nthreads=1,irls.reg=0.0,epsilon = 1e-07,maxit = 200,
             mgcv.tol=1e-7,mgcv.half=15,trace = FALSE,
             rank.tol=.Machine$double.eps^0.5,nlm=list(),
             optim=list(),newton=list(),outerPIsteps=0,
             idLinksBases=TRUE,scalePenalty=TRUE,efs.lspmax=15,
             efs.tol=.1,keepData=FALSE, scale.est="fletcher",
             efs.tol=.1,keepData=FALSE, edge.correct=FALSE)
```

Arguments

- `nthreads` Some parts of some smoothing parameter selection methods (e.g. REML) can use some parallelization in the C code if your R installation supports openMP, and `nthreads` is set to more than 1. Note that it is usually better to use the number of physical cores here, rather than the number of hyper-threading cores.
For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and irls.reg is the size of the penalty.

epsilon
This is used for judging conversion of the GLM IRLS loop in gam.fit or gam.fit3.

maxit
Maximum number of IRLS iterations to perform.

mgcv.tol
The convergence tolerance parameter to use in GCV/UBRE optimization.

mgcv.half
If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.

trace
Set this to TRUE to turn on diagnostic output.

rank.tol
The tolerance used to estimate the rank of the fitting problem.

nlm
list of control parameters to pass to nlm if this is used for outer estimation of smoothing parameters (not default). See details.

optim
list of control parameters to pass to optim if this is used for outer estimation of smoothing parameters (not default). See details.

newton
list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.

outerPIsteps
The number of performance iteration steps used to initialize outer iteration.

idLinksBases
If smooth terms have their smoothing parameters linked via the id mechanism (see s), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set scalePenalty to FALSE as well in this case).

scalePenalty

gamm is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accommodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set idLinksBases to FALSE.

efs lspmax
maximum log smoothing parameters to allow under extended Fellner Schall smoothing parameter optimization.

efs.tol
change in REML to count as negligible when testing for EFS convergence. If the step is small and the last 3 steps led to a REML change smaller than this, then stop.

keepData
Should a copy of the original data argument be kept in the gam object? Strict compatibility with class glm would keep it, but it wastes space to do so.

scale.est
How to estimate the scale parameter for exponential family models estimated by outer iteration. See gam.scale.

edge.correct
With RE/ML smoothing parameter selection in gam using the default Newton RE/ML optimizer, it is possible to improve inference at the ‘completely smooth’ edge of the smoothing parameter space, by decreasing smoothing parameters until there is a small increase in the negative RE/ML (e.g. 0.02). Set to TRUE or to a number representing the target increase to use. Only changes the corrected smoothing parameter matrix, Vc.
Details

Outer iteration using `newton` is controlled by the list `newton` with the following elements: `conv.tol` (default 1e-6) is the relative convergence tolerance; `maxNstep` is the maximum length allowed for an element of the Newton search direction (default 5); `maxSstep` is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); `maxHalf` is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements: (i) `ndigit` is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`; (ii) `gradtol` is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to 10*`epsilon`; (iii) `stepmax` is the maximum allowable log smoothing parameter step - defaults to 2; (iv) `steptol` is the minimum allowable step length - defaults to 1e-4; (v) `iterlim` is the maximum number of optimization steps allowed - defaults to 200; (vi) `check.analyticals` indicates whether the built in exact derivative calculations should be checked numerically - defaults to `FALSE`. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value 1e7.

gam.convergence

GAM convergence and performance issues

Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The fitting methods used by `gam` opt for certainty of convergence over speed of fit. `bam` opts for speed.

`gam` uses a nested iteration method (see `gam.outer`), in which each trial set of smoothing parameters proposed by an outer Newton algorithm require an inner Newton algorithm (penalized iteratively re-weighted least squares, PIRLS) to find the corresponding best fit model coefficients. Implicit differentiation is used to find the derivatives of the coefficients with respect to log smoothing parameters, so that the derivatives of the smoothness selection criterion can be obtained, as required by the outer iteration. This approach is less expensive than it at first appears, since excellent starting
values for the inner iteration are available as soon as the smoothing parameters start to converge. See Wood (2011) and Wood, Pya and Saefken (2016).

**bam** uses an alternative approach similar to ‘performance iteration’ or ‘PQL’. A single PIRLS iteration is run to find the model coefficients. At each step this requires the estimation of a working penalized linear model. Smoothing parameter selection is applied directly to this working model at each step (as if it were a Gaussian additive model). This approach is more straightforward to code and in principle less costly than the nested approach. However it is not guaranteed to converge, since the smoothness selection criterion is changing at each iteration. It is sometimes possible for the algorithm to cycle around a small set of smoothing parameter, coefficient combinations without ever converging. **bam** includes some checks to limit this behaviour, and the further checks in the algorithm used by bam(..., discrete=TRUE) actually guarantee convergence in some cases, but in general guarantees are not possible. See Wood, Goude and Shaw (2015) and Wood et al. (2017).

**gam** when used with ‘general’ families (such as `multinom` or `cox.ph`) can also use a potentially faster scheme based on the extended Fellner-Schall method (Wood and Fasiolo, 2017). This also operates with a single iteration and is not guaranteed to converge, theoretically.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the "bfgs" method option in `gam` argument optimizer: this can be faster than the default. (ii) Try using `bam` (iii) For large datasets it may be worth changing the smoothing basis to use bs="cr" (see `s` for details) for 1-d smooths, and to use `te` smooths in place of `s` smooths for smooths of more than one variable. This is because the default thin plate regression spline basis "tp" is costly to set up for large datasets.

If you have convergence problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in `gam.control`, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the min.sp argument of `gam`: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.

Please report convergence problems, especially if you there is no obvious pathology in the data/model that suggests convergence should fail.

gam.fit

GAM P-IRLS estimation with GCV/UBRE smoothness estimation

Description

This is an internal function of package mgcv. It is a modification of the function glm.fit, designed to be called from gam when performance iteration is selected (not the default). The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine magic. For further information on usage see code for gam. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see gam.control). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

Usage

```r
 gam.fit(G, start = NULL, etastart = NULL,  
        mustart = NULL, family = gaussian(),  
        control = gam.control(), gamma=1,  
        fixedSteps=(control$maxit+1),...)  
```

Arguments

- **G**: An object of the type returned by `gam` when `fit=FALSE`.
- **start**: Initial values for the model coefficients.
- **etastart**: Initial values for the linear predictor.
- **mustart**: Initial values for the expected response.
- **family**: The family object, specifying the distribution and link to use.
- **control**: Control option list as returned by `gam.control`.
- **gamma**: Parameter which can be increased to up the cost of each effective degree of freedom in the GCV or AIC/UBRE objective.
- **fixedSteps**: How many steps to take: useful when only using this routine to get rough starting values for other methods.
- **...**: Other arguments: ignored.
Value
A list of fit information.

Gu and Wahba (1991) Minimizing GCV/GML scores with multiple smoothing parameters via the
Wood, S.N. (2000) Modelling and Smoothing Parameter Estimation with Multiple Quadratic Penal-

See Also
gam.fit3, gam, magic

Description
Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV,
GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme
used to estimate the model given smoothing parameters.
This routine estimates a GAM (any quadratically penalized GLM) given log smoothing paramaters,
and evaluates derivatives of the smoothness selection scores of the model with respect to the log
smoothing parameters. Calculation of exact derivatives is generally faster than approximating them
by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML
score minimization.
The approach is to run the P-IRLS to convergence, and only then to iterate for first and second
derivatives.
Not normally called directly, but rather service routines for gam.

Usage
```r
gam.fit3(x, y, sp, Eb, UrS=list(),
weights = rep(1, nobs), start = NULL, etastart = NULL,
mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
Mp = -1, family = gaussian(), control = gam.control(),
intercept = TRUE, deriv=2, gamma=1, scale=1,
printWarn=TRUE, scoreType="REML", null.coef=rep(0, ncol(x)),
pearson.extra=0, dev.extra=0, n.true=-1, S1=NULL,...)
```
Arguments

- **x**: The model matrix for the GAM (or any penalized GLM).
- **y**: The response variable.
- **sp**: The log smoothing parameters.
- **Eb**: A balanced version of the total penalty matrix: used for numerical rank determination.
- **UrS**: List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.
- **weights**: prior weights for fitting.
- **start**: optional starting parameter guesses.
- **etastart**: optional starting values for the linear predictor.
- **mustart**: optional starting values for the mean.
- **offset**: the model offset
- **U1**: An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.
- **Mp**: The dimension of the total penalty null space — required for ML smoothness estimation only.
- **family**: the family - actually this routine would never be called with `gaussian()`.
- **control**: control list as returned from `glm.control`.
- **intercept**: does the model have and intercept, TRUE or FALSE.
- **deriv**: Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.
- **gamma**: The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.
- **scale**: The scale parameter - needed for the UBRE/AIC score.
- **printWarn**: Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.
- **scoreType**: specifies smoothing parameter selection criterion to use.
- **null.coef**: coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.
- **pearson.extra**: Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.
- **dev.extra**: Extra component to add to deviance for REML/ML type smoothness selection criteria.
- **n.true**: Number of data to assume in smoothness selection criteria. <=0 indicates that it should be the number of rows of X.
- **Sl**: A smooth list suitable for passing to `gam.fit5`.
- **...**: Other arguments: ignored.
Details

This routine is basically \texttt{glm.fit} with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed 'outer' iteration.

Note that use of non-standard families with this routine requires modification of the families as described in \texttt{fix.family.link}.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

The routine has been modified from \texttt{glm.fit} in R 2.0.1, written by the R core (see \texttt{glm.fit} for further credits).

\---

\texttt{gam.fit5.post.proc} Post-processing output of \texttt{gam.fit5}

Description

INTERNAL function for post-processing the output of \texttt{gam.fit5}.

Usage

\texttt{gam.fit5.post.proc(object, Sl, L, lsp0, S, off)}
Arguments

- **object**: output of `gam.fit5`
- **S1**: penalty object, output of `S1.setup`
- **L**: matrix mapping the working smoothing parameters
- **lsp0**: log smoothing parameters
- **S**: penalty matrix
- **off**: vector of offsets

Value

A list containing:

- \( R \): unpivoted Choleski of estimated expected hessian of log-likelihood.
- \( V_b \): the Bayesian covariance matrix of the model parameters.
- \( V_e \): "frequentist" alternative to \( V_b \).
- \( V_c \): corrected covariance matrix.
- \( F \): matrix of effective degrees of freedom (EDF).
- \( \text{edf} \): \( \text{diag}(F) \).
- \( \text{edf2} \): \( \text{diag}(2F-FF) \).

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

Description

GAM coefficients can be simulated directly from the Gaussian approximation to the posterior for the coefficients, or using a simple Metropolis Hastings sampler. See also `ginla`.

Usage

```r
  gam.mh(b, ns=10000, burn=1000, t.df=40, rw.scale=.25, thin=1)
```

Arguments

- **b**: a fitted model object from `gam`, `bam` fits are not supported.
- **ns**: the number of samples to generate.
- **burn**: the length of any initial burn in period to discard (in addition to codens).
- **t.df**: degrees of freedom for static multivariate t proposal. Lower for heavier tailed proposals.
- **rw.scale**: Factor by which to scale posterior covariance matrix when generating random walk proposals. Negative or non finite to skip the random walk step.
- **thin**: retain only every thin samples.
Details

Posterior simulation is particularly useful for making inferences about non-linear functions of the model coefficients. Simulate random draws from the posterior, compute the function for each draw, and you have a draw from the posterior for the function. In many cases the Gaussian approximation to the posterior of the model coefficients is accurate, and samples generated from it can be treated as samples from the posterior for the coefficients. See example code below. This approach is computationally very efficient.

In other cases the Gaussian approximation can become poor. A typical example is in a spatial model with a log or logit link when there is a large area of observations containing only zeroes. In this case the linear predictor is poorly identified and the Gaussian approximation can become useless (an example is provided below). In that case it can sometimes be useful to simulate from the posterior using a Metropolis Hastings sampler. A simple approach alternates fixed proposals, based on the Gaussian approximation to the posterior, with random walk proposals, based on a shrunken version of the approximate posterior covariane matrix. `gam.mh` implements this. The fixed proposal often promotes rapid mixing, while the random walk component ensures that the chain does not become stuck in regions for which the fixed Gaussian proposal density is much lower than the posterior density.

The function reports the acceptance rate of the two types of step. If the random walk acceptance probability is higher than a quarter then `rw.step` should probably be increased. Similarly if the acceptance rate is too low, it should be decreased. The random walk steps can be turned off altogether (see above), but it is important to check the chains for stuck sections if this is done.

Value

A list containing the retained simulated coefficients in matrix `bs` and two entries for the acceptance probabilities.

## Gaussian approximation!
Specifically let $y_i$ denote an independent random variable with mean $\mu_i$ and an exponential family
distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood
methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = X_i \beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \ldots$$

where $g$ is a known smooth monotonic ‘link’ function, $X_i \beta$ is the parametric part of the linear
predictor, the $x_j$ are predictor variables, the $f_j$ are smooth functions and $L_i$ is some linear functional
of $f_3$. There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as
a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more
of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or
generalized linear models, but still has much more structure than the completely general model that
says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually
have to be constrained to have zero mean (usually taken over the set of covariate values). The
constraint is needed if the term involving the smooth includes a constant function in its span. *gam*
always applies such constraints unless there is a by variable present, in which case an assessment is
made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for *gam*. Specification of the distribution
and link function is done using the *family* argument to *gam* and works in the same way as for *glm*.
This page therefore concentrates on the model formula for *gam*.

**Models with simple smooth terms**

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables $y_i$ has expectation $\mu_i$ and $g$ is a link function.

The *gam* formula for this would be

$$y \sim x_1 + x_2 + s(x_3) + s(x_4, x_5).$$

This would use the default basis for the smooths (a thin plate regression spline basis for each), with
automatic selection of the effective degrees of freedom for both smooths. The dimension of the
smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on
the maximum possible degrees of freedom for the basis - the limit is typically one less than basis
dimension). Full details of how to control smooths are given in *s* and *te*, and further discussion of
basis dimension choice can be found in *choose.k*. For the moment suppose that we would like to
change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while
fixing the second term at 25 degrees of freedom. The appropriate formula would be:

$$y \sim x_1 + x_2 + s(x_3, bs="cr", k=20) + s(x_4, x_5, k=26, fx=TRUE).$$

The above assumes that $x_4$ and $x_5$ are naturally on similar scales (e.g. they might be co-ordinates),
so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing
might be better (see *te*).

$$y \sim x_1 + x_2 + s(x_3) + te(x_4, x_5)$$

would generate a tensor product smooth of $x_4$ and $x_5$. By default this smooth would have basis
dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

$$y \sim x_1 + x_2 + s(x_3) + te(x_4, x_5, bs=c("cr", "ps"), k=c(6,7))$$

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7
P-spline marginal to create a smooth with basis dimension 42.
Nested terms/functional ANOVA

Sometimes it is interesting to specify smooth models with a main effects + interaction structure such as

\[ E(y_i) = f_1(x_i) + f_2(z_i) + f_3(x_i, z_i) \]

or

\[ E(y_i) = f_1(x_i) + f_2(z_i) + f_3(v_i) + f_4(x_i, z_i) + f_5(z_i, v_i) + f_6(z_i, v_i) + f_7(x_i, z_i, v_i) \]

for example. Such models should be set up using `ti` terms in the model formula. For example:

\[ y \sim ti(x) + ti(z) + ti(x, z) \]

or

\[ y \sim ti(x) + ti(z) + ti(v) + ti(x, z) + ti(x, v) + ti(z, v) + ti(x, z, v) \]

The `ti` terms produce interactions with the component main effects excluded appropriately. (There is in fact no need to use `ti` terms for the main effects here, `s` terms could also be used.)

`gam` allows nesting (or ‘overlap’) of `te` and `s` smooths, and automatically generates side conditions to make such models identifiable, but the resulting models are much less stable and interpretable than those constructed using `ti` terms.

‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The `s` and `te` terms used to specify smooths accept an argument `by`, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a `by` variable is numeric, then its \(i^{th}\) element multiplies the \(i^{th}\) row of the model matrix corresponding to the smooth term concerned.

Factor smooth interactions (see also `factor.smooth.interaction`). If a `by` variable is a `factor` then it generates an indicator vector for each level of the factor, unless it is an `ordered` factor.

In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter). `ordered` by variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see `b3` example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor by variables.

As an example, consider the model

\[ E(y_i) = \beta_0 + f(x_i)z_i \]

where \(f\) is a smooth function, and \(z_i\) is a numeric variable. The appropriate formula is:

\[ y \sim s(x, by=z) \]

- the by argument ensures that the smooth function gets multiplied by covariate \(z\). Note that when using factor by variables, centering constraints are applied to the smooths, which usually means that the by variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor by variables.

by variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a `by` variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the by variable is a constant vector, or, (ii) for a matrix by variable, \(L\%*%\text{rep}(1,\text{ncol}(L))\) is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute "always.apply".
Linking smooths with ‘id’

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the id argument to s or te terms. Smooths which share an id will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an id have the same basis functions as the first smooth occurring with that id. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that \( E(y_i) = \mu_i \) and

\[
g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})
\]

but that \( f_1 \) and \( f_3 \) should have the same smoothing parameters (and \( x_2 \) and \( x_3 \) are on different scales). Then the gam formula

\[
y \sim s(x_1, id=1) + te(x_2, x_3) + s(x_4, id=1)
\]

would achieve the desired result. id can be numbers or character strings. Giving an id to a term with a factor by variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term ids are not supported by gamm.

Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in mgcv using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any by variable matrix must be of the same dimension. Consider, for example the term

\[
s(X,Z, by=L)
\]

where \( X, Z \) and \( L \) are \( n \times p \) matrices. Let \( f \) denote the thin plate regression spline specified. The resulting contribution to the \( i \)th element of the linear predictor is

\[
\sum_{j=1}^{p} L_{ij} f(X_{ij}, Z_{ij})
\]

If no \( L \) is supplied then all its elements are taken as 1. In R code terms, let \( F \) denote the \( n \times p \) matrix obtained by evaluating the smooth at the values in \( X \) and \( Z \). Then the contribution of the term to the linear predictor is rowSums(L*F) (note that it’s element by element multiplication here!).

The summation convention applies to te terms as well as s terms. More details and examples are provided in linear.functional.terms.

Random effects

Random effects can be added to gam models using s(...) terms (see smooth.construct.re.smooth.spec), or the paraPen argument to gam covered below. See gam.vcomp, random.effects and smooth.construct.re.smooth.spec for further details. An alternative is to use the approach of gamm.
Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, by variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, **gam** also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix $X$, and want to penalize the corresponding coefficients, $\beta$ with two penalties $\beta^T S_1 \beta$ and $\beta^T S_2 \beta$. Then something like the following would be appropriate:

```
    gam(y ~ X -1,paraPen=list(X=list(S1,S2)))
```

The `paraPen` argument should be a list with elements having names corresponding to the terms being penalized. Each element of `paraPen` is itself a list, with optional elements `L`, `rank` and `sp`: all other elements must be penalty matrices. If present, `rank` is a vector giving the rank of each penalty matrix (if absent this is determined numerically). `L` is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. `sp` is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of `paraPen` is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’ example below.

P-values for penalized parametric terms should be treated with caution. If you must have them, then use the option `freq=TRUE` in `anova.gam` and `summary.gam`, which will tend to give reasonable results for random effects implemented this way, but not for terms with a rank deficient penalty (or penalties with a wide eigen-spectrum).

gam.outer  

*Minimize GCV or UBRE score of a GAM using 'outer' iteration*

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using newton (default), bfgs, optim or nlm. Exact (first and second) derivatives of the score can be used by fitting with gam.fit3. This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for gam.

**Usage**

```
gam.outer(lsp, fscale, family, control, method, optimizer,
          criterion, scale, gamma, G, start=NULL, ...)
```

**Arguments**

- `lsp`  
The log smoothing parameters.
- `fscale`  
Typical scale of the GCV or UBRE/AIC score.
- `family`  
the model family.
- `control`  
control argument to pass to gam.fit if pure finite differencing is being used.
- `method`  
method argument to gam defining the smoothness criterion to use (but depending on whether or not scale known).
- `optimizer`  
The argument to gam defining the numerical optimization method to use.
- `criterion`  
Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".
- `scale`  
Supplied scale parameter. Positive indicates known.
- `gamma`  
The degree of freedom inflation factor for the GCV/UBRE/AIC score.
- `G`  
List produced by mgcv:::gam.setup, containing most of what's needed to actually fit a GAM.
- `start`  
starting parameter values.
- `...`  
other arguments, typically for passing on to gam.fit3 (ultimately).
Details

See Wood (2008) for full details on ‘outer iteration’.

gam.reparam  Finding stable orthogonal re-parameterization of the square root penalty.

Description

INTERNAL function for finding an orthogonal re-parameterization which avoids "dominant machine zero leakage" between components of the square root penalty.

Usage

gam.reparam(rS, lsp, deriv)

Arguments

rS  list of the square root penalties: last entry is root of fixed penalty, if fixed.penalty==TRUE (i.e. length(rS)>length(sp)). The assumption here is that rS[[i]] are in a null space of total penalty already; see e.g. totalPenaltySpace and mini.roots.
lsp  vector of log smoothing parameters.
deriv  if deriv==1 also the first derivative of the log-determinant of the penalty matrix is returned, if deriv>1 also the second derivative is returned.

Value

A list containing

- S: the total penalty matrix similarity transformed for stability.
- rS: the component square roots, transformed in the same way.
- Qs: the orthogonal transformation matrix $S = t(Qs) * S0 * Qs$, where S0 is the untransformed total penalty implied by sp and rS on input.
- det: log|S|.
- det1: dlog|S|/dlog(sp) if deriv >0.
- det2: hessian of log|S| wrt log(sp) if deriv>1.

Description
Scale parameter estimation in \texttt{gam} depends on the type of family. For extended families then the RE/ML estimate is used. For conventional exponential families, estimated by the default outer iteration, the scale estimator can be controlled using argument \texttt{scale.est} in \texttt{gam.control}. The options are "fletcher" (default), "pearson" or "deviance". The Pearson estimator is the (weighted) sum of squares of the pearson residuals, divided by the effective residual degrees of freedom. The Fletcher (2012) estimator is an improved version of the Pearson estimator. The deviance estimator simply substitutes deviance residuals for Pearson residuals.

Usually the Pearson estimator is recommended for GLMs, since it is asymptotically unbiased. However, it can also be unstable at finite sample sizes, if a few Pearson residuals are very large. For example, a very low Poisson mean with a non zero count can give a huge Pearson residual, even though the deviance residual is much more modest. The Fletcher (2012) estimator is designed to reduce these problems.

For performance iteration the Pearson estimator is always used.

\texttt{gamm} uses the estimate of the scale parameter from the underlying call to \texttt{lme}. \texttt{bam} uses the REML estimator if the method is "fREML". Otherwise the estimator is a Pearson estimator.

\texttt{gam.control}

Description
This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.
Smoothness selection criteria

Given a model structure specified by a gam model formula, gam() attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows’ Cp (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The method argument to gam selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these ‘flat’ regions can be separated from regions of lower score by a small ‘lip’. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see gam arguments method and optimizer) and see if the estimates change, or try changing some or all of the smoothing parameters ‘manually’ (argument sp of gam, or sp arguments to s or te).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as ‘completely smooth’ and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby ‘selected out’ of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes cs.smooth and tprs.smooth (specified by "cs" and "ts" respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively ‘completely smooth’ according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the ‘completely smooth’ functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The select argument to gam turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposiong the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as
the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be take to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

Interactive term selection

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated theta parameter is a special case: the GCV score is not informative, because of the theta estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by summary.gam, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

Caveats/platitudes

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn’t fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with ‘everything in’ and hoping that automatic selection will find the right structure is not often successful.

dat$x4 <- runif(n, 0, 1);dat$x5 <- runif(n, 0, 1) ## spurious
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3)+s(x4)+s(x5),data=dat,
family=poisson,select=TRUE,method="REML")
summary(b)
plot(b,pages=1)

Description
GAM formulae with repeated variables may only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from mgcv:::gam.setup and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

Usage
gam.side(sm,Xp,tol=.Machine$double.eps*.5,with.pen=FALSE)

Arguments
sm A list of smooth objects as returned by smooth.construct.
Xp The model matrix for the strictly parametric model components.
tol The tolerance to use when assessing linear dependence of smooths.
with.pen Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints.
Details

Models such as \( y = s(x) + s(z) + s(x, z) \) can be estimated by gam, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using fixDependence. This makes the routine rather general, and not dependent on any particular basis.

Xp is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute "del.index", listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

WARNINGS

Much better statistical stability will be obtained by using models like \( y = s(x) + s(z) + ti(x, z) \) or \( y = ti(x) + ti(z) + ti(x, z) \) rather than \( y = s(x) + s(z) + s(x, z) \), since the former are designed not to require further constraint.

gam.vcomp

Report gam smoothness estimates as variance components

Description

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

Usage

gam.vcomp(x,rescale=TRUE,conf.lev=.95)

Arguments

x a fitted model object of class gam as produced by gam().
rescale the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if TRUE this rescaling is reversed, so that the variance components are on the original scale.
conf.lev when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at.

Details

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term’s coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth’s coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for gam models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by gam in which random effects have been incorporated.
Value

Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

For models in which there are more smoothing parameters than actually estimated (e.g. if some were fixed, or smoothing parameters are linked) then a list is returned. The \( vc \) element is as above, the \( all \) element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

Objective functions for GAM smoothing parameter estimation

Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by optim or nlm. Not normally called directly, but rather service routines for gam.outer.

Usage

gam2objective(lsp, args,...)
gam2derivative(lsp, args, ...)

Arguments

lsp The log smoothing parameters.
args List of arguments required to call gam.fit3.
... Other arguments for passing to gam.fit3.

Details

gam2objective and gam2derivative are functions suitable for calling by optim, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.
gam4objective is an equivalent to gam2objective, suitable for optimization by nlm - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

**gamlss.etamu**  
*Transform derivatives wrt mu to derivatives wrt linear predictor*

**Description**

Mainly intended for internal use in specifying location scale models. Let \( g(mu) = lp \), where \( lp \) is the linear predictor, and \( g \) is the link function. Assume that we have calculated the derivatives of the log-likelihood wrt \( mu \). This function uses the chain rule to calculate the derivatives of the log-likelihood wrt \( lp \). See `trind.generator` for array packing conventions.

**Usage**

```r
gamlss.etamu(l1, l2, l3 = NULL, l4 = NULL, ig1, g2, g3 = NULL, g4 = NULL, i2, i3 = NULL, i4 = NULL, deriv = 0)
```

**Arguments**

- `l1`: array of 1st order derivatives of log-likelihood wrt mu.
- `l2`: array of 2nd order derivatives of log-likelihood wrt mu.
- `l3`: array of 3rd order derivatives of log-likelihood wrt mu.
- `l4`: array of 4th order derivatives of log-likelihood wrt mu.
- `ig1`: reciprocal of the first derivative of the link function wrt the linear predictor.
- `g2`: array containing the 2nd order derivative of the link function wrt the linear predictor.
- `g3`: array containing the 3rd order derivative of the link function wrt the linear predictor.
- `g4`: array containing the 4th order derivative of the link function wrt the linear predictor.
- `i2`: two-dimensional index array, such that \( l2[,i2[i,j]] \) contains the partial w.r.t. params indexed by \( i,j \) with no restriction on the index values (except that they are in \( 1,...,\text{ncol}(l1) \)).
- `i3`: third-dimensional index array, such that \( l3[,i3[i,j,k]] \) contains the partial w.r.t. params indexed by \( i,j,k \).
- `i4`: third-dimensional index array, such that \( l4[,i4[i,j,k,l]] \) contains the partial w.r.t. params indexed by \( i,j,k,l \).
- `deriv`: if \( \text{deriv}==0 \) only first and second order derivatives will be calculated. If \( \text{deriv}==1 \) the function goes up to 3rd order, and if \( \text{deriv}==2 \) it provides also 4th order derivatives.

**Value**

A list where the arrays \( l1, l2, l3, l4 \) contain the derivatives (up to order four) of the log-likelihood wrt the linear predictor.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>. 

...
gamlss.gH

Calculating derivatives of log-likelihood wrt regression coefficients

Description

Mainly intended for internal use with location scale model families. Given the derivatives of the log-likelihood wrt the linear predictor, this function obtains the derivatives and Hessian wrt the regression coefficients and derivatives of the Hessian w.r.t. the smoothing parameters. For input derivative array packing conventions see `trind.generator`.

Usage

```r
gamlss.gH(X, jj, l1, l2, i2, l3 = 0, i3 = 0, l4 = 0, i4 = 0, d1b = 0, d2b = 0, deriv = 0, fh = NULL, D = NULL)
```

Arguments

- **X**: matrix containing the model matrices of all the linear predictors.
- **jj**: list of index vectors such that `X[,jj[[i]]]` is the model matrix of the i-th linear predictor.
- **l1**: array of 1st order derivatives of each element of the log-likelihood wrt each parameter.
- **l2**: array of 2nd order derivatives of each element of the log-likelihood wrt each parameter.
- **i2**: two-dimensional index array, such that `l2[,i2[i,j]]` contains the partial w.r.t. params indexed by i,j with no restriction on the index values (except that they are in 1,...,ncol(l1)).
- **l3**: array of 3rd order derivatives of each element of the log-likelihood wrt each parameter.
- **i3**: third-dimensional index array, such that `l3[,i3[i,j,k]]` contains the partial w.r.t. params indexed by i,j,k.
- **l4**: array of 4th order derivatives of each element of the log-likelihood wrt each parameter.
- **i4**: third-dimensional index array, such that `l4[,i4[i,j,k,l]]` contains the partial w.r.t. params indexed by i,j,k,l.
- **d1b**: first derivatives of the regression coefficients wrt the smoothing parameters.
- **d2b**: second derivatives of the regression coefficients wrt the smoothing parameters.
- **deriv**: if `deriv==0` only first and second order derivatives will be calculated. If `deriv==1` the function return also the diagonal of the first derivative of the Hessian, if `deriv==2` it return the full 3rd order derivative and if `deriv==3` it provides also 4th order derivatives.
- **fh**: eigen-decomposition or Cholesky factor of the penalized Hessian.
- **D**: diagonal matrix, used to provide some scaling.

gamm

Generalized Additive Mixed Models

Description

Fits the specified generalized additive mixed model (GAMM) to data, by a call to lme in the normal errors identity link case, or by a call to gammPQL (a modification of glmmPQL from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than gam, and not quite as numerically robust.

To use lme4 in place of nlme as the underlying fitting engine, see gamm4 from package gamm4.

Smooths are specified as in a call to gam as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for lme are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of gam and lme.

Usage

gamm(formula, random=NULL, correlation=NULL, family=gaussian(), data=list(), weights=NULL, subset=NULL, na.action=knots=NULL, control=list(niterEM=0, optimMethod="L-BFGS-B", returnObject=TRUE), niterPQL=20, verbosePQL=TRUE, method="ML", drop.unused.levels=TRUE, mustart=NULL, etastart=NULL,...)

Arguments

formula

A GAM formula (see also formula.gam and gam.models). This is like the formula for a glm except that smooth terms (s, te etc.) can be added to the right hand side of the formula. Note that ids for smooths and fixed smoothing parameters are not supported. Any offset should be specified in the formula.
random  The (optional) random effects structure as specified in a call to \texttt{lme}: only the \texttt{list} form is allowed, to facilitate manipulation of the random effects structure within \texttt{gamm} in order to deal with smooth terms. See example below.

correlation  An optional \texttt{corStruct} object (see \texttt{corClasses}) as used to define correlation structures in \texttt{lme}. Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of \texttt{lme}). This is a GEE approach to correlation in the generalized case. See examples below.

family  A family as used in a call to \texttt{glm} or \texttt{gam}. The default gaussian with identity link causes \texttt{gamm} to fit by a direct call to \texttt{lme} provided there is no offset term, otherwise \texttt{gammPQL} is used.

data  A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from \texttt{environment(formula)}, typically the environment from which \texttt{gamm} is called.

weights  In the generalized case, weights with the same meaning as \texttt{glm} weights. An \texttt{lme} type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for \texttt{lme} for details of how to use such an argument).

subset  an optional vector specifying a subset of observations to be used in the fitting process.

na.action  a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.

knots  this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.

control  A list of fit control parameters for \texttt{lme} to replace the defaults returned by \texttt{lmeControl}. Note the setting for the number of EM iterations used by \texttt{lme}: smooths are set up using custom \texttt{pdMat} classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include \texttt{niterEM=0}, as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The \texttt{optimMethod} option is only used if your version of \texttt{R} does not have the \texttt{n1mnb} optimizer function.

\texttt{niterPQL}  Maximum number of PQL iterations (if any).

\texttt{verbosePQL}  Should PQL report its progress as it goes along?

\texttt{method}  Which of “ML” or “REML” to use in the Gaussian additive mixed model case when \texttt{lme} is called directly. Ignored in the generalized case (or if the model has an offset), in which case \texttt{gammPQL} is used.

\texttt{drop.unused.levels}  by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

\texttt{mustart}  starting values for mean if PQL used.

\texttt{etastart}  starting values for linear predictor if PQL used (over-rides \texttt{mustart} if supplied).

\texttt{...}  further arguments for passing on e.g. to \texttt{lme}
The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as lme. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in glmmPQL by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the nlme library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using lme or gammPQL in gamm can be found in Wood (2004,2006a,b). In addition gamm obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in gam, although adaptive smoothing bases are not available. Prediction from the returned gam object is straightforward using predict.gam, but this will set the random effects to zero. If you want to predict with random effects set to their predicted values then you can adapt the prediction code given in the examples below.

In the event of lme convergence failures, consider modifying options(mgcv.vc.logrange): reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See notExp2 for more information on this option. Failing that, you can try increasing the niterEM option in control: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of gamm works best with R 2.2.0 or above and nlme, 3.1-62 and above, since these use an improved optimizer.

Value

Returns a list with two items:

- **gam**: an object of class gam, less information relating to GCV/UBRE model selection. At present this contains enough information to use predict, summary and print methods and vis.gam, but not to use e.g. the anova method function to compare models. This is based on the working model when using gammPQL.

- **lme**: the fitted model object returned by lme or gammPQL. Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to lme and gammPQL are constructed.

WARNINGS

- gamm has a somewhat different argument list to gam, gam arguments such as gamma supplied to gamm will just be ignored.

- gamm performs poorly with binary data, since it uses PQL. It is better to use gam with s(...,bs="re") terms, or gamm4.
gamm assumes that you know what you are doing! For example, unlike glmPQL from MASS it will return the complete lme object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument random.

gamm is not as numerically stable as gam: an lme call will occasionally fail. See details section for suggestions, or try the ‘gamm4’ package.

gamm is usually much slower than gam, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see memory.limit).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the gam object part of the returned object is not complete in the sense of having all the elements defined in gamObject and does not inherit from glm: hence e.g. multi-model anova calls will not work. It is also based on the working model when PQL is used.

The parameterization used for the smoothing parameters in gamm, bounds them above and below by an effective infinity and effective zero. See notExp2 for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

gammals

Gamma location-scale model family

Description

The gammals family implements gamma location scale additive models in which the log of the mean and the log of the scale parameter (see details) can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae.

Usage

gammals(link=list("identity","log"),b=-7)
Arguments

link  two item list specifying the link for the mean and the standard deviation. See details for meaning which may not be intuitive.

b     The minumum log scale parameter.

Details

Used with gam to fit gamma location - scale models parameterized in terms of the log mean and the log scale parameter (the response variance is the mean multiplied by the scale parameter). Note that identity links mean that the linear predictors give the log mean and scale directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument b: if $\eta$ is the linear predictor for the log scale parameter, $\phi$, then $\log \phi = b + \log(1 + e^\eta)$.

gam is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the log mean on the right hand side. The second is one sided, specifying the linear predictor for the log scale on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean (on original, not log, scale), and the second column is the log scale. Predictions using predict.gam will also produce 2 column matrices for type "link" and "response". The first column is on the original data scale when type="response" and on the log mean scale of the linear predictor when type="link". The second column when type="response" is again the log scale parameter, but is on the linear predictor when type="link".

The null deviance reported for this family computed by setting the fitted values to the mean response, but using the model estimated scale.

Value

An object inheriting from class general.family.

mu <- exp(f0(x0)+f2(x2))/5
th <- exp(f1(x1)/2-2)
y <- rgamma(n,shape=1/th,scale=mu*th)

b1 <- gam(list(y~s(x0)+s(x2),~s(x1)+s(x3)),family=gammals)
plot(b1,pages=1)
summary(b1)
```r
gamObject

Description

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

Value

A `gam` object has the following elements:

- `aic`: AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE.
- `assign`: Array whose elements indicate which model term (listed in `pterms`) each parameter relates to: applies only to non-smooth terms.
- `boundary`: did parameters end up at boundary of parameter space?
- `call`: the matched call (allows `update` to be used with `gam` objects, for example).
- `cmX`: column means of the model matrix (with elements corresponding to smooths set to zero) — useful for componentwise CI calculation.
- `coefficients`: the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.
- `control`: the `gam` control list used in the fit.
- `converged`: indicates whether or not the iterative fitting method converged.
- `data`: the original supplied data argument (for class "glm" compatibility). Only included if `gam` control argument element `keepData` is set to `TRUE` (default is `FALSE`).
- `db.drho`: matrix of first derivatives of model coefficients w.r.t. log smoothing parameters.
- `deviance`: model deviance (not penalized deviance).
- `df.null`: null degrees of freedom.
- `df.residual`: effective residual degrees of freedom of the model.
- `edf`: estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.
- `edf1`: similar, but using alternative estimate of EDF. Useful for testing.
if estimation is by ML or REML then an edf that accounts for smoothing parameter uncertainty can be computed, this is it. edf1 is a heuristic upper bound for edf2.

family object specifying distribution and link used.

fitted model predictions of expected value for each datum.

the model formula.

full array of smoothing parameters multiplying penalties (excluding any contribution from min.sp argument to gam). May be larger than sp if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the sp argument of gam.

Degrees of freedom matrix. This may be removed at some point, and should probably not be used.

The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.

array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.

number of iterations of P-IRLS taken to get convergence.

fitted model prediction of link function of expected value for each datum.

One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "1me.ML" or "1me.REML", depending on the fitting criterion used.

A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: full.rank, The apparent rank of the problem given the model matrix and constraints; rank, The numerical rank of the problem; fully.converged, TRUE if multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; hess.pos.def, Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; iter, How many iterations were required to find the smoothing parameters?; score.calls, and how many times did the GCV/UBRE score have to be evaluated?; rms.grad, root mean square of the gradient of the GCV/UBRE score at convergence.

Minimum possible degrees of freedom for whole model.

model frame containing all variables needed in original model fit.

The na.action used in fitting.

number of parametric, non-smooth, model terms including the intercept.

deviance for single parametric, non-smooth, model including the intercept.

model offset.

optimizer argument to gam, or "magic" if it's a pure additive model.

If 'outer' iteration has been used to fit the model (see gam argument optimizer) then this is present and contains whatever was returned by the optimization routine used (currently nlm or optim).

If the paraPen argument to gam was used then this provides information on the parametric penalties. NULL otherwise.

one sided formula containing variables needed for prediction, used by predict.gam
prior.weights  prior weights on observations.

pterms terms object for strictly parametric part of model.

R Factor R from QR decomposition of weighted model matrix, unpivoted to be in
same column order as model matrix (so need not be upper triangular).

rank apparent rank of fitted model.

reml.scale The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness
estimation.

residuals the working residuals for the fitted model.

rV If present, rV%*%t(rV)*sig2 gives the estimated Bayesian covariance matrix.

scale when present, the scale (as sig2)

scale.estimated TRUE if the scale parameter was estimated, FALSE otherwise.

sig2 estimated or supplied variance/scale parameter.

smooth list of smooth objects, containing the basis information for each term in the
model formula in the order in which they appear. These smooth objects are
what gets returned by the smooth.construct objects.

sp estimated smoothing parameters for the model. These are the underlying
smoothing parameters, subject to optimization. For the full set of smoothing
parameters multiplying the penalties see full.sp. Divide the scale parameter
by the smoothing parameters to get, variance components, but note that this is
not valid for smooths that have used rescaling to improve conditioning.

terms terms object of model model frame.

var.summary A named list of summary information on the predictor variables. If a paramet-
ic variable is a matrix, then the summary is a one row matrix, containing the
observed data value closest to the column median, for each matrix column. If
the variable is a factor the then summary is the modal factor level, returned as
a factor, with levels corresponding to those of the data. For numerics and ma-
trix arguments of smooths, the summary is the mean, nearest observed value to
median and maximum, as a numeric vector. Used by vis.gam, in particular.

Ve frequentist estimated covariance matrix for the parameter estimators. Particu-
larly useful for testing whether terms are zero. Not so useful for CI's as smooths
are usually biased.

Vp estimated covariance matrix for the parameters. This is a Bayesian posterior
covariance matrix that results from adopting a particular Bayesian model of the
smoothing process. Particularly useful for creating credible/confidence intervals.

Vc Under ML or REML smoothing parameter estimation it is possible to correct the
covariance matrix Vp for smoothing parameter uncertainty. This is the corrected
version.

weights final weights used in IRLS iteration.

y response data.

WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow
smoothing parameter estimation etc.

gamSim

Simulate example data for GAMs

Description

Function used to simulate data sets to illustrate the use of \texttt{gam} and \texttt{gamm}. Mostly used in help files to keep down the length of the example code sections.

Usage

gamSim(eg=1,n=400,dist="normal",scale=2,verbose=TRUE)

Arguments

- \texttt{eg} numeric value specifying the example required.
- \texttt{n} number of data to simulate.
- \texttt{dist} character string which may be used to specify the distribution of the response.
- \texttt{scale} Used to set noise level.
- \texttt{verbose} Should information about simulation type be printed?

Details

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

Value

Depends on \texttt{eg}, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or help file examples where the function is used for further information.

gaulss

Gaussian location-scale model family

Description

The gaulss family implements Gaussian location scale additive models in which the mean and the logb of the standard deviation (see details) can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae.

Usage

gaulss(link=list("identity","logb"),b=0.01)

Arguments

link        two item list specifying the link for the mean and the standard deviation. See details.
b        The minimum standard deviation, for the "logb" link.

Details

Used with gam to fit Gaussian location - scale models. gam is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the mean on the right hand side. The second is one sided, specifying the linear predictor for the standard deviation on the right hand side.

Link functions "identity", "inverse", "log" and "sqrt" are available for the mean. For the standard deviation only the "logb" link is implemented: \( \eta = \log(\sigma - b) \) and \( \sigma = b + \exp(\eta) \). This link is designed to avoid singularities in the likelihood caused by the standard deviation tending to zero. Note that internally the family is parameterized in terms of the \( \tau = \sigma^{-1} \), i.e. the standard deviation of the precision, so the link and inverse link are coded to reflect this, however the relationships between the linear predictor and the standard deviation are as given above.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the inverse of the standard deviation. Predictions using predict.gam will also produce 2 column matrices for type "link" and "response". The second column when type="response" is again on the reciprocal standard deviation scale (i.e. the square root precision scale). The second column when type="link" is \( \log(\sigma - b) \). Also plot.gam will plot smooths relating to \( \sigma \) on the \( \log(\sigma - b) \) scale (so high values correspond to high standard deviation and low values to low standard deviation). Similarly the smoothing penalties are applied on the (log) standard deviation scale, not the log precision scale.
The null deviance reported for this family is the sum of squares of the difference between the response and the mean response divided by the standard deviation of the response according to the model. The deviance is the sum of squares of residuals divided by model standard deviations.

**Value**

An object inheriting from class `general.family`.

**References**

**Examples**

```r
library(mgcv);library(MASS)
b <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
data=mcycle,family=gaulss())
summary(b)
plot(b,pages=1,scale=0)
```

---

**get.var**

*Get named variable or evaluate expression from list or data.frame*

**Description**

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then `NULL` is returned. The routine is useful for processing `gam` formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

**Usage**

```r
get.var(txt,data,vecMat=TRUE)
```

**Arguments**

- `txt` a text string which is either the name of a variable in `data` or when parsed is an expression that can be evaluated in `data`. It can also be neither in which case the function returns `NULL`.
- `data` A data frame or list.
- `vecMat` Should matrices be coerced to numeric vectors?

**Value**

The evaluated variable or `NULL`. May be coerced to a numeric vector if it’s a matrix.

**gevlss**  
*Generalized Extreme Value location-scale model family*

**Description**

The gevlss family implements Generalized Extreme Value location scale additive models in which the location, scale and shape parameters depend on additive smooth predictors. Usable only with gam, the linear predictors are specified via a list of formulae.

**Usage**

```r
gevlss(link = list("identity","identity","logit"))
```

**Arguments**

- `link`: three item list specifying the link for the location scale and shape parameters. See details.

**Details**

Used with gam to fit Generalized Extreme Value location scale and shape models. gam is called with a list containing 3 formulae: the first specifies the response on the left hand side and the structure of the linear predictor for the location parameter on the right hand side. The second is one sided, specifying the linear predictor for the log scale parameter on the right hand side. The third is one sided specifying the linear predictor for the shape parameter.

Link functions "identity" and "log" are available for the location (mu) parameter. There is no choice of link for the log scale parameter (\( \rho = \log \sigma \)). The shape parameter (xi) defaults to a modified logit link restricting its range to (-1..5), the upper limit is required to ensure finite variance, while the lower limit ensures consistency of the MLE (Smith, 1985).

The fitted values for this family will be a three column matrix. The first column is the location parameter, the second column is the log scale parameter, the third column is the shape parameter.

This family does not produce a null deviance. Note that the distribution for \( \xi = 0 \) is approximated by setting \( \xi \) to a small number.
The derivative system code for this family is mostly auto-generated, and the family is still somewhat experimental.

The GEV distribution is rather challenging numerically, and for small datasets or poorly fitting models improved numerical robustness may be obtained by using the extended Fellner-Schall method of Wood and Fasiolo (2017) for smoothing parameter estimation. See examples.

Value

An object inheriting from class `general.family`.

---

**ginla**

**GAM Integrated Nested Laplace Approximation Newton Enhanced**

**Description**

Apply Integrated Nested Laplace Approximation (INLA, Rue et al. 2009) to models estimable by `gam` or `bam`, using the INLA variant described in Wood (2019). Produces marginal posterior densities for each coefficient, selected coefficients or linear transformations of the coefficient vector.

**Usage**

```r
ginla(G,A=NULL,nk=16,nb=100,J=1,interactive=FALSE,int=0,approx=0)
```

**Arguments**

- `G`: A pre-fit `gam` object, as produced by `gam(...,fit=FALSE)` or `bam(...,discrete=TRUE,fit=FALSE)`.
- `A`: Either a matrix of transforms of the coefficients that are of interest, or an array of indices of the parameters of interest. If `NULL` then distributions are produced for all coefficients.
- `nk`: Number of values of each coefficient at which to evaluate its log marginal posterior density. These points are then spline interpolated.
- `nb`: Number of points at which to evaluate posterior density of coefficients for returning as a gridded function.
- `J`: How many determinant updating steps to take in the log determinant approximation step. Not recommended to increase this.
- `interactive`: If this is `>0` or `TRUE` then every approximate posterior is plotted in red, overlaid on the simple Gaussian approximate posterior. If `2` then waits for user to press return between each plot. Useful for judging whether anything is gained by using INLA approach.
- `int`: 0 to skip integration and just use the posterior modal smoothing parameter. >0 for integration using the CCD approach proposed in Rue et al. (2009).
- `approx`: 0 for full approximation; 1 to update Hessian, but use approximate modes; 2 as 1 and assume constant Hessian. See details.
Details

Let $\beta$, $\theta$, and $y$ denote the model coefficients, hyperparameters/smoothing parameters and response data, respectively. In principle, INLA employs Laplace approximations for $\pi(\beta_i|\theta, y)$ and $\pi(\theta|y)$ and then obtains the marginal posterior distribution $\pi(\beta_i|y)$ by intergrating the approximations to $\pi(\beta_i|\theta, y)\pi(\theta|y)$ w.r.t $\theta$ (marginals for the hyperparameters can also be produced). In practice the Laplace approximation for $\pi(\beta_i|\theta, y)$ is too expensive to compute for each $\beta_i$ and must itself be approximated. To this end, there are two quantities that have to be computed: the posterior mode $\beta^*|\beta_i$ and the determinant of the Hessian of the joint log density $\log \pi(\beta, \theta, y)$ w.r.t. $\beta$ at the mode. Rue et al. (2009) originally approximated the posterior conditional mode by the conditional mode implied by a simple Gaussian approximation to the posterior $\pi(\beta|y)$. They then approximated the log determinant of the Hessian as a function of $\beta_i$ using a first order Taylor expansion, which is cheap to compute for the sparse model representation that they use, but not when using the dense low rank basis expansions used by $\text{gam}$. They also offer a more expensive alternative approximation based on computing the log determinant with respect only to those elements of $\beta$ with sufficiently high correlation with $\beta_i$ according to the simple Gaussian posterior approximation: efficiency again seems to rest on sparsity. Wood (2018) suggests computing the required posterior modes exactly, and basing the log determinant approximation on a BFGS update of the Hessian at the unconditional model. The latter is efficient with or without sparsity, whereas the former is a 'for free' improvement. Both steps are efficient because it is cheap to obtain the Cholesky factor of $H$ - see $\text{choldrop}$. This is the approach taken by this routine.

The approx argument allows two further approximations to speed up computations. For approx==1 the exact posterior conditional modes are not used, but instead the conditional modes implied by the simple Gaussian posterior approximation. For approx==2 the same approximation is used for the modes and the Hessian is assumed constant. The latter is quite fast as no log joint density gradient evaluations are required.

Note that for many models the INLA estimates are very close to the usual Gaussian approximation to the posterior, the interactive argument is useful for investigating this issue.

$bam$ models are only supported with the discrete=TRUE option. The discrete=FALSE approach would be too inefficient. AR1 models are not supported (related arguments are simply ignored).

Value

A list with elements beta and density, both of which are matrices. Each row relates to one coefficient (or linear coefficient combination) of interest. Both matrices have nb columns. If int!=0 then a further element reml gives the integration weights used in the CCD integration, with the central point weight given first.

WARNINGS

This routine is still somewhat experimental, so details are liable to change. Also currently not all steps are optimally efficient.

The routine is written for relatively expert users.

ginla is not designed to deal with rank deficient models.

### gumbls

**Gumbel location-scale model family**

#### Description

The `gumbls` family implements Gumbel location scale additive models in which the location and scale parameters (see details) can depend on additive smooth predictors. Useable only with `gam`, the linear predictors are specified via a list of formulae.

#### Usage

```r
gumbls(link=list("identity","log"),b=-7)
```

#### Arguments

- `link` two item list specifying the link for the location \( \mu \) and log scale parameter \( \beta \). See details for meaning, which may not be intuitive.

- `b` The minimum log scale parameter.

#### Details

Let \( z = (y - \mu)e^{-\beta} \), then the log Gumbel density is \( l = -\beta - z - e^{-z} \). The expected value of a Gumbel r.v. is \( \mu + \gamma e^{\beta} \) where \( \gamma \) is Euler's constant (about 0.57721566). The corresponding variance is \( \pi^2 e^{2\beta}/6 \).
gumbels is used with \texttt{gam} to fit Gumbel location - scale models parameterized in terms of scale parameter $\mu$ and the log scale parameter $\beta$. Note that identity link for the scale parameter means that the corresponding linear predictor gives $\beta$ directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument $b$: if $\eta$ is the linear predictor for the log scale parameter, $\beta$, then $\beta = b + \log(1 + e^{\eta})$.

gam is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for location parameter, $\mu$, on the right hand side. The second is one sided, specifying the linear predictor for the log scale, $\beta$, on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the log scale parameter, $\beta$. Predictions using \texttt{predict.gam} will also produce 2 column matrices for type "link" and "response". The first column is on the original data scale when type="response" and on the log mean scale of the linear predictor when type="link". The second column when type="response" is again the log scale parameter, but is on the linear predictor when type="link".

\textbf{Value}

An object inheriting from class \texttt{general.family}.

\textbf{References}

\textbf{Examples}

\begin{verbatim}
library(mgcv)
## simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 * (10 * x)^3 * (1 - x)^10
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- f0(x0)+f1(x1)
beta <- exp(f2(x2)/5)
y <- mu - beta*log(-log(runif(n))) ## Gumbel quantile function
b <- gam(list(y~s(x0)+s(x1),~s(x2)+s(x3)),family=gumbels)
plot(b,pages=1,scale=0)
summary(b)
gam.check(b)
\end{verbatim}
Smooth terms are generally only identifiable up to an additive constant. In consequence sum-to-zero identifiability constraints are imposed on most smooth terms. The exceptions are terms with by variables which cause the smooth to be identifiable without constraint (that doesn’t include factor by variables), and random effect terms. Alternatively smooths can be set up to pass through zero at a user specified point.

By default each smooth term is subject to the sum-to-zero constraint

\[ \sum_i f(x_i) = 0. \]

The constraint is imposed by reparameterization. The sum-to-zero constraint causes the term to be orthogonal to the intercept: alternative constraints lead to wider confidence bands for the constrained smooth terms.

No constraint is used for random effect terms, since the penalty (random effect covariance matrix) anyway ensures identifiability in this case. Also if a by variable means that the smooth is anyway identifiable, then no extra constraint is imposed. Constraints are imposed for factor by variables, so that the main effect of the factor must usually be explicitly added to the model (the example below is an exception).

Occasionally it is desirable to substitute the constraint that a particular smooth curve should pass through zero at a particular point: the `pc` argument to `s`, `te`, `ti` and `t2` allows this: if specified then such constraints are always applied.

Simon N. Wood (s.wood@r-project.org)

## Example of three groups, each with a different smooth dependence on x
## but each starting at the same value...
require(mgcv)
set.seed(53)
n <- 100;x <- runif(3*n);z <- runif(3*n)
fac <- factor(rep(c("a","b","c"),each=100))
y <- c(sin(x[1:100]*4),exp(3*x[101:200])/10-.1,exp(-10*(x[201:300]-.5))/(1+exp(-10*(x[201:300]-.5)))-0.9933071) + z*(1-z)*5 + rnorm(100)*.4

## 'pc' used to constrain smooths to 0 at x=0...
b <- gam(y~s(x,by=fac,pc=0)+s(z))
plot(b,pages=1)

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as ‘inside’ if they are interior to an odd number of polygons.
Usage

in.out(bnd,x)

Arguments

bnd
A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed. Alternatively can be a lists where bnd[[i]][[1]], bnd[[i]][[2]] defines the i_th boundary loop.

x
A two column matrix. Each row is a point to test for inclusion in the region defined by bnd. Can also be a 2-vector, defining a single point.

Details

The algorithm works by counting boundary crossings (using compiled C code).

Value

A logical vector of length nrow(x). TRUE if the corresponding row of x is inside the boundary and FALSE otherwise.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

https://www.maths.ed.ac.uk/~swood34/

Examples

library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd,type="n")
polygon(bnd)
x <- seq(7.9,8.7,length=20)
y <- seq(13.7,14.3,length=20)
gr <- as.matrix(expand.grid(x,y))
inside <- in.out(bnd,gr)
points(gr,col=as.numeric(inside)+1)

influence.gam

Extract the diagonal of the influence/hat matrix for a GAM

Description

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted gam object.

Usage

## S3 method for class 'gam'
influence(model,...)
initial.sp

Arguments

model  fitted model objects of class gam as produced by gam().

Details

Simply extracts hat array from fitted model. (More may follow!)

Value

An array (see above).

Author(s)

Simon N. Wood <simon.wood@r-project.org>

See Also

gam

Description

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea
is to find values such that the estimated degrees of freedom per penalized parameter should be well
away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of
parameter space where the smoothing parameter estimation criterion is varying substantially with
smoothing parameter value.

Usage

initial.sp(X,S,off,expensive=FALSE,XX=FALSE)

Arguments

X  is the model matrix.
S  is a list of of penalty matrices. S[[i]] is the ith penalty matrix, but note that it
is not stored as a full matrix, but rather as the smallest square matrix including
all the non-zero elements of the penalty matrix. Element 1,1 of S[[i]] occupies
element off[i], off[i] of the ith penalty matrix. Each S[[i]] must be positive
semi-definite.
off  is an array indicating the first parameter in the parameter vector that is penalized
by the penalty involving S[[i]].
expensive  if TRUE then the overall amount of smoothing is adjusted so that the average
degrees of freedom per penalized parameter is exactly 0.5: this is numerically
costly.
XX  if TRUE then X contains $X^T X$, rather than X.
inSide

Details
Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.’s away from 0 and 1.
Usually only called by magic and gam.

Value
An array of initial smoothing parameter estimates.

Author(s)
Simon N. Wood <simon.wood@r-project.org>

See Also
magic, gam.outer, gam.

Description
Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

Usage
inSide(bnd,x,y)

Arguments
bnd
This should have two equal length columns with names matching whatever is supplied in x and y. This may contain several sections of boundary separated by NA. Alternatively bnd may be a list, each element of which contains 2 columns named as above. See below for details.

x
x co-ordinates of points to be tested.

y
y co-ordinates of points to be tested.

Details
Segments of boundary are separated by NAs, or are in separate list elements. The boundary co-ordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).
The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner ‘islands’ completely enclosed in the outer loop.
The routine calls compiled C code and operates by an exhaustive search for each point in x,y.
Value

The function returns a logical array of the same dimension as x and y. TRUE indicates that the corresponding x, y point lies inside the boundary.

```r
require(mgcv)
m <- 300; n <- 150
xm <- seq(-1, 4, length=m); ym <- seq(-1, 1, length=n)
x <- rep(xm, n); y <- rep(ym, rep(m, n))
er <- matrix(fs.test(x, y), m, n)
bnd <- fs.boundary()
in.bnd <- inSide(bnd, x, y)
plot(x, y, col = as.numeric(in.bnd) + 1, pch = ".")
lines(bnd$x, bnd$y, col = 3)
points(x, y, col = as.numeric(in.bnd) + 1, pch = ".")
## check boundary details ...
plot(x, y, col = as.numeric(in.bnd) + 1, pch = ",", ylim = c(-1, 0), xlim = c(3, 3.5))
lines(bnd$x, bnd$y, col = 3)
points(x, y, col = as.numeric(in.bnd) + 1, pch = ",")
```

interpret.gam  
Interpret a GAM formula

Description

This is an internal function of package mgcv. It is a service routine for gam which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

Usage

```
interpret.gam(gf, extra.special = NULL)
```

Arguments

- `gf`: A GAM formula as supplied to `gam` or `gamm`, or a list of such formulae, as supplied for some `gam` families.
- `extra.special`: Name of any extra special in formula in addition to s, te, ti and t2.
Value

An object of class \texttt{split.gam.formula} with the following items:

- \texttt{pf}: A model formula for the strictly parametric part of the model.
- \texttt{pfok}: \texttt{TRUE} if there is a \texttt{pf} formula.
- \texttt{smooth.spec}: A list of class \texttt{xx.smooth.spec} objects where \texttt{xx} depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)
- \texttt{full.formula}: An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.
- \texttt{fake.formula}: A formula suitable for use in evaluating a model frame.
- \texttt{response}: Name of the response variable.

\texttt{gam} \texttt{gamm}

Description

Facilities to auto-generate model specification code and associated data to simulate with GAMs in JAGS (or BUGS). This is useful for inference about models with complex random effects structure best coded in JAGS. It is a very inefficient approach to making inferences about standard GAMs. The idea is that \texttt{jagam} generates template JAGS code, and associated data, for the smooth part of the model. This template is then directly edited to include other stochastic components. After simulation with the resulting model, facilities are provided for plotting and prediction with the model smooth components.

Usage

\begin{verbatim}
jagam(formula,family=gaussian,data=list(),file,weights=NULL,na.action,
offset=NULL,knots=NULL,sp=NULL,drop.unused.levels=TRUE,
control=gam.control(),centred=TRUE,sp.prior = "gamma",diagonalize=FALSE)
sim2jam(sam,pregam,edf.type=2,burnin=0)
\end{verbatim}
Arguments

**formula**
A GAM formula (see `formula.gam` and also `gam.models`). This is exactly like the formula for a GLM except that smooth terms, `s`, `te`, `ti` and `t2` can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).

**family**
This is a family object specifying the distribution and link function to use. See `glm` and `family` for more details. Currently only gaussian, poisson, binomial and Gamma families are supported, but the user can easily modify the assumed distribution in the JAGS code.

**data**
A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`: typically the environment from which `jagam` is called.

**file**
Name of the file to which JAGS model specification code should be written. See `setwd` for setting and querying the current working directory.

**weights**
prior weights on the data.

**na.action**
a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.

**offset**
Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in `formula`: this conforms to the behaviour of `lm` and `glm`.

**control**
A list of fit control parameters to replace defaults returned by `gam.control`. Any control parameters not supplied stay at their default values. little effect on `jagam`.

**knots**
this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See `tprs` for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

**sp**
A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula (without forgetting null space penalties). Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then `length(sp)` must correspond to the number of underlying smoothing parameters.

**drop.unused.levels**
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

**centred**
Should centring constraints be applied to the smooths, as is usual with GAMS? Only set this to `FALSE` if you know exactly what you are doing. If `FALSE` there is a (usually global) intercept for each smooth.

**sp.prior**
"gamma" or "log.uniform" prior for the smoothing parameters? Do check that the default parameters are appropriate for your model in the JAGS code.

**diagonalize**
Should smooths be re-parameterized to have i.i.d. Gaussian priors (where possible)? For Gaussian data this allows efficient conjugate samplers to be used, and it can also work well with GLMs if the JAGS "glm" module is loaded, but otherwise it is often better to update smoothers blockwise, and not do this.
sam  jags sample object, containing at least fields b (coefficients) and rho (log smoothing parameters). May also contain field mu containing monitored expected response.

pregam  standard mgcv GAM setup data, as returned in jagam return list.

edf.type  Since EDF is not uniquely defined and may be affected by the stochastic structure added to the JAGS model file, 3 options are offered. See details.

burnin  the amount of burn in to discard from the simulation chains. Limited to .9 of the chain length.

Details

Smooths are easily incorporated into JAGS models using multivariate normal priors on the smooth coefficients. The smoothing parameters and smoothing penalty matrices directly specify the prior multivariate normal precision matrix. Normally a smoothing penalty does not correspond to a full rank precision matrix, implying an improper prior inappropriate for Gibbs sampling. To rectify this problem the null space penalties suggested in Marra and Wood (2011) are added to the usual penalties.

In an additive modelling context it is usual to centre the smooths, to avoid the identifiability issues associated with having an intercept for each smooth term (in addition to a global intercept). Under Gibbs sampling with JAGS it is technically possible to omit this centring, since we anyway force propriety on the priors, and this propriety implies formal model identifiability. However, in most situations this formal identifiability is rather artificial and does not imply statistically meaningful identifiability. Rather it serves only to massively inflate confidence intervals, since the multiple intercept terms are not identifiable from the data, but only from the prior. By default then, jagam imposes standard GAM identifiability constraints on all smooths. The centred argument does allow you to turn this off, but it is not recommended. If you do set centred=FALSE then chain convergence and mixing checks should be particularly stringent.

The final technical issue for model setup is the setting of initial conditions for the coefficients and smoothing parameters. The approach taken is to take the default initial smoothing parameter values used elsewhere by mgcv, and to take a single PIRLS fitting step with these smoothing parameters in order to obtain starting values for the smooth coefficients. In the setting of fully conjugate updating the initial values of the coefficients are not critical, and good results are obtained without supplying them. But in the usual setting in which slice sampling is required for at least some of the updates then very poor results can sometimes be obtained without initial values, as the sampler simply fails to find the region of the posterior mode.

The sim2jam function takes the partial gam object (pregam) from jagam along with simulation output in standard rjags form and creates a reduced version of a gam object, suitable for plotting and prediction of the model’s smooth components. sim2gam computes effective degrees of freedom for each smooth, but it should be noted that there are several possibilities for doing this in the context of a model with a complex random effects structure. The simplest approach (edf.type=0) is to compute the degrees of freedom that the smooth would have had if it had been part of an unweighted Gaussian additive model. One might choose to use this option if the model has been modified so that the response distribution and/or link are not those that were specified to jagam. The second option is (edf.type=1) uses the edf that would have been computed by gam had it produced these estimates - in the context in which the JAGS model modifications have all been about modifying the random effects structure, this is equivalent to simply setting all the random effects to zero for the effective degrees of freedom calculation. The default option (edf.type=2) is to base the EDF on the sample covariance matrix, Vp, of the model coefficients. If the simulation output (sim) includes a mu field, then this will be used to form the weight matrix W in \[ W = (X'W^tX)^{-1} \], where the EDF is computed from rowSums(Vp*XWX)*scale. If mu is not supplied then it is estimated from the the model matrix X and the mean of the simulated coefficients, but the resulting W may not be
strictly compatible with the Vp matrix in this case. In the situation in which the fitted model is very different in structure from the regression model of the template produced by \texttt{jagam} then the default option may make no sense, and indeed it may be best to use option 0.

**Value**

For \texttt{jagam} a three item list containing

- \texttt{pregam} standard \texttt{mgcv} GAM setup data.
- \texttt{jags.data} list of arguments to be supplied to JAGS containing information referenced in model specification.
- \texttt{jags.ini} initialization data for smooth coefficients and smoothing parameters.

For \texttt{sim2jam} an object of class "\texttt{jam}": a partial version of an \texttt{mgcv} \texttt{gamObject}, suitable for plotting and predicting.

**WARNINGS**

Gibb's sampling is a very slow inferential method for standard GAMs. It is only likely to be worthwhile when complex random effects structures are required above what is possible with direct GAMM methods.

Check that the parameters of the priors on the parameters are fit for your purpose.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

Here is a key early reference to smoothing using BUGS (although the approach and smooths used are a bit different to \texttt{jagam})

**Examples**

```r
## the following illustrates a typical workflow. To run the
## 'Not run' code you need \texttt{rjags} (and JAGS) to be installed.
require(mgcv)
set.seed(2) ## simulate some data...
## regular \texttt{gam} fit for comparison...
b0 <- \texttt{gam(y=s(x0)+s(x1) + s(x2)+s(x3),data=dat,method="REML")}
```
## Set directory and file name for file containing jags code.
## In real use you would *never* use tempdir() for this. It is
## only done here to keep CRAN happy, and avoid any chance of
## an accidental overwrite. Instead you would use
## setwd() to set an appropriate working directory in which
## to write the file, and just set the file name to what you
## want to call it (e.g. "test.jags" here).

jags.file <- paste(tempdir(),"/test.jags",sep="")

## Set up JAGS code and data. In this one might want to diagonalize
## to use conjugate samplers. Usually call 'setwd' first, to set
## directory in which model file ("test.jags") will be written.

jd <- jagam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,file=jags.file,
sp.prior="gamma",diagonalize=TRUE)

## In normal use the model in "test.jags" would now be edited to add
## the non-standard stochastic elements that require use of JAGS....

## Not run:
require(rjags)
load.module("glm") ## improved samplers for GLMs often worth loading
jm <- jags.model(jags.file,data=jd$jags.data,inits=jd$jags.ini,n.chains=1)
list.samplers(jm)
sam <- jags.samples(jm,c("b","rho","scale"),n.iter=10000,thin=10)
jam <- sim2jam(sam,jd$pregam)
plot(jam,pages=1)

## End(Not run)

## a gamma example...
set.seed(1); n <- 400
data <- gamSim(1,n=n,dist="normal",scale=2)
scale <- .5; Ey <- exp(data$f/2)
data$y <- rgamma(n,shape=1/scale,shape=Ey*scale)
jd <- jagam(y=s(x0)+te(x1,x2)+s(x3),data=dat,family=Gamma(link=log),

### k.check

#### Checking smooth basis dimension

**Description**

Takes a fitted `gam` object produced by `gam()` and runs diagnostic tests of whether the basis dimension choices are adequate.

**Usage**

```r
k.check(b, subsample=5000, n.rep=400)
```

**Arguments**

- **b**: a fitted `gam` object as produced by `gam()`.
- **subsample**: above this number of data, testing uses a random sub-sample of data of this size.
- **n.rep**: how many re-shuffles to do to get p-value for k testing.

**Details**

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the k-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled n.rep times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than subsample data, the tests are based of subsample randomly sampled data. Low p-values may indicate that the basis dimension, k, has been set too low, especially if the reported edf is close to k, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect k and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low k. See `choose.k` for fuller discussion.

**Value**

A matrix containing the output of the tests described above.

ldetS
Getting log generalized determinant of penalty matrices

Description
INTERNAL function calculating the log generalized determinant of penalty matrix S stored block-wise in an Sl list (which is the output of Sl.setup).

Usage
ldetS(Sl, rho, fixed, np, root = FALSE, repara = TRUE, nt = 1,deriv=2,sparse=FALSE)

Arguments
Sl the output of Sl.setup.
rho the log smoothing parameters.
fixed an array indicating whether the smoothing parameters are fixed (or free).
np number of coefficients.
root indicates whether or not to return the matrix square root, E, of the total penalty S_tot.
repara if TRUE multi-term blocks will be re-parameterized using gam.reparam, and a re-parameterization object supplied in the returned object.
nt number of parallel threads to use.
deriv order of derivative to use
sparse should E be sparse?
**ldTweedie**

**Value**

A list containing:

- `ldetS`: the log-determinant of S.
- `ldetS1`: the gradient of the log-determinant of S.
- `ldetS2`: the Hessian of the log-determinant of S.
- `Sl`: with modified rS terms, if needed and rho added to each block
- `rp`: a re-parameterization list.
- `rp`: E a total penalty square root such that `t(E) %*% E = S_tot` (if root==TRUE).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

**ldTweedie**

*Log Tweedie density evaluation*

**Description**

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter, phi, and p, or w.r.t. rho=log(phi) and theta where \( p = \frac{(a+b*exp(theta))}{1+exp(theta)} \).

**Usage**

```r
ldTweedie(y,mu=y,p=1.5,phi=1,rho=NA,theta=NA,a=1.001,b=1.999,all.derivs=FALSE)
```

**Arguments**

- `y` values at which to evaluate density.
- `mu` corresponding means (either of same length as y or a single value).
- `p` the variance of y is proportional to its mean to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.
- `phi` The scale parameter. Variance of y is \( phi*mu^p \).
- `rho` optional log scale parameter. Over-rides phi if theta also supplied.
- `theta` parameter such that \( p = \frac{(a+b*exp(theta))}{1+exp(theta)} \). Over-rides p if rho also supplied.
- `a` lower limit parameter (>1) used in definition of p from theta.
- `b` upper limit parameter (<2) used in definition of p from theta.
- `all.derivs` if TRUE then derivatives w.r.t. mu are also returned. Only available with rho and phi parameterization.
Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1.

ldTweedie is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on p the calculation of Tweedie densities is less straightforward. If you really need this case then the tweedie package is the place to start.

The rho, theta parameterization is useful for optimization of p and phi, in order to keep p bounded well away from 1 and 2, and phi positive. The derivatives near p=1 tend to infinity.

Note that if p and phi (or theta and rho) both contain only a single unique value, then the underlying code is able to use buffering to avoid repeated calls to expensive log gamma, di-gamma and tri-gamma functions (mu can still be a vector of different values). This is much faster than is possible when these parameters are vectors with different values.

Value

A matrix with 6 columns, or 10 if all.derivs=TRUE. The first is the log density of y (log probability if p=1). The second and third are the first and second derivatives of the log density w.r.t. phi. 4th and 5th columns are first and second derivative w.r.t. p, final column is second derivative w.r.t. phi and p.

If rho and theta were supplied then derivatives are w.r.t. these. In this case, and if all.derivs=TRUE then the 7th column is the derivative w.r.t. mu, the 8th is the 2nd derivative w.r.t. mu, the 9th is the mixed derivative w.r.t. theta and mu and the 10th is the mixed derivative w.r.t. rho and mu.

linear.functional.terms

Linear functionals of a smooth in GAMs

Description

gam allows the response variable to depend on linear functionals of smooth terms. Specifically
dependancies of the form

\[ g(\mu_i) = \ldots + \sum_j L_{ij} f(x_{ij}) + \ldots \]

are allowed, where the \( x_{ij} \) are covariate values and the \( L_{ij} \) are fixed weights. i.e. the response can
depend on the weighted sum of the same smooth evaluated at different covariate values. This allows,
for example, for the response to depend on the derivatives or integrals of a smooth (approximated
by finite differencing or quadrature, respectively). It also allows dependence on predictor functions
(sometimes called 'signal regression').

The mechanism by which this is achieved is to supply matrices of covariate values to the model
smooth terms specified by \texttt{s} or \texttt{te} terms in the model formula. Each column of the covariate matrix
gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of
evaluated smooth values be \( F \) (\( F \) will have the same dimension as the covariate matrices). In the
absense of a \texttt{by} variable then these columns are simply summed and added to the linear predictor.
I.e. the contribution of the term to the linear predictor is \( \text{rowSums}(F) \). If a \texttt{by} variable is present
then it must be a matrix, \( L \), of the same dimension as \( F \) (and the covariate matrices), and it
contains the weights \( L_{ij} \) in the summation given above. So in this case the contribution to the linear
predictor is \( \text{rowSums}(L*F) \).

Note that if a \texttt{L1} (i.e. \( \text{rowSums}(L) \)) is a constant vector, or there is no \texttt{by} variable then the smooth
will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also
that for centred smooths it can be worth replacing the constant term in the model with \( \text{rowSums}(L) \)
in order to ensure that predictions are automatically on the right scale.

\texttt{predict.gam} can accept matrix predictors for prediction with such terms, in which case its \texttt{newdata}
argument will need to be a list. However when predicting from the model it is not necessary to
provide matrix covariate and \texttt{by} variable values. For example to simply examine the underlying
smooth function one would use vectors of covariate values and vector \texttt{by} variables, with the \texttt{by}
and equivalent of \texttt{L1}, above, set to vectors of ones.

The mechanism is usable with random effect smooths which take factor arguments, by using a trick
to create a 2D array of factors. Simply create a factor vector containing the columns of the factor
matrix stacked end to end (column major order). Then reset the dimensions of this vector to create
the appropriate 2D array: the first dimension should be the number of response data and the second
the number of columns of the required factor matrix. You can not use \texttt{matrix} or \texttt{data.matrix} to
set up the required matrix of factor levels. See example below.

plot(b,shade=TRUE);lines(x,f,col=2)
**logLik.gam**

**Description**

Function to extract the log-likelihood for a fitted gam model (note that the models are usually fitted by penalized likelihood maximization). Used by AIC. See details for more information on AIC computation.

**Usage**

```r
## S3 method for class 'gam'
logLik(object,...)
```

**Arguments**

- `object`: fitted model objects of class `gam` as produced by `gam()`.
- `...`: un-used in this case

**Details**

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that AIC functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). See e.g. Wood, Pya and Saefken (2016) for a derivation of an appropriate AIC.

There are two possibile AIC’s that might be considered for use with GAMs. Marginal AIC is based on the marginal likelihood of the GAM, that is the likelihood based on treating penalized (e.g. spline) coefficients as random and integrating them out. The degrees of freedom is then the number of smoothing/variance parameters + the number of fixed effects. The problem with Marginal AIC is that marginal likelihood underestimates variance components/oversmooths, so that the approach favours simpler models excessively (substituting REML does not work, because REML is not comparable between models with different unpenalized/fixed components). Conditional AIC uses the likelihood of all the model coefficients, evaluated at the penalized MLE. The degrees of freedom to use then is the effective degrees of freedom for the model. However, Greven and Kneib (2010) show that the neglect of smoothing parameter uncertainty can lead to this conditional AIC being excessively likely to select larger models. Wood, Pya and Saefken (2016) propose a simple correction to the effective degrees of freedom to fix this problem. mgcv applies this correction whenever possible: that is when using ML or REML smoothing parameter selection with `gam` or `bam`. The correction is not computable when using the Extended Fellner Schall or BFGS optimizer (since the correction requires an estimate of the covariance matrix of the log smoothing parameters).

**Value**

Standard `logLik` object: see `logLik`.

**Author(s)**

**ls.size**

*Size of list elements*

**Description**

Produces a named array giving the size, in bytes, of the elements of a list.

**Usage**

`ls.size(x)`

**Arguments**

- `x` A list.

**Value**

A numeric vector giving the size in bytes of each element of the list `x`. The elements of the array have the same names as the elements of the list. If `x` is not a list then its size in bytes is returned, un-named.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

[https://www.maths.ed.ac.uk/~swood34/](https://www.maths.ed.ac.uk/~swood34/)

**Examples**

```r
library(mgcv)

"The world is ruled by idiots because only an idiot would want to rule the world.",
fam=binomial())
ls.size(b)
```
magic

Stable Multiple Smoothing Parameter Estimation by GCV or UBRE

Description

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton’s method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

Usage

```r
magic(y, X, sp, S, off, L = NULL, lsp0 = NULL, rank = NULL, H = NULL, C = NULL,
      w = NULL, gamma = 1, scale = 1, gcv = TRUE, ridge.parameter = NULL,
      control = list(tol = 1e-6, step.half = 25, rank.tol = 
        .Machine$double.eps^0.5), extra.rss = 0, n.score = length(y), nthreads = 1)
```

Arguments

- `y` is the response data vector.
- `X` is the model matrix (more columns than rows are allowed).
- `sp` is the array of smoothing parameters. The vector \(L \times \log(sp) + 1 \text{sp}0\) contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in \(S\) (\(L\) is taken as the identity if \(NULL\)). Any \(sp\) values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value.
- `S` is a list of penalty matrices. \(S[[i]]\) is the \(i\)th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of \(S[[i]]\) occupies element \(off[i], off[i]\) of the \(i\)th penalty matrix. Each \(S[[i]]\) must be positive semi-definite. Set to `list()` if there are no smoothing parameters to be estimated.
- `off` is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving \(S[[i]]\).
- `L` is a matrix mapping \(\log(sp)\) to the log smoothing parameters that actually multiply the penalties defined by the elements of \(S\). Taken as the identity, if \(NULL\). See above under \(sp\).
- `lsp0` If \(L\) is not \(NULL\) this is a vector of constants in the linear transformation from \(\log(sp)\) to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the \(S[[i]]\) are given by \(L \times \log(sp) + 1 \text{sp}0\). Taken as 0 if \(NULL\).
- `rank` is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.
**Details**

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

\[
\minimise \| W(Xb - y) \|^2 + b'Hb + \sum_{i=1}^{m} \theta_i S_i b
\]

possibly subject to constraints \( Cb = 0 \). \( X \) is a design matrix, \( b \) a parameter vector, \( y \) a data vector, \( W \) a weight matrix, \( S_i \) a positive semi-definite matrix of coefficients defining the \( i \)th penalty with associated smoothing parameter \( \theta_i \), \( H \) is the positive semi-definite offset penalty matrix and \( C \) a matrix of coefficients defining any linear equality constraints on the problem. \( X \) need not be of full column rank.

The \( \theta_i \) are chosen to minimize either the GCV score:
\[ V_g = \frac{n\|W(y - Ay)\|^2}{\text{tr}(I - \gamma A)^2} \]

or the UBRE score:

\[ V_u = \frac{\|W(y - Ay)\|^2}{n - 2\phi \text{tr}(I - \gamma A)/n + \phi} \]

where \( \gamma \) is gamma the inflation factor for degrees of freedom (usually set to 1) and \( \phi \) is scale, the scale parameter. \( A \) is the hat matrix (influence matrix) for the fitting problem (i.e. the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through \( A \).

The method operates by Newton or steepest descent updates of the logs of the \( \theta_i \). A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small \( \theta_i \), it’s important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a \( \log(\theta_i) \) change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal \( b \) parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

**Value**

The function returns a list with the following items:

- **b** The best fit parameters given the estimated smoothing parameters.
- **scale** the estimated (GCV) or supplied (UBRE) scale parameter.
- **score** the minimized GCV or UBRE score.
- **sp** an array of the estimated smoothing parameters.
- **sp.full** an array of the smoothing parameters that actually multiply the elements of \( S \) (same as \( sp \) if \( L \) was NULL). This is \( \exp(L*%*\log(sp)) \). 
- **rV** a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters \( b \) is given by \( rV%*%t(rV)*\text{scale} \).
- **gcv.info** is a list of information about the performance of the method with the following elements:
  - **full.rank** The apparent rank of the problem: number of parameters less number of equality constraints.
  - **rank** The estimated actual rank of the problem (at the final iteration of the method).
  - **fully.converged** is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it covered by failing to decrease the score along the search direction.
**hess.pos.def** is TRUE if the hessian of the UBRE or GCV score was positive definite at convergence.

**iter** is the number of Newton/Steepest descent iterations taken.

**score.calls** is the number of times that the GCV/UBRE score had to be evaluated.

**rms.grad** is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.

**R** The factor R from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to $X$. So it may not be upper triangular.

Note that some further useful quantities can be obtained using **magic.post.proc**.

---

### magic.post.proc

**Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

**Usage**

```r
magic.post.proc(X,object,w=NULL)
```

**Arguments**

- `X` is the model matrix.
- `object` is the list returned by `magic` after fitting the model with model matrix `X`.
- `w` is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to `magic`, if one was.). If `w` is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If `w` is a matrix then `t(w)%*%w` should typically give the inverse of the covariance matrix of the response data supplied to `magic`. 

---

### magic.post.proc

**Auxilliary information from magic fit**

**Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

**Usage**

```r
magic.post.proc(X,object,w=NULL)
```

**Arguments**

- `X` is the model matrix.
- `object` is the list returned by `magic` after fitting the model with model matrix `X`.
- `w` is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to `magic`, if one was.). If `w` is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If `w` is a matrix then `t(w)%*%w` should typically give the inverse of the covariance matrix of the response data supplied to `magic`. 

Details

The `object` contains `rV` (V, say), and scale (φ, say) which can be used to obtain the required quantities as follows. The Bayesian covariance matrix of the parameters is VV′φ. The vector of estimated degrees of freedom for each parameter is the leading diagonal of VV′X′W′WX where W is either the weight matrix w or the matrix diag(w). The hat/influence matrix is given by WXV′X′W′. The frequentist parameter estimator covariance matrix is VV′X′W′WXV′φ: it is sometimes useful for testing terms for equality to zero.

Value

A list with three items:

- `Vb` the Bayesian covariance matrix of the model parameters.
- `Ve` the frequentist covariance matrix for the parameter estimators.
- `hat` the leading diagonal of the hat (influence) matrix.
- `edf` the array giving the estimated degrees of freedom associated with each parameter.

FAQ list

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the `summary.gam`. Alternatively, simple random effects can be fitted with `gam`, which makes comparison straightforward. Package `gamm4` is an alternative, which allows AIC type model selection for generalized models.

2. **How do I get the equation of an estimated smooth?** This slightly misses the point of semi-parametric modelling: the idea is that we estimate the form of the function from data without assuming that it has a particular simple functional form. Of course for practical computation the functions do have underlying mathematical representations, but they are not very helpful, when written down. If you do need the functional forms then see chapter 5 of Wood (2017). However for most purposes it is better to use `predict.gam` to evaluate the function for whatever argument values you need. If derivatives are required then the simplest approach is to use finite differencing (which also allows SEs etc to be calculated).
3. Some of my smooths are estimated to be straight lines and their confidence intervals vanish at some point in the middle. What is wrong? Nothing. Smooths are subject to sum-to-zero identifiability constraints. If a smooth is estimated to be a straight line then it consequently has one degree of freedom, and there is no choice about where it passes through zero — so the CI must vanish at that point.

4. How do I test whether a smooth is significantly different from a straight line. See tprs and the example therein.

5. An example from an mgcv helpfile gives an error - is this a bug? It might be, but first please check that the version of mgcv you have loaded into R corresponds to the version from which the helpfile came. Many such problems are caused by trying to run code only supported in a later mgcv version in an earlier version. Another possibility is that you have an object loaded whose name clashes with an mgcv function (for example you are trying to use the mgcv multinom function, but have another object called multinom loaded.)

6. Some code from Wood (2006) causes an error: why? The book was written using mgcv version 1.3. To allow for REML estimation of smoothing parameters in versions 1.5, some changes had to be made to the syntax. In particular the function gam.method no longer exists. The smoothness selection method (GCV, REML etc) is now controlled by the method argument to gam while the optimizer is selected using the optimizer argument. See gam for details.

7. Why is a model object saved under a previous mgcv version not usable with the current mgcv version? I’m sorry about this issue, I know it’s really annoying. Here’s my defence. Each mgcv version is run through an extensive test suite before release, to ensure that it gives the same results as before, unless there are good statistical reasons why not (e.g. improvements to p-value approximation, fixing of an error). However it is sometimes necessary to modify the internal structure of model objects in a way that makes an old style object unusable with a newer version. For example, bug fixes or new R features sometimes require changes in the way that things are computed which in turn require modification of the object structure. Similarly improvements, such as the ability to compute smoothing parameters by RE/ML require object level changes. The only fix to this problem is to access the old object using the original mgcv version (available on CRAN), or to recompute the fit using the current mgcv version.

8. When using gamm or gamm4, the reported AIC is different for the gam object and the lme or lmer object. Why is this? There are several reasons for this. The most important is that the models being used are actually different in the two representations. When treating the GAM as a mixed model, you are implicitly assuming that if you gathered a replicate dataset, the smooths in your model would look completely different to the smooths from the original model, except for having the same degree of smoothness. Technically you would expect the smooths to be drawn afresh from their distribution under the random effects model. When viewing the gam from the usual penalized regression perspective, you would expect smooths to look broadly similar under replication of the data. i.e. you are really using Bayesian model for the smooths, rather than a random effects model (it’s just that the frequentist random effects and Bayesian computations happen to coincide for computing the estimates). As a result of the different assumptions about the data generating process, AIC model comparisons can give rather different answers depending on the model adopted. Which you use should depend on which model you really think is appropriate. In addition the computations of the AICs are different. The mixed model AIC uses the marginal likelihood and the corresponding number of model parameters. The gam model uses the penalized likelihood and the effective degrees of freedom.

9. What does ’mgcv’ stand for? ’Mixed GAM Computation Vehicle’, is my current best effort (let me know if you can do better). Originally it stood for ‘Multiple GCV’, which has long since ceased to be usefully descriptive, (and I can’t really change ’mgcv’ now without causing disruption). On a bad inbox day ’Mad GAM Computing Vulture’.
10. **My new method is failing to beat mgcv, what can I do?** If speed is the problem, then make sure that you use the slowest basis possible ("tp") with a large sample size, and experiment with different optimizers to find one that is slow for your problem. For prediction error/MSE, then leaving the smoothing basis dimensions at their arbitrary defaults, when these are inappropriate for the problem setting, is a good way of reducing performance. Similarly, using p-splines in place of derivative penalty based splines will often shave a little more from the performance here. Unlike REML/ML, prediction error based smoothness selection criteria such as Mallows Cp and GCV often produce a small proportion of severe overfits, so careful choice of smoothness selection method can help further. In particular GCV etc. usually result in worse confidence interval and p-value performance than ML or REML. If all this fails, try using a really odd simulation setup for which mgcv is clearly not suited: for example poor performance is almost guaranteed for small noisy datasets with large numbers of predictors.

Simon N. Wood <simon.wood@r-project.org>

**References**

**Description**

`mgcv` provides functions for generalized additive modelling (`gam` and `bam`) and generalized additive mixed modelling (`gamm`, and `random.effects`). The term GAM is taken to include any model dependent on unknown smooth functions of predictors and estimated by quadratically penalized (possibly quasi-) likelihood maximization. Available distributions are covered in `family.mgcv` and available smooths in `smooth.terms`.

Particular features of the package are facilities for automatic smoothness selection (Wood, 2004, 2011), and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available. In addition to the main modelling functions, `jagam` provided facilities to ease the set up of models for use with JAGS, while `ginla` provides marginal inference via a version of Integrated Nested Laplace Approximation.

**Details**

`mgcv` provides generalized additive modelling functions `gam`, `predict.gam` and `plot.gam`, which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other
functions such as `summary.gam` and `anova.gam` are also provided, for extracting information from a fitted `gamObject`.

Use of `gam` is much like use of `glm`, except that within a `gam` model formula, isotropic smooths of any number of predictors can be specified using `s` terms, while scale invariant smooths of any number of predictors can be specified using `te`, `ti` or `t2` terms. `smooth_terms` provides an overview of the built in smooth classes, and `random.effects` should be referred to for an overview of random effects terms (see also `mrf` for Markov random fields). Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE or (RE)ML. See `gam`, `gam.models`, `linear.functional.terms` and `gam.selection` for some discussion of model specification and selection. For detailed control of fitting see `gam.convergence`, `gam` arguments method and optimizer and `gam.control`. For checking and visualization see `gam.check`, `choose.k`, `vis.gam` and `plot.gam`. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see `smooth.construct`, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals (see Marra and Wood, 2012). The Bayesian covariance matrix for the model coefficients is returned in `Vp` of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas (see Wood, 2013a,b). Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

For large datasets (that is large n) see `bam` which is a version of `gam` with a much reduced memory footprint.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`. See also `mgcv.FAQ`.

### mgcv.parallel

**Parallel computation in mgcv.**

**Description**

*mgcv* can make some use of multiple cores or a cluster.

- **bam** can use an openMP based parallelization approach alongside discretisation of covariates to achieve substantial speed ups. This is selected using the `discrete=TRUE` option to `bam`, with the number of threads controlled via the `nthreads` argument. This is the approach that scales best. See example below.

- Alternatively, function `bam` can use the facilities provided in the `parallel` package. See examples below. Note that most multi-core machines are memory bandwidth limited, so parallel speed up tends to be rather variable.

- Function `gam` can use parallel threads on a (shared memory) multi-core machine via openMP (where this is supported). To do this, set the desired number of threads by setting `nthreads` to the number of cores to use, in the `control` argument of `gam`. Note that, for the most part, only the dominant $O(n p^2)$ steps are parallelized ($n$ is number of data, $p$ number of parameters). For additive Gaussian models estimated by GCV, the speed up can be disappointing as these employ an $O(p^3)$ SVD step that can also have substantial cost in practice.

- `magic` can also use multiple cores, but the same comments apply as for the GCV Gaussian additive model.

If `control$nthreads` is set to more than the number of cores detected, then only the number of detected cores is used. Note that using virtual cores usually gives very little speed up, and can even slow computations slightly. For example, many Intel processors reporting 4 cores actually have 2 physical cores, each with 2 virtual cores, so using 2 threads gives a marked increase in speed, while using 4 threads makes little extra difference.

Note that on Intel and similar processors the maximum performance is usually achieved by disabling Hyper-Threading in BIOS, and then setting the number of threads to the number of physical cores used. This prevents the operating system scheduler from sending 2 floating point intensive threads
to the same physical core, where they have to share a floating point unit (and cache) and therefore slow each other down. The scheduler tends to do this under the manager - worker multi-threading approach used in mgcv, since the manager thread looks very busy up to the point at which the workers are set to work, and at the point of scheduling the scheduler has no way of knowing that the manager thread actually has nothing more to do until the workers are finished. If you are working on a many cored platform where you can not disable hyper-threading then it may be worth setting the number of threads to one less than the number of physical cores, to reduce the frequency of such scheduling problems.

mgcv’s work splitting always makes the simple assumption that all your cores are equal, and you are not sharing them with other floating point intensive threads.

In addition to hyper-threading several features may lead to apparently poor scaling. The first is that many CPUs have a Turbo mode, whereby a few cores can be run at higher frequency, provided the overall power used by the CPU does not exceed design limits, however it is not possible for all cores on the CPU to run at this frequency. So as you add threads eventually the CPU frequency has to be reduced below the Turbo frequency, with the result that you don’t get the expected speed up from adding cores. Secondly, most modern CPUs have their frequency set dynamically according to load. You may need to set the system power management policy to favour high performance in order to maximize the chance that all threads run at the speed you were hoping for (you can turn off dynamic power control in BIOS, but then you turn off the possibility of Turbo also).

Because the computational burden in mgcv is all in the linear algebra, then parallel computation may provide reduced or no benefit with a tuned BLAS. This is particularly the case if you are using a multi threaded BLAS, but a BLAS that is tuned to make efficient use of a particular cache size may also experience loss of performance if threads have to share the cache.

---

**mini.roots**

*Obtain square roots of penalty matrices*

**Description**

INTERNAL function to obtain square roots, $B[i]$, of the penalty matrices $S[i]$'s having as few columns as possible.

**Usage**

mini.roots(S, off, np, rank = NULL)

**Arguments**

- **S**: a list of penalty matrices, in packed form.
- **off**: a vector where the i-th element is the offset for the i-th matrix. The elements in columns 1:off[i] of $B[i]$ will be equal to zero.
- **np**: total number of parameters.
- **rank**: here rank[i] is optional supplied rank of $S[i]$. Set rank[i] < 1, or rank=NULL to estimate.

**Value**

A list of matrix square roots such that $S[i]=B[i]\%*\%t(B[i])$.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.
Description

If there are missing values in the response or covariates of a GAM then the default is simply to use only the ‘complete cases’. If there are many missing covariates, this can get rather wasteful. One possibility is then to use imputation. Another is to substitute a simple random effects model in which the by variable mechanism is used to set \( s(x) \) to zero for any missing \( x \), while a Gaussian random effect is then substituted for the ‘missing’ \( s(x) \). See the example for details of how this works, and `gam.models` for the necessary background on by variables.

  drop <- sample(1:n,300)  ## to
  for (i in 2:5) dat[drop[1:75+(i-2)*75],i] <- NA
  ## process data.frame producing binary indicators of missingness,
  ## mx0, mx1 etc. For each missing value create a level of a factor
  ## idx0, idx1, etc. So idx0 has as many levels as x0 has missing
  ## values. Replace the NA’s in each variable by the mean of the
  ## non missing for that variable...
  dname <- names(dat)[2:5]
  dat1 <- dat
  for (i in 1:4) {
    by.name <- paste("m",dname[i],sep="")
    dat1[[by.name]] <- is.na(dat1[[dname[i]]])
    dat1[[dname[i]]][dat1[[by.name]]] <- mean(dat1[[dname[i]]],na.rm=TRUE)
    lev <- rep(1,n);lev[dat1[[by.name]]] <- 1:sum(dat1[[by.name]])
    id.name <- paste("id",dname[i],sep="")
    dat1[[id.name]] <- factor(lev)
    dat1[[by.name]] <- as.numeric(dat1[[by.name]])
  }
  ## Fit a gam, in which any missing value contributes zero
  ## to the linear predictor from its smooth, but each
```
## missing has its own random effect, with the random effect variances being specific to the variable. e.g.
## for s(x0,by=ordered(!mx0)), declaring the 'by' as an ordered factor ensures that the smooth is centred, but multiplied by zero when mx0 is one (indicating a missing x0). This means that any value (within range) can be put in place of the NA for x0. s(idx0,bs="re",by=mx0) produces a separate Gaussian random effect for each missing value of x0 (in place of s(x0), effectively). The 'by' variable simply sets the random effect to zero when x0 is non-missing, so that we can set idx0 to any existing level for these cases.

```r
b <- bam(y=s(x0,by=ordered(!mx0))+s(x1,by=ordered(!mx1))+
         s(x2,by=ordered(!mx2))+s(x3,by=ordered(!mx3))+
         s(id0,bs="re",by=mx0)+s(id1,bs="re",by=mx1)+
         s(id2,bs="re",by=mx2)+s(id3,bs="re",by=mx3),
data=dat1,discrete=TRUE)
```

for (i in 1:4) plot(b,select=i) ## plot the smooth effects from b

```r
## fit the model to the 'complete case' data...
b2 <- gam(y=s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="REML")
plot(b2) ## plot the complete case results
```

gam

Examples

```r
require(mgcv)
n <- 15
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=6),knots=list(x=seq(0,1,length=6)))
model.matrix(mod)
```

Description

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the gam, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

Usage

```r
mono.con(x, up=TRUE, lower=NA, upper=NA)
```

Arguments

- `x` The array of knot locations.
- `up` If TRUE then the constraints imply increase, if FALSE then decrease.
- `lower` This specifies the lower bound on the spline unless it is NA in which case no lower bound is imposed.
- `upper` This specifies the upper bound on the spline unless it is NA in which case no upper bound is imposed.

Details

Consider the natural cubic spline passing through the points \( \{x_i, p_i : i = 1 \ldots n\} \). Then it is possible to find a relatively small set of linear constraints on \( p \) sufficient to ensure monotonicity (and bounds if required): \( Ap \geq b \). Details are given in Wood (1994).
mroot

Value

A list containing constraint matrix A and constraint vector b.

---

**Description**

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleksi decomposition or singular value decomposition to do this.

**Usage**

```r
mroot(A, rank=NULL, method="chol")
```

**Arguments**

- **A** The positive semi-definite matrix, a square root of which is to be found.
- **rank** if the rank of the matrix A is known then it should be supplied. NULL or <1 imply that it should be estimated.
- **method** "chol" to use pivoted choleksi decompositon, which is fast but tends to over-estimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank.

**Details**

The function uses SVD, or a pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

**Value**

A matrix, B with as many columns as the rank of A, and such that $A = BB'$. 
Author(s)

Simon N. Wood <simon.wood@r-project.org>

Examples

```r
require(mgcv)
set.seed(0)
a <- matrix(runif(24),6,4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B))); chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
svd.err <- max(abs(A-B%*%t(B))); svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

Description

Family for use with `gam`, implementing regression for categorical response data. Categories must be coded 0 to K, where K is a positive integer. `gam` should be called with a list of K formulae, one for each category except category zero (extra formulae for shared terms may also be supplied: see `formula.gam`). The first formula also specifies the response variable.

Usage

`multinom(K=1)`

Arguments

K

There are K+1 categories and K linear predictors.

Details

The model has K linear predictors, \( \eta_j \), each dependent on smooth functions of predictor variables, in the usual way. If response variable, \( y \), contains the class labels \( 0, \ldots, K \) then the likelihood for \( y>0 \) is \( \exp(\eta_y)/\{1 + \sum_j \exp(\eta_j)\} \). If \( y=0 \) the likelihood is \( 1/\{1 + \sum_j \exp(\eta_j)\} \). In the two class case this is just a binary logistic regression model. The implementation uses the approach to GAMLSS models described in Wood, Pya and Saefken (2016).

The residuals returned for this model are simply the square root of -2 times the deviance for each observation, with a positive sign if the observed \( y \) is the most probable class for this observation, and a negative sign otherwise.

Use `predict` with `type="response"` to get the predicted probabilities in each category.

Note that the model is not completely invariant to category relabelling, even if all linear predictors have the same form. Realistically this model is unlikely to be suitable for problems with large numbers of categories. Missing categories are not supported.
multinom

Value

An object of class `general.family`.

Examples

```r
library(mgcv)
set.seed(6)
## simulate some data from a three class model
n <- 1000
f1 <- function(x) sin(3*pi*x)*exp(-x)
f2 <- function(x) x^3
f3 <- function(x) .5*exp(-x^2)-.2
f4 <- function(x) 1
x1 <- runif(n);x2 <- runif(n)
eta1 <- 2*(f1(x1) + f2(x2))-.5
eta2 <- 2*(f3(x1) + f4(x2))-1
p <- exp(cbind(0,eta1,eta2))
p <- p/rowSums(p) ## prob. of each category
cp <- t(apply(p,1,cumsum)) ## cumulative prob.
## simulate multinomial response with these probabilities
## see also ?rmultinom
y <- apply(cp,1,function(x) min(which(x>runif(1))))-1
## plot simulated data...
plot(x1,x2,col=y+3)
## now fit the model...
b <- gam(list(y~s(x1)+s(x2),~s(x1)+s(x2)),family=multinom(K=2))
plot(b,pages=1)
gam.check(b)

## now a simple classification plot...
expand.grid(x1=seq(0,1,length=40),x2=seq(0,1,length=40)) -> gr
pp <- predict(b,newdata=gr,type="response")
pc <- apply(pp,1,function(x) which(max(x)==x)[1])-1
plot(gr,col=pc+3,pch=19)
```
Description

Family for use with \texttt{gam} implementing smooth multivariate Gaussian regression. The means for each dimension are given by a separate linear predictor, which may contain smooth components. Extra linear predictors may also be specified giving terms which are shared between components (see \texttt{formula.gam}). The Choleski factor of the response precision matrix is estimated as part of fitting.

Usage

\texttt{mvn(d=2)}

Arguments

d The dimension of the response (>1).

Details

The response is a dimensional multivariate normal, where the covariance matrix is estimated, and the means for each dimension have separate linear predictors. Model specification is via a list of \texttt{gam} like formulae - one for each dimension. See example.

Currently the family ignores any prior weights, and is implemented using first derivative information sufficient for BFGS estimation of smoothing parameters. "response" residuals give raw residuals, while "deviance" residuals are standardized to be approximately independent standard normal if all is well.

Value

An object of class \texttt{general.family}.

negbin

GAM negative binomial families

Description

The gam modelling function is designed to be able to use the negbin family (a modification of MASS library negative.binomial family by Venables and Ripley), or the nb function designed for integrated estimation of parameter theta. \( \theta \) is the parameter such that \( \text{var}(y) = \mu + \mu^2 / \theta \), where \( \mu = E(y) \).

Two approaches to estimating theta are available (with gam only):

- With negbin then if ‘performance iteration’ is used for smoothing parameter estimation (see gam), then smoothing parameters are chosen by GCV and theta is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection with the nb family then theta is estimated alongside the smoothing parameters by ML or REML.

To use the first option, set the optimizer argument of gam to “perf” (it can sometimes fail to converge).

Usage

negbin(theta = stop("'theta' must be specified"), link = "log")
nb(theta = NULL, link = "log")
Arguments
theta Either i) a single value known value of theta or ii) two values of theta specifying the endpoints of an interval over which to search for theta (this is an option only for negbin, and is deprecated). For nb then a positive supplied theta is treated as a fixed known parameter, otherwise it is estimated (the absolute value of a negative theta is taken as a starting value).
link The link function: one of "log", "identity" or "sqrt"

Details

negbin allows estimation of the theta parameter alongside the model smoothing parameters, but is only usable with gam or bam (not gamm). For negbin, if a single value of theta is supplied then it is always taken as the known fixed value and this is useable with bam and gamm. If theta is two numbers (theta[2]>theta[1]) then they are taken as specifying the range of values over which to search for the optimal theta. This option is deprecated and should only be used with performance iteration estimation (see gam argument optimizer), in which case the method of estimation is to choose $\hat{\theta}$ so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial). In this case $\theta$ estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the $\theta$ estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except $\theta$ and then searching for the $\hat{\theta}$ which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter <1.

Value

For negbin an object inheriting from class family, with additional elements
dvar the function giving the first derivative of the variance function w.r.t. mu.
d2var the function giving the second derivative of the variance function w.r.t. mu.
getTheta A function for retrieving the value(s) of theta. This also useful for retriving the estimate of theta after fitting (see example).

For nb an object inheriting from class extended.family.

WARNINGS

gamm does not support theta estimation
The negative binomial functions from the MASS library are no longer supported.

rm(dat)

new.name

Obtain a name for a new variable that is not already in use

Description

gamm works by transforming a GAMM into something that can be estimated by lme, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if neccessary modifies it so that there is no clash.

Usage

new.name(proposed,old.names)

Arguments

  proposed      a suggested name
  old.names     An array of names that must not be duplicated

Value

  A name that is not in old.names.

notExp Functions for better-than-log positive parameterization

Description
It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter a should be non-negative then we use a=exp(b) and optimize with respect to the unconstrained parameter b. This often works well, but it does imply a rather limited working range for b: using 8 byte doubles, for example, if b’s magnitude gets much above 700 then a overflows or underflows. This can cause problems for numerical optimization methods.

notExp is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than exp. It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

notLog is the inverse function of notExp.

The major use of these functions was originally to provide more robust pdMat classes for lme for use by gamm. Currently the notExp2 and notLog2 functions are used in their place, as a result of changes to the nlm optimization routines.

Usage
notExp(x)
notLog(x)

Arguments
x Argument array of real numbers (notExp) or positive real numbers (notLog).

Value
An array of function values evaluated at the supplied argument values.

Examples

```r
## Illustrate the notExp function:
## less steep than exp, but still monotonic.
require(mgcv)
x <- -100:100/10
op <- par(mfrow=c(2,2))
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

notExp2

**Alternative to log parameterization for variance components**

Description

notLog2 and notExp2 are alternatives to log and exp or notLog and notExp for re-parameterization of variance parameters. They are used by the pdTens and pdIdnot classes which in turn implement smooths for gamm.

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.
This reparameterization was made necessary by some modifications to the underlying optimization method in `lme` introduced in `nlme 3.1-62`. It is possible that future releases will return to the `notExp` parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

### Usage

```r
notExp2(x, d = .Options$mgcv.vc.logrange, b = 1/d)
notLog2(x, d = .Options$mgcv.vc.logrange, b = 1/d)
```

### Arguments

- `x`: Argument array of real numbers (notExp) or positive real numbers (notLog).
- `d`: the range of `notExp2` runs from `exp(-d)` to `exp(d)`. To change the range used by `gamm` reset `mgcv.vc.logrange` using `options`.
- `b`: determines the period of the cycle of `notExp2`.

### Value

An array of function values evaluated at the supplied argument values.

```
null.space.dimension

The basis of the space of un-penalized functions for a TPRS

Description

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. null.space.dimension finds the dimension of this space, \( M \), given the number of covariates that the smoother is a function of, \( d \), and the order of the smoothing penalty, \( m \). If \( m \) does not satisfy \( 2m > d \) then the smallest possible dimension for the null space is found given \( d \) and the requirement that the smooth should be visually smooth.

Usage

null.space.dimension(d,m)

Arguments

d
  is a positive integer - the number of variables of which the t.p.s. is a function.

m
  a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

Details

Thin plate splines are only visually smooth if the order of the wiggleness penalty, \( m \), satisfies \( 2m > d + 1 \). If \( 2m < d + 1 \) then this routine finds the smallest \( m \) giving visual smoothness for the given \( d \), otherwise the supplied \( m \) is used. The null space dimension is given by:

\[ M = \frac{(m + d - 1)!}{(d!(m - 1)!)} \]

which is the value returned.

Value

An integer (array), the null space dimension \( M \).

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

Examples

require(mgcv)
null.space.dimension(2,0)
GAM ordered categorical family

Description

Family for use with `gam` or `bam`, implementing regression for ordered categorical data. A linear predictor provides the expected value of a latent variable following a logistic distribution. The probability of this latent variable lying between certain cut-points provides the probability of the ordered categorical variable being of the corresponding category. The cut-points are estimated along side the model smoothing parameters (using the same criterion). The observed categories are coded 1, 2, 3, ... up to the number of categories.

Usage

```r
ocat(theta=NULL, link="identity", R=NULL)
```

Arguments

- `theta`: cut point parameter vector (dimension R-2). If supplied and all positive, then taken to be the cut point increments (first cut point is fixed at -1). If any are negative then absolute values are taken as starting values for cutpoint increments.
- `link`: The link function: only "identity" allowed at present (possibly for ever).
- `R`: the number of categories.

Details

Such cumulative threshold models are only identifiable up to an intercept, or one of the cut points. Rather than remove the intercept, `ocat` simply sets the first cut point to -1. Use `predict.gam` with `type="response"` to get the predicted probabilities in each category.

Value

An object of class `extended.family`.

predict(b,dat[1:2,],type="response",se=TRUE)

one.se.rule

The one standard error rule for smoother models

Description

The ‘one standard error rule’ (see e.g. Hastie, Tibshirani and Friedman, 2009) is a way of producing smoother models than those directly estimated by automatic smoothing parameter selection methods. In the single smoothing parameter case, we select the largest smoothing parameter within one standard error of the optimum of the smoothing parameter selection criterion. This approach can be generalized to multiple smoothing parameters estimated by REML or ML.

Details

Under REML or ML smoothing parameter selection an asymptotic distributional approximation is available for the log smoothing parameters. Let \( \rho \) denote the log smoothing parameters that we want to increase to obtain a smoother model. The large sample distribution of the estimator of \( \rho \) is \( N(\rho, V) \) where \( V \) is the matrix returned by \texttt{sp.vcov}. Drop any elements of \( \rho \) that are already at ‘effective infinity’, along with the corresponding rows and columns of \( V \). The standard errors of the log smoothing parameters can be obtained from the leading diagonal of \( V \). Let the vector of these be \( d \). Now suppose that we want to increase the estimated log smoothing parameters by an amount \( \alpha d \). We choose \( \alpha \) so that \( \alpha d^T V^{-1} d = \sqrt{2p} \), where \( p \) is the dimension of \( d \) and \( 2p \) the variance of a chi-squared r.v. with \( p \) degrees of freedom.

The idea is that we increase the log smoothing parameters in proportion to their standard deviation, until the RE/ML is increased by 1 standard deviation according to its asymptotic distribution.

Simon N. Wood <simon.wood@r-project.org>
Penalized Constrained Least Squares Fitting

Description

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

Usage

pcls(M)

Arguments

M is the single list argument to pcls. It should have the following elements:

y The response data vector.
w A vector of weights for the data (often proportional to the reciprocal of the variance).
X The design matrix for the problem, note that ncol(M$X) must give the number of model parameters, while nrow(M$X) should give the number of data.
C Matrix containing any linear equality constraints on the problem (e.g. C in Cp = c). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector c, it is defined implicitly by the initial parameter estimates p.
A list of penalty matrices. $S[[i]]$ is the smallest contiguous matrix including all the non-zero elements of the $i$th penalty matrix. The first parameter it penalizes is given by $of[i]+1$ (starting counting at 1).

**off** Offset values locating the elements of $M\infty S$ in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)

**sp** An array of smoothing parameter estimates.

**p** An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.

**Ain** Matrix for the inequality constraints $A_{in}p \succ b_{in}$.

**bin** vector in the inequality constraints.

**Details**

This solves the problem:

\[
\text{minimise} \quad \|W^{1/2}(Xp - y)\|^2 + \sum_{i=1}^{m} \lambda_i p'S_i p
\]

subject to constraints $Cp = c$ and $A_{in}p \succ b_{in}$, w.r.t. $p$ given the smoothing parameters $\lambda_i$. $X$ is a design matrix, $p$ a parameter vector, $y$ a data vector, $W$ a diagonal weight matrix, $S_i$ a positive semi-definite matrix of coefficients defining the $i$th penalty and $C$ a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the $\lambda_i$. Note that $X$ must be of full column rank, at least when projected into the null space of any equality constraints. $A_{in}$ is a matrix of coefficients defining the inequality constraints, while $b_{in}$ is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e. $X'X$ is not formed explicitly. See Gill et al. 1981.

**Value**

The function returns an array containing the estimated parameter vector.

pdIdnot

Overflow proof pdMat class for multiples of the identity matrix

Description

This set of functions is a modification of the pdMat class pdIdent from library nlme. The modification is to replace the log parameterization used in pdMat with a notLog2 parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the pdTens class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the pdTens class it is easy to do so.

Usage

pdIdnot(value = numeric(0), form = NULL, nam = NULL, data = sys.frame(sys.parent()))

Arguments

value Initialization values for parameters. Not normally used.
form A one sided formula specifying the random effects structure.
nam a names argument, not normally used with this class.
data data frame in which to evaluate formula.

Details

The following functions are provided: Dim.pdIdnot, coef.pdIdnot, corMatrix.pdIdnot, logDet.pdIdnot, pdConstruct.pdIdnot, pdFactor.pdIdnot, pdMatrix.pdIdnot, solve.pdIdnot, summary.pdIdnot. (e.g. mgcv:::coef.pdIdnot to access.)

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is initialised with estimates of the scaled covariance matrix itself.

Value

A class pdIdnot object, or related quantities. See the nlme documentation for further details.

**pdTens**

Functions implementing a pdMat class for tensor product smooths

**Description**

This set of functions implements an nlme library pdMat class to allow tensor product smooths to be estimated by lme as called by gamm. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It’s not possible to transform the problem to make the required random effects covariance matrix look like one of the standard pdMat classes: hence the need for the pdTens class. A notLog2 parameterization ensures that the parameters are positive.

These functions (pdTens, pdConstruct.pdTens, pdFactor.pdTens, pdMatrix.pdTens, coef.pdTens and summary.pdTens) would not normally be called directly.

**Usage**

```r
pdTens(value = numeric(0), form = NULL,
       nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

- `value`: Initialization values for parameters. Not normally used.
- `form`: A one sided formula specifying the random effects structure. The formula should have an attribute `S` which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects.
- `nam`: a names argument, not normally used with this class.
- `data`: data frame in which to evaluate formula.

**Details**

If using this class directly note that it is worthwhile scaling the `S` matrices to be of ‘moderate size’, for example by dividing each matrix by its largest singular value: this avoids problems with lme defaults (smooth.construct.tensor.smooth.spec does this automatically).

This appears to be the minimum set of functions required to implement a new pdMat class.

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes intialized with its inverse.
**Value**

A class pdTens object, or its coefficients or the matrix it represents or the factor of that matrix. `pdFactor` returns the factor as a vector (packed column-wise) (`pdMatrix` always returns a matrix).

# see gamm
```

---

**pen.edf**

*Extract the effective degrees of freedom associated with each penalty in a gam fit*

**Description**

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for `t2` terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. `te` terms).

**Usage**

```r
pen.edf(x)
```

**Arguments**

- `x` an object inheriting from `gam`

**Details**

Useful for models containing `t2` terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

**Value**

A vector of EDFs, named with labels identifying which penalty each EDF relates to.

t2

Examples

```r
require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400,scale=2) ## simulate data
## following 't2' smooth basically separates smooth
## of x0,x1 into main effects + interaction....

b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
data=dat,method="ML")
pen.edf(b)
## label "rr" indicates interaction edf (range space times range space)
## label "nr" (null space for x0 times range space for x1) is main
## effect for x1.
## label "rn" is main effect for x0
## clearly interaction is negligible

## second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)+s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)
## In this case the EDF is negligible for all terms in the t2 smooth
## apart from the 'main effects' (r2 and 2r). To understand the labels
## consider the following 2 examples....
## "r1" relates to the interaction of the range space of the first
## marginal smooth and the first basis function of the null
## space of the second marginal smooth
## "2r" relates to the interaction of the second basis function of
## the null space of the first marginal smooth with the range
## space of the second marginal smooth.
```

place.knots

Automatically place a set of knots evenly through covariate values

Description
Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

Usage

```r
place.knots(x,nk)
```
Arguments

- **x**: array of covariate values (need not be sorted).
- **nk**: integer indicating the required number of knots.

Details

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

Value

An array of knot locations.

require(mgcv)
x<-runif(30)
place.knots(x,7)
rm(x)
```

plot.gam

**Default GAM plotting**

Description

Takes a fitted gam object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

Usage

```r
## S3 method for class 'gam'
plot(x, residuals=FALSE, rug=NULL, se=TRUE, pages=0, select=NULL, scale=-1,
     n=100, n2=40, n3=3, pers=FALSE, theta=30, phi=30, jit=FALSE, xlab=NULL,
     ylab=NULL, main=NULL, ylim=NULL, xlim=NULL, too.far=0.1,
     all.terms=FALSE, shade=FALSE, shade.col="gray80", shift=0,
     trans=I, seWithMean=FALSE, unconditional=FALSE, by.resids=FALSE,
     scheme=0,...)
```
Arguments

x

a fitted `gam` object as produced by `gam()`.

residuals

If `TRUE` then partial residuals are added to plots of 1-D smooths. If `FALSE` then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If `TRUE` then the residuals are the working residuals from the IRLS iteration weighted by the (square root) IRLS weights, in order that they have constant variance if the model is correct. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals).

rug

When `TRUE` the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth. The default of `NULL` sets `rug` to `TRUE` when the dataset size is <= 10000 and `FALSE` otherwise.

se

when `TRUE` (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlayed on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also `shade`, below.

pages

(default 0) the number of pages over which to spread the output. For example, if `pages=1` then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.

select

Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set `select=2`.

scale

set to `-1` (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if `ylim` supplied.

n

number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.

n2

Square root of number of points used to grid estimates of 2-d functions for contouring.

n3

Square root of number of panels to use when displaying 3 or 4 dimensional functions.

pers

Set to `TRUE` if you want perspective plots for 2-d terms.

theta

One of the perspective plot angles.

phi

The other perspective plot angle.

jit

Set to `TRUE` if you want rug plots for 1-d terms to be jittered.

xlab

If supplied then this will be used as the x label for all plots.

ylab

If supplied then this will be used as the y label for all plots.

main

Used as title (or z axis label) for plots if supplied.

yylim

If supplied then this pair of numbers are used as the y limits for each plot.

xlim

If supplied then this pair of numbers are used as the x limits for each plot.

too.far

If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before
deciding what to exclude, and too.far is a distance within the unit square. Setting to zero can make plotting faster for large datasets, but care then needed with interpretation of plots.

all.terms if set to TRUE then the partial effects of parametric model components are also plotted, via a call to termplot. Only terms of order 1 can be plotted in this way.

shade Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using termplot).

shade.col define the color used for shading confidence bands.

shift constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with trans.

trans monotonic function to apply to each smooth (after any shift), before plotting. Monotonicity is not checked, but default plot limits assume it. shift and trans are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.

seWithMean if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. If seWithMean=2 then the intervals include the uncertainty in the mean of the fixed effects (but not in the mean of any un-centred smooths or random effects). Marra and Wood (2012) suggests that TRUE results in better coverage performance, and this is also suggested by simulation.

unconditional if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used to compute uncertainty bands, if available. Otherwise the bands treat the smoothing parameters as fixed.

by.resids Should partial residuals be plotted for terms with by variables? Usually the answer is no, they would be meaningless.

scheme Integer or integer vector selecting a plotting scheme for each plot. See details.

Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by termplot.

For smooth terms plot.gam actually calls plot method functions depending on the class of the smooth. Currently random.effects, Markov random fields (mrf), Spherical.Spline and factor.smooth.interaction terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled s(cov, edf) where cov is the covariate name, and edf the estimated (or user defined for regression splines) degrees of freedom of the smooth. scheme == 0 produces a smooth curve with dashed curves indicating 2 standard error bounds. scheme == 1 illustrates the error bounds using a shaded region.

For scheme==0, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like s(var1, var2, edf), indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When se=TRUE, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If se is a positive number then contour plots are at plus or minus se multiplied by the s.e. Contour levels are chosen to try and
ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths scheme==1 produces a perspective plot, while scheme==2 produces a heatmap, with overlaid contours and scheme==3 a greyscale heatmap (contour.col controls the contour colour).

Smooths of 3 and 4 variables are displayed as tiled heatmaps with overlaid contours. In the 3 variable case the third variable is discretized and a contour plot of the first 2 variables is produced for each discrete value. The panels in the lower and upper rows are labelled with the corresponding third variable value. The lowest value is bottom left, and highest at top right. For 4 variables, two of the variables are coarsely discretized and a square array of image plots is produced for each combination of the discrete values. The first two arguments of the smooth are the ones used for the image/contour plots, unless a tensor product term has 2D marginals, in which case the first 2D marginal is image/contour plotted. n3 controls the number of panels. See also vis.gam.

Fine control of plots for parametric terms can be obtained by calling termplot directly, taking care to use its terms argument.

Note that, if seWithMean=TRUE, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka’s (1988) results presented in Marra and Wood (2012). There are two possible variants of this approach. In the default variant the extra uncertainty is in the mean of all other terms in the model (fixed and random, including uncentred smooths). Alternatively, if seWithMean=2 then only the uncertainty in parametric fixed effects is included in the extra uncertainty (this latter option actually tends to lead to wider intervals when the model contains random effects).

Several smooth plots methods using image will accept an hcolors argument, which can be anything documented in heat.colors (in which case something like hcolors=rainbow(50) is appropriate), or the grey function (in which case something like hcolors=grey(0:50/50) is needed). Another option is contour.col which will set the contour colour for some plots. These options are useful for producing grey scale pictures instead of colour.

Sometimes you may want a small change to a default plot, and the arguments to plot.gam just won’t let you do it. In this case, the quickest option is sometimes to clone the smooth.construct and Predict.matrix methods for the smooth concerned, modifying only the returned smoother class (e.g. to foo.smooth). Then copy the plot method function for the original class (e.g. mgcv:::plot.mgcv.smooth), modify the source code to plot exactly as you want and rename the plot method function (e.g. plot.foo.smooth). You can then use the cloned smooth in models (e.g. s(x,bs="foo")), and it will automatically plot using the modified plotting function.

Value

The functions main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

WARNING

Note that the behaviour of this function is not identical to plot.gam() in S-PLUS.

Plotting can be slow for models fitted to large datasets. Set rug=FALSE to improve matters. If it’s still too slow set too.far=0, but then take care not to overinterpret smooths away from supporting data.
Plots of 2-D smooths with standard error contours shown can not easily be customized.
The function can not deal with smooths of more than 2 variables!

Author(s)

Simon N. Wood <simon.wood@r-project.org>
Henric Nilsson <henric.nilsson@statisticon.se> donated the code for the shade option.
The design is inspired by the S function of the same name described in Chambers and Hastie (1993)
(but is not a clone).

---

**polys.plot**

*Plot geographic regions defined as polygons*

**Description**

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

**Usage**

`polys.plot(pc,z=NULL,scheme="heat",lab="",...)

**Arguments**

- **pc** A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several polygons, then each of these must be separated by an NA row in the matrix. See *mrf* for an example.
predict.bam

z
A vector of values associated with each area (item) of pc. If the vector elements have names then these are used to match elements of z to areas defined in pc. Otherwise pc and z are assumed to be in the same order. If z is NULL then polygons are not filled.
scheme
One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of z.
lab
label for plot.
...
other arguments to pass to plot (currently only if z is NULL).

Details
Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing mrf smooths.

Value
Simply produces a plot.

predict.bam

Description
Essentially a wrapper for predict.gam for prediction from a model fitted by bam. Can compute on a parallel cluster.
Takes a fitted bam object produced by bam and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).
## S3 method for class 'bam'

predict(object,newdata,type="link",se.fit=FALSE,terms=NULL,
exclude=NULL,block.size=50000,newdata.guaranteed=FALSE,
na.action=na.pass,cluster=NULL,discrete=TRUE,n.threads=1,...)

### Arguments

*object*  
a fitted `bam` object as produced by `bam`.

*newdata*  
A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If `newdata` is provided then it should contain all the variables needed for prediction: a warning is generated if not.

*type*  
When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When `type="terms"` each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. `type="iterms"` is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When `type="response"` predictions on the scale of the response are returned (possibly with approximate standard errors). When `type="lpmatrix"` then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case `se.fit` is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).

*se.fit*  
when this is TRUE (not default) standard error estimates are returned for each prediction.

*terms*  
if `type=="terms"` or `type="iterms"` then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If `NULL` then all terms are included.

*exclude*  
if `type=="terms"` or `type="iterms"` then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If `NULL` then no terms are excluded. To avoid supplying covariate values for excluded terms, set `newdata.guaranteed=TRUE`, but note that this skips all checks of `newdata`.

*block.size*  
maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.

*newdata.guaranteed*  
Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but `newdata` must be complete, with no NA values for predictors required in the model.

*na.action*  
what to do about NA values in newdata. With the default `na.pass`, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). `na.exclude` or `na.omit` result in the dropping of newdata rows, if they contain any NA values for required predictors. If `newdata` is missing then NA handling is determined from `object$na.action`. 
predict.bam

predict.bam can compute in parallel using `parLapply` from the `parallel` package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for `bam`.

discrete
if TRUE then discrete prediction methods used with model fitted by discrete methods. FALSE for regular prediction.

n.threads
if se.fit=TRUE and discrete prediction is used then parallel computation can be used to speed up se calculation. This specifies number of threads to use.

... other arguments.

Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters Vp in the fitted bam object.

To facilitate plotting with `termplot`, if object possesses an attribute "para.only" and type="terms" then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to `gam` as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples in `predict.gam` for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

Value

If `type="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is TRUE then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or model.frame: if it’s a model frame then all variables must be supplied.

WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples in `predict.gam`.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

predict.gam  Prediction from fitted GAM model

Description

Takes a fitted `gam` object produced by `gam()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

Usage

## S3 method for class 'gam'
predict(object, newdata, type="link", se.fit=FALSE, terms=NULL, exclude=NULL, block.size=NULL, newdata.guaranteed=FALSE, na.action=na.pass, unconditional=FALSE, i terms.type=NULL, ...)
integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).

se.fit when this is TRUE (not default) standard error estimates are returned for each prediction.

terms if type=="terms" or type="iterms" then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If NULL then all terms are included.

exclude if type=="terms" or type="iterms" then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If NULL then no terms are excluded. Note that this is the term names as it appears in the model summary, see example. You can avoid providing the covariates for the excluded terms by setting newdata.guaranteed=TRUE, which will avoid all checks on newdata.

block.size maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this. If NULL then block size is 1000 if new data supplied, and the number of rows in the model frame otherwise.

newdata.guaranteed Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.

na.action what to do about NA values in newdata. With the default na.pass, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). na.exclude or na.omit result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from object$na.action.

unconditional if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used, when available, otherwise the covariance matrix conditional on the estimated smoothing parameters is used.

iterms.type if type=="iterms" then standard errors can either include the uncertainty in the overall mean (default, with fixed and random effects included) or the uncertainty in the mean of the non-smooth fixed effects only (iterms.type=2).

... other arguments.

Details

The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters Vp in the fitted gam object.

When predicting from models with linear.functional.terms then there are two possibilities. If the summation convention is to be used in prediction, as it was in fitting, then newdata should be a list, with named matrix arguments corresponding to any variables that were matrices in fitting. Alternatively one might choose to simply evaluate the constituent smooths at particular values in which case arguments that were matrices can be replaced by vectors (and newdata can be a dataframe). See linear.functional.terms for example code.

To facilitate plotting with termplot, if object possesses an attribute "para.only" and type=="terms" then only parametric terms of order 1 are returned (i.e. those that termplot can handle).
Note that, in common with other prediction functions, any offset supplied to \texttt{gam} as an argument is always ignored when predicting, unlike offsets specified in the \texttt{gam} model formula. See the examples for how to use the \texttt{lpmatrix} for obtaining credible regions for quantities derived from the model.

**Value**

If \texttt{type=="lpmatrix"} then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if \texttt{se.fit} is \texttt{TRUE} then a 2 item list is returned with items (both arrays) \texttt{fit} and \texttt{se.fit} containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether \texttt{type} is "\texttt{terms}" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

\texttt{newdata} can be a data frame, list or model.frame: if it’s a model frame then all variables must be supplied.

**WARNING**

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples.

Note that the behaviour of this function is not identical to \texttt{predict.gam()} in Splus. \texttt{type=="terms"} does not exactly match what \texttt{predict.lm} does for parametric model components.

---

Predict.matrix

Prediction methods for smooth terms in a GAM

Description

Takes smooth objects produced by smooth.construct methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function PredictMat.

Usage

Predict.matrix(object,data)
Predict.matrix2(object,data)

Arguments

object is a smooth object produced by a smooth.construct method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate Predict.matrix function to produce a prediction matrix for new covariate values. Further details are given in smooth.construct.

data A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for smooth.construct and smooth.construct2.

Details

Smooth terms in a GAM formula are turned into smooth specification objects of class xx.smooth.spec during processing of the formula. Each of these objects is converted to a smooth object using an appropriate smooth.construct function. The Predict.matrix functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.
Note that new smooth classes can be added by writing a new \code{smooth.construct} method function and a corresponding \code{Predict.matrix} method function: see the example code provided for \code{smooth.construct} for details.

**Value**

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in \code{object}. If the smooth class is one which generates offsets the corresponding offset is returned as attribute "offset" of the matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

# See smooth.construct examples

```
Predict.matrix.cr.smooth
```

\emph{Predict matrix method functions}

**Description**

The various built in smooth classes for use with \code{gam} have associate \code{Predict.matrix} method functions to enable prediction from the fitted model.

**Usage**

```r
## S3 method for class 'cr.smooth'
Predict.matrix(object, data)
## S3 method for class 'cs.smooth'
Predict.matrix(object, data)
## S3 method for class 'cyclic.smooth'
Predict.matrix(object, data)
## S3 method for class 'pspline.smooth'
Predict.matrix(object, data)
## S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
## S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
## S3 method for class 'ts.smooth'
Predict.matrix(object, data)
## S3 method for class 't2.smooth'
Predict.matrix(object, data)
```
Arguments

object  a smooth object, usually generated by a smooth.construct method having processed a smooth specification object generated by an s or te term in a gam formula.

data A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for smooth.construct and smooth.construct2.

Details

The Predict matrix function is not normally called directly, but is rather used internally by predict.gam etc. to predict from a fitted gam model. See Predict.matrix for more details, or the specific smooth.construct pages for details on a particular smooth class.

Value

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

Examples

## see smooth.construct

Predict.matrix.soap.film

Prediction matrix for soap film smooth

Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the Predict.matrix method function required by gam.

Usage

## S3 method for class 'soap.film'
Predict.matrix(object, data)
## S3 method for class 'sw'
Predict.matrix(object, data)
## S3 method for class 'sf'
Predict.matrix(object, data)
Arguments

object: A class "soap.film", "sf" or "sw" object.

data: A list list or data frame containing the arguments of the smooth at which predictions are required.

Details

The smooth object will be largely what is returned from smooth.construct.so.smooth.spec, although elements X and S are not needed, and need not be present, of course.

Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

lines(fsb[[1]]$x,fsb[[1]]$y,lwd=3)
points(x,y,pch=".")
contour(xm,yn,matrix(fv.gam,m,n),levels=seq(-5,5,by=.25),add=TRUE)
```

---

**print.gam**  
*Print a Generalized Additive Model object.*

### Description

The default print method for a gam object.
## S3 method for class 'gam'

print(x, ...)

### Arguments

- **x, ...** fitted model objects of class `gam` as produced by `gam()`.

### Details

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See `gamObject` (or `names(x)`) for a listing of what the object contains. `summary.gam` provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBRE(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

If rank deficiency of the model was detected then the apparent rank is reported, along with the length of the coefficient vector (rank in absence of rank deficiency). Rank deficiency occurs when not all coefficients are identifiable given the data. Although the fitting routines (except `gamm`) deal gracefully with rank deficiency, interpretation of rank deficient models may be difficult.

## psum.chisq

**Evaluate the c.d.f. of a weighted sum of chi-squared deviates**

### Description

Evaluates the c.d.f. of a weighted sum of chi-squared random variables by the method of Davies (1973, 1980). That is it computes

\[
P(q < \sum_{i=1}^{r} \lambda_i X_i + \sigma Z)
\]

where \( X_i \) is a chi-squared random variable with \( \text{df}[j] \) (integer) degrees of freedom and non-centrality parameter \( \text{nc}[j] \), while \( Z \) is a standard normal deviate.
Usage

\texttt{psum.chisq(q, lb, df=rep(1, length(lb)), nc=rep(0, length(lb)), sigz=0,
lower.tail=FALSE, tol=2e-5, nlim=100000, trace=FALSE)}

Arguments

- \texttt{q} is the vector of quantile values at which to evaluate.
- \texttt{lb} contains $\lambda_i$, the weight for deviate $i$. Weights can be positive and/or negative.
- \texttt{df} is the integer vector of chi-squared degrees of freedom.
- \texttt{nc} is the vector of non-centrality parameters for the chi-squared deviates.
- \texttt{sigz} is the multiplier for the standard normal deviate. Non-positive to exclude this term.
- \texttt{lower.tail} indicates whether lower of upper tail probabilities are required.
- \texttt{tol} is the numerical tolerance to work to.
- \texttt{nlim} is the maximum number of integration steps to allow
- \texttt{trace} can be set to \texttt{TRUE} to return some trace information and a fault code as attributes.

Details

This calls a C translation of the original Algol60 code from Davies (1980), which numerically inverts the characteristic function of the distribution (see Davies, 1973). Some modifications have been made to remove goto statements and global variables, to use a slightly more efficient sorting of \texttt{lb} and to use R functions for $\log(1+x)$. In addition the integral and associated error are accumulated in single terms, rather than each being split into 2, since only their sums are ever used. If \texttt{q} is a vector then \texttt{psum.chisq} calls the algorithm separately for each \texttt{q[i]}.

If the Davies algorithm returns an error then an attempt will be made to use the approximation of Liu et al (2009) and a warning will be issued. If that is not possible then an \texttt{NA} is returned. A warning will also be issued if the algorithm detects that round off errors may be significant.

If \texttt{trace} is set to \texttt{TRUE} then the result will have two attributes. "\texttt{ifault}" is 0 for no problem, 1 if the desired accuracy can not be obtained, 2 if round-off error may be significant, 3 is invalid parameters have been supplied or 4 if integration parameters can not be located. "\texttt{trace}" is a 7 element vector: 1. absolute value sum; 2. total number of integration terms; 3. number of integrations; 4. integration interval in main integration; 5. truncation point in initial integration; 6. sd of convergence factor term; 7. number of cycles to locate integration parameters. See Davies (1980) for more details.

Note that for vector \texttt{q} these attributes relate to the final element of \texttt{q}.

**qq.gam**

**QQ plots for gam model residuals**

### Description

Takes a fitted `gam` object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

### Usage

```r
qq.gam(object, rep=0, level=.9,s.rep=10,
  type=c("deviance","pearson","response"),
  pch=".", rl.col=2, rep.col="gray80", ...)```

### Arguments

- **object**
  a fitted `gam` object as produced by `gam()` (or a `glm` object).

- **rep**
  How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.

- **level**
  If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated.

- **s.rep**
  how many times to randomize uniform quantiles to data under direct computation.

- **type**
  what sort of residuals should be plotted? See `residuals.gam`.

- **pch**
  plot character to use. 19 is good.
QQ-plots of the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficients and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended).

Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

random.effects

Description

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. `gamm` and `gamm4` from the `gamm4` package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with `gam` by making use of `s(...,bs="re")` terms in a model: see `smooth.construct.re.smooth.spec`, for full details. The basic idea is that, e.g., `s(x,z,g,bs="re")` generates an i.i.d. Gaussian random effect with model matrix given by `model.matrix(~x:z:g-1)` — in principle such terms can take any number of arguments. This simple approach is sufficient for implementing a wide range of commonly used random effect structures. For example if `g` is a factor then `s(g,bs="re")` produces a random coefficient for each level of `g`, with the random coefficients all modelled as i.i.d. normal. If `g` is a factor and `x` is numeric, then `s(x,g,bs="re")` produces an i.i.d. normal random slope relating the response to `x` for each level of `g`. If `h` is another factor then `s(h,g,bs="re")` produces the usual i.i.d. normal `g-h` interaction. Note that a rather useful approximate test for zero random effect is also implemented for such terms based on Wood (2013). If the precision matrix is known to within a multiplicative constant, then this can be supplied via the `xt` argument of `s`. See `smooth.construct.re.smooth.spec` for details and example.

Alternatively, but less straightforwardly, the `paraPen` argument to `gam` can be used: see `gam.models`. If smoothing parameter estimation is by ML or REML (e.g. `gam(...,method="REML")`) then this approach is a completely conventional likelihood based treatment of random effects.

`gam` can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However `gam` is often faster and more reliable than `gamm` or `gamm4`, when the number of random effects is modest.

To facilitate the use of random effects with `gam`, `gam.vcomp` is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see `summary.gam` and `anova.gam`.

residuals.gam

Generalized Additive Model residuals

Description

Returns residuals for a fitted gam model object. Pearson, deviance, working and response residuals are available.
Usage

```r
## S3 method for class 'gam'
residuals(object, type = "deviance", ...)
```

Arguments

- `object`: a `gam` fitted model object.
- `type`: the type of residuals wanted. Usually one of "deviance", "pearson", "scaled.pearson", "working", or "response".
- `...`: other arguments.

Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter): ((y − μ) / √V(μ)), where y is data, μ is model fitted value and V is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

Families can supply their own residual function, which is used in place of the standard function if present, (e.g. `cox.ph`).

Value

A vector of residuals.

**rig**

*Generate inverse Gaussian random deviates*

Description

Generates inverse Gaussian random deviates.

Usage

```r
rig(n, mean, scale)
```
Arguments

\texttt{n} \hspace{1cm} \text{the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required.}

\texttt{mean} \hspace{1cm} \text{vector of mean values.}

\texttt{scale} \hspace{1cm} \text{vector of scale parameter values (lambda, see below)}

Details

If \( x \) if the returned vector, then \( E(x) = \text{mean} \) while \( \text{var}(x) = \text{scale} \times \text{mean}^3 \). For density and distribution functions see the \texttt{statmod} package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that \texttt{scale} here is the scale parameter in the GLM sense, which is the reciprocal of the usual ‘lambda’ parameter.

Value

A vector of inverse Gaussian random deviates.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

https://www.maths.ed.ac.uk/~swood34/

Examples

```r
require(mgcv)
set.seed(7)
## An inverse.gaussian GAM example, by modify `gamSim' output...
dat <- gamSim(1,n=400,dist="normal",scale=1)
dat$f <- dat$f/4 ## true linear predictor
ey <- exp(dat$f);scale <- .5 ## mean and GLM scale parameter
## simulate inverse Gaussian response...
dat$y <- rig(ey,mean=ey,scale=.2)
big <- gam(y ~ s(x0)+ s(x1)+s(x2)+s(x3),family=inverse.gaussian(link=log),
data=dat,method="REML")
plot(big,pages=1)
gam.check(big)
summary(big)
```
Generate from or evaluate multivariate normal or t densities.

Description

Generates multivariate normal or t random deviates, and evaluates the corresponding log densities.

Usage

\texttt{rmvn(n,mu,V)}
\texttt{r.mvt(n,mu,V,df)}
\texttt{dmvn(x,mu,V,R=NULL)}
\texttt{d.mvt(x,mu,V,df,R=NULL)}

Arguments

\texttt{n} \hspace{1cm} \text{number of simulated vectors required.}
\texttt{mu} \hspace{1cm} \text{the mean of the vectors: either a single vector of length } p=\text{ncol}(V) \text{ or an } n \times p \text{ matrix.}
\texttt{V} \hspace{1cm} \text{A positive semi definite covariance matrix.}
\texttt{df} \hspace{1cm} \text{The degrees of freedom for a t distribution.}
\texttt{x} \hspace{1cm} \text{A vector or matrix to evaluate the log density of.}
\texttt{R} \hspace{1cm} \text{An optional Cholesky factor of } V \text{ (not pivoted).}

Details

Uses a ‘square root’ of \texttt{V} to transform standard normal deviates to multivariate normal with the correct covariance matrix.

Value

An \texttt{n} row matrix, with each row being a draw from a multivariate normal or t density with covariance matrix \texttt{V} and mean vector \texttt{mu}. Alternatively each row may have a different mean vector if \texttt{mu} is a vector.

For density functions, a vector of log densities.

crossprod(sweep(z,2,colMeans(z)))/n ## observed covariance matrix
colMeans(z) ## observed mu
dmvn(z,mu,V)
```

---

**Rrank**

Find rank of upper triangular matrix

Description

Finds rank of upper triangular matrix R, by estimating condition number of upper rank by rank block, and reducing rank until this is acceptably low. Assumes R has been computed by a method that uses pivoting, usually pivoted QR or Choleski.

Usage

```r
Rrank(R,tol=.Machine$double.eps^.9)
```

Arguments

- **R**: An upper triangular matrix, obtained by pivoted QR or pivoted Choleski.
- **tol**: the tolerance to use for judging rank.

Details

The method is based on Cline et al. (1979) as described in Golub and van Loan (1996).

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

Examples

```r
set.seed(0)
n <- 10;p <- 5
X <- matrix(runif(n*(p-1)),n,p)
qrx <- qr(X,LAPACK=TRUE)
Rrank(qr.R(qrx))
```
Generate Tweedie random deviates

Description

Generates Tweedie random deviates, for powers between 1 and 2.

Usage

rTweedie(mu, p=1.5, phi=1)

Arguments

mu          vector of expected values for the deviates to be generated. One deviate generated for each element of mu.

p          the variance of a deviate is proportional to its mean, mu to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.

phi          The scale parameter. Variance of the deviates is given by is phi*mu^p.

Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution, with mean \( \mu^{2-p}/((2-p)*\phi) \). The Gamma random variables that are summed have shape parameter \((2-p)/(p-1)\) and scale parameter \(\phi*(p-1)*\mu^{p-1}\) (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of rtweddie from the tweedie package.

Value

A vector of random deviates from a Tweedie distribution, expected value vector mu, variance vector phi*mu^p.

n <- 300
x <- runif(n)
mu <- exp(f2(x)/3+.1); x <- x*10 - 4
y <- rTweedie(mu,p=1.5,phi=1.3)
b <- gam(y~s(x,k=20),family=Tweedie(p=1.5))
b
plot(b)
```

---

**s**

Defining smooths in GAM formulae

Description

Function used in definition of smooth terms within gam model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

Usage

```r
s(..., k=-1,fx=FALSE,bs="tp",m=NA,by=NA,xt=NULL,id=NULL,sp=NULL,pc=NULL)
```

Arguments

- `...` a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `s(log(x))` is fine, but `s(I(x/sd(x)))` is not (see `predict.gam`).
- `k` the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. `k` should not be less than the dimension of the null space of the penalty for the term (see `null.space.dimension`), but will be reset if it is. See `choose.k` for further information.
- `fx` indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
- `bs` a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see `smooth.terms` for an overview of what is available.
- `m` The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.r.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.
- `by` a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). For the numeric by variable case the resulting smooth is not usually subject to a centering constraint (so the by variable should not be added as an additional main effect). In the factor by variable case a replicate of the smooth is produced for
each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See `gam.models` for further details. A by variable may also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see `gam.models` and `linear.functional.terms` for details).

xt
Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis.

id
A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An id with a factor by variable causes the smooths at each factor level to have the same smoothing parameter.

sp
any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to `gam`. Ignored by `gamm`.

pc
If not `NULL`, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See `identifiability`.

Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in `smooth.construct`.

Value

A class xx.smooth.spec object, where xx is a basis identifying code given by the bs argument of s. These smooth.spec objects define smooths and are turned into bases and penalties by smooth.construct method functions.

The returned object contains the following items:

term
An array of text strings giving the names of the covariates that the term is a function of.

bs.dim
The dimension of the basis used to represent the smooth.

fixed
TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline.

dim
The dimension of the smoother - i.e. the number of covariates that it is a function of.

p.order
The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.

by
is the name of any by variable as text ("NA" for none).

label
A suitable text label for this smooth term.

xt
The object passed in as argument xt.

id
An identifying label or number for the smooth, linking it to other smooths. Defaults to NULL for no linkage.

sp
array of smoothing parameters for the term (negative for auto-estimation). Defaults to NULL.
scat

GAM scaled t family for heavy tailed data

Description

Family for use with gam or bam, implementing regression for the heavy tailed response variables, y, using a scaled t model. The idea is that \((y - \mu)/\sigma \sim t_\nu\) where \(\mu\) is determined by a linear predictor, while \(\sigma\) and \(\nu\) are parameters to be estimated alongside the smoothing parameters.

Usage

```r
scat(theta = NULL, link = "identity", min.df=3)
```
sdiag

Arguments

theta  the parameters to be estimated $\nu = b + \exp(\theta_1)$ (where 'b' is min.df) and $\sigma = \exp(\theta_2)$. If supplied and both positive, then taken to be fixed values of $\nu$ and $\sigma$. If any negative, then absolute values taken as starting values.

link  The link function: one of "identity", "log" or "inverse".

min.df  minimum degrees of freedom. Should not be set to 2 or less as this implies infinite response variance.

Details

Useful in place of Gaussian, when data are heavy tailed. min.df can be modified, but lower values can occasionally lead to convergence problems in smoothing parameter estimation. In any case min.df should be >2, since only then does a t random variable have finite variance.

Value

An object of class extended.family.

sdiag  Extract or modify diagonals of a matrix

Description

Extracts or modifies sub- or super- diagonals of a matrix.

Usage

sdiag(A,k=0)
sdiag(A,k=0) <- value
Arguments

A  a matrix
k  sub- (negative) or super- (positive) diagonal of a matrix. 0 is the leading diagonal.
value  single value, or vector of the same length as the diagonal.

Value

A vector containing the requested diagonal, or a matrix with the requested diagonal replaced by value.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

Examples

```r
require(mgcv)
A <- matrix(1:35,7,5)
A
sdiag(A,1) ## first super diagonal
sdiag(A,-1) ## first sub diagonal
sdiag(A) <- 1 ## leading diagonal set to 1
sdiag(A,3) <- c(-1,-2) ## set 3rd super diagonal
```

Description

The shash family implements the four-parameter sinh-arcsinh (shash) distribution of Jones and Pewsey (2009). The location, scale, skewness and kurtosis of the density can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae. It is worth carefully considering whether the data are sufficient to support estimation of such a flexible model before using it.

Usage

```r
shash(link = list("identity", "logeb", "identity", "identity"),
      b = 1e-2, phiPen = 1e-3)
```

Arguments

link  vector of four characters indicating the link function for location, scale, skewness and kurtosis parameters.
b  positive parameter of the logeb link function, see Details.
phiPen  positive multiplier of a ridge penalty on kurtosis parameter. Do not touch it unless you know what you are doing, see Details.
Details

The density function of the shash family is

\[ p(y|\mu, \sigma, \epsilon, \delta) = C(z) \exp\left(-\frac{S(z)^2}{2\sigma^2} + \frac{1}{2}\right) \]

where \( C(z) = 1 + S(z)^2/2, S(z) = \sinh\delta\sinh(1)(z) - \epsilon \) and \( z = (y - \mu)/(\sigma\delta) \). Here \( \mu \) and \( \sigma > 0 \) control, respectively, location and scale, \( \epsilon \) determines skewness, while \( \delta > 0 \) controls tailweight. Shash can model skewness to either side, depending on the sign of \( \epsilon \). Also, shash can have tails that are lighter \((\delta > 1)\) or heavier \((0 < \delta < 1)\) that a normal. For fitting purposes, here we are using \( \tau = \log(\sigma) \) and \( \phi = \log(\delta) \).

The link function used for \( \tau \) is logeb with is \( \eta = \logexp(\tau) - b \) so that the inverse link is \( \tau = \log(\sigma) = \logexp(\eta) + b \). The point is that we are don’t allow \( \sigma \) to become smaller than a small constant \( b \). The likelihood includes a ridge penalty \(-\phiPen \times \phi^2\), which shrinks \( \phi \) toward zero. When sufficient data is available the ridge penalty does not change the fit much, but it is useful to include it when fitting the model to small data sets, to avoid \( \phi \) diverging to +infinity (a problem already identified by Jones and Pewsey (2009)).

Value

An object inheriting from class `general.family`.

Single index models contain smooth terms with arguments that are linear combinations of other covariates. e.g. $s(X\alpha)$ where $\alpha$ has to be estimated. For identifiability, assume $\|\alpha\| = 1$ with positive first element. One simple way to fit such models is to use `gam` to profile out the smooth model coefficients and smoothing parameters, leaving only the $\alpha$ to be estimated by a general purpose optimizer.

Example code is provided below, which can be easily adapted to include multiple single index terms, parametric terms and further smooths. Note the initialization strategy. First estimate $\alpha$ without penalization to get starting values and then do the full fit. Otherwise it is easy to get trapped in a local optimum in which the smooth is linear. An alternative is to initialize using fixed penalization (via the `sp` argument to `gam`).

Examples

```r
require(mgcv)

si <- function(theta,y,x,z,opt=TRUE,k=10,fx=FALSE) {
  ## Fit single index model using gam call, given theta (defines alpha).
  ## Return ML if opt=TRUE and fitted gam with theta added otherwise.
  ## Suitable for calling from 'optim' to find optimal theta/alpha.
  alpha <- c(1,theta) ## constrained alpha defined using free theta
  kk <- sqrt(sum(alpha^2))
  alpha <- alpha/kk ## so now $||alpha||=1$
  a <- x%*%alpha ## argument of smooth
  b <- gam(y~s(a,fx=fx,k=k)+s(z),family=poisson,method="ML") ## fit model
  if (opt) return(b$gcv.ubre) else {
    b$alpha <- alpha ## add alpha
    J <- outer(alpha,-theta/kk^2) ## compute Jacobian
    for (j in 1:length(theta)) J[j+1,j] <- J[j+1,j] + 1/kk
    b$J <- J ## dalpha_i/dtheta_j
    return(b)
  }
}

## simulate some data from a single index model...

set.seed(1)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
       (10 * x)^3 * (1 - x)^10
```
n <- 200; m <- 3
x <- matrix(runif(n*m),n,m) ## the covariates for the single index part
z <- runif(n) ## another covariate
alpha <- c(1,-1,.5); alpha <- alpha/sqrt(sum(alpha^2))
etta <- as.numeric(f2((x%*%alpha+.41)/1.4)+1+z^2*2)/4
mu <- exp(etta)
y <- rpois(n,mu) ## Poi response

## now fit to the simulated data...

th0 <- c(-.8,.4) ## close to truth for speed
## get initial theta, using no penalization...
f0 <- nlm(si,th0,y=y,x=x,z=z,fx=TRUE,k=5)
## now get theta/alpha with smoothing parameter selection...
f1 <- nlm(si,f0$estimate,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <- f1$estimate

## Alternative using 'optim'...

th0 <- rep(0,m-1)
## get initial theta, using no penalization...
f0 <- optim(th0,si,y=y,x=x,z=z,fx=TRUE,k=5)
## now get theta/alpha with smoothing parameter selection...
f1 <- optim(f0$par,si,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <- f1$par

## extract and examine fitted model...

b <- si(theta.est,y,x,z,opt=FALSE) ## extract best fit model
plot(b,pages=1)
b
b$alpha
## get sd for alpha...
Vt <- b$J%*%solve(f1$hessian,t(b$J))
diag(Vt)^.5

---

Sl.inirep

Re-parametrizing model matrix X

### Description

INTERNAL routine to apply initial SI re-parameterization to model matrix X, or, if inverse==TRUE, to apply inverse re-parametrization to parameter vector or covariance matrix.

### Usage

```r
Sl.inirep(Sl,X,1,r,nt=1)
```

```r
Sl.initial.repara(Sl, X, inverse = FALSE, both.sides = TRUE, cov = TRUE, nt = 1)
```
**Arguments**

- `r`: the output of `Sl.setup`.
- `X`: the model matrix.
- `l`: if non-zero apply transform (positive) or inverse transform from left. 1 or -1 of transform, 2 or -2 for transpose.
- `r`: if non-zero apply transform (positive) or inverse transform from right. 1 or -1 of transform, 2 or -2 for transpose.
- `inverse`: if TRUE an inverse re-parametrization is performed.
- `both.sides`: if `inverse==TRUE` and `both.sides==FALSE` then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If `both.sides==FALSE, X` is a vector and `inverse==FALSE` then `X` is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix).
- `cov`: boolean indicating whether `X` is a covariance matrix.
- `nt`: number of parallel threads to be used.

**Value**

A re-parametrized version of `X`.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

**Description**

INTERNAL routine to apply re-parameterization from log-determinant of penalty matrix, ldetS to model matrix, `X`, blockwise.

**Usage**

```
Sl.repara(rp, X, inverse = FALSE, both.sides = TRUE)
```

**Arguments**

- `rp`: reparametrization.
- `X`: if `X` is a matrix it is assumed to be a model matrix whereas if `X` is a vector it is assumed to be a parameter vector.
- `inverse`: if TRUE an inverse re-parametrization is performed.
- `both.sides`: if `inverse==TRUE` and `both.sides==FALSE` then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If `both.sides==FALSE, X` is a vector and `inverse==FALSE` then `X` is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix).
Value
A re-parametrized version of X.

Author(s)
Simon N. Wood <simon.wood@r-project.org>.

Description
INTERNAL function for setting up a list representing a block diagonal penalty matrix from the object produced by gam.setup.

Usage
Sl.setup(G,cholesky=FALSE,no.repara=FALSE,sparse=FALSE)

Arguments
- G: the output of gam.setup.
- cholesky: re-parameterize using Cholesky only.
- no.repara: set to TRUE to turn off all initial reparameterization.
- sparse: sparse setup?

Value
A list with an element for each block. For block, b, Sl[[b]] is a list with the following elements:

- `repara`: should re-parameterization be applied to model matrix, etc? Usually FALSE if non-linear in coefficients.
- `start,stop`: such that start:stop are the indexes of the parameters of this block.
- `S`: a list of penalty matrices for the block (dim = stop-start+1) If length(S)=1 then this will be an identity penalty. Otherwise it is a multiple penalty, and an rS list of square root penalty matrices will be added. S (if repara==TRUE) and rS (always) will be projected into range space of total penalty matrix.
- `rS`: square root of penalty matrices if multiple penalties are used.
- `D`: a reparameterization matrix for the block. Applies to cols/params in start:stop. If numeric then X[,start:stop]%*%diag(D) is re-parametrization of X[,start:stop], and b.orig = D*b.repara (where b.orig is the original parameter vector). If matrix then X[,start:stop]%*%D is re-parametrization of X[,start:stop], and b.orig = D%*%b.repara (where b.orig is the original parameter vector).

Author(s)
Simon N. Wood <simon.wood@r-project.org>.
Description

Uses Lanczos iteration to find the truncated eigen-decomposition of a symmetric matrix.

Usage

\[
\text{slanczos}(A, k=10, kl=-1, \text{tol}=.\text{Machine}$\text{double.eps}^{.5}, \text{nt}=1)
\]

Arguments

- **A**
  - A symmetric matrix.
- **k**
  - Must be non-negative. If \( kl \) is negative, then the \( k \) largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If \( k \) is non-negative then the \( k \) highest eigenvalues are found together with their eigenvectors and the \( k \) lowest eigenvalues with eigenvectors are also returned.
- **kl**
  - If \( k \) is non-negative then the \( kl \) lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the \( k \) highest eigenvalues + eigenvectors). Negative \( k \) signals that the \( k \) largest magnitude eigenvalues should be returned, with eigenvectors.
- **tol**
  - Tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by \( \text{tol} \) (or the machine precision!).
- **nt**
  - Number of threads to use for leading order iterative multiplication of \( A \) by vector. May show no speed improvement on two processor machine.

Details

If \( k \) is non-negative, returns the highest \( k \) and lowest \( k \) eigenvalues, with their corresponding eigenvectors. If \( k \) is negative, returns the largest magnitude \( k \) eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of \( A \), as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small \( k \) and \( k \) the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner triadiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

Value

A list with elements `values` (array of eigenvalues); `vectors` (matrix with eigenvectors in its columns); `iter` (number of iterations required).

## compare timings of slanczos and eigen
system.time(er <- slanczos(A,10))
system.time(um <- eigen(A,symmetric=TRUE))

## confirm values are the same...
ind <- c(1:6,(n-3):n)
range(er$values-um$values[ind]);range(abs(er$vectors)-abs(um$vectors[,ind]))
```

smooth.construct

Constructor functions for smooth terms in a GAM

Description

Smooth terms in a GAM formula are turned into smooth specification objects of class xx.smooth.spec during processing of the formula. Each of these objects is converted to a smooth object using an appropriate smooth.construct function. New smooth classes can be added by writing a new smooth.construct method function and a corresponding Predict.matrix method function (see example code below).

In practice, smooth.construct is usually called via smooth.construct2 and the wrapper function smoothCon, in order to handle by variables and centering constraints (see the smoothCon documentation if you need to handle these things directly, for a user defined smooth class).

Usage

smooth.construct(object, data, knots)
smooth.construct2(object, data, knots)

Arguments

- **object** is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the bs argument of `s` (this convention allows the user to add their own smoothers). If `object` is not class `tensor.smooth.spec` it will have the following elements:
  - **term** The names of the covariates for this smooth, in an array.
bs.dim  Argument k of the s term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for cc terms). bs.dim<0 indicates that the constructor should set this to the default value.

fixed  TRUE if the term is to be unpenalized, otherwise FALSE.

dim  the number covariates of which this smooth is a function.

p.order  the order of the smoothness penalty or NA for autoselection of this. This is argument m of the s term that generated object.

by  the name of any by variable to multiply this term as supplied as an argument to s. "NA" if there is no such term.

label  A suitable label for use with this term.

xt  An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).

id  Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

sp  Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides sp argument to gam.

If object is of class tensor.smooth.spec then it was generated by a te term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

margin  is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.

term  is the array of names of the covariates that are arguments of the smooth.

by  is the name of any by variable, or "NA".

fx  is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

label  A suitable label for use with this term.

dim  is the number of covariates of which this smooth is a function.

mp  TRUE if multiple penalties are to be used.

np  TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

id  Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

sp  Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides sp argument to gam.

data  For smooth.construct a data frame or list containing the evaluation of the elements of object$term, with names given by object$term. The last entry will be the by variable, if object$by is not "NA". For smooth.construct2 data need only be an object within which object$term can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

knots  an optional data frame or list containing the knots relating to object$term. If it is NULL then the knot locations are generated automatically. The structure of knots should be as for data, depending on whether smooth.construct or smooth.construct2 is used.
Details

There are built-in methods for objects with the following classes: `tp.smooth.spec` (thin plate regression splines; see `tprs`); `ts.smooth.spec` (thin plate regression splines with shrinkage-to-zero); `cr.smooth.spec` (cubic regression splines; see `cubic.regression.spline`); `cs.smooth.spec` (cubic regression splines with shrinkage-to-zero); `cc.smooth.spec` (cyclic cubic regression splines); `ps.smooth.spec` (Eilers and Marx (1986) style P-splines; see `p.spline`); `cp.smooth.spec` (cyclic P-splines); `ad.smooth.spec` (adaptive smooths of 1 or 2 variables; see `adaptive.smooth`); `re.smooth.spec` (simple random effect terms); `mrf.smooth.spec` (Markov random field smoothers for smoothing over discrete districts); `tensor.smooth.spec` (tensor products).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default `mgcv.smooth` method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for `mgcv:::plot.sos.smooth`, `mgcv:::plot.random.effect`, `mgcv:::plot.mgcv.smooth` for example code.

Value

The input argument `object`, assigned a new class to indicate what type of smooth it is and with at least the following items added:

- `X` The model matrix from this term. This may have an "offset" attribute: a vector of length `nrow(X)` containing any contribution of the smooth to the model offset term. By variables do not need to be dealt with here, but if they are then an item by done must be added to the object.
- `S` A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.
- `rank` An array giving the ranks of the penalties.
- `null.space.dim` The dimension of the penalty null space (before centering).

The following items may be added:

- `C` The matrix defining any identifiability constraints on the term, for use when fitting. If this is NULL then `smoothCon` will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied `C` has an attribute "always.apply" then it is never ignored, even if any by variables of a smooth imply that no constraint is actually needed. Code for creating `C` should check whether the specification object already contains a zero row matrix, and leave this unchanged if it is (since this signifies no constraint should be produced).
- `Cp` An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.
- `no.rescale` If this is non-NULL then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because `gamm` requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.
smooth.construct
df

the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is null then smoothCon will set it to the basis dimension. smoothCon will reduce this by the number of constraints.

te.ok

0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 is it can be used but not plotted. Set to 1 if NULL.

plot.me

Set to FALSE if this smooth should not be plotted by plot.gam. Set to TRUE if NULL.

side.constrain

Set to FALSE to ensure that the smooth is never subject to side constraints as a result of nesting.

L

smooths may depend on fewer ‘underlying’ smoothing parameters than there are elements of S. In this case L is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the S[[i]]. L=NULL signifies that there is one smoothing parameter per S[[i]].

Usually the returned object will also include extra information required to define the basis, and used by Predict.matrix methods to make predictions using the basis. See the details section for links to the information included for the built in smooth classes.

tensor.smooth returned objects will additionally have each element of the margin list updated in the same way. tensor.smooths also have a list, XP, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

WARNING

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

The code given in the example is based on the smooths advocated in:
However if you want p-splines, rather than splines with derivative based penalties, then the built in "ps" class is probably a marginally better bet. It’s based on
https://www.maths.ed.ac.uk/~swood34/

Adaptive smooths in GAMs

Description

gam can use adaptive smooths of one or two variables, specified via terms like s(...,bs="ad",...). (gamm can not use such terms — check out package AdaptFit if this is a problem.) The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the k argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the m argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables k is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making k a two element vector. Similarly, in the two dimensional case m is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then m specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument xt with a character vector xt$bs specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting m=10 for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.
smooth.construct.ad.smooth.spec

Usage

## S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)

Arguments

object  
a smooth specification object, usually generated by a term s(...,bs="ad",...)
data  
a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots  
a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL

Details

The constructor is not normally called directly, but is rather used internally by \texttt{gam}. To use for basis setup it is recommended to use \texttt{smooth.construct2}.

This class can not be used as a marginal basis in a tensor product smooth, nor by \texttt{gamm}.

Value

An object of class "pspline.smooth" in the 1D case or "tensor.smooth" in the 2D case.

b <- gam(y~s(x,bs="ad",k=40,m=5,xt=list(bs="cr")))
smooth.construct.bs.smooth.spec

### Description

`gam` can use smoothing splines based on univariate B-spline bases with derivative based penalties, specified via terms like `s(x,bs="bs",m=c(3,2))`. `m[1]` controls the spline order, with `m[1]=3` being a cubic spline, `m[1]=2` being quadratic, and so on. The integrated square of the `m[2]`th derivative is used as the penalty. So `m=c(3,2)` is a conventional cubic spline. Any further elements of `m`, after the first 2, define the order of derivative in further penalties. If `m` is supplied as a single number, then it is taken to be `m[1]` and `m[2]=m[1]-1`, which is only a conventional smoothing spline in the `m=3`, cubic spline case. Notice that the definition of the spline order in terms of `m[1]` is intuitive, but differs to that used with the `tpsr` and `p.spline` bases. See details for options for controlling the interval over which the penalty is evaluated (which can matter if it is necessary to extrapolate).
### Usage

```r
## S3 method for class 'bs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'Bspline.smooth'
Predict.matrix(object, data)
```

### Arguments

- **object**: a smooth specification object, usually generated by a term `s(x, bs="bs", ...)`
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be `NULL`. See details for further information.

### Details

The basis and penalty are sparse (although sparse matrices are not used to represent them). `m[2]>m[1]` will generate an error, since in that case the penalty would be based on an undefined derivative of the basis, which makes no sense. The terms can have multiple penalties of different orders, for example `s(x, bs="bs", m=c(3,2,1,0))` specifies a cubic basis with 3 penalties: a conventional cubic spline penalty, an integrated square of first derivative penalty, and an integrated square of function value penalty.

The default basis dimension, `k`, is the larger of 10 and `m[1]`. `m[1]` is the lower limit on basis dimension. If knots are supplied, then the number of supplied knots should be `k + m[1] + 1`, and the range of the middle `k-m[1]+1` knots should include all the covariate values. Alternatively, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (making this range too wide mean that there is no information about some basis coefficients, because the corresponding basis functions have a span that includes no data). Unlike P-splines, splines with derivative based penalties can have uneven knot spacing, without a problem.

Another option is to supply 4 knots. Then the outer 2 define the interval over which the penalty is to be evaluated, while the inner 2 define an interval within which all but the outermost 2 knots should lie. Normally the outer 2 knots would be the interval over which predictions might be required, while the inner 2 knots define the interval within which the data lie. This option allows the penalty to apply over a wider interval than the data, while still placing most of the basis functions where the data are. This is useful in situations in which it is necessary to extrapolate slightly with a smooth. Only applying the penalty over the interval containing the data amounts to asserting certainty that the function has some derivative zeroed away from the data, which is equally unreasonable. It is preferable to build a model in which the same smoothness assumptions apply over both data and extrapolation intervals, but not over the whole real line. See example code for practical illustration.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior `k-m[1]+1` knots — the interval over which the penalty is evaluated). Such extrapolation is not allowed in basis construction, but is when predicting.

It is possible to set a `deriv` flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it.
An object of class "Bspline.smooth". See smooth.construct, for the elements that this object will contain.

**WARNING**

m[1] directly controls the spline order here, which is intuitively sensible, but different to other bases.

## over this range...
```
Penalized Cubic regression splines in GAMs

Description

`gam` can use univariate penalized cubic regression spline smooths, specified via terms like `s(x,bs="cr")`. `s(x,bs="cs")` specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) `s(x,bs="cc")` specifies a cyclic penalized cubic regression spline smooth.
‘Cardinal’ spline bases are used: Wood (2017) sections 5.3.1 and 5.3.2 gives full details. These bases have very low setup costs. For a given basis dimension, \( k \), they typically perform a little less well then thin plate regression splines, but a little better than p-splines. See \texttt{te} to use these bases in tensor product smooths of several variables.

Default \( k \) is 10.

**Usage**

```r
## S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cyclic.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

- **object**: a smooth specification object, usually generated by a term \( s(\ldots, bs="cr", \ldots), s(\ldots, bs="cs", \ldots) \) or \( s(\ldots, bs="cc", \ldots) \)
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to \texttt{object$term} (and \texttt{object$by}). The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as \texttt{data}. Can be \texttt{NULL}. See details.

**Details**

The constructor is not normally called directly, but is rather used internally by \texttt{gam}. To use for basis setup it is recommended to use \texttt{smooth.construct2}.

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of \( x \) then there would be a knot at every 10th (ordered) \( x \) value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

**Value**

An object of class "cr.smooth" "cs.smooth" or "cyclic.smooth". In addition to the usual elements of a smooth class documented under \texttt{smooth.construct}, this object will contain:
xp giving the knot locations used to generate the basis.

F For class "cr.smooth" and "cs.smooth" objects t(F) transforms function values at the knots to second derivatives at the knots.

BD class "cyclic.smooth" objects include matrix BD which transforms function values at the knots to second derivatives at the knots.

smooth.construct.ds.smooth.spec

Description
Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like s(x,z,bs="ds",m=c(1,.5) in a

gam model formula. In the notation of Duchon (1977) m is given by m[1] (default value 2), while s

is given by m[2] (default value 0).

Duchon’s (1977) construction generalizes the usual thin plate spline penalty as follows. The usual

TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial

mth order derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the

Low rank Duchon 1977 splines
Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the
fourier frequencies, raised to the power 2s. s is a user selected constant taking integer values divided
by 2. If d is the number of arguments of the smooth, then it is required that -d/2 < s < d/2. To obtain
continuous functions we further require that m + s > d/2. If s=0 then the usual thin plate spline is
recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003)
to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is
used here. For large datasets the same subsampling approach as is used in the tprs case is employed
here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin
plate splines, while still yielding continuous functions. For example, we can set m = 1 and s = d/2 -.5 in order to use first derivative penalization for any d (which has the advantage that the dimension
of the null space of unpenalized functions is only d+1).

Usage

```r
## S3 method for class 'ds.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'duchon.spline'
Predict.matrix(object, data)
```

Arguments

- **object**
a smooth specification object, usually generated by a term
s(...,bs="ds",...).

- **data**
a list containing just the data (including any by variable) required by this term,
with names corresponding to object$term (and object$by). The by variable
is the last element.

- **knots**
a list containing any knots supplied for basis setup — in same order and with
same names as data. Can be NULL

Details

The default basis dimension for this class is k=M+k.def where M is the null space dimension (dimen-
sion of unpenalized function space) and k.def is 10 for dimension 1, 30 for dimension 2 and 100
for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized
regression smoothers, results are statistically insensitive to the exact choice, provided it is not so
small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by
its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis
setup it is recommended to use `smooth.construct2`.

For these classes the specification object will contain information on how to handle large datasets
in their xt field. The default is to randomly subsample 2000 ‘knots’ from which to produce a
reduced rank eigen approximation to the full basis, if the number of unique predictor variable com-
binations in excess of 2000. The default can be modified via the xt argument to s. This is supplied
as a list with elements max.knots and seed containing a number to use in place of 2000, and the
random number seed to use (either can be missing). Note that the random sampling will not effect
the state of R's RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation
of the tp basis can be time-consuming. The user can retain most of the advantages of the approach
by supplying a reduced set of covariate values from which to obtain the basis - typically the number
of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, \( k \). This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds \( \text{max.knots} \). The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, \( k \). For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

**Value**

An object of class "duchon.spline". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

- **shift**: A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
- **Xu**: A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
- **UZ**: The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.
- **null.space.dimension**: The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

```
smooth.construct.fs.smooth.spec

Factor smooth interactions in GAMs

Description

Simple factor smooth interactions, which are efficient when used with \texttt{gamm}. This smooth class allows a separate smooth for each level of a factor, with the same smoothing parameter for all smooths. It is an alternative to using factor by variables.

See the discussion of by variables in \texttt{gam.models} for more general alternatives for factor smooth interactions (including interactions of tensor product smooths with factors).

Usage

\begin{verbatim}
## S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'fs.interaction'
Predict.matrix(object, data)
\end{verbatim}

Arguments

- \texttt{object}: For the \texttt{smooth.construct} method a smooth specification object, usually generated by a term \texttt{s(x,...,bs="fs",)}. May have a \texttt{gamm} attribute: see details. For the \texttt{predict.Matrix} method an object of class \texttt{"fs.interaction"} produced by the \texttt{smooth.construct} method.
- \texttt{data}: a list containing just the data (including any by variable) required by this term, with names corresponding to \texttt{object\$term}.
- \texttt{knots}: a list containing any knots supplied for smooth basis setup.

Details

This class produces a smooth for each level of a single factor variable. Within a \texttt{gam} formula this is done with something like \texttt{s(x,fac,bs="fs"),} which is almost equivalent to \texttt{s(x,by=Fac, id=1)} (with the \texttt{gam} argument \texttt{select=TRUE}). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with \texttt{gamm}, where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) \texttt{gamm} only allows one conditioning factor for smooths, so \texttt{s(x)+s(z,fac,bs="fs")} is OK, but \texttt{s(x)+s(z,fac1,bs="fs")+s(v,fac2,bs="fs")} is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction. To facilitate this the constructor is called from \texttt{gamm} with an attribute \texttt{"gamm"} attached to the smooth specification object. The result differs from that resulting from the case where this is not done.

Note that \texttt{gamm4} from the \texttt{gamm4} package suffers from none of the restrictions that apply to \texttt{gamm}, and \texttt{"fs"} terms can be used without side-effects. Constructor is still called with a smooth specification object having a \texttt{"gamm"} attribute.

Any singly penalized basis can be used to smooth at each factor level. The default is \texttt{"tp"}, but alternatives can be supplied in the xt argument of \texttt{s} (e.g. \texttt{s(x,fac,bs="fs"\ xt="cr")} or
s(x, fac, bs="fs", xt=list(bs="cr")) The k argument to s(..., bs="fs") refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently gamm (or gamm4) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down k.

The plot method for this class has two schemes. scheme==0 is in colour, while scheme==1 is black and white.

Value

An object of class "fs.interaction" or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves. The contents of an "fs.interaction" object will depend on whether or not smooth.construct was called with an object with attribute gamm: see below.

##       s(x2,k=20),method="ML")
## ... is exactly equivalent.
Description

Gaussian process/kriging models based on simple covariance functions can be written in a very similar form to thin plate and Duchon spline models (e.g. Handcock, Meier, Nychka, 1994), and low rank versions produced by the eigen approximation method of Wood (2003). Kammann and Wand (2003) suggest a particularly simple form of the Matern covariance function with only a single smoothing parameter to estimate, and this class implements this and other similar models.

Usually invoked by an \( s(..., bs=\text{"gp"}) \) term in a gam formula. Argument \( m \) selects the covariance function, sets the range parameter and any power parameter. If \( m \) is not supplied then it defaults to \( \text{NA} \) and the covariance function suggested by Kammann and Wand (2003) along with their suggested range parameter is used. Otherwise \( m[1] \) between 1 and 5 selects the correlation function from respectively, spherical, power exponential, and Matern with \( \kappa = 1.5, 2.5 \) or \( 3.5 \). \( m[2] \) if present specifies the range parameter, with non-positive or absent indicating that the Kammann and Wand estimate should be used. \( m[3] \) can be used to specify the power for the power exponential which otherwise defaults to 1.

Usage

```r
## S3 method for class 'gp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'gp.smooth'
Predict.matrix(object, data)
```

Arguments

- `object`: a smooth specification object, usually generated by a term \( s(\ldots, bs=\text{"ms"}, \ldots) \).
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be \( \text{NULL} \).

Details

Let \( \rho > 0 \) be the range parameter, \( 0 < \kappa \leq 2 \) and \( d \) denote the distance between two points. Then the correlation functions indexed by \( m[1] \) are:

1. \( 1 - 1.5d/\rho + 0.5(d/\rho)^3 \) if \( d \leq \rho \) and 0 otherwise.
2. \( \exp(-d/\rho)^\kappa \).
3. \( \exp(-d/\rho)(1 + d/\rho) \).
4. \( \exp(-d/\rho)(1 + d/\rho + (d/\rho)^2/3) \).
5. \( \exp(-d/\rho)(1 + d/\rho + 2(d/\rho)^2/5 + (d/\rho)^3/15) \).
See Fahrmeir et al. (2013) section 8.1.6, for example. Note that setting τ to too small a value will lead to unpleasant results, as most points become all but independent (especially for the spherical model. Note: Wood 2017, Figure 5.20 right is based on a buggy implementation).

The default basis dimension for this class is $k = M + k_{\text{def}}$ where $M$ is the null space dimension (dimension of unpenalized function space) and $k_{\text{def}}$ is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 ‘knots’ from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R’s RNG.

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, $k$. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, $k$. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

Value

An object of class "gp.smooth". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

- `shift` A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
- `Xu` A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
- `UZ` The matrix mapping the smoother parameters back to the parameters of a full GP smooth.
- `null.space.dimension` The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.
- `gp.defn` the type, range parameter and power parameter defining the correlation function.

Markov Random Field Smooths

Description
For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for mgcv. See details for how to deal with regions with missing data.

Usage

## S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'mrf.smooth'
Predict.matrix(object, data)

References

Examples

require(mgcv)
eg <- gamSim(2,n=200,scale=.05)
attach(eg)
op <- par(mfrow=c(2,2),mar=c(4,4,1,1))
b0 <- gam(y~s(x,z,k=50),data=data)  ## tps
b <- gam(y~s(x,z,bs="gp",k=50),data=data)  ## Matern spline default range
b1 <- gam(y~s(x,z,bs="gp",k=50,m=c(1,.5)),data=data)  ## spherical
persp(truth$x,truth$z,truth$f,theta=30)  ## truth
vis.gam(b0,theta=30)
vis.gam(b,theta=30)
vis.gam(b1,theta=30)
detach(eg)
Arguments

**object**
For the smooth.construct method a smooth specification object, usually generated by a term `s(x,...,bs="mrf",xt=list(polys=foo))`. `x` is a factor variable giving labels for geographic districts, and the `xt` argument is obligatory: see details. For the Predict.Matrix method an object of class "mrf.smooth" produced by the smooth.construct method.

**data**
a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.

**knots**
If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).

Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the `xt` argument to `s`. This must contain at least one of the elements `polys`, `nb` or `penalty`.

**polys** contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. `names(polys)` must correspond to the levels of the argument of the smooth, in any order (i.e. it gives the area labels). `polys[[1]]` is a 2 column matrix the rows of which specify the vertices of the polygon(s) defining the boundary of the ith area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any `polys[[i]]` should not be a hole. An example of the structure is provided by `columb.polys` (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix.

Plotting of the smooth is not possible without a `polys` object.

If `polys` is the only element of `xt` provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one of more vertices.

**nb** is a named list defining the neighbourhood structure. `names(nb)` must correspond to the levels of the covariate of the smooth (i.e. the area labels), but can be in any order. `nb[[1]]` is a numeric vector indexing the neighbours of the ith area (and should not include i). All indices are relative to `nb` itself, but can be translated using `names(nb)`. See example code. As an alternative each `nb[[1]]` can be an array of the names of the neighbours, but these will be converted to the arrays of numeric indices internally.

If no penalty is provided then it is computed automatically from this list. The ith row of the penalty matrix will be zero everywhere, except in the ith column, which will contain the number of neighbours of the ith geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

**penalty** if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite. Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2017) Section 5.4.2. See Wood (2017, section 5.8.1).
Note that smooths of this class have a built in plot method, and that the utility function `in.out` can be useful for working with discrete area data. The plot method has two schemes, `scheme==0` is colour, `scheme==1` is grey scale.

The situation in which there are areas with no data requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, `gam`, `bam` or `gamm`, having first ensured that any fixed effect factors do not contain unobserved levels. Also make sure that the basis dimension is set to ensure that the total number of coefficients is less than the number of observations.

Value

An object of class "mrf.smooth" or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in `data`.

Author(s)

Simon N. Wood <simon.wood@r-project.org> and Thomas Kneib (Fabian Scheipl prototyped the low rank MRF idea)

nb[[1]] ## same by index
## ... and get the names of these neighbours from their indices...
names(nb)[nb[[1]]]
b1 <- gam(crime ~ s(district,bs="mrf",k=20,xt=list(nb=nb))+s(income),
data=columb,method="REML")
b1 ## fit unchanged
plot(b1) ## but now there is no information with which to plot the mrf

smooth.construct.ps.smooth.spec

P-splines in GAMs

Description

gam can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like
s(x,bs="ps"). These terms use B-spline bases penalized by discrete penalties applied directly
to the basis coefficients. Cyclic P-splines are specified by model terms like s(x,bs="cp",...).
These bases can be used in tensor product smooths (see te).
The advantage of P-splines is the flexible way that penalty and basis order can be mixed. This often
provides a useful way of 'taming' an otherwise poorly behave smooth. However, in regular use,
splines with derivative based penalties (e.g. "tp" or "cr" bases) tend to result in slightly better
MSE performance, presumably because the good approximation theoretic properties of splines are
rather closely connected to the use of derivative penalties.

Usage

## S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)

Arguments

object a smooth specification object, usually generated by a term s(x,bs="ps",...)
or s(x,bs="cp",...)
data a list containing just the data (including any by variable) required by this term,
with names corresponding to object$term (and object$by). The by variable
is the last element.
knots a list containing any knots supplied for basis setup — in same order and with
same names as data. Can be NULL. See details for further information.

Details

A smooth term of the form s(x,bs="ps",m=c(2,3)) specifies a 2nd order P-spline basis (cubic
spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If m is
a single number then it is taken as the basis order and penalty order. The default is the 'cubic spline
like' m=c(2,2).
The default basis dimension, $k$, is the larger of 10 and $m[1]+1$ for a "ps" terms and the larger of 10 and $m[1]$ for a "cp" term. $m[1]+1$ and $m[1]$ are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. $k+1$) for a "cp" smooth. For the "ps" basis the number of supplied knots should be $k + m[1] + 2$, and the range of the middle $k-m[1]$ knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don’t make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions have a span that includes no data!). Note that P-splines don’t make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior $k-m[1]$ knots). Such extrapolation is not allowed in basis construction, but is when predicting.

For the "ps" basis it is possible to set flags in the smooth specification object, requesting setup according to the SCOP-spline monotonic smoother construction of Pya and Wood (2015). As yet this is not supported by any modelling functions in mgcv (see package scam). Similarly it is possible to set a deriv flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it. See examples below.

**Value**

An object of class "pspline.smooth" or "cp.smooth". See smooth.construct, for the elements that this object will contain.

**Examples**

```r
## see ?gam
## cyclic example ...
require(mgcv)
set.seed(6)
x <- sort(runif(200)*10)
z <- runif(200)
f <- sin(x*2*pi/10)+.5
y <- rpois(exp(f),exp(f))
## finished simulating data, now fit model...
b <- gam(y ~ s(x,bs="cp") + s(z,bs="ps"),family=poisson)
```
## Example with supplied knot ranges for x and z (can do just one)

```r
b <- gam(y ~ s(x, bs="cp") + s(z, bs="ps"), family=poisson,
        knots=list(x=c(0,10), z=c(0,1)))
```

## Example with supplied knots...

```r
bk <- gam(y ~ s(x, bs="cp", k=12) + s(z, bs="ps", k=13), family=poisson,
           knots=list(x=seq(0,10, length=13), z=(-3):13/10))
```

## Plot results...

```r
par(mfrow=c(2,2))
plot(b, select=1, shade=TRUE); lines(x, f-mean(f), col=2)
plot(b, select=2, shade=TRUE); lines(z, 0*z, col=2)
plot(bk, select=1, shade=TRUE); lines(x, f-mean(f), col=2)
plot(bk, select=2, shade=TRUE); lines(z, 0*z, col=2)
```

## Example using monotonic constraints via the SCOP-spline

```r
## construction, and of computing derivatives...

x <- seq(0,1,length=100); dat <- data.frame(x)
spec <- s(x, bs="ps")
spec$mono <- 1
sm <- smoothCon(spec, dat)[[1]]
sm$deriv <- 1
Xd <- PredictMat(sm, dat)
```

## Generate random coefficients in the unconstrained parameterization...

```r
b <- runif(10)*3-2.5
## exponentiate those parameters indicated by sm$g.index
## to obtain coefficients meeting the constraints...

b[sm$g.index] <- exp(b[sm$g.index])
```

## Plot monotonic spline and its derivative

```r
par(mfrow=c(2,2))
plot(x, sm$X%*%b, type="l", ylab="f(x)")
plot(x, Xd%*%b, type="l", ylab="f' Var(x)")
```

## Repeat for decrease...

```r
spec$mono <- -1
sm1 <- smoothCon(spec, dat)[[1]]
sm1$deriv <- 1
Xd1 <- PredictMat(sm1, dat)
plot(x, sm1$X%*%b, type="l", ylab="f(x)")
plot(x, Xd1%*%b, type="l", ylab="f' Var(x)")
```

## Now with sum to zero constraints as well...

```r
spec$mono <- 1
sm <- smoothCon(spec, dat, absorb.cons=TRUE)[[1]]
sm$deriv <- 1
Xd <- PredictMat(sm, dat)
b <- b[-1] ## dropping first param
plot(x, sm$X%*%b, type="l", ylab="f(x)")
plot(x, Xd%*%b, type="l", ylab="f' Var(x)")
```

```r
spec$mono <- -1
sm1 <- smoothCon(spec, dat, absorb.cons=TRUE)[[1]]
sm1$deriv <- 1
Xd1 <- PredictMat(sm1, dat)
plot(x, sm1$X%*%b, type="l", ylab="f(x)")
plot(x, Xd1%*%b, type="l", ylab="f' Var(x)")
```
smooth.construct.re.smooth.spec

Simple random effects in GAMs

Description

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x,bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

Usage

```r
## S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'random.effect'
Predict.matrix(object, data)
```

Arguments

- `object`: For the `smooth.construct` method a smooth specification object, usually generated by a term `s(x,...,bs="re",.)`. For the `predict.Matrix` method an object of class "random.effect" produced by the `smooth.construct` method.
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: generically a list containing any knots supplied for basis setup — unused at present.

Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x,z,bs="re")`. This will result in the model matrix component corresponding to `~x:z-1` being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x,bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x,v,w,bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

If the random effect precision matrix is of the form $\sum_j \lambda_j S_j$ for known matrices $S_j$ and unknown parameters $\lambda_j$, then a list containing the $S_j$ can be supplied in the `xt` argument of `s`. In this case an array rank should also be supplied in `xt` giving the ranks of the $S_j$ matrices. See simple example below.
Note that smooth id's are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when \texttt{gamm4} or \texttt{gamm} may be better alternatives. Note also that \texttt{gam} will not support models with more coefficients than data.

The situation in which factor variable random effects intentionally have unobserved levels requires special handling. You should set \texttt{drop.unused.levels=FALSE} in the model fitting function, \texttt{gam}, \texttt{bam} or \texttt{gamm}, having first ensured that any fixed effect factors do not contain unobserved levels.

The implementation is designed so that supplying random effect factor levels to \texttt{predict.gam} that were not levels of the factor when fitting, will result in the corresponding random effect (or interactions involving it) being set to zero (with zero standard error) for prediction. See \texttt{random.effects} for an example. This is achieved by the \texttt{Predict.matrix} method zeroing any rows of the prediction matrix involving factors that are \texttt{NA}. \texttt{predict.gam} will set any factor observation to \texttt{NA} if it is a level not present in the fit data.

\textbf{Value}

An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

### smooth.construct.so.smooth.spec

**Soap film smoother constructor**

Sets up basis functions and wiggliness penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The so version sets up the full smooth. The sf version sets up just the boundary interpolating soap film, while the sw version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with `gamm` and `gamm4`. To use these to simply set up a basis, then call via the wrapper `smooth.construct2` or `smoothCon`.

#### Usage

```r
## S3 method for class 'so.smooth.spec'
smooth.construct(object,data,knots)
## S3 method for class 'sf.smooth.spec'
smooth.construct(object,data,knots)
## S3 method for class 'sw.smooth.spec'
smooth.construct(object,data,knots)
```

#### Arguments

- **object**: A smooth specification object as produced by a `s(....,bs="so",xt=list(bnd=bnd,...))` term in a `gam` formula. Note that the `xt` argument to `s` *must* be supplied, and should be a list, containing at least a boundary specification list (see details). `xt` may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the `k` argument of `s`, either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops.

- **data**: A list or data frame containing the arguments of the smooth.

- **knots**: list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the *interior* basis dimension (i.e. it is *not* supplied via argument `k` of `s`).
Details

For soap film smooths the following *must* be supplied:

- \( k \) the basis dimension for each boundary loop smooth.
- \( xt\_bnd \) the boundary specification for the smooth.
- \( \text{knots} \) the locations of the interior knots for the smooth.

When used in a GAM then \( k \) and \( xt \) are supplied via \( s \) while \( \text{knots} \) are supplied in the \( \text{knots} \) argument of \text{gam}.

The \( \text{bnd} \) element of the \( xt \) list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number of boundary loops. Each boundary loop list may also contain a column \( f \) giving known boundary conditions on a loop.

The \( \text{bndSpec} \) element of \( xt \), if non-NULL, should contain

- \( bs \) the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument \( m \) must be supplied.
- \( \text{knot.space} \) set to "even" to get even knot spacing with the "cc" basis.
- \( m \) 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints get awkward).

Note that the function \text{locator} provides a simple means for defining boundaries graphically, using something like \text{bnd} <- \text{as.data.frame(locator(type="l"))}, after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don’t want to smooth across, but doesn’t follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element \( nmax \) (default 200) of the list supplied as argument \( xt \) of \( s \) in a \text{gam} formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth \( f(x, y) \) is defined as the solution of

\[
 f_{xx} + f_{yy} = g
\]

subject to the condition that \( f = s \), on the boundary curve, where \( s \) is a smooth function (usually a cyclic penalized regression spline). The function \( g \) is defined as the solution of

\[
 g_{xx} + g_{yy} = 0
\]

where \( g = 0 \) on the boundary curve and \( g(x_k, y_k) = c_k \) at the ‘knots’ of the surface; the \( c_k \) are model coefficients.

In the simplest case, estimation of the coefficients of \( f \) (boundary coefficients plus \( c_k \)'s) is by minimization of

\[
 ||z - f||^2 + \lambda_s J_s(s) + \lambda_f J_f(f)
\]

where \( J_s \) is usually some cubic spline type wiggliness penalty on the boundary smooth and \( J_f \) is the integral of \( (f_{xx} + f_{yy})^2 \) over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The \( \lambda \)’s are smoothing parameters, selectable by GCV, REML, AIC, etc. \( z \) represents noisy observations of \( f \).
Value

A list with all the elements of object plus

- sd: A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix.
- X: The model matrix: this will have an "offset" attribute, if there are any known boundary conditions.
- S: List of smoothing penalty matrices (in smallest non-zero submatrix form).
- irng: A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.

In addition there are all the elements usually added by smooth.construct methods.

WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

---

**Description**

The `gam` function can use isotropic smooths on the sphere, via terms like `s(1a,1o,bs="sos",m=2,k=100)`. There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees) and the second longitude (in degrees). `m` (default 0) is an integer in the range -1 to 4 determining...
the order of the penalty used. For \( m > 0 \), \((m+2)/2\) is the penalty order, with \( m = 2 \) equivalent to the usual second derivative penalty. \( m = 0 \) signals to use the 2nd order spline on the sphere, computed by Wendelberger's (1981) method. \( m = -1 \) results in a Duchon.spline being used (with \( m = 2 \) and \( s = 1/2 \)), following an unpublished suggestion of Jean Duchon.

\( k \) (default 50) is the basis dimension.

**Usage**

```r
## S3 method for class 'sos.smooth.spec'
sos.smooth.spec

## S3 method for class 'sos.smooth'
Predict.matrix
```

**Arguments**

- `object`: a smooth specification object, usually generated by a term `s(...,bs="sos",...)`.
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`.

**Details**

For \( m > 0 \), the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of \( A \) — the \( A \) given in the 1981 paper is correct). For \( m = 0 \) (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For \( m = -1 \) a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a "normal" thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. \( \theta, \phi \) give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. \( \lambda, \phi \) gridlines are also plotted.

`scheme==1` is as `scheme==0`, but in black and white, without the image plot. `scheme>1` calls the default plotting method with `scheme` decremented by 2.

**Value**

An object of class "sos.smooth". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:
A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.

smooth.construct.t2.smooth.spec

**Tensor product smoothing constructor**

**Description**

**Usage**

```r
## S3 method for class 't2.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

- **object**: a smooth specification object of class t2.smooth.spec, usually generated by a term like `t2(x,z)` in a `gam` model formula.
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.

**Details**

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic
A special smooth.construct method function for creating tensor product smooths from any combination of single penalty marginal smooths.

Usage

```r
## S3 method for class 'tensor.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- `object` a smooth specification object of class tensor.smooth.spec, usually generated by a term like `te(x,z)` in a gam model formula
- `data` a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots` a list containing any knots supplied for basis setup — in same order and with same names as data. Can be `NULL`. See details for further information.
Details

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See `te`, `smooth.construct` and `smooth.terms`.

Value

An object of class "tensor.smooth". See `smooth.construct`, for the elements that this object will contain.

Examples

```r
## see ?gam
```
The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample max.knots unique data locations if there are more than max.knots such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). max.knots is 2000, by default. Both seed and max.knots can be modified using the xt argument to s. Alternatively the user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

Usage

```r
## S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- `object`: a smooth specification object, usually generated by a term `s(...,bs="tp",...)` or `s(...,bs="ts",...)`
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL

Details

The default basis dimension for this class is \( k = M + k.\text{def} \) where \( M \) is the null space dimension (dimension of unpenalized function space) and \( k.\text{def} \) is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).

The default is to set \( m \) (the order of derivative in the thin plate spline penalty) to the smallest value satisfying \( 2m > d+1 \) where \( d \) if the number of covariates of the term: this yields ‘visually smooth’ functions. In any case \( 2m > d \) must be satisfied.

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 ‘knots’ from which to produce a tprs basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and seed containing a number to use in place of 2000, and the random number seed to use (either can be missing).

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the t.p.r.s. approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, \( k \). This approach is the one taken automatically if the
number of unique covariate values (combinations) exceeds max.knots. The second possibility is to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, k. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Value
An object of class "tprs.smooth" or "ts.smooth". In addition to the usual elements of a smooth class documented under smooth.construct, this object will contain:

shift A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.

Xu A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

UZ The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.

null.space.dimension The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

smooth.info

Generic function to provide extra information about smooth specification

Description

Takes a smooth specification object and adds extra basis specific information to it before smooth constructor called. Default method returns supplied object unmodified.

Usage

smooth.info(object)

Arguments

object is a smooth specification object

Details

Sometimes it is necessary to know something about a smoother before it is constructed, beyond what is in the initial smooth specification object. For example, some smooth terms could be set up as tensor product smooths and it is useful for bam to take advantage of this when discrete covariate methods are used. However, bam needs to know whether a smoother falls into this category before it is constructed in order to discretize its covariates marginally instead of jointly. Rather than bam having a hard coded list of such smooth classes it is preferable for the smooth specification object to report this themselves. smooth.info method functions are the means for achieving this. When interpreting a gam formula the smooth.info function is applied to each smooth specification object as soon as it is produced (in interpret.gam0).

Value

A smooth specification object, which may be modified in some way.

smooth.terms

Smooth terms in GAM

Description
Smooth terms are specified in a gam formula using s, te, ti and t2 terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see user.defined.smooth). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by s terms, or as building blocks for tensor product smoothing via te, ti or t2 terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the mgcv package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in gam models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in linear.functional.terms.

The single penalty built in smooth classes are summarized as follows

Thin plate regression splines bs="tp". These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for s terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See tprs for further details.

bs="ts" is as "tp" but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.
Duchon splines bs="ds". These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See Duchon.spline for further details.

Cubic regression splines bs="cr". These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see cubic.regression.spline and e.g. Wood (2006a).

bs="cs" specifies a shrinkage version of "cr".
bs="cc" specifies a cyclic cubic regression splines (see cyclic.cubic.spline). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

Splines on the sphere bs="sos". These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See Spherical.Spline for details.

P-splines bs="ps". These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

bs="cp" gives a cyclic version of a P-spline (see cyclic.p.spline).

Random effects bs="re". These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See smooth.construct.re.smooth.spec.

Markov Random Fields bs="mrf". These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See mrf for details and an example.

Gaussian process smooths bs="gp". Gaussian process models with a variety of simple correlation functions can be represented as smooths. See gp.smooth for details.

Soap film smooths bs="so" (actually not single penalitied, but bs="sw" and bs="sf" allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See soap for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via te, ti or t2 terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006b) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions.

te te smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See Wood (2006b).
**smooth.terms**

**ti** ti smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable and interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predictors \( f_1(x) + f_2(z) + f_3(x, z) \), we might use model formula \( y \sim s(x) + s(z) + ti(x, z) \) or \( y \sim ti(x) + ti(z) + ti(x, z) \). A similar construction involving te terms instead will be much less statistically stable.

**t2** t2 uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the gamm4 package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See Wood, Scheipl and Faraway (2012/13).

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see te for an example of this). Note that te terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

**Adaptive smoothers** bs="ad" Univariate and bivariate adaptive smooths are available (see adaptive.smooth). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by gamm.

**Factor smooth interactions** bs="fs" Smooth factor interactions are often produced using by variables (see gam.models), but a special smoother class (see factor.smooth.interaction) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The "fs" smoothers are set up to be efficient when used with gamm, and have penalties on each null space component (i.e. they are fully ‘random effects’).

smooth2random

Convert a smooth to a form suitable for estimating as random effect

Description
A generic function for converting mgcv smooth objects to forms suitable for estimation as random effects by e.g. lme. Exported mostly for use by other package developers.

Usage
smooth2random(object,vnames,type=1)

Arguments

object an mgcv smooth object.

vnames a vector of names to avoid as dummy variable names in the random effects form.

Value
A list.

rand a list of random effects, including grouping factors, and a fixed effects matrix. Grouping factors, model matrix and model matrix name attached as attributes, to each element. Alternatively, for type=2 a list of random effect model matrices, each corresponding to an i.i.d. Gaussian random effect with a single variance component.
trans.U  A matrix, trans.U, that transforms coefs, in order [rand1, rand2,... fix] back to
original parameterization. If null, then not needed. If null then taken as identity.

Xf  A matrix for the fixed effects, if any.

fixed  TRUE/FALSE, indicating if term was unpenalized or not. If unpenalized then
other stuff may not be returned (it’s not a random effect).

rind  an index vector such that if br is the vector of random coefficients for the term,
br[rind] is the coefs in order for this term.

pen.ind  index of which penalty penalizes each coefficient: 0 for unpenalized.

Examples

## Simple type 1 ’lme' style...
library(mgcv)
x <- runif(30)
sm <- smoothCon(s(x),data.frame(x=x))[[1]]
smooth2random(sm,"")

## Now type 2 'lme4' style...
z <- runif(30)
dat <- data.frame(x=x,z=z)
sm <- smoothCon(t2(x,z),dat)[[1]]
re <- smooth2random(sm,"",2)
str(re)

## For prediction after fitting we might transform parameters back to
## original parameterization using 'rind', 'trans.D' and 'trans.U',
## and call PredictMat(sm,newdata) to get the prediction matrix to
## multiply these transformed parameters by.
## Alternatively we could obtain fixed and random effect Prediction
## matrices corresponding to the results from smooth2random, which
## can be used with the fit parameters without transforming them.
## The following shows how...
s2rPred <- function(sm,re,data) {
  ## Function to aid prediction from smooths represented as type==2
  ## random effects. re must be the result of smooth2random(sm,...,type=2).
  X <- PredictMat(sm,data)  ## get prediction matrix for new data
  ## transform to r.e. parameterization
  if (!is.null(re$trans.U)) X <- X%*%re$trans.U
  X <- t(t(X)*re$trans.D)
  ## re-order columns according to random effect re-ordering...
  X[,re$rind] <- X[,re$pen.ind!=0]
smoothCon

Prediction/Construction wrapper functions for GAM smooth terms

Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles 'by' variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

Usage

```r
smoothCon(object, data, knots=NULL, absorb.cons=FALSE,
          scale.penalty=TRUE, n=nrow(data), dataX=NULL,
          null.space.penalty=FALSE, sparse.cons=0,
          diagonal.penalty=FALSE, apply.by=TRUE, modCon=0)
PredictMat(object, data, n=nrow(data))
```

Arguments

- **object**: is a smooth specification object or a smooth object.
- **data**: A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it’s a list then n must be supplied.
- **knots**: An optional data frame supplying any knot locations to be supplied for basis construction.
- **absorb.cons**: Set to TRUE in order to have identifiability constraints absorbed into the basis.
- **scale.penalty**: should the penalty coefficient matrix be scaled to have approximately the same ‘size’ as the inner product of the terms model matrix with itself? This can improve the performance of gamm fitting.

Example:

```r
## re-order penalization index in same way
pen.ind <- re$pen.ind; pen.ind[re$rind] <- pen.ind[pen.ind>0]
## start return object...
for (i in 1:length(re$rand)) { 
  r$rand[[i]] <- X[,which(pen.ind==i),drop=FALSE]
  attr(r$rand[[i]],"s.label") <- attr(re$rand[[i]],"s.label")
}
```

```r
er <- list(rand=list(),Xf=X[,which(re$pen.ind==0),drop=FALSE])
```
smoothCon

n  number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if data is a list.

dataX  Sometimes the basis should be set up using data in data, but the model matrix should be constructed with another set of data provided in dataX — n is assumed to be the same for both. Facilitates smooth id’s.

null.space.penalty  Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.

apply.by  set to FALSE to have basis setup exactly as in default case, but to return add an additional matrix X0 to the return object, containing the model matrix without the by variable, if a by variable is present. Useful for bam discrete method setup.

sparse.cons  If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with bam). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint.

diagonal.penalty  If TRUE then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix diagRP in the returned object for use by PredictMat.

modCon  force modification of any smooth supplied constraints. 0 - do nothing. 1 - delete supplied constraints, replacing with automatically generated ones. 2 - set fit and predict constraint to predict constraint. 3 - set fit and predict constraint to fit constraint.

Details

These wrapper functions exist to allow smooths specified using smooth.construct and Predict.matrix method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine’s also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object by .done. If this does not exist then smoothCon will use the default code. Similarly if a user defined Predict.matrix method handles by variables internally then the returned matrix should have a "by .done" attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix C of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix C should have no rows. There is an option to use centering constraint that generate no, or limited infil, if the smoother has a sparse model matrix.

smoothCon returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. smoothCon modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by PredictMat.

The parameterization used by gam can be controlled via gam.control.
smoothCon

Value

From smoothCon a list of smooth objects returned by the appropriate smooth.construct method function. If constraints are to be absorbed then the objects will have attributes "qrC" and "nCons". "nCons" is the number of constraints. "qrC" is usually the qr decomposition of the constraint matrix (returned by qr), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

## Same again but using a penalized regression spline of ## rank 30....
sm <- smoothCon(s(times,k=30),data=mcycle,knots=NULL)[[1]]
E <- t(mroot(sm$S[[1]])) ## square root penalty
X <- rbind(sm$X,0.1*E) ## augmented model matrix
y <- c(mcycle$accel,rep(0,nrow(E))) ## augmented data
beta <- coef(lm(y~X-1)) ## fit penalized regression spline
Xp <- PredictMat(sm,data.frame(times=times)) ## prediction matrix
with(mcycle,plot(times,accel)) ## plot data
lines(times,Xp%*%beta) ## overlay smooth
```
sp.vcov

Extract smoothing parameter estimator covariance matrix from
(RE)ML GAM fit

Description

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated gam object, provided the fit was with a method that evaluated the required Hessian.

Usage

sp.vcov(x, edge.correct=TRUE, reg=1e-3)

Arguments

x
a fitted model object of class gam as produced by gam().

edge.correct
if the model was fitted with edge.correct=TRUE (see gam.control), then the returned covariance matrix will be for the edge corrected log smoothing parameters.

reg
regularizer for Hessian - default is equivalent to prior variance of 1000 on log smoothing parameters.

Details

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

Value

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise NULL. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter. If edge.correct=TRUE and this was used in fitting then the edge corrected smoothing parameters are in attribute lsp of the returned matrix.

**spasm.construct**

*Experimental sparse smoothers*

**Description**

These are experimental sparse smoothing functions, and should be left well alone!

**Usage**

```r
spasm.construct(object, data)
spasm.sp(object, sp, w=rep(1, object$nobs), get.trH=TRUE, block=0, centre=FALSE)
spasm.smooth(object, X, residual=FALSE, block=0)
```

**Arguments**

- `object`: sparse smooth object
- `data`: data frame
- `sp`: smoothing parameter value
- `w`: optional weights
- `get.trH`: Should (estimated) trace of sparse smoother matrix be returned
- `block`: index of block, 0 for all blocks
- `centre`: should sparse smooth be centred?
- `X`: what to smooth
- `residual`: apply residual operation?

**WARNING**

It is not recommended to use these yet

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>
Description

There is no `step.gam` in package `mgcv`. The `mgcv` default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows’ Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way, i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: “cs” and “ts”, based on cubic regression spline and thin plate regression spline smoothers (see `s`)

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggliness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to `gam` causes this latter approach to be used. Unpenalized terms (e.g. `s(x,fx=TRUE)` remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

### summary.gam

#### Summary for a GAM fit

**Description**

Takes a fitted `gam` object produced by `gam()` and produces various useful summaries from it. (See `sink` to divert output to a file.)

**Usage**

```r
## S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, re.test=TRUE, ...)

## S3 method for class 'summary.gam'
print(x, digits = max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

- `object` a fitted `gam` object as produced by `gam()`.
- `x` a `summary.gam` object produced by `summary.gam()`.
- `dispersion` A known dispersion parameter. `NULL` to use estimate or default (e.g. 1 for Poisson).
- `freq` By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to `TRUE` then the frequentist covariance matrix of the parameters is used instead.
- `re.test` Should tests be performed for random effect terms (including any term with a zero dimensional null space)? For large models these tests can be computationally expensive.
digits
controls number of digits printed in output.

signif.stars
Should significance stars be printed alongside output.

... other arguments.

Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix $A$ for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let $P_i$ be the matrix giving the parameters of the $i$th smooth when applied to the data (or pseudodata in the generalized case) and let $X$ be the design matrix of the model. Then $tr(XP_i)$ is the edf for the $i$th term. Clearly this definition causes the edf’s to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of $2A - AA$.

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka’s (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurvature).

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (freq=TRUE), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the paraPen argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting freq=TRUE is appropriate.

Value

`summary.gam` produces a list of summary information for a fitted `gam` object.

p.coeff is an array of estimates of the strictly parametric model coefficients.

p.t is an array of the p.coeff’s divided by their standard errors.
p.pv is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.

m The number of smooth terms in the model.

chi.sq An array of test statistics for assessing the significance of model smooth terms. See details.

s.pv An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.

se array of standard error estimates for all parameter estimates.

r.sq The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that r.sq does not include any offset in the one parameter model.

dev.expl The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so dev.expl can be substantially lower than r.sq when an offset is present.

edf array of estimated degrees of freedom for the model terms.

residual.df estimated residual degrees of freedom.

n number of data.

np number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).

rank apparent model rank.

method The smoothing selection criterion used.

sp.criterion The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.

scale estimated (or given) scale parameter.

family the family used.

formula the original GAM formula.

dispersion the scale parameter.

pTerms.df the degrees of freedom associated with each parametric term (excluding the constant).

pTerms.chi.sq a Wald statistic for testing the null hypothesis that the each parametric term is zero.

pTerms.pv p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.

cov.unscaled The estimated covariance matrix of the parameters (or estimators if freq=TRUE), divided by scale parameter.

cov.scaled The estimated covariance matrix of the parameters (estimators if freq=TRUE).

p.table significance table for parameters

s.table significance table for smooths

p.Terms significance table for parametric model terms
WARNING

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

t2

**Define alternative tensor product smooths in GAM formulae**

### Description

Alternative to `te` for defining tensor product smooths in a `gam` formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl (mgcv implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with `gamm4` from package `gamm4`.

### Usage

```r
t2(..., k=NA,bs="cr",m=NA,d=NA,by=NA,xt=NULL,
  id=NULL,sp=NULL,full=FALSE,ord=NULL,pc=NULL)
```

### Arguments

- `...` a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. t2(log(x),z) is fine, but t2(I(x/sd(x)),z) is not (see `predict.gam`).
- `k` the dimension(s) of the bases used to represent the smooth term. If not supplied then set to 5^d. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See `choose.k` for further information.
bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See smooth.terms for details and full list. User defined bases can also be used here (see smooth.construct for an example). If only one basis code is given then this is used for all bases.

m The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. p.spline and Duchon.spline), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set d=c(2,1). Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See gam.models for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see gam.models and linear.functional.terms for details).

xt Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

sp any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal autoinitialization. Over-rides values supplied in sp argument to gam. Ignored by gamm.

full If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.

ord an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.

pc If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See identifiability.
Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See pen.edf for some further information.

Note that there are two ways to construct the product. When full=FALSE then the null space bases are treated as a whole in each product, but when full=TRUE each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

Value

A class t2.smooth.spec object defining a tensor product smooth to be turned into a basis and penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

margin A list of smooth.spec objects of the type returned by s, defining the basis from which the tensor product smooth is constructed.

term An array of text strings giving the names of the covariates that the term is a function of.

by is the name of any by variable as text ("NA" for none).

fx logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.

label A suitable text label for this smooth term.
The dimension of the smoother - i.e. the number of covariates that it is a function of.

mp
TRUE is multiple penalties are to be used (default).

np
TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).

id
the id argument supplied to te.

sp
the sp argument supplied to te.

Define tensor product smooths or tensor product interactions in GAM formulae

Description

Functions used for the definition of tensor product smooths and interactions within \texttt{gam} model formulae. \texttt{te} produces a full tensor product smooth, while \texttt{ti} produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present.

The functions do not evaluate the smooth - they exists purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).
Usage

te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
    np=TRUE, xt=NULL, id=NULL, sp=NULL, pc=NULL)
ti(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
    np=TRUE, xt=NULL, id=NULL, sp=NULL, mc=NULL, pc=NULL)

Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. \texttt{te(log(x),z)} is fine, but \texttt{te(I(x/sd(x)),z)} is not (see \texttt{predict.gam}).

k the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See \texttt{choose.k} for further information.

bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See \texttt{smooth.terms} for details and full list. User defined bases can also be used here (see \texttt{smooth.construct} for an example). If only one basis code is given then this is used for all bases.

m The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different $m$ for each margin. For marginals that take vector $m$ (e.g. \texttt{p.spline} and \texttt{Duchon.spline}), then a list can be supplied, with a vector element for each margin. NA autoinitializes. $m$ is ignored by some bases (e.g. "cr").

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set $d=c(2,1)$. Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See \texttt{gam.models} for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see \texttt{gam.models} and \texttt{linear.functional.terms} for details).

fx indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).

np TRUE to use the ‘normal parameterization’ for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at ‘knots’, spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.

xt Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id
then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

**sp**

any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in `sp` argument to `gam`. Ignored by `gamm`.

**mc**

For `ti` smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or `FALSE/TRUE` values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that `ti` only applies constraints to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work.

**pc**

If not `NULL`, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See `identifiability`.

**Details**

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in `tensor.prod.model.matrix` and `tensor.prod.penalties`, to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use, and is deprecated: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

\[
f_1(x) + f_2(z) + f_3(x, z)
\]

This functional ANOVA decomposition is supported by `ti` terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the \(~ ti(x) + ti(z) + ti(x, z)\) would produce the above main effects + interaction structure. This is much better than attempting the same thing with `s` or `te` terms representing the interactions (although mgcv does not forbid it). Technically `ti` terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework). See Wood (2017, section 5.6.3).

The ‘normal parameterization’ (`np=TRUE`) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done...
for marginals of a single variable. This parameterization can reduce numerical stability when used
with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set np=FALSE.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if
any marginals would not need centering. The constructor for tensor product smooths ensures that
this happens.

The function does not evaluate the variable arguments.

Value

A class tensor.smooth.spec object defining a tensor product smooth to be turned into a basis and
penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

margin A list of smooth.spec objects of the type returned by s, defining the basis from
which the tensor product smooth is constructed.
term An array of text strings giving the names of the covariates that the term is a
function of.
by is the name of any by variable as text ("NA" for none).
fx logical array with element for each penalty of the term (tensor product smooths
have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.
label A suitable text label for this smooth term.
dim The dimension of the smoother - i.e. the number of covariates that it is a function
of.
mp TRUE is multiple penalties are to be used (default).
np TRUE to re-parameterize 1-D marginal smooths in terms of function values (de-
fault).
id the id argument supplied to te.
sp the sp argument supplied to te.
inter TRUE if the term was generated by ti, FALSE otherwise.
mc the argument mc supplied to ti.

par(op)
Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth (marginals and results can be sparse). The model matrix construction uses row Kronecker products.

Usage

tensor.prod.model.matrix(X)
tensor.prod.penalties(S)

a %.%b

Arguments

X a list of model matrices for the marginal bases of a smooth. Items can be class "matrix" or "dgCMatrix", but not a mixture of the two.

S a list of penalties for the marginal bases of a smooth.

a a matrix with the same number of rows as A.

b a matrix with the same number of rows as B.

Details

If X[[1]], X[[2]] ... X[[m]] are the model matrices of the marginal bases of a tensor product smooth then the ith row of the model matrix for the whole tensor product smooth is given by X[[1]][i,]%x%X[[2]][i,]%x% ... X[[m]][i,], where %x% is the Kronecker product. Of course the routine operates column-wise, not row-wise!

A %.%B is the operator form of this ‘row Kronecker product’.

If S[[1]], S[[2]] ... S[[m]] are the penalty matrices for the marginal bases, and I[[1]], I[[2]] ... I[[m]] are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has m associate penalties of the form:

S[[1]]%x%I[[2]]%x% ... I[[m]],
I[[1]]%x%S[[2]]%x% ... I[[m]]

...
I[[1]]%x%I[[2]]%x% ... S[[m]].

Of course it’s important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

Value

Either a single model matrix for a tensor product smooth (of the same class as the marginals), or a list of penalty terms for a tensor product smooth.

### totalPenaltySpace

Obtaining (orthogonal) basis for null space and range of the penalty matrix

**Description**

INTERNAL function to obtain (orthogonal) basis for the null space and range space of the penalty, and obtain actual null space dimension components are roughly rescaled to avoid any dominating.

**Usage**

```r
totalPenaltySpace(S, H, off, p)
```

**Arguments**

- `S` a list of penalty matrices, in packed form.
- `H` the coefficient matrix of an user supplied fixed quadratic penalty on the parameters of the GAM.
- `off` a vector where the i-th element is the offset for the i-th matrix.
- `p` total number of parameters.

**Value**

A list of matrix square roots such that \(S[[i]] = B[[i]]%*%t(B[[i]])\).
trichol

**Description**

Computes Choleski decomposition of a (symmetric positive definite) tri-diagonal matrix stored as a leading diagonal and sub/super diagonal.

**Usage**

```r
trichol(ld, sd)
```

**Arguments**

- `ld`: leading diagonal of matrix
- `sd`: sub-super diagonal of matrix

**Details**

Calls `dpttrf` from LAPACK. The point of this is that it has $O(n)$ computational cost, rather than the $O(n^3)$ required by dense matrix methods.

**Value**

A list with elements `ld` and `sd`. `ld` is the leading diagonal and `sd` is the super diagonal of bidiagonal matrix $B$ where $B^TB = T$ and $T$ is the original tridiagonal matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

`bandchol`
Examples

```r
require(mgcv)
## simulate some diagonals...
set.seed(19); k <- 7
ld <- runif(k)+1
sd <- runif(k-1) -.5
## get diagonals of chol factor...
trichol(ld,sd)
## compare to dense matrix result...
A <- diag(ld);for (i in 1:(k-1)) A[i,i+1] <- A[i+1,i] <- sd[i]
R <- chol(A)
diag(R);diag(R[,-1])
```

trind.generator  
Generates index arrays for upper triangular storage

Description

Generates index arrays for upper triangular storage up to order four. Useful when working with higher order derivatives, which generate symmetric arrays. Mainly intended for internal use.

Usage

```r
trind.generator(K = 2)
```

Arguments

- `K`  
  positive integer determining the size of the array.

Details

Suppose that \( m=1 \) and you fill an array using code like
```r
for(i in 1:K) for(j in i:K) for(k in j:K) for(l in k:K) {a[,m] <-something; m <-m+1 }
```
and do this because actually the same "something" would be stored for any permutation of the indices \( i,j,k,l \). Clearly in storage we have the restriction \( l>=k>=j>=i \), but for access we want no restriction on the indices. \( i4[i,j,k,l] \) produces the appropriate \( m \) for unrestricted indices. \( i3 \) and \( i2 \) do the same for 3d and 2d arrays.

Value

A list where the entries \( i1 \) to \( i4 \) are arrays in up to four dimensions, containing \( K \) indexes along each dimension.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.
Examples

```r
library(mgcv)
A <- trind.generator(3)

# All permutations of c(1, 2, 3) point to the same index (5)
A$i3[1, 2, 3]
A$i3[2, 1, 3]
A$i3[2, 3, 1]
A$i3[3, 1, 2]
A$i3[1, 3, 2]
```

Tweedie

GAM Tweedie families

Description

Tweedie families, designed for use with `gam` from the `mgcv` library. Restricted to variance function powers between 1 and 2. A useful alternative to `quasi` when a full likelihood is desirable. `Tweedie` is for use with fixed `p`. `tw` is for use when `p` is to be estimated during fitting. For fixed `p` between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power `p`.

`tw` is only useable with `gam` and `bam` but not `gamm`. Tweedie works with all three.

Usage

```r
Tweedie(p=1, link = power(0))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```

Arguments

- `p`: the variance of an observation is proportional to its mean to the power `p`. `p` must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.
- `link`: The link function: one of "log", "identity", "inverse", "sqrt", or a `power` link (Tweedie only).
- `theta`: Related to the Tweedie power parameter by \( p = (a + b \exp(\theta))/(1 + \exp(\theta)) \). If this is supplied as a positive value then it is taken as the fixed value for `p`. If it is a negative values then its absolute value is taken as the initial value for `p`.
- `a`: lower limit on `p` for optimization.
- `b`: upper limit on `p` for optimization.

Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1, and is therefore highly multimodal. See `ldTweedie` for more on this behaviour.

Tweedie is based partly on the `poisson` family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function.
The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. \( p \) and the scale parameter. Without restricting \( p \) to \((1,2)\) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over \texttt{quasi}. If you need this case then the \texttt{tweedie} package is the place to start.

**Value**

For Tweedie, an object inheriting from class \texttt{family}, with additional elements

- \texttt{dvar} the function giving the first derivative of the variance function w.r.t. \( \mu \).
- \texttt{d2var} the function giving the second derivative of the variance function w.r.t. \( \mu \).
- \texttt{ls} A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter.

For \texttt{tw}, an object of class \texttt{extended.family}.

**Author(s)**

```r
library(mgcv)
set.seed(3)
n<-400
## Simulate data...
dat <- gamSim(1,n=n,dist="poisson",scale=.2)
dat$y <- rTweedie(exp(dat$f),p=1.3,phi=.5) ## Tweedie response

## Fit a fixed p Tweedie, with wrong link ...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=Tweedie(1.25,power(.1)),
data=dat)
plot(b,pages=1)
print(b)

## Same by approximate REML...
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=Tweedie(1.25,power(.1)),
```
## twlss

### Description

Tweedie family in which the mean, power and scale parameters can all depend on smooth linear predictors. Restricted to estimation via the extended Fellner Schall method of Wood and Fasiolo (2017). Only usable with `gam`. Tweedie distributions are exponential family with variance given by \( \phi \mu^p \) where \( \phi \) is a scale parameter, \( p \) a parameter (here between 1 and 2) and \( \mu \) is the mean.

### Usage

```r
twlss(link=list("log","identity","identity"), a=1.01, b=1.99)
```

### Arguments

- **link**
  
  The link function list: currently no choice.

- **a**
  
  lower limit on the power parameter relating variance to mean.

- **b**
  
  upper limit on power parameter.

### Details

A Tweedie random variable with \( 1<p<2 \) is a sum of \( N \) gamma random variables where \( N \) has a Poisson distribution. The \( p=1 \) case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For \( 1<p<2 \) the distribution is supported on the positive reals with a point mass at zero. \( p=2 \) is a gamma distribution. As \( p \) gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at \( p=1 \), and is therefore highly multimodal. See `ldTweedie` for more on this behaviour.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. \( p \) and the scale parameter. Without restricting \( p \) to \((1,2)\) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over `quasi`. If you need this case then the `tweedie` package is the place to start.

### Value

An object inheriting from class `general.family`.
uniquecombs

find the unique rows in a matrix

Description

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit need not be the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

Usage

uniquecombs(x, ordered=FALSE)
Arguments

x is an R matrix (numeric), or data frame.

ordered set to TRUE to have the rows of the returned object in the same order regardless of input ordering.

Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model. When x has only one column then the routine uses unique and match to get the index. When there are multiple columns then it uses paste0 to produce labels for each row, which should be unique if the row is unique. Then unique and match can be used as in the single column case. Obviously the pasting is inefficient, but still quicker for large n than the C based code that used to be called by this routine, which had O(nlog(n)) cost. In principle a hash table based solution in C would be only O(n) and much quicker in the multicolumn case.

unique and duplicated, can be used in place of this, if the full index is not needed. Relative performance is variable.

If x is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

Value

A matrix or data frame consisting of the unique rows of x (in arbitrary order). The matrix or data frame has an "index" attribute. index[i] gives the row of the returned matrix that contains row i of the original matrix.

WARNINGS

If a dataframe contains variables of a type other than numeric, logical, factor or character, which either have no as.character method, or whose as.character method is a many to one mapping, then the routine is likely to fail.

If the character representation of a dataframe variable (other than of class factor of character) contains * then in principle the method could fail (but with a warning).

Examples

require(mgcv)

## matrix example...
X <- matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
Xu <- uniquecombs(X);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]
## same with fixed output ordering
Xu <- uniquecombs(X,TRUE);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]

## data frame example...
df <- data.frame(f=factor(c("er","3","b","er","3","1","2","b")),
x=c(.5,1,1.4,.5,1,.6,4,3,1.7),
bb = c(rep(TRUE,5),rep(FALSE,4)),
fred = c("foo","a","b","foo","a","v","er","r","g"),
stringsAsFactors=FALSE)
uniquecombs(df)

vcov.gam

Extract parameter (estimator) covariance matrix from GAM fit

## Description
Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted gam object.

## Usage
### S3 method for class 'gam'
vcov(object, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)

## Arguments
- **object**: fitted model object of class gam as produced by gam().
- **freq**: TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters.
- **dispersion**: a value for the dispersion parameter: not normally used.
- **unconditional**: if TRUE (and freq==FALSE) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.
- **...**: other arguments, currently ignored.

## Details
Basically, just extracts object$Ve or object$Vp from a gamObject.

## Value
A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators(coefficients), or the estimated posterior covariance matrix of the parameters, depending on the argument freq.

## Author(s)
Henric Nilsson. Maintained by Simon N. Wood <simon.wood@r-project.org>

gam

Examples

```r
require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

vis.gam

Visualization of GAM objects

Description

Produces perspective or contour plot views of gam model predictions, fixing all but the values in view to the values supplied in cond.

Usage

```r
vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA, color="heat", contour.col=NULL, se=-1, type="link", plot.type="persp", zlim=NULL, nCol=50, ...)
```

Arguments

- **x**: a gam object, produced by `gam()`
- **view**: an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won’t work as view variables, and vis.gam can not detect that this has happened when setting defaults.
- **cond**: a named list of the values to use for the other predictor terms (not in view). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occuring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median.
- **n.grid**: The number of grid nodes in each direction used for calculating the plotted surface.
- **too.far**: plot grid nodes that are too far from the points defined by the variables given in view can be excluded from the plot. too.far determines what is too far. The grid is scaled into the unit square along with the view variables and then grid nodes more than too.far from the predictor variables are excluded.
The colours for the facets of the plot. If this is NA then if se>0 the facets are transparent, otherwise the colour scheme specified in color is used. If col is not NA then it is used as the facet colour.

color

the colour scheme to use for plots when se<=0. One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when se>0.

contour.col

sets the colour of contours when using plot.type="contour". Default scheme used if NULL.

se

if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus se standard errors, one at the predicted values and one at the predicted values plus se standard errors.

type

"link" to plot on linear predictor scale and "response" to plot on the response scale.

plot.type

one of "contour" or "persp".

zlim

a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.

nCol

The number of colors to use in color schemes.

... other options to pass on to persp, image or contour. In particular ticktype="detailed" will add proper axes labelling to the plots.

Details

The x and y limits are determined by the ranges of the terms named in view. If se<=0 then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- se standard errors. Parts of the x-y plane too far from data can be excluded by setting too.far.

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the default values used by vis.gam.

Value

Simply produces a plot.

WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a view variable. When setting default view variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

**Internal functions for discretized model matrix handling**

### Description

Routines for computing with discretized model matrices as described in Wood et al. (2017) and Li and Wood (2019).
Usage

XWXd(X, w, k, ks, ts, dt, v, qc, nthreads=1, drop=NULL, ar.stop=-1, ar.row=-1, ar.w=-1, lt=NULL, rt=NULL)
XWyd(X, w, y, k, ks, ts, dt, v, qc, drop=NULL, ar.stop=-1, ar.row=-1, ar.w=-1, lt=NULL)
Xbd(X, beta, k, ks, ts, dt, v, qc, drop=NULL, lt=NULL)
diagXVXd(X, V, k, ks, ts, dt, v, qc, drop=NULL, nthreads=1, lt=NULL, rt=NULL)

Arguments

X A list of the matrices containing the unique rows of model matrices for terms of a full model matrix, or the model matrices of the terms margins. If term subsetting arguments lt and rt are non-NULL then this requires an "lpip" attribute: see details. The elements of X may be sparse matrices of class "dgCMatrix", in which case the list requires attributes "r" and "off" defining reverse indices (see details).

w An n-vector of weights

y n-vector of data.

beta coefficient vector.

k A matrix whose columns are index n-vectors each selecting the rows of an X[i] required to create the full matrix.

ks The ith term has index vectors ks[i,1]: (ks[i,2]-1). The corresponding full model matrices are summed over.

ts The element of X at which each model term starts.

dt How many elements of X contribute to each term.

v v[i] is Householder vector for ith term, if qc[i]>0.

qc if qc[i]>0 then term has a constraint.

nthreads number of threads to use

drop list of columns of model matrix/parameters to drop

ar.stop Negative to ignore. Otherwise sum rows (ar.stop[i-1]+1):ar.stop[i] of the rows selected by ar.row and weighted by ar.w to get ith row of model matrix to use.

ar.row extract these rows...

ar.w weight by these weights, and sum up according to ar.stop. Used to implement AR models.

lt use only columns of X corresponding to these model matrix terms (for left hand X in XWXd).

rt as lt for right hand X.

V Coefficient covariance matrix.

Details

These functions are really intended to be internal, but are exported so that they can be used in the initialization code of families without problem. They are primarily used by bam to implement the methods given in the references. XWXd produces X’WX, XWy produces X’TWy, Xbd produces Xβ and diagXVXd produces the diagonal of XVX’. The "lpip" attribute of X is a list of the coefficient indices for each term. Required if subsetting via lt and rt.
X can be a list of sparse matrices of class "dgCMatrix", in which case reverse indices are needed, mapping stored matrix rows to rows in the full matrix (that is the reverse of k which maps full matrix rows to the stored unique matrix rows). r is the same dimension as k while off is a list with as many elements as k has columns. r and off are supplied as attributes to X. For simplicity let r and codeoff denote a single column and element corresponding to each other: then coder[off[j]:off[j+1]-1] contains the rows of the full matrix corresponding to row j of the stored matrix. The reverse indices are essential for efficient computation with sparse matrices. See the example code for how to create them efficiently from the forward index matrix, k.

ziP GAM zero-inflated (hurdle) Poisson regression family

Description
Family for use with gam or bam, implementing regression for zero inflated Poisson data when the complimentary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

Usage
ziP(theta = NULL, link = "identity",b=0)

Arguments
theta the 2 parameters controlling the slope and intercept of the linear transform of the mean controlling the zero inflation rate. If supplied then treated as fixed parameters ($\theta_1$ and $\theta_2$), otherwise estimated.

link The link function: only the "identity" is currently supported.

b a non-negative constant, specifying the minimum dependence of the zero inflation rate on the linear predictor.
**Details**

The probability of a zero count is given by $1 - p$, whereas the probability of count $y > 0$ is given by the truncated Poisson probability function $p \mu^y/((\exp(\mu) - 1)y!))$. The linear predictor gives $\log \mu$, while $\eta = \log(-\log(1 - p))$ and $\eta = \theta_1 + b + \exp(\theta_2) \log \mu$. The theta parameters are estimated alongside the smoothing parameters. Increasing the $b$ parameter from zero can greatly reduce identifiability problems, particularly when there are very few non-zero data.

The fitted values for this model are the log of the Poisson parameter. Use the predict function with type="response" to get the predicted expected response. Note that the theta parameters reported in model summaries are $\theta_1$ and $b + \exp(\theta_2)$.

These models should be subject to very careful checking, especially if fitting has not converged. It is quite easy to set up models with identifiability problems, particularly if the data are not really zero inflated, but simply have many zeroes because the mean is very low in some parts of the covariate space. See example for some obvious checks. Take convergence warnings seriously.

**Value**

An object of class extended.family.

**WARNINGS**

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes *given the model mean* may imply zero inflation.

ziplss

Zero inflated (hurdle) Poisson location-scale model family

Description

The ziplss family implements a zero inflated (hurdle) Poisson model in which one linear predictor controls the probability of presence and the other controls the mean given presence. Useable only with gam, the linear predictors are specified via a list of formulae. Should be used with care: simply having a large number of zeroes is not an indication of zero inflation.

Requires integer count data.

Usage

ziplss(link=list("identity","identity"))
Arguments

link two item list specifying the link - currently only identity links are possible, as parameterization is directly in terms of log of Poisson response and logit of probability of presence.

Details

Used with `gam` to fit 2 stage zero inflated Poisson models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the Poisson parameter on the right hand side. The second is one sided, specifying the linear predictor for the probability of presence on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the log of the Poisson parameter, and the second column is the complimentary log log of probability of presence. Predictions using `predict.gam` will also produce 2 column matrices for type “link” and “response”.

The null deviance computed for this model assumes that a single probability of presence and a single Poisson parameter are estimated.

For data with large areas of covariate space over which the response is zero it may be advisable to use low order penalties to avoid problems. For 1D smooths uses e.g. `s(x,m=1)` and for isotropic smooths use `Duchon.splines` in place of thin plate terms with order 1 penalties, e.g `s(x,z,m=c(1,.5))` — such smooths penalize towards constants, thereby avoiding extreme estimates when the data are uninformative.

Value

An object inheriting from class `general.family`.

WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes *given the model mean* may imply zero inflation.

The nlme package

---

**ACF**

*Autocorrelation Function*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls` and `lme`.

**Usage**

```
ACF(object, maxLag, ...)
```

**Arguments**

- `object` any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted.
- `maxLag` maximum lag for which the autocorrelation should be calculated.
- `...` some methods for this generic require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <Bates@stat.wisc.edu>

**References**

**See Also**

`ACF.gls`, `ACF.lme`, `plot.ACF`
Examples

## see the method function documentation

### ACF.gls

#### Autocorrelation Function for gls Residuals

**Description**

This method function calculates the empirical autocorrelation function for the residuals from a gls fit. If a grouping variable is specified in `form`, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```r
## S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

**Arguments**

- `object`: an object inheriting from class "gls", representing a generalized least squares fitted model.
- `maxLag`: an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.
- `resType`: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `form`: an optional one sided formula of the form ~ t, or ~ t | g, specifying a time covariate `t` and, optionally, a grouping factor `g`. The time covariate must be integer valued. When a grouping factor is present in `form`, the autocorrelations are calculated using residual pairs within the same group. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes ACF.gls to print an error message and terminate if there are any incomplete observations.
- `...`: some methods for this generic require additional arguments.

**Value**

A data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
ACF(fm1, form = ~ 1 | Mare)
# Pinheiro and Bates, p. 255-257
fm1Dial.gls <- gls(rate ~ (pressure+I(pressure^2)+I(pressure^3)+I(pressure^4))*QB, Dialyzer)
fm2Dial.gls <- update(fm1Dial.gls, weights = varPower(form = ~ pressure))
ACF(fm2Dial.gls, form = ~ 1 | Subject)
```

ACF.lme

*Autocorrelation Function for lme Residuals*

Description

This method function calculates the empirical autocorrelation function for the within-group residuals from an *lme* fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

Usage

```r
## S3 method for class 'lme'
ACF(object, maxLag, resType, ...)
```

Arguments

- **object**
  - an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- **maxLag**
  - an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.
- **resType**
  - an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- **...**
  - some methods for this generic require additional arguments – not used.
Value

A data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

plot(ACF.fm1Over, alpha=0.01)
```

Alfalfa

Split-Plot Experiment on Varieties of Alfalfa

Description

The Alfalfa data frame has 72 rows and 4 columns.

Format

This data frame contains the following columns:

- **Variety** a factor with levels Cossack, Ladak, and Ranger
- **Date** a factor with levels None S1 S20 07
- **Block** a factor with levels 1 2 3 4 5 6
- **Yield** a numeric vector
Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a $3 \times 4$ full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (Cossac, Ladak, and Ranger) were assigned randomly to the blocks and the dates of third cutting (None, S1—September 1, S20—September 20, and O7—October 7) were randomly assigned to the plots. All four dates were used on each block.

**allCoef**

*Extract Coefficients from a Set of Objects*

**Description**

The extractor function is applied to each object in ..., with the result being converted to a vector. A map attribute is included to indicate which pieces of the returned vector correspond to the original objects in dots.

**Usage**

```r
callCoef(..., extract)
```

**Arguments**

- `...`: objects to which `extract` will be applied. Generally these will be model components, such as `corStruct` and `varFunc` objects.
- `extract`: an optional extractor function. Defaults to `coef`.

**Value**

A vector with all elements, generally coefficients, obtained by applying `extract` to the objects in ... .

**Author(s)**

José’ Pinheiro and Douglas Bates

**See Also**

`lmeStruct`, `nlmeStruct`

**Examples**

```r
cs1 <- corAR1(0.1)
vf1 <- varPower(0.5)
allCoef(cs1, vf1)
```
anova.gls

Description

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are `NULL`), a combination of model terms (when Terms in not `NULL`), or linear combinations of the model coefficients (when L is not `NULL`). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If `test=TRUE`, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

Usage

```r
## S3 method for class 'gls'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

Arguments

- `object`: a fitted model object inheriting from class `gls`, representing a generalized least squares fit.
- `...`: other optional fitted model objects inheriting from classes `"gls"`, `"gnls"`, `"lm"`, `"lme"`, `"lmList"`, `"nlme"`, `"nlstlist"`, or `"nls"`.
- `test`: an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by `object` and the objects in `...`. Defaults to `TRUE`.
- `type`: an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".
- `adjustSigma`: an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{\frac{n_{\text{obs}}}{n_{\text{obs}} - n_{\text{par}}}}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
- `Terms`: an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is `NULL`.
- `L`: an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will...
be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

`verbose` an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if `verbose = FALSE`. Defaults to FALSE.

### Value

a data frame inheriting from class "anova.lme".

### Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

        form = ~ latitude + longitude, nugget = TRUE))
# Test a specific contrast
anova(fm3Wheat2, L = c(-1, 0, 1))
test

an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.

type

an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".

adjustSigma

an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.

Terms

an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

L

an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

verbose

an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

Value

a data frame inheriting from class "anova.lme".

Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

### as.matrix.corStruct

*Matrix of a corStruct Object*

#### Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.
Usage

```r
## S3 method for class 'corStruct'
as.matrix(x, ...)
```

Arguments

- `x` An object inheriting from class "corStruct", representing a correlation structure.
- `...` Further arguments passed from other methods.

Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with `object`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**as.matrix.pdMat**

*Matrix of a pdMat Object*

Description

This method function extracts the positive-definite matrix represented by `x`.

Usage

```r
## S3 method for class 'pdMat'
as.matrix(x, ...)
```

Arguments

- `x` An object inheriting from class "pdMat", representing a positive-definite matrix.
- `...` Further arguments passed from other methods.
Value

a matrix corresponding to the positive-definite matrix represented by \( x \).

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

asOneFormula

Combine Formulas of a Set of Objects

Description

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

Usage

asOneFormula(..., omit)

Arguments

... objects, or lists of objects, from which a formula can be extracted.
omit an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(".", "pi").

Value

a one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in omit.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

formula, all.vars

Examples

asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))
Assay data frame has 60 rows and 4 columns.

This data frame contains the following columns:

- **Block**: an ordered factor with levels 2 < 1 identifying the block where the wells are measured.
- **sample**: a factor with levels a to f identifying the sample corresponding to the well.
- **dilut**: a factor with levels 1 to 5 indicating the dilution applied to the well.
- **logDens**: a numeric vector of the log-optical density.

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

Create a tabular representation of the response in a balanced groupedData object.

**Usage**

```r
asTable(object)
```

**Arguments**

- **object**: A balanced groupedData object
Details

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

Value

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

groupedData, isBalanced, balancedGrouped

Examples

```r
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

Description

Predicted values are obtained at the specified values of primary. If object has a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. If level has more than one element, predictions are obtained for each level of the max(level) grouping factor. If other covariates besides primary are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

```r
augPred(object, primary, minimum, maximum, length.out, ...)
```

## S3 method for class 'lme'
augPred(object, primary = NULL,
minimum = min(primary), maximum = max(primary),
length.out = 51, level = Q, ...)
Arguments

object      a fitted model object from which predictions can be extracted, using a predict method.
primary     an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate object (using getCovariate), it will be used as primary.
minimum     an optional lower limit for the primary covariate. Defaults to min(primary).
maximum     an optional upper limit for the primary covariate. Defaults to max(primary).
length.out  an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
level       an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

...         some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: original for the observed values and predicted (single or no grouping factor) or predict.groupVar (multiple levels of grouping), with groupVar replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class "augPred".

Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

balancedGrouped

Create a groupedData object from a matrix

Description

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

Usage

balancedGrouped(form, data, labels=NULL, units=NULL)

Arguments

form
A formula of the form y ~ x | g giving the name of the response, the primary covariate, and the grouping factor.

data
A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate.

labels
an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.

units
an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.

Value

A balanced groupedData object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

groupedData, isBalanced, asTable

Examples

OrthoMat <- asTable( Orthodont )
Orth2 <- balancedGrouped(distance ~ age | Subject, data = OrthoMat,
labels = list(x = "Age",
y = "Distance from pituitary to pterygomaxillary fissure"),
units = list(x = "(yr)", y = "(mm)"))
Orth2[ 1:10, ]  ## check the first few entries
ergoStool.mat <- asTable(ergoStool)
balancedGrouped(effort~Type|Subject, 
    data=ergoStool.mat)

bdf

### Language scores

**Description**

The `bdf` data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

**Usage**

```r
data(bdf)
```

**Format**

- **schoolNR**: a factor denoting the school.
- **pupilNR**: a factor denoting the pupil.
- **IQ.verb**: a numeric vector of verbal IQ scores.
- **IQ.perf**: a numeric vector of IQ scores.
- **sex**: Sex of the student.
- **Minority**: a factor indicating if the student is a member of a minority group.
- **repeatgr**: an ordered factor indicating if one or more grades have been repeated.
- **aritPRET**: a numeric vector.
- **classNR**: a numeric vector.
- **aritPOST**: a numeric vector.
- **langPRET**: a numeric vector.
- **langPOST**: a numeric vector.
- **ses**: a numeric vector of socioeconomic status indicators.
- **denomina**: a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.
- **schoolSES**: a numeric vector.
- **satiprin**: a numeric vector.
- **natitest**: a factor with levels `0` and `1`.
- **meetings**: a numeric vector.
- **currmeet**: a numeric vector.
- **mixedgra**: a factor indicating if the class is a mixed-grade class.
- **percmino**: a numeric vector.
- **aritdiff**: a numeric vector.
- **homework**: a numeric vector.
- **classsiz**: a numeric vector.
- **groupsiz**: a numeric vector.

BodyWeight Rat weight over time for different diets

Description

The BodyWeight data frame has 176 rows and 4 columns.

Format

This data frame contains the following columns:

- **weight** a numeric vector giving the body weight of the rat (grams).
- **Time** a numeric vector giving the time at which the measurement is made (days).
- **Rat** an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.
- **Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Source

**Description**

The Cefamandole data frame has 84 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Subject** a factor giving the subject from which the sample was drawn.
- **Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).
- **conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

**Details**

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

**Source**

**Examples**

```r
plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)
```

**Assign Values to Coefficients**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "pdMat", "corStruct" and "varFunc" classes, "reStruct", and "modelStruct".

**Usage**

```r
coeff(object, ...) <- value
```
**Argument**

object any object representing a fitted model, or, by default, any object with a `coef` component.

... some methods for this generic function may require additional arguments.

value a value to be assigned to the coefficients associated with `object`.

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

calc

### Examples

## see the method function documentation

---

**Description**

This method function extracts the coefficients associated with the correlation structure represented by `object`.

**Usage**

```r
## S3 method for class 'corStruct'
calc(object, unconstrained, ...)
## S3 replacement method for class 'corStruct'
calc(object, ...) <- value
```

**Arguments**

object an object inheriting from class "corStruct", representing a correlation structure.

unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.

value a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `calc(object)` and must be given in unconstrained form.

... some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using Initialize) before new values can be assigned to its coefficients.

coef(cst1)

---

c coef.gnls

Extract gnls Coefficients

Description

The estimated coefficients for the nonlinear model represented by object are extracted.

Usage

## S3 method for class 'gnls'
coef(object, ...)

Arguments

object an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the estimated coefficients for the nonlinear model represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
coef.lme

See Also
gnls

Examples

```r
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
weights = varPower())
coef(fm1)
```

Description

The estimated coefficients at level \( i \) are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to \( i \). The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

Usage

```r
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
omitGroupingFactor, subset, ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `augFrame`: an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `level`: an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
- `which`: an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both factor and ordered. The `Mode` function,
defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor
an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset
an optional expression specifying a subset

...some methods for this generic require additional arguments. None are used in this method.

Value
a data frame inheriting from class "coef.lme" with the estimated coefficients at level level and, optionally, other covariates summarized over groups. The returned object also inherits from classes "ranef.lme" and "data.frame".

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

coef(fm1, augFrame = TRUE)

---

### coef.lmList

Extract lmList Coefficients

**Description**
The coefficients of each lm object in the object list are extracted and organized into a data frame, with rows corresponding to the lm components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the lm components.

**Usage**
```r
## S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN, 
   omitGroupingFactor, ...)
```
Arguments

object
an object inheriting from class "lmList", representing a list of lm objects with a common model.

augFrame
an optional logical value. If TRUE, the returned data frame is augmented with variables defined in the data frame used to produce object; else, if FALSE, only the coefficients are returned. Defaults to FALSE.

data
an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.

which
an optional positive integer or character vector specifying which columns of the data frame used to produce object should be used in the augmentation of the returned data frame. Defaults to all variables in the data.

FUN
an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor
an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

a data frame inheriting from class "coef.lmList" with the estimated coefficients for each "lm" component of object and, optionally, other covariates summarized over the groups corresponding to the "lm" components. The returned object also inherits from classes "ranef.lmList" and "data.frame".

**coef.modelStruct**

*Extract modelStruct Object Coefficients*

**Description**

This method function extracts the coefficients associated with each component of the `modelStruct` list.

**Usage**

```r
## S3 method for class 'modelStruct'
coeff(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coeff(object, ...) <- value
```

**Arguments**

- **object**
  - an object inheriting from class "modelStruct", representing a list of model components, such as "corStruct" and "varFunc" objects.
- **unconstrained**
  - a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", possibly constrained, form. Defaults to `TRUE`.
- **value**
  - a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coeff(object)` and must be given in unconstrained form.
- **...**
  - some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with all coefficients corresponding to the components of `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`Initialize`
Examples

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                   corStruct = corAR1(0.3))
coef(lms1)
```

---

**coef.pdMat**

*pdMat Object Coefficients*

**Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

**Usage**

```r
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

**Arguments**

- `object`: an object inheriting from class "pdMat", representing a positive-definite matrix.
- `unconstrained`: a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to TRUE.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

**Author(s)**

José Pinheiro and Douglas Bates

coef(rs1)
```

coef.varFunc

### Description

This method function extracts the coefficients associated with the variance function structure represented by `object`.

### Usage

```r
## S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent'
 coef(object, ...) <- value
```

### Arguments

- **object**: an object inheriting from class "varFunc" representing a variance function structure.
- **unconstrained**: a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", generally constrained form. Defaults to TRUE.
- **allCoef**: a logical value. If FALSE only the coefficients which may vary during the optimization are returned. If TRUE all coefficients are returned. Defaults to FALSE.
- **value**: a vector with the replacement values for the coefficients associated with `object`. It must be have the same length of `coef(object)` and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients.
- **...**: some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with the coefficients corresponding to `object`.

### SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

collapse

Collapse According to Groups

Description

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a groupedData method is available.

Usage

collapse(object, ...)

Arguments

object an object to be collapsed, usually a data frame.
...
some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

collapse.groupedData

Examples

## see the method function documentation
Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

Usage

```r
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel,
          outer, inner, preserve, FUN, subset, ...)
```

Arguments

- **object**: an object inheriting from class groupedData, generally with multiple grouping factors.
- **collapseLevel**: an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
- **displayLevel**: an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is `collapseLevel`.
- **outer**: an optional logical value or one-sided formula, indicating covariates that are outer to the `displayLevel` grouping factor. If equal to `TRUE`, the `displayLevel` element `attr(object,"outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.
- **inner**: an optional logical value or one-sided formula, indicating a covariate that is inner to the `displayLevel` grouping factor. If equal to `TRUE`, `attr(object,"outer")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.
- **preserve**: an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the `collapseLevel` grouping factor. The collapsing factor is obtained by pasting together the levels of the `collapseLevel` grouping factor and the values of the covariate to be preserved. Default is `NULL`, meaning that no covariates need to be preserved.
- **FUN**: an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by `collapseLevel`. Invariant variables are always summarized by group using the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables.
The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

**Usage**

\[
\text{compareFits(object1, object2, which)}
\]

**Arguments**

- **object1, object2**
  - data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. `lme` and `lmList` objects).

- **which**
  - an optional integer or character vector indicating which columns in object1 and object2 are to be used in the returned object. Defaults to all columns.
Value

a three-dimensional array, with the third dimension given by the number of unique column names in either object1 or object2. To each column name there corresponds a matrix with as many rows as the rows in object1 and two columns, corresponding to object1 and object2. The returned object inherits from class compareFits.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

plot.compareFits, pairs.compareFits, comparePred, coef, random.effects

Examples

fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
(cF12 <- compareFits(coef(fm1), coef(fm2)))

Description

Predicted values are obtained at the specified values of primary for each object. If either object1 or object2 have a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides primary are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

comparePred(object1, object2, primary, minimum, maximum, length.out, level, ...)

Arguments

object1, object2

fitted model objects, from which predictions can be extracted using the predict method.

primary

an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using getCovariate), it will be used as primary.

minimum

an optional lower limit for the primary covariate. Defaults to min(primary), after primary is evaluated in the data used in fitting object1.

maximum

an optional upper limit for the primary covariate. Defaults to max(primary), after primary is evaluated in the data used in fitting object1.
length.out  an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.

level  an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.

...  some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects’ names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes comparePred and augPred.

Note

This function is generic: method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

corAR1  AR(1) Correlation Structure

description

This function is a constructor for the corAR1 class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corAR1(value, form, fixed)
Arguments

value  the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).

form  a one sided formula of the form \(~ t\), or \(~ t | g\), specifying a time covariate \(t\) and, optionally, a grouping factor \(g\). A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corAR1, representing an autocorrelation structure of order 1.

corARMA

ARMA(p,q) Correlation Structure

Description

This function is a constructor for the corARMA class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corARMA(value, form, p, q, fixed)

Arguments

value
  a vector with the values of the autoregressive and moving average parameters, which must have length p + q and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.

form
  a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

p, q
  non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.

fixed
  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.
corARMA

Value

an object of class corARMA, representing an autocorrelation-moving average correlation structure.

fm1Ovar.lme <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time),
                  data = Ovary, random = pdDiag(~sin(2*pi*Time)))
fm5Ovar.lme <- update(fm1Ovar.lme,
                       corr = corARMA(p = 1, q = 1))

# p. 396
fm1Ovar.nlme <- nlme(follicles~A+B*sin(2*pi*w*Time)+C*cos(2*pi*w*Time),
                      data=Ovary, fixed=A+B+C+w~1,
                      random=pdDiag(A+B+w~1),
                      start=c(fixef(fm5Ovar.lme), 1) )
# p. 397
fm3Ovar.nlme <- update(fm1Ovar.nlme,
                       corr=corARMA(p=0, q=2) )
```
corCAR1  

Continuous AR(1) Correlation Structure

Description
This function is a constructor for the corCAR1 class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate Initialize method.

Usage
```
corCAR1(value, form, fixed)
```

Arguments
- `value`: the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.
- `form`: a one sided formula of the form `~ t`, or `~ t | g`, specifying a time covariate `t` and, optionally, a grouping factor `g`. Covariates for this correlation structure need not be integer valued. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- `fixed`: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

Value

an object of class corCAR1, representing an autocorrelation structure of order 1, with a continuous time covariate.

## covariate is Time and grouping factor is Mare
cs1 <- corCAR1(0.2, form = ~ Time | Mare)

# Pinheiro and Bates, pp. 240, 243
fm1Ovar.lme <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time),
data = Ovary, random = pdDiag(~sin(2*pi*Time)))
fm4Ovar.lme <- update(fm1Ovar.lme, correlation = corCAR1(form = ~Time))
```

### corClasses

**Correlation Structure Classes**

**Description**

Standard classes of correlation structures (corStruct) available in the nlme package.

**Value**

Available standard classes:

- `corAR1` autoregressive process of order 1.
- `corARMA` autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components.
- `corCAR1` continuous autoregressive process (AR(1) process for a continuous time covariate).
- `corCompSymm` compound symmetry structure corresponding to a constant correlation.
- `corExp` exponential spatial correlation.
- `corGaus` Gaussian spatial correlation.
- `corLin` linear spatial correlation.
- `corRatio` Rational quadratics spatial correlation.
- `corSpher` spherical spatial correlation.
- `corSymm` general correlation matrix, with no additional structure.

**Note**

Users may define their own corStruct classes by specifying a constructor function and, at a minimum, methods for the functions corMatrix and coef. For examples of these functions, see the methods for classes corSymm and corAR1.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corCompSymm

\textit{Compound Symmetry Correlation Structure}

Description
This function is a constructor for the \texttt{corCompSymm} class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage
\begin{verbatim}
corCompSymm(value, form, fixed)
\end{verbatim}

Arguments
\begin{itemize}
  \item \texttt{value} the correlation between any two correlated observations. Defaults to 0.
  \item \texttt{form} a one sided formula of the form $\sim t$, or $\sim t | g$, specifying a time covariate $t$ and, optionally, a grouping factor $g$. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$, which corresponds to using the order of the observations in the data as a covariate, and no groups.
  \item \texttt{fixed} an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to \texttt{FALSE}, in which case the coefficients are allowed to vary.
\end{itemize}

Value
an object of class \texttt{corCompSymm}, representing a compound symmetry correlation structure.

### corExp

**Examples**

```r
## covariate is observation order and grouping factor is Subject
cs1 <- corCompSymm(0.5, form = ~ 1 | Subject)
```

# Pinheiro and Bates, pp. 222-225
```r
fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight, random = ~ Time)
# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())
# p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)
```

---

### Description

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-r/d)$ when no nugget effect is present and $(1-n)\exp(-r/d)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

### Usage

```r
corExp(value, form, nugget, metric, fixed)
```

### Arguments

- **value**: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form $\sim S1+...+Sp$, or $\sim S1+...+Sp | g$, specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

---

**Exponential Correlation Structure**

---

**corExp**

---

**Description**

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-r/d)$ when no nugget effect is present and $(1-n)\exp(-r/d)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```r
corExp(value, form, nugget, metric, fixed)
```

**Arguments**

- **value**: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form $\sim S1+...+Sp$, or $\sim S1+...+Sp | g$, specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.  

---

**Exponential Correlation Structure**
metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

corFactor

Factor of a Correlation Matrix

description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

usage

corFactor(object, ...)

arguments

object an object from which a correlation matrix can be extracted.

... some methods for this generic function require additional arguments.

value

will depend on the method function used; see the appropriate documentation.

author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corFactor.corStruct, recalc.corStruct

examples

### see the method function documentation
Factor of a corStruct Object Matrix

Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by object. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. This method extracts $L^{-t}$.

Usage

```r
## S3 method for class 'corStruct'
corfactor(object, ...)
```

Arguments

- `object`: an object inheriting from class "corStruct" representing a correlation structure, which must have been initialized (using Initialize).
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with object stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

Note

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The corMatrix method function can be used to obtain transpose inverse square-root factors in matrix form.

cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corfactor(cs1)
```
corGaus

Gaussian Correlation Structure

Description

This function is a constructor for the corGaus class, representing a Gaussian spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( \exp\left(-\left(\frac{r}{d}\right)^2\right) \) when no nugget effect is present and \( (1 - n) \exp\left(-\left(\frac{r}{d}\right)^2\right) \) when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate 'Initialize' method.

Usage

corGaus(value, form, nugget, metric, fixed)

Arguments

- **value**: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

An object of class corGaus, also inheriting from class corSpatial, representing a Gaussian spatial correlation structure.
**corLin**

**Linear Correlation Structure**

**Description**

This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r < d$ apart is $1 - (r/d)$ when no nugget effect is present and $(1 - n)(1 - (r/d))$ when a nugget effect is assumed. If $r \geq d$ the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```
corLin(value, form, nugget, metric, fixed)
```
Arguments

value an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corLin, also inheriting from class corSpatial, representing a linear spatial correlation structure.

corMatrix

### Extract Correlation Matrix

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

**Usage**

```r
corMatrix(object, ...)
```

**Arguments**

- `object` an object for which a correlation matrix can be extracted.
- `...` some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`corMatrix.corStruct, corMatrix.pdMat`

**Examples**

```r
## see the method function documentation
```
**Description**

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to `covariate` and `object`. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L' L$. When `corr = FALSE`, this method extracts $L^{-1}$.

**Usage**

```r
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

**Arguments**

- `object` an object inheriting from class "corStruct" representing a correlation structure.
- `covariate` an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.
- `corr` a logical value. If TRUE the function returns the correlation matrix, or list of correlation matrices, represented by `object`. If FALSE the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

cs1Exp <- Initialize(cs1Exp, spatDat)
corMatrix(cs1Exp)
```

corMatrix.pdMat

Extract Correlation Matrix from a pdMat Object

Description

The correlation matrix corresponding to the positive-definite matrix represented by object is obtained.

Usage

```r
## S3 method for class 'pdMat'
corMatrix(object, ...)
```

Arguments

- `object`: an object inheriting from class "pdMat", representing a positive definite matrix.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the correlation matrix corresponding to the positive-definite matrix represented by object.
description

This method function extracts the correlation matrices corresponding to the pdMat elements of object.

usage

```r
## S3 method for class 'reStruct'
corMatrix(object, ...)
```

arguments

- **object**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **...**: some methods for this generic require additional arguments. None are used in this method.

value

a list with components given by the correlation matrices corresponding to the elements of object.

Examples

```r
rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
corMatrix(rs1)
```
corNatural

General correlation in natural parameterization

Description

This function is a constructor for the corNatural class, representing a general correlation structure in the “natural” parameterization, which is described under pdNatural. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corNatural(value, form, fixed)

Arguments

value
an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form
a one sided formula of the form \(~ t\), or \(~ t \mid g\), specifying a time covariate \(t\) and, optionally, a grouping factor \(g\). A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corNatural representing a general correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Initialize.corNatural, pdNatural, summary.corNatural

Examples

## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
corRatio

Rational Quadratic Correlation Structure

Description

This function is a constructor for the corRatio class, representing a rational quadratic spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( 1/(1 + (r/d)^2) \) when no nugget effect is present and \( (1 - n)/(1 + (r/d)^2) \) when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate Initialize method.

Usage

corRatio(value, form, nugget, metric, fixed)

Arguments

- **value**: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.
- **form**: a one sided formula of the form \( \sim S1+...+Sp \) or \( \sim S1+...+Sp \mid g \), specifying spatial covariates \( S1 \) through \( Sp \) and, optionally, a grouping factor \( g \). When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \( \sim 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.
- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corRatio, also inheriting from class corSpatial, representing a rational quadratic spatial correlation structure.

---

**corSpatial**

**Spatial Correlation Structure**

**Description**

This function is a constructor for the corSpatial class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: corExp, corGaus, corLin, corRatio, and corSpher. The returned object will inherit from one of these "real" classes, determined by the type argument, and from the "virtual" corSpatial class. Objects created using this constructor must later be initialized using the appropriate Initialize method.
corSpatial

Usage

corSpatial(value, form, nugget, type, metric, fixed)

Arguments

value an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

type an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions corSpher, corExp, corGaus, corLin, and corRatio for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class determined by the type argument and also inheriting from class corSpatial, representing a spatial correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

corSpher

Spherical Correlation Structure

Description

This function is a constructor for the corSpher class, representing a spherical spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r < d$ apart is $1 - 1.5(r/d) + 0.5(r/d)^3$ when no nugget effect is present and $(1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3)$ when a nugget effect is assumed. If $r \geq d$ the correlation is zero.

Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corSpher(value, form, nugget, metric, fixed)

Arguments

value

an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form

a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget

an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.
metric

an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed

an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSpher, also inheriting from class corSpatial, representing a spherical spatial correlation structure.

corSymm

General Correlation Structure

Description
This function is a constructor for the corSymm class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

```
corSymm(value, form, fixed)
```

Arguments

- `value` an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

- `form` a one sided formula of the form `~ t`, or `~ t | g`, specifying a time covariate `t` and, optionally, a grouping factor `g`. A covariate for this correlation structure must be integer valued. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- `fixed` an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

Value

an object of class corSymm representing a general correlation structure.

```

Covariate  Assign Covariate Values

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all “varFunc” classes.

Usage

covariate(object) <- value

Arguments

object any object with a covariate component.
value a value to be assigned to the covariate associated with object.

Value

will depend on the method function; see the appropriate documentation.
Covariate.varFunc

Description

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

Usage

## S3 replacement method for class 'varFunc'
covariate(object) <- value

Arguments

object an object inheriting from class "varFunc", representing a variance function structure.
value a value to be assigned to the covariate associated with object.

Value

a varFunc object similar to object, but with its covariate attribute replaced by value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

getCovariate.varFunc

Examples

vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont["age"]
**Description**

The Dialyzer data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject.
- **QB**: a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- **pressure**: a numeric vector giving the transmembrane pressure (dmHg).
- **rate**: the hemodialyzer ultrafiltration rate (mL/hr).
- **index**: index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

**Dim**

**Extract Dimensions from an Object**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: "corSpatial", "corStruct", "pdCompSymm", "pdDiag", "pdIdent", "pdMat", and "pdSymm".

**Usage**

Dim(object, ...
Arguments

object any object for which dimensions can be extracted.

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Note

If dim allowed more than one argument, there would be no need for this generic function.

Dim.corSpatial  Dimensions of a corSpatial Object

Description

if groups is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

Usage

## S3 method for class 'corSpatial'
Dim(object, groups, ...)

Arguments

object an object inheriting from class "corSpatial", representing a spatial correlation structure.

groups an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.

... further arguments to be passed to or from methods.
**Value**

a list with components:

- **N** length of groups
- **M** number of groups
- **spClass** an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin
- **sumLenSq** sum of the squares of the number of observations per group
- **len** an integer vector with the number of observations per group
- **start** an integer vector with the starting position for the distance vectors in each group, beginning from zero

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`Dim`, `Dim.corStruct`

**Examples**

```r
Dim(corGaus(), getGroups(Orthodont))

cs1ARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
cs1ARMA <- Initialize(cs1ARMA, data = Orthodont)
Dim(cs1ARMA)
```

---

**Description**

If `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```r
## S3 method for class 'corStruct'
Dim(object, groups, ...)
```

**Arguments**

- **object** an object inheriting from class "corStruct", representing a correlation structure.
- **groups** an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
- **...** some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components:

- \( N \) length of groups
- \( M \) number of groups
- \( \text{maxLen} \) maximum number of observations in a group
- \( \text{sumLenSq} \) sum of the squares of the number of observations per group
- \( \text{len} \) an integer vector with the number of observations per group
- \( \text{start} \) an integer vector with the starting position for the observations in each group, beginning from zero

**Author(s)**

Examples

Dim(pdSymm(diag(3)))

<table>
<thead>
<tr>
<th>Earthquake</th>
<th>Earthquake Intensity</th>
</tr>
</thead>
</table>

Description

The Earthquake data frame has 182 rows and 5 columns.

Format

This data frame contains the following columns:

- **Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 8 < 3 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.

- **Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.

- **distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).

- **soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.

- **accel** maximum horizontal acceleration observed (g).

Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

Source

ergoStool  
Ergometrics experiment with stool types

Description
The ergoStool data frame has 36 rows and 3 columns.

Format
This data frame contains the following columns:
- **effort**: a numeric vector giving the effort (Borg scale) required to arise from a stool.
- **Type**: a factor with levels T1, T2, T3, and T4 giving the stool type.
- **Subject**: an ordered factor giving a unique identifier for the subject in the experiment.

Details
Devore (2000) cites data from an article in Ergometrics (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

Source

Examples
```r
fm1 <-
  lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fm1 )
```

Fatigue  
Cracks caused by metal fatigue

Description
The Fatigue data frame has 262 rows and 3 columns.

Format
This data frame contains the following columns:
- **Path**: an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.
- **cycles**: number of test cycles at which the measurement is made (millions of cycles).
- **relLength**: relative crack length (dimensionless).
These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

### Details

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

### Usage

```r
fHess(pars, fun, ..., relStep = .Machine$double.eps^(1/3), minAbsPar = 0)
```

### Arguments

- **pars**: the numeric values of the parameters at which to evaluate the function `fun` and its derivatives.
- **fun**: a function depending on the parameters `pars` that returns a numeric scalar.
- **...**: Optional additional arguments to `fun`
- **relStep**: The relative step size to use in the finite differences. It defaults to the cube root of `Machine$double.eps`
- **minAbsPar**: The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero.

### Details

This function uses a second-order response surface design known as a “Koschal design” to determine the parameter values at which the function is evaluated.

### Value

A list with components

- **mean**: the value of function `fun` evaluated at the parameter values `pars`
- **gradient**: an approximate gradient (of length `length(pars)`).
- **Hessian**: a matrix whose upper triangle contains an approximate Hessian.
fitted.glsStruct

Calculate glsStruct Fitted Values

Description

The fitted values for the linear model represented by object are extracted.

Usage

```r
## S3 method for class 'glsStruct'
fitted(object, glsFit, ...)
```

Arguments

- `object`: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.
- `glsFit`: an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to `attr(object,"glsFit")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the fitted values for the linear model represented by object.

Note

This method function is generally only used inside gls and fitted.gls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, residuals.glsStruct
fitted.gnlsStruct | Calculate gnlsStruct Fitted Values

Description
The fitted values for the nonlinear model represented by object are extracted.

Usage
## S3 method for class 'gnlsStruct'
fitted(object, ...)

Arguments
- object: an object inheriting from class "gnlsStruct", representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.
- ...: some methods for this generic require additional arguments. None are used in this method.

Value
a vector with the fitted values for the nonlinear model represented by object.

Note
This method function is generally only used inside gnls and fitted.gnls.

fitted.lme | Extract lme Fitted Values

Description
The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$.

Usage
## S3 method for class 'lme'
fitted(object, level, asList, ...)

Arguments

object an object inheriting from class "lme", representing a fitted linear mixed-effects model.

level an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

asList an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

If a single level of grouping is specified in level, the returned value is either a list with the fitted values split by groups (asList = TRUE) or a vector with the fitted values (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the napredict method is applied.

Description

The fitted values at level \( i \) are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to \( i \). The resulting values estimate the best linear unbiased predictions (BLUPs) at level \( i \).
fitted.lmList

Usage

### S3 method for class 'lmeStruct'

fitted(object, level, conLin, lmeFit, ...)

Arguments

- **object**: an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object,"conLin").
- **lmeFit**: an optional list with components beta and b containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to attr(object,"lmeFit").
- **...**: some methods for this generic accept other optional arguments.

Value

If a single level of grouping is specified in level, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside lme and fitted.lme.

fitted.lmList | Extract lmList Fitted Values

Description

The fitted values are extracted from each lm component of object and arranged into a list with as many components as object, or combined into a single vector.

Usage

### S3 method for class 'lmList'

fitted(object, subset, asList, ...)
Arguments

object an object inheriting from class "lmList", representing a list of \( \text{lm} \) objects with a common model.

subset an optional character or integer vector naming the \( \text{lm} \) components of object from which the fitted values are to be extracted. Default is NULL, in which case all components are used.

asList an optional logical value. If TRUE, the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by the fitted values of each \( \text{lm} \) component of object, or a vector with the fitted values for all \( \text{lm} \) components of object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

*Extract pdBlocked Formula*

**Description**

The `formula` attributes of the `pdMat` elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the `pdMat` elements do not have a `formula` attribute, a `NULL` value is returned.

**Usage**

```r
## S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

**Arguments**

- `x`  
  an object inheriting from class "pdBlocked", representing a positive definite block diagonal matrix.

- `asList`  
  an optional logical value. If `TRUE`, a list with the formulas for the individual block diagonal elements of `x` is returned; else, if `FALSE`, a one-sided formula combining all individual formulas is returned. Defaults to `FALSE`.

- `...`  
  some methods for this generic require additional arguments. None are used in this method.

**Value**

a list of one-sided formulas, or a single one-sided formula, or `NULL`.

**Author(s)**

José Pinheiro and Douglas Bates `<bates@stat.wisc.edu>`

**See Also**

`pdBlocked`, `pdMat`

**Examples**

```r
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```
Description

This method function extracts the formula associated with a pdMat object, in which the column and row names are specified.

Usage

```r
## S3 method for class 'pdMat'
formula(x, asList, ...)
```

Arguments

- `x`: an object inheriting from class "pdMat", representing a positive definite matrix.
- `asList`: logical. Should the asList argument be applied to each of the components? Never used.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

If `x` has a `formula` attribute, its value is returned, else `NULL` is returned.

Note

Because factors may be present in `formula(x)`, the pdMat object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`pdMat`

Examples

```r
pd1 <- pdSymm(~Sex*age)
formula(pd1)
```
Description

This method function extracts a formula from each of the components of x, returning a list of formulas.

Usage

```r
## S3 method for class 'reStruct'
formula(x, asList, ...)
```

Arguments

- `x`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `asList`: logical. Should the asList argument be applied to each of the components?
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a list with the formulas of each component of x.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `formula`

Examples

```r
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

gapply

Apply a Function by Groups

Description

Applies the function to the distinct sets of rows of the data frame defined by groups.

Usage

```r
gapply(object, which, FUN, form, level, groups, ...)
```
Arguments

object   an object to which the function will be applied - usually a groupedData object or a data.frame. Must inherit from class "data.frame".

which   an optional character or positive integer vector specifying which columns of object should be used with FUN. Defaults to all columns in object.

FUN   function to apply to the distinct sets of rows of the data frame object defined by the values of groups.

form   an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

level   an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

groups   an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

...   optional additional arguments to the summary function FUN. Often it is helpful to specify na.rm = TRUE.

Value

Returns a data frame with as many rows as there are levels in the groups argument.

Examples

```r
## Find number of non-missing "conc" observations for each Subject
gapply( Phenobarb, FUN = function(x) sum(!is.na(x$conc)) )

# Pinheiro and Bates, p. 127
table( gapply(Quinidine, "conc", function(x) sum(!is.na(x))) )
changeRecords <- gapply( Quinidine, FUN = function(frm)
  any(is.na(frm["conc"])) & is.na(frm["dose"]))
```
Gasoline: Refinery yield of gasoline

Description
The Gasoline data frame has 32 rows and 6 columns.

Format
This data frame contains the following columns:

- **yield**: a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation
- **endpoint**: a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized
- **Sample**: an ordered factor giving the inferred crude oil sample number
- **API**: a numeric vector giving the crude oil gravity (degrees API)
- **vapor**: a numeric vector giving the vapor pressure of the crude oil (lbf/in²)
- **ASTM**: a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

Details
Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate—endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

Source

getCovariate: Extract Covariate from an Object

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, corSpatial, data.frame, and varFunc.
Usage

getCovariate(object, form, data)

Arguments

object any object with a covariate component
form an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to formula(object).
data a data frame in which to evaluate the variables defined in form.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

getcovariate.corStruct, getCovariate.data.frame, getCovariate.varFunc, getCovariateFormula

Examples

## see the method function documentation

getcovariate.corStruct

Extract corStruct Object Covariate

Description

This method function extracts the covariate(s) associated with object.

Usage

## S3 method for class 'corStruct'
getcovariate(object, form, data)

Arguments

object an object inheriting from class corStruct representing a correlation structure.
form this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified.
data an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the covariate needs to be evaluated.
when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with object. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

getCovariate

Examples
```r
cs1 <- corAR1(form = ~ 1 | Subject)
getcovariate(cs1, data = Orthodont)
```

Getting Covariate Data Frame

The right hand side of form, stripped of any conditioning expression (i.e. an expression following a | operator), is evaluated in object.

Usage
```r
## S3 method for class 'data.frame'
getcovariate(object, form, data)
```

Arguments
- `object`: an object inheriting from class data.frame.
- `form`: an optional formula specifying the covariate to be evaluated in object. Defaults to `formula(object)`.
- `data`: some methods for this generic require a separate data frame. Not used in this method.

Value
the value of the right hand side of form, stripped of any conditional expression, evaluated in object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
Description

This method function extracts the covariate(s) associated with the variance function represented by `object`, if any is present.

Usage

```r
## S3 method for class 'varFunc'
getcovariate(object, form, data)
```

Arguments

- `object`: an object inheriting from class `varFunc`, representing a variance function structure.
- `form`: an optional formula specifying the covariate to be evaluated in `object`. Defaults to `formula(object)`.
- `data`: some methods for this generic require a `data` object. Not used in this method.

Value

- If `object` has a `covariate` attribute, its value is returned; else `NULL` is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `covariate<-.varFunc`

Examples

```r
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
getcovariate(vf1)
```
getCovariateFormula  Extract Covariates Formula

Description

The right hand side of `formula(object)`, without any conditioning expressions (i.e. any expressions after a `|` operator) is returned as a one-sided formula.

Usage

```r
getCovariateFormula(object)
```

Arguments

- `object` any object from which a formula can be extracted.

Value

a one-sided formula describing the covariates associated with `formula(object)`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `getCovariate`

Examples

```r
getCovariateFormula(y ~ x | g)
getcovariateFormula(y ~ x)
```

getData  Extract Data from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `gls`, `lme`, and `lmList`.

Usage

```r
getData(object)
```

Arguments

- `object` an object from which a data.frame can be extracted, generally a fitted model object.
**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

glsls, getData.lme, getData.lmList

**Examples**

```r
## see the method function documentation

glsls
```

---

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```r
## S3 method for class 'gls'
getData(object)
```

**Arguments**

- `object`: an object inheriting from class gls, representing a generalized least squares fitted linear model.

**Value**

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

gls, getData

**Examples**

```r
fml <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary, correlation = corAR1(form = ~ 1 | Mare))
getData(fml)
```
getData.lme  Extract lme Object Data

Description

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

Usage

## S3 method for class 'lme'
getData(object)

Arguments

object an object inheriting from class lme, representing a linear mixed-effects fitted model.

Value

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if na.action = na.omit, and does not omit at all if na.action = na.exclude. That is generally what is wanted for plotting, the main use of this function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

lme, getData

Examples

fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
          random = ~ sin(2*pi*Time))
getData(fm1)
### getData.lmList

**Extract lmList Object Data**

**Description**

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

**Usage**

```r
## S3 method for class 'lmList'
getData(object)
```

**Arguments**

- `object` an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.

**Value**

if a data argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `lmList`, `getData`

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
data(fm1)
```

### getGroups

**Extract Grouping Factors from an Object**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `data.frame`, `gls`, `lme`, `lmList`, and `varFunc`.

**Usage**

```
getGroups(object, form, level, data, sep)
```
getGroups.corStruct

Arguments

object any object
form an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object).
level a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting.
data a data frame in which to interpret the variables named in form. Optional for most methods.
sep character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

## see the method function documentation

getGroups.corStruct Extract corStruct Groups

Description

This method function extracts the grouping factor associated with object, if any is present.

Usage

## S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
getGroups.data.frame

Extract Groups from a Data Frame

Arguments

object  an object inheriting from class \texttt{corStruct} representing a correlation structure.
form    this argument is included to make the method function compatible with the generic. It will be assigned the value of \texttt{formula(object)} and should not be modified.
level   this argument is included to make the method function compatible with the generic and is not used.
data    an optional data frame in which to evaluate the variables defined in \texttt{form}, in case \texttt{object} is not initialized and the grouping factor needs to be evaluated.
sep     character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.

Value

if a grouping factor is present in the correlation structure represented by \texttt{object}, the function returns the corresponding factor vector; else the function returns \texttt{NULL}.

Author(s)

José Pinheiro and Douglas Bates <\texttt{bates@stat.wisc.edu}>

See Also

getGroups

Examples

\begin{verbatim}
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
\end{verbatim}

Description

Each variable named in the expression after the | operator on the right hand side of \texttt{form} is evaluated in \texttt{object}. If more than one variable is indicated in \texttt{level} they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in \texttt{form} and \texttt{level} \geq 1, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to \texttt{level}, to ensure their uniqueness.

Usage

\begin{verbatim}
## S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
\end{verbatim}
getGroups.gls

Arguments

object  — an object inheriting from class data.frame.
form    — an optional formula with a conditioning expression on its right hand side (i.e. an
expression involving the \| operator). Defaults to formula(object).
level   — a positive integer vector with the level(s) of grouping to be used when multiple
nested levels of grouping are present. Defaults to all levels of nesting.
sep     — character, the separator to use between group levels when multiple levels are
collapsed. The default is '\/'.

Value

either a data frame with columns given by the grouping factors indicated in level, from outer to
inner, or, when a single level is requested, a factor representing the selected grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

pp. 100, 461.

geroupGroupsFormula

Examples

groups <- getGroups(Pixel)
groups <- getGroups(Pixel, level = 2)

groups <- getGroups.gls

Description

If present, the grouping factor associated to the correlation structure for the linear model represented
by object is extracted.

Usage

## S3 method for class 'gls'
getGroups(object, form, level, data, sep)
Arguments

object
an object inheriting from class gls, representing a generalized least squares fitted linear model.

form
an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the \( | \) operator). Defaults to \( \text{formula(object)} \). Not used.

level
a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.

data
a data frame in which to interpret the variables named in \( \text{form} \). Optional for most methods. Not used.

sep
character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’. Not used.

Value

if the linear model represented by \( \text{object} \) incorporates a correlation structure and the corresponding corStruct object has a grouping factor, a vector with the group values is returned; else, \( \text{NULL} \) is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

gls, corClasses

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, corAR1(form = ~ 1 | Mare))
getGroups(fm1)
```

Description

The grouping factors corresponding to the linear mixed-effects model represented by \( \text{object} \) are extracted. If more than one level is indicated in \( \text{level} \), the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

Usage

```r
## S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```
Arguments

object  an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
form  this argument is included to make the method function compatible with the generic and is ignored in this method.
level  an optional integer vector giving the level(s) of grouping to be extracted from object. Defaults to the highest or innermost level of grouping.
data  unused
sep  character, the separator to use between group levels when multiple levels are collapsed. The default is `/`.

Value

either a data frame with columns given by the grouping factors indicated in level, or, when a single level is requested, a factor representing the selected grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`lme`

Examples

```r
fm1 <- lme(pixel ~ day + day^2, Pixel,
  random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
```

Description

The grouping factor determining the partitioning of the observations used to produce the `lm` components of object is extracted.

Usage

```r
## S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```
getGroups.varFunc

Arguments

object an object inheriting from class \texttt{lmList}, representing a list of \texttt{lm} objects with a common model.
form an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to \texttt{formula(object)}. Not used.
level a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
data a data frame in which to interpret the variables named in \texttt{form}. Optional for most methods. Not used.
sep character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used.

Value

a vector with the grouping factor corresponding to the \texttt{lm} components of \texttt{object}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{lmList}

Examples

\begin{verbatim}
fm1 <- lmList(distance ~ age | Subject, Orthodont)
groups(fm1)
\end{verbatim}

Description

This method function extracts the grouping factor associated with the variance function represented by \texttt{object}, if any is present.

Usage

\begin{verbatim}
## S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
\end{verbatim}
getGroupsFormula

Arguments

object an object inheriting from class varFunc, representing a variance function structure.
form an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object). Not used.
level a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
data a data frame in which to interpret the variables named in form. Optional for most methods. Not used.
sep character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’. Not used.

Value

if object has a groups attribute, its value is returned; else NULL is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)

getGroupsFormula Extract Grouping Formula

Description

The conditioning expression associated with formula(object) (i.e. the expression after the | operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of asList. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

Usage

getGroupsFormula(object, asList, sep)

Arguments

object any object from which a formula can be extracted.
asList an optional logical value. If TRUE the returned value will be a list of formulas; else, if FALSE the returned value will be a one-sided formula. Defaults to FALSE.
sep character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’.
extract response variable from an object

getResponse

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include data.frame, gls, lme, and lmList.

Usage

getResponse(object, form)

Arguments

object any object
form an optional two-sided formula. Defaults to formula(object).

Value

will depend on the method function used; see the appropriate documentation.

tExamples

getResponseFormula(y ~ x | g)

getVarCov  Extract Variance-Covariance Matrix

Description

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

Usage

gVarCov(obj, ...)

## S3 method for class 'lme'
gVarCov(obj, individuals,
    type = c("random.effects", "conditional", "marginal"), ...)

## S3 method for class 'gls'
gVarCov(obj, individual = 1, ...)
Arguments

obj A fitted model. Methods are available for models fit by `lme` and by `gls`.

individuals For models fit by `lme` a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.

individual For models fit by `gls` the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument `individual` specifies the group of responses.

type For models fit by `lme` the type argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional variance-covariance of the responses or "marginal" for the marginal variance-covariance of the responses.

... Optional arguments for some methods, as described above

Value

A variance-covariance matrix or a list of variance-covariance matrices.

Author(s)

Mary Lindstrom <lindstro@biostat.wisc.edu>

lme, gls

Examples

```r
fm1 <- lme(distance ~ age, data = Orthodont, subset = Sex == "Female")
getVarCov(fm1)
getVarCov(fm1, individual = "F01", type = "marginal")
getVarCov(fm1, type = "conditional")
fm2 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
```

---

**gls**  
*Fit Linear Model Using Generalized Least Squares*

Description

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage

```r
gls(model, data, correlation, weights, subset, method, na.action, control, verbose)
```

## S3 method for class 'gls'

```r
update(object, model., ..., evaluate = TRUE)
```
Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted linear model.

model a two-sided linear formula object describing the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right.

model. Changes to the model – see update.formula for details.

data an optional data frame containing the variables named in model, correlation, weights, and subset. By default the variables are taken from the environment from which gls is called.

correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gls to print an error message and terminate if there are any incomplete observations.

control a list of control values for the estimation algorithm to replace the default values returned by the function glsControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Value

an object of class "gls" representing the linear model fit. Generic functions such as print, plot, and summary have methods to show the results of the fit. See glsObject for the components of the fit. The functions resid, coef and fitted, can be used to extract some of its components.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corClasses, glsControl, glsObject, glsStruct, plot.gls, predict.gls, qqnorm.gls, residuals.gls, summary.gls, varClasses, varFunc

Examples

# AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, correlation = corAR1(form = ~ 1 | Mare))
# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
Arguments

- **maxIter**: maximum number of iterations for the gls optimization algorithm. Default is 50.
- **msMaxIter**: maximum number of iterations for the optimization step inside the gls optimization. Default is 50.
- **tolerance**: tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.
- **msTol**: tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.
- **msVerbose**: a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE.
- **singular.ok**: a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE.
- **returnObject**: a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
- **apVar**: a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
- **opt**: the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default).
- **optimMethod**: character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
- **minAbsParApVar**: numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
- **natural**: logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.
- **sigma**: optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

Examples

# decrease the maximum number iterations in the optimization call and
# request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
glsObject

**Fitted gls Object**

**Description**

An object returned by the `gls` function, inheriting from class “gls” and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "gls" object.

- **apVar**: an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the list of control values used in the call to `gls`, this component is equal to `NULL`.
- **call**: a list containing an image of the `gls` call that produced the object.
- **coefficients**: a vector with the estimated linear model coefficients.
- **contrasts**: a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
- **dims**: a list with basic dimensions used in the model fit, including the components `N` - the number of observations in the data and `p` - the number of coefficients in the linear model.
- **fitted**: a vector with the fitted values.
- **glsStruct**: an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.
- **groups**: a vector with the correlation structure grouping factor, if any is present.
- **logLik**: the log-likelihood at convergence.
- **method**: the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
- **numIter**: the number of iterations used in the iterative algorithm.
- **residuals**: a vector with the residuals.
- **sigma**: the estimated residual standard error.
- **varBeta**: an approximate covariance matrix of the coefficients estimates.

glsStruct

Generalized Least Squares Structure

Description

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A glsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the glsStruct list.

Usage

```r
glsStruct(corStruct, varStruct)
```

Arguments

- **corStruct**: an optional corStruct object, representing a correlation structure. Default is NULL.
- **varStruct**: an optional varFunc object, representing a variance function structure. Default is NULL.

Value

A list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Glucose

Glucose levels over time

Description

The Glucose data frame has 378 rows and 4 columns.

Format

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4
- **Time**: a numeric vector
- **conc**: a numeric vector of glucose levels
- **Meal**: an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm
Source

### Glucose2

*Glucose Levels Following Alcohol Ingestion*

#### Description
The Glucose2 data frame has 196 rows and 4 columns.

#### Format
This data frame contains the following columns:

- **Subject**: a factor with levels 1 to 7 identifying the subject whose glucose level is measured.
- **Date**: a factor with levels 1 2 indicating the occasion in which the experiment was conducted.
- **Time**: a numeric vector giving the time since alcohol ingestion (in min/10).
- **glucose**: a numeric vector giving the blood glucose level (in mg/dl).

#### Details
Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

### gnlsv

*Fit Nonlinear Model Using Generalized Least Squares*

#### Description
This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

#### Usage
gnlsv(model, data, params, start, correlation, weights, subset, na.action, naPattern, control, verbose)
Arguments

model  a two-sided formula object describing the model, with the response on the left of a ~ operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame.

data  an optional data frame containing the variables named in model, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which gnls is called.

params  an optional two-sided linear formula of the form p1+...+pn~x1+...+xm, or list of two-sided formulas of the form p1~x1+...+xm, with possibly different models for each parameter. The p1,...,pn represent parameters included on the right hand side of model and x1+...+xm define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of start.

start  an optional named list, or numeric vector, with the initial values for the parameters in model. It can be omitted when a selfStarting function is used in model, in which case the starting estimates will be obtained from a single call to the nls function.

correlation  an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights  an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset  an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action  a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gnls to print an error message and terminate if there are any incomplete observations.

naPattern  an expression or formula object, specifying which returned values are to be regarded as missing.

control  a list of control values for the estimation algorithm to replace the default values returned by the function gnlsControl. Defaults to an empty list.

verbose  an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

Value

an object of class gnls, also inheriting from class gls, representing the nonlinear model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See
gnlsObject for the components of the fit. The functions resid, coef, and fitted can be used to extract some of its components.

Examples
# variance increases with a power of the absolute fitted values
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean, weights = varPower())
summary(fm1)

## Description
The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gnls function.
Usage

gnlsControl(maxIter = 50, nlsMaxIter = 7, msMaxIter = 50, minScale = 0.001, 
tolerance = 1e-6, nlsTol = 0.001, msTol = 1e-7, 
returnObject = FALSE, msVerbose = FALSE, 
apVar = TRUE, .relStep =, 
opt = c("nlminb", "optim"), optimMethod = "BFGS", 
minAbsParApVar = 0.05, sigma = NULL)

Arguments

maxIter maximum number of iterations for the gnls optimization algorithm. Default is 50.
nlsMaxIter maximum number of iterations for the nls optimization step inside the gnls optimization. Default is 7.
msMaxIter maximum number of iterations for the ms optimization step inside the gnls optimization. Default is 50.
minScale minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the nls step. Default 0.001.
tolerance tolerance for the convergence criterion in the gnls algorithm. Default is 1e-6.
nlsTol tolerance for the convergence criterion in nls step. Default is 1e-3.
msTol tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.
returnObject a logical value indicating whether the fitted object should be returned with a warning (instead of an error via stop()) when the maximum number of iterations is reached without convergence of the algorithm.
msVerbose a logical value passed as the trace argument to the optimizer chosen by opt; see documentation on that. Default is FALSE.
apVar a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.relStep relative step for numerical derivatives calculations. Default is .Machine$double.eps*(1/3) (about 6e-6).
opt the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default).
optimMethod character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
minAbsParApVar numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
sigma optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.
gnlsObject

gnls

Examples

# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
gnlsControl(msMaxIter = 20, msVerbose = TRUE)

Description

An object returned by the gnls function, inheriting from class gnls and also from class gls, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions anova, coef, fitted, formula, getGroups, getResponse, intervals, logLik, plot, predict, print, residuals, summary, and update.

Value

The following components must be included in a legitimate gnls object.

- **apVar**: an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to gnls, this component is equal to NULL.
- **call**: a list containing an image of the gnls call that produced the object.
- **coefficients**: a vector with the estimated nonlinear model coefficients.
- **contrasts**: a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
- **dims**: a list with basic dimensions used in the model fit, including the components N - the number of observations used in the fit and p - the number of coefficients in the nonlinear model.
- **fitted**: a vector with the fitted values.
- **modelStruct**: an object inheriting from class gnlsStruct, representing a list of model components, such as corStruct and varFunc objects.
- **groups**: a vector with the correlation structure grouping factor, if any is present.
- **logLik**: the log-likelihood at convergence.
- **numIter**: the number of iterations used in the iterative algorithm.
- **plist**
- **pmap**
- **residuals**: a vector with the residuals.
- **sigma**: the estimated residual standard error.
- **varBeta**: an approximate covariance matrix of the coefficients estimates.

**gnlsStruct**  
*Generalized Nonlinear Least Squares Structure*

**Description**

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

**Usage**

```r
gnlsStruct(corStruct, varStruct)
```

**Arguments**

- `corStruct`: an optional `corStruct` object, representing a correlation structure. Default is `NULL`.
- `varStruct`: an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

**Value**

A list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

gnls1 <- gnlsStruct(corAR1(), varPower())
```
groupedData

Construct a groupedData Object

Description

An object of the groupedData class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of outer, inner, labels, and units that are given. If order.groups is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: nfnGroupedData - numeric covariate, single level of nesting; nffGroupedData - factor covariate, single level of nesting; and nmGroupedData - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a groupedData object to construct default plots and models.

Usage

groupedData(formula, data, order.groups, FUN, outer, inner, labels, units)
## S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN, outer, inner, labels, units, ...)

Arguments

object an object inheriting from class groupedData.
formula a formula of the form resp ~ cov | group where resp is the response, cov is the primary covariate, and group is the grouping factor. The expression 1 can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the / symbol as in fact1/fact2. In an expression like this the fact2 factor is nested within the fact1 factor.
data a data frame in which the expressions in formula can be evaluated. The resulting groupedData object will consist of the same data values in the same order but with additional attributes.
order.groups an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function FUN applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE.
FUN an optional summary function that will be applied to the values of the response for each level of the grouping factor, when order.groups = TRUE, to determine the ordering. Defaults to the max function.
an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument outer = TRUE causes the panels to be determined by the outer formula. The points within the panels are associated by level of the grouping factor. Defaults to NULL, meaning that no outer covariates are present.

inner an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to NULL, meaning that no inner covariates are present.

labels an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.

units an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.

... some methods for this generic require additional arguments. None are used in this method.

Value

an object of one of the classes nfnGroupedData, nffGroupedData, or nmGroupedData, and also inheriting from classes groupedData and data.frame.

Author(s)

Douglas Bates and José Pinheiro

fm1 <- lme( Orth.new ) # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

---

**gsummary**

*Summarize by Groups*

**Description**

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a groupedData object to examine the variables by group.

**Usage**

```
gsummary(object, FUN, omitGroupingFactor, form, level, 
groups, invariantsOnly, ...)```

**Arguments**

- **object**
  an object to be summarized - usually a groupedData object or a data.frame.

- **FUN**
  an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in object that vary within the groups defined by groups. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

- **omitGroupingFactor**
  an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to FALSE.
form

an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

level

an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

groups

an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

invariantsOnly

an optional logical value. When TRUE only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in object. By definition, the grouping factor itself must be an invariant. When combined with omitGroupingFactor = TRUE, this option can be used to discover if there are invariant covariates in the data frame. Defaults to FALSE.

...

optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify na.rm = TRUE.

Value

A data.frame with one row for each level of the grouping factor. The number of columns is at most the number of columns in object.

**Gun**

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

- **rounds** a numeric vector
- **Method** a factor with levels M1 M2
- **Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H
- **Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

### Source

---

**IGF**

### Description

The IGF data frame has 237 rows and 3 columns.

### Format

This data frame contains the following columns:

- **Lot** an ordered factor giving the radioactive tracer lot.
- **age** a numeric vector giving the age (in days) of the radioactive tracer.
- **conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

### Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.
Initialize

Source

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, lmeStruct, reStruct, and varFunc.

### Usage

```
Initialize(object, data, ...)  
```

### Arguments

- **object**: any object requiring initialization, e.g. "plug-in" structures such as corStruct and varFunc objects.
- **data**: a data frame to be used in the initialization procedure.
- **...**: some methods for this generic function require additional arguments.

### Value

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### See Also

`Initialize.corStruct`, `Initialize.lmeStruct`, `Initialize.glsStruct`, `Initialize.varFunc`, `isInitialized`

### Examples

```
## see the method function documentation
```
**Initialize.corStruct**

**Initialize corStruct Object**

**Description**

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

**Usage**

```r
## S3 method for class 'corStruct'
Initialize(object, data, ...)  
```

**Arguments**

- `object`: an object inheriting from class "corStruct" representing a correlation structure.
- `data`: a data frame in which to evaluate the variables defined in formula(object).
- `...`: this argument is included to make this method compatible with the generic.

**Value**

an initialized object with the same class as object representing a correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`Dim.corStruct`

**Examples**

```r
 cs1 <- corAR1(form = ~ 1 | Subject)
 cs1 <- Initialize(cs1, data = Orthodont)
```
Initialize.glsStruct  Initialize a glsStruct Object

Description

The individual linear model components of the glsStruct list are initialized.

Usage

## S3 method for class 'glsStruct'
Initialize(object, data, control, ...)

Arguments

object  
an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and varFunc objects.
data  
a data frame in which to evaluate the variables defined in formula(object).
control  
an optional list with control parameters for the initialization and optimization algorithms used in gls. Defaults to list(singular.ok = FALSE), implying that linear dependencies are not allowed in the model.
...

some methods for this generic require additional arguments. None are used in this method.

Value

a glsStruct object similar to object, but with initialized model components.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, Initialize.corStruct, Initialize.varFunc, Initialize

Initialize.lmeStruct  Initialize an lmeStruct Object

Description

The individual linear mixed-effects model components of the lmeStruct list are initialized.

Usage

## S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)

**Initialize.reStruct**

### Arguments

- **object**: an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- **data**: a data frame in which to evaluate the variables defined in `formula(object)`.
- **groups**: a data frame with the grouping factors corresponding to the lme model associated with `object` as columns, sorted from innermost to outermost grouping level.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object,"conLin")`.
- **control**: an optional list with control parameters for the initialization and optimization algorithms used in `lme`. Defaults to `list(niterEM=20,gradHess=TRUE)`, implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the reStruct component of `object` and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm.
- **...**: some methods for this generic require additional arguments. None are used in this method.

### Value

An `lmeStruct` object similar to `object`, but with initialized model components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme,Initialize.reStruct,Initialize.corStruct,Initialize.varFunc,Initialize`
Initialize.varFunc

Arguments

object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
data a data frame in which to evaluate the variables defined in formula(object).
conLin a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
control an optional list with a single component niterEM controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other Initialize methods. Defaults to list(niterEM = 20).
... some methods for this generic require additional arguments. None are used in this method.

Value

an reStruct object similar to object, but with all pdMat components initialized.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

reStruct, pdMat, Initialize

Initialize.varFunc Initialize varFunc Object

Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data; determining if the covariate(s) need to be updated when the values of the coefficients associated with object change; initializing the log-likelihood and the weights associated with object; and assigning initial values for the coefficients in object, if none were present. The covariate(s) will only be initialized if no update is needed when coef(object) changes.

Usage

## S3 method for class 'varFunc'
Initialize(object, data, ...)

Arguments

object an object inheriting from class "varFunc", representing a variance function structure.
data a data frame in which to evaluate the variables named in formula(object).
... this argument is included to make this method compatible with the generic.
**Value**

an initialized object with the same class as object representing a variance function structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

*Initialize*

**Examples**

```r
vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )
```

---

**Description**

Confidence intervals on the parameters associated with the model represented by `object` are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Usage**

```r
intervals(object, level, ...)
```

**Arguments**

- `object`: a fitted model object from which parameter estimates can be extracted.
- `level`: an optional numeric value for the interval confidence level. Defaults to 0.95.
- `...`: some methods for the generic may require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`intervals.lme`, `intervals.lmList`, `intervals.gls`

**Examples**

```r
## see the method documentation
```
Confidence Intervals on gls Parameters

Description

Approximate confidence intervals for the parameters in the linear model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

Usage

```r
## S3 method for class 'gls'
intervals(object, level, which, ...)  
```

Arguments

- `object`: an object inheriting from class "gls", representing a generalized least squares fitted linear model.
- `level`: an optional numeric value for the interval confidence level. Defaults to 0.95.
- `which`: an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all".
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- `coef`: linear model coefficients, only present when `which` is not equal to "var-cov".
- `corStruct`: correlation parameters, only present when `which` is not equal to "coef" and a correlation structure is used in `object`.
- `varFunc`: variance function parameters, only present when `which` is not equal to "coef" and a variance function structure is used in `object`.
- `sigma`: residual standard error.

Description

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The pdNatural parametrization is used for general positive-definite matrices.

Usage

```r
## S3 method for class 'lme'
intervals(object, level = 0.95,
          which = c("all", "var-cov", "fixed"), ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `level`: an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
- `which`: an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all".
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- `fixed`: fixed effects, only present when which is not equal to "var-cov".
- `reStruct`: random effects variance-covariance parameters, only present when which is not equal to "fixed".

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
intervals(fm1)

intervals.lmList  Confidence Intervals on lmList Coefficients

Description
Confidence intervals on the linear model coefficients are obtained for each lm component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by lower, est., and upper corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

Usage
## S3 method for class 'lmList'
intervals(object, level = 0.95, pool = attr(object, "pool"), ...)

Arguments
object  an object inheriting from class "lmList", representing a list of lm objects with a common model.
level  an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
pool  an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object,"pool").
...  some methods for this generic require additional arguments. None are used in this method.
isBalanced

Is a Design Balanced?

Description

A design is considered balanced if the number of observations at each level of the grouping factors and the covariate is constant and the times at which the observations are taken are also constant.

Usage

isBalanced(object, countOnly, level)

Arguments

object A groupedData object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.

countOnly A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to FALSE.

level An optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If countOnly is FALSE the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.
isInitialized

Value

TRUE or FALSE according to whether the data are balanced or not

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

table, groupedData

Examples

isBalanced(Orthodont) # should return TRUE
isBalanced(Orthodont, countOnly = TRUE) # should return TRUE
isBalanced(Pixel) # should return FALSE
isBalanced(Pixel, level = 1) # should return FALSE

isInitialized Check if Object is Initialized

Description

Checks if object has been initialized (generally through a call to Initialize), by searching for components and attributes which are modified during initialization.

Usage

isInitialized(object)

Arguments

object any object requiring initialization.

Value

a logical value indicating whether object has been initialized.

Author(s)

José Pinheiro and Douglas Bates

See Also

Initialize

Examples

pd1 <- pdDiag(~age)
isInitialized(pd1)
LDEsysMat

Generate system matrix for LDEs

Description

Generate the system matrix for the linear differential equations determined by a compartment model.

Usage

LDEsysMat(pars, incidence)

Arguments

pars a numeric vector of parameter values.
incidence an integer matrix with columns named From, To, and Par. Values in the Par column must be in the range 1 to length(pars). Values in the From column must be between 1 and the number of compartments. Values in the To column must be between 0 and the number of compartments.

Details

A compartment model describes material transfer between \( k \) in a system of \( k \) compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

Value

A \( k \times k \) numeric matrix.

Author(s)

Douglas Bates <bates@stat.wisc.edu>

References

Examples

# incidence matrix for a two compartment open system
incidence <-
  matrix(c(1,1,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
    dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
Description

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

The methods \texttt{lme.lmList} and \texttt{lme.groupedData} are documented separately.

Usage

\begin{verbatim}
lme(fixed, data, random, correlation, weights, subset, method, na.action, control, contrasts = NULL, keep.data = TRUE)
\end{verbatim}

\texttt{lme} is a \texttt{S3} method for class \texttt{'lme'}.

\texttt{update(object, fixed., ..., evaluate = TRUE)}

Arguments

\begin{itemize}
\item \texttt{object} an object inheriting from class \texttt{lme}, representing a fitted linear mixed-effects model.
\item \texttt{fixed} a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a \texttt{~} operator and the terms, separated by + operators, on the right, an "\texttt{lmList}" object, or a "\texttt{groupedData}" object.
\item \texttt{data} an optional data frame containing the variables named in \texttt{fixed}, \texttt{random}, \texttt{correlation}, \texttt{weights}, and \texttt{subset}. By default the variables are taken from the environment from which \texttt{lme} is called.
\item \texttt{random} optionally, any of the following: (i) a one-sided formula of the form \texttt{~ x1 + \ldots + xn | g1/\ldots/gm}, with \texttt{x1 + \ldots + xn} specifying the model for the random effects and \texttt{g1/\ldots/gm} the grouping structure (\texttt{m} may be equal to 1, in which case \texttt{no/} is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form \texttt{~ x1 + \ldots + xn | g}, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form \texttt{~ x1 + \ldots + xn}, or a \texttt{pdMat} object with a formula (i.e. a non-NULL value for \texttt{formula(object)}), or a list of such formulas or \texttt{pdMat} objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class "\texttt{groupedData}"; (iv) a named list of formulas or \texttt{pdMat} objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an \texttt{reStruct} object. See the documentation on \texttt{pdClasses} for a description of the available \texttt{pdMat} classes. Defaults to a formula consisting of the right hand side of \texttt{fixed}.
\end{itemize}
correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations.

control a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list.

contrasts an optional list. See the contrasts.arg of model.matrix.default.

keep.data logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Value An object of class "lme" representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

Note The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

Author(s) José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References The computational methods follow the general framework of Lindstrom and Bates (1988). The model formulation is described in Laird and Ware (1982). The variance-covariance parametrizations are described in Pinheiro and Bates (1996). The different correlation structures available for the correlation argument are described in Box, Jenkins and Reinsel (1994), Littell et al (1996), and Venables and Ripley (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian and Giltinan (1995).

fm2 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
summary(fm1)
summary(fm2)

lme.groupedData

LME fit from groupedData Object

Description

The response variable and primary covariate in formula(fixed) are used to construct the fixed effects model formula. This formula and the groupedData object are passed as the fixed and data arguments to lme.formula, together with any other additional arguments in the function call. See the documentation on lme.formula for a description of that function.

Usage

## S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
   subset, method, na.action, control, contrasts, keep.data = TRUE)
Arguments

fixed
a data frame inheriting from class "groupedData".

data
this argument is included for consistency with the generic function. It is ignored in this method function.

random
optionally, any of the following: (i) a one-sided formula of the form \( ~x_1+\ldots+x_n \mid g_1/\ldots/g_m \), with \( x_1+\ldots+x_n \) specifying the model for the random effects and \( g_1/\ldots/g_m \) the grouping structure (\( m \) may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form \( ~x_1+\ldots+x_n \mid g \), with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form \( ~x_1+\ldots+x_n \), or a pdMat object with a formula (i.e. a non-NULL value for formula(object)), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an reStruct object. See the documentation on pdClasses for a description of the available pdMat classes. Defaults to a formula consisting of the right hand side of fixed.

correlation
an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

weights
an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset
an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method
a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action
a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations.

control
a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list.

contrasts
an optional list. See the contrasts.arg of model.matrix.default.

keep.data
logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

Value
an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the
components of the fit. The functions \texttt{resid}, \texttt{coef}, \texttt{fitted}, \texttt{fixed.effects}, and \texttt{random.effects} can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

\texttt{lme}, \texttt{groupedData}, \texttt{lmeObject}

**Examples**

```r
fm1 <- lme(Orthodont)
summary(fm1)
```
**Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the fixed and data arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

**Usage**

```r
## S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
   na.action, control, contrasts, keep.data)
```

**Arguments**

- `fixed` an object inheriting from class "`lmList`.", representing a list of `lm` fits with a common model.
- `data` this argument is included for consistency with the generic function. It is ignored in this method function.
- `random` an optional one-sided linear formula with no conditioning expression, or a `pdMat` object with a `formula` attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of `formula(fixed)`.
- `correlation` an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations.
- `weights` an optional `varFunc` object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to `varFixed`, corresponding to fixed variance weights. See the documentation on `varClasses` for a description of the available `varFunc` classes. Defaults to `NULL`, corresponding to homoscedastic within-group errors.
- `subset` an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `method` a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
- `na.action` a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `lme` to print an error message and terminate if there are any incomplete observations.
- `control` a list of control values for the estimation algorithm to replace the default values returned by the function `lmeControl`. Defaults to an empty list.
lme.lmList

contrasts

an optional list. See the contrasts.arg of model.matrix.default.

keep.data

logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
summary(fm1)
summary(fm2)
Specifying Control Values for lme Fit

Description

The values supplied in the lmeControl() call replace the defaults, and a list with all settings (i.e., values for all possible arguments) is returned. The returned list is used as the control argument to the lme function.

Usage

lmeControl(maxIter = 50, msMaxIter = 50, tolerance = 1e-6, niterEM = 25, 
msMaxEval = 200, 
msTol = 1e-7, msVerbose = FALSE, 
returnObject = FALSE, gradHess = TRUE, apVar = TRUE, 
.relStep = .Machine$double.eps^((1/3)), minAbsParApVar = 0.05, 
opt = c("nlminb", "optim"), 
optimMethod = "BFGS", natural = TRUE, 
sigma = NULL, 
allow.n.lt.q = FALSE, 
...)

Arguments

- **maxIter**: maximum number of iterations for the lme optimization algorithm. Default is 50.
- **msMaxIter**: maximum number of iterations for the optimization step inside the lme optimization. Default is 50.
- **tolerance**: tolerance for the convergence criterion in the lme algorithm. Default is 1e-6.
- **niterEM**: number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
- **msMaxEval**: maximum number of evaluations of the objective function permitted for nlminb. Default is 200.
- **msTol**: tolerance for the convergence criterion on the first iteration when optim is used. Default is 1e-7.
- **msVerbose**: a logical value passed as the trace argument to nlminb or optim. Default is FALSE.
- **returnObject**: a logical value indicating whether the fitted object should be returned with a warning (instead of an error via stop()) when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
- **gradHess**: a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE.
- **apVar**: a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.relStep

relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3).

opt

the optimizer to be used, either "nlminb" (the default) or "optim".

optimMethod

color character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".

minAbsParApVar

numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

natural

a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

sigma

optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

allow.n.lt.q

logical indicating if it is ok to have less observations than random effects for each group. The default, FALSE signals an error; if NA, such a situation only gives a warning, as in nlme versions prior to 2019; if true, no message is given at all.

...

further named control arguments to be passed, depending on opt, to nlminb (those from abs.tol down) or optim (those except trace and maxit; reltol is used only from the second iteration).

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

See Also

lme, nlminb, optim

Examples

# decrease the maximum number iterations in the ms call and # request that information on the evolution of the ms iterations be printed str(lCtr <- lmeControl(msMaxIter = 20, msVerbose = TRUE)) ## This should always work: do.call(lmeControl, lCtr)

Description

An object returned by the lme function, inheriting from class lme and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, sigma, summary, update, and vcov.
The following components must be included in a legitimate \texttt{lme} object.

- \texttt{apVar} an approximate covariance matrix for the variance-covariance coefficients. If \texttt{apVar} = \texttt{FALSE} in the control values used in the call to \texttt{lme}, this component is \texttt{NULL}.
- \texttt{call} a list containing an image of the \texttt{lme} call that produced the object.
- \texttt{coefficients} a list with two components, \texttt{fixed} and \texttt{random}, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the \texttt{random} list, the columns refer to the random effects and the rows to the groups.
- \texttt{contrasts} a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the \texttt{lme} model, this component will be an empty list.
- \texttt{dims} a list with basic dimensions used in the \texttt{lme} fit, including the components \texttt{N} - the number of observations in the data, \texttt{Q} - the number of grouping levels, \texttt{qvec} - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), \texttt{ngrps} - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and \texttt{ncol} - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
- \texttt{fitted} a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
- \texttt{fixDF} a list with components \texttt{X} and \texttt{terms} specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
- \texttt{groups} a data frame with the grouping factors as columns. The grouping level increases from left to right.
- \texttt{logLik} the (restricted) log-likelihood at convergence.
- \texttt{method} the estimation method: either \texttt{"ML"} for maximum likelihood, or \texttt{"REML"} for restricted maximum likelihood.
- \texttt{modelStruct} an object inheriting from class \texttt{lmeStruct}, representing a list of mixed-effects model components, such as \texttt{reStruct}, \texttt{corStruct}, and \texttt{varFunc} objects.
- \texttt{numIter} the number of iterations used in the iterative algorithm.
- \texttt{residuals} a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
- \texttt{sigma} the estimated within-group error standard deviation.
- \texttt{varFix} an approximate covariance matrix of the fixed effects estimates.

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
Description
A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An lmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the lmeStruct list.

Usage
lmeStruct(reStruct, corStruct, varStruct)

Arguments
- reStruct: a reStruct representing a random effects structure.
- corStruct: an optional corStruct object, representing a correlation structure. Default is NULL.
- varStruct: an optional varFunc object, representing a variance function structure. Default is NULL.

Value
a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
corClasses, lme, residuals.lmeStruct, reStruct, varFunc

Examples
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
lmList

List of lm Objects with a Common Model

Description

Data is partitioned according to the levels of the grouping factor g and individual lm fits are obtained for each data partition, using the model defined in object.

Usage

lmList(object, data, level, subset, na.action = na.fail, pool = TRUE, warn.lm = TRUE)
## S3 method for class 'lmList'
update(object, formula., ..., evaluate = TRUE)
## S3 method for class 'lmList'
print(x, pool, ...) 

Arguments

object
For lmList, either a linear formula object of the form y ~ x1+...+xn | g or a groupedData object. In the formula object, y represents the response, x1,...,xn the covariates, and g the grouping factor specifying the partitioning of the data according to which different lm fits should be performed. The grouping factor g may be omitted from the formula, in which case the grouping structure will be obtained from data, which must inherit from class groupedData. The method function lmList.groupedData is documented separately. For the method update.lmList, object is an object inheriting from class lmList.

formula
(used in update.lmList only) a two-sided linear formula with the common model for the individuals lm fits.

formula.
Changes to the formula – see update.formula for details.

data
a data frame in which to interpret the variables named in object.

level
an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.

subset
an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action
a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations.

pool
an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.

warn.lm
logical indicating if lm() errors (all of which are caught by tryCatch) should be signalled as a “summarizing” warning.

x
an object inheriting from class lmList to be printed.

... some methods for this generic require additional arguments. None are used in this method.

evaluate
If TRUE evaluate the new call else return the call.
lmList.groupedData

Value

A list of \texttt{lm} objects with as many components as the number of groups defined by the grouping factor. Generic functions such as \texttt{coef}, \texttt{fixed.effects}, \texttt{lme}, \texttt{pairs}, \texttt{plot}, \texttt{predict}, \texttt{random.effects}, \texttt{summary}, and \texttt{update} have methods that can be applied to an \texttt{lmList} object.

References

See Also

\texttt{lm}, \texttt{lme.lmList}, \texttt{plot.lmList}, \texttt{pooledSD}, \texttt{predict.lmList}, \texttt{residuals.lmList}, \texttt{summary.lmList}

Examples

\begin{verbatim}
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
\end{verbatim}

---

\texttt{lmList.groupedData} \hspace{1cm} \textit{lmList Fit from a groupedData Object}

Description

The response variable and primary covariate in \texttt{formula(object)} are used to construct the linear model formula. This formula and the \texttt{groupedData} object are passed as the \texttt{object} and \texttt{data} arguments to \texttt{lmList.formula}, together with any other additional arguments in the function call. See the documentation on \texttt{lmList.formula} for a description of that function.

Usage

\begin{verbatim}
## S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action = na.fail, 
       pool = TRUE, warn.lm = TRUE)
\end{verbatim}

Arguments

- \texttt{object} : a data frame inheriting from class \texttt{"groupedData"}.
- \texttt{data} : this argument is included for consistency with the generic function. It is ignored in this method function.
- \texttt{level} : an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
- \texttt{subset} : an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- \texttt{na.action} : a function that indicates what should happen when the data contain NAs. The default action (\texttt{na.fail}) causes \texttt{lmList} to print an error message and terminate if there are any incomplete observations.
- \texttt{pool, warn.lm} : optional \texttt{logicals}, see \texttt{lmList}. 

---

\texttt{lmList} \hspace{1cm} \textit{lmList Fit from a groupedData Object}
Value

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

fm1 <- lmList(Orthodont)
summary(fm1)

logDet

Extract the Logarithm of the Determinant

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, several pdMat classes, and reStruct.

Usage

logDet(object, ...)

Arguments

object any object from which a matrix, or list of matrices, can be extracted
...
some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

logLik, logDet.corStruct, logDet.pdMat, logDet.reStruct

Examples

## see the method function documentation
logDet.corStruct

Extract corStruct Log-Determinant

Description

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

Usage

## S3 method for class 'corStruct'
logDet(object, covariate, ...)

Arguments

- **object**: an object inheriting from class "corStruct", representing a correlation structure.
- **covariate**: an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to getCovariate(object).
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the log-determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

logLik.corStruct, corMatrix.corStruct, logDet

Examples

cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
logDet.pdMat  Extract Log-Determinant from a pdMat Object

Description
This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by object.

Usage
## S3 method for class 'pdMat'
logDet(object, ...)

Arguments

object  an object inheriting from class "pdMat", representing a positive definite matrix.

...  some methods for this generic require additional arguments. None are used in this method.

Value
the log-determinant of a square-root factor of the positive-definite matrix represented by object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
pdMat, logDet

Examples
pd1 <- pdSymm(diag(1:3))
logDet(pd1)

logDet.reStruct  Extract reStruct Log-Determinants

Description
Calculates, for each of the pdMat components of object, the logarithm of the determinant of a square-root factor.

Usage
## S3 method for class 'reStruct'
logDet(object, ...)

logLik.corStruct

Arguments

object

an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the log-determinants of square-root factors of the pdMat components of object.

Author(s)

José Pinheiro

See Also

reStruct, pdMat, logDet

Examples

rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
   B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)

logLik.corStruct

Description

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by object.

Usage

## S3 method for class 'corStruct'
logLik(object, data, ...)

Arguments

object

an object inheriting from class "corStruct", representing a correlation structure.

data this argument is included to make this method function compatible with other logLik methods and will be ignored.

... some methods for this generic require additional arguments. None are used in this method.

Value

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by object.
Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
logDet.corStruct, logLik.lme,

Examples

```r
cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```

logLik.glsStruct

Log-Likelihood of a glsStruct Object

Description

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

Usage

```r
## S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.
- `Pars`: the parameter values at which the (restricted) log-likelihood is to be evaluated.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to attr(object,"conLin").
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the (restricted) log-likelihood for the linear model described by object, evaluated at Pars.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
gls, glsStruct, logLik.lme
logLik.gnls

Description
Returns the log-likelihood value of the nonlinear model represented by object evaluated at the estimated coefficients.

Usage

## S3 method for class 'gnls'
logLik(object, REML, ...)

Arguments

object
an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.

REML
an logical value for consistency with logLik.gls, but only FALSE is accepted.

...
some methods for this generic require additional arguments. None are used in this method.

Value
the log-likelihood of the linear model represented by object evaluated at the estimated coefficients.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
gnls, logLik.lme

Examples

fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
weights = varPower())
logLik(fm1)

logLik.gnlsStruct

Description
Pars is used to update the coefficients of the model components of object and the individual log-likelihood contributions of each component are added together.

Usage

## S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)

---

**logLik.gnls**

*Log-Likelihood of a gnls Object*

**Description**

Returns the log-likelihood value of the nonlinear model represented by object evaluated at the estimated coefficients.

**Usage**

```r
## S3 method for class 'gnls'
logLik(object, REML, ...)
```

**Arguments**

- `object`: an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
- `REML`: an logical value for consistency with logLik.gls, but only FALSE is accepted.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood of the linear model represented by object evaluated at the estimated coefficients.

**Author(s)**
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

gnls, logLik.lme

**Examples**

fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
weights = varPower())
logLik(fm1)
```

---

**logLik.gnlsStruct**

*Log-Likelihood of a gnlsStruct Object*

**Description**

Pars is used to update the coefficients of the model components of object and the individual log-likelihood contributions of each component are added together.

**Usage**

```r
## S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)
```
Arguments

- **object**: an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.
- **Pars**: the parameter values at which the log-likelihood is to be evaluated.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to `attr(object, "conLin")`.

... some methods for this generic require additional arguments. None are used in this method.

Value

the log-likelihood for the linear model described by `object`, evaluated at `Pars`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`gnls`, `gnlsStruct`, `logLik.gnls`

```r
fm1 <- lme(distance ~ Sex * age, Orthodont, random = ~ age, method = "ML")
logLik(fm1)
logLik(fm1, REML = TRUE)
```

Description
Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

Usage
```
## S3 method for class 'lmeStruct'
logLik(object, Pars, conLin, ...)
```

Arguments
- **object**: an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- **Pars**: the parameter values at which the (restricted) log-likelihood is to be evaluated.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object,"conLin")`.
- **...**: some methods for this generic require additional arguments. None are used in this method.
logLik.lmList

Log-Likelihood of an lmList Object

Description

If pool=FALSE, the (restricted) log-likelihoods of the lm components of object are summed together. Else, the (restricted) log-likelihood of the lm fit with different coefficients for each level of the grouping factor associated with the partitioning of the object components is obtained.

Usage

## S3 method for class 'lmList'
logLik(object, REML, pool, ...)

Arguments

object an object inheriting from class "lmList", representing a list of lm objects with a common model.
REML an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.
pool an optional logical value indicating whether all lm components of object may be assumed to have the same error variance. Default is attr(object,"pool").
... some methods for this generic require additional arguments. None are used in this method.

Value

either the sum of the (restricted) log-likelihoods of each lm component in object, or the (restricted) log-likelihood for the lm fit with separate coefficients for each component of object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lmList, logLik.lme,
Examples

```r
fm1 <- lmlist(distance ~ age | Subject, Orthodont)
logLik(fm1)  # returns NA when it should not
```

Description

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The settings attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

Usage

```r
## S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix \( X \) combined with a response vector \( y \), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef(object)`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`reStruct`, `pdMat`, `logLik.lme`
Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by object, which is equal to the sum of the logarithms of the corresponding weights.

Usage

## S3 method for class 'varFunc'
logLik(object, data, ...)

Arguments

object an object inheriting from class "varFunc", representing a variance function structure.
data this argument is included to make this method function compatible with other logLik methods and will be ignored.
... some methods for this generic require additional arguments. None are used in this method.

Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by object.

**Machines**

*Productivity Scores for Machines and Workers*

**Description**

The **Machines** data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Worker**: an ordered factor giving the unique identifier for the worker.
- **Machine**: a factor with levels A, B, and C identifying the machine brand.
- **score**: a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

**Source**

**MathAchieve**

*Mathematics achievement scores*

**Description**

The **MathAchieve** data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

- **School**: an ordered factor identifying the school that the student attends
- **Minority**: a factor with levels No Yes indicating if the student is a member of a minority racial group.
- **Sex**: a factor with levels Male Female
- **SES**: a numeric vector of socio-economic status.
- **MathAch**: a numeric vector of mathematics achievement scores.
- **MEANSES**: a numeric vector of the mean SES for the school.
Details

Each row in this data frame contains the data for one student.

Examples

```r
summary(MathAchieve)
```

---

**MathAchSchool**  
*School demographic data for MathAchieve*

Description

The MathAchSchool data frame has 160 rows and 7 columns.

Format

This data frame contains the following columns:

- **School**: a factor giving the school on which the measurement is made.
- **Size**: a numeric vector giving the number of students in the school.
- **Sector**: a factor with levels Public Catholic.
- **PRACAD**: a numeric vector giving the percentage of students on the academic track.
- **DISCLIM**: a numeric vector measuring the discrimination climate.
- **HIMINTY**: a factor with levels 0 1.
- **MEANSES**: a numeric vector giving the mean SES score.

Details

These variables give the school-level demographic data to accompany the MathAchieve data.

---

**Matrix**  
*Assign Matrix Values*

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `pdMat`, `pdBlocked`, and `reStruct`.

Usage

```r
matrix(object) <- value
```

Arguments

- **object**: any object to which `as.matrix` can be applied.
- **value**: a matrix, or list of matrices, with the same dimensions as `as.matrix(object)` with the new values to be assigned to the matrix associated with `object`. 
Assign Matrix to a pdMat or pdBlocked Object

Description

The positive-definite matrix represented by object is replaced by value. If the original matrix had row and/or column names, the corresponding names for value can either be NULL, or a permutation of the original names.

Usage

## S3 replacement method for class 'pdMat'
matrix(object) <- value

## S3 replacement method for class 'pdBlocked'
matrix(object) <- value

Arguments

object an object inheriting from class "pdMat", representing a positive definite matrix.

value a matrix with the new values to be assigned to the positive-definite matrix represented by object. Must have the same dimensions as as.matrix(object).

Value

a pdMat or pdBlocked object similar to object, but with its coefficients modified to produce the matrix in value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

as.matrix, also for examples, matrix<-.pdMat, matrix<-.reStruct.

class(pd1 <- pdSymm(diag(3))) # "pdSymm" "pdMat"
matrix(pd1) <- diag(1:3)
pd1
**Matrix.reStruct**

*Assign reStruct Matrices*

**Description**

The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

**Usage**

```r
## S3 replacement method for class 'reStruct'
matrix(object) <- value
```

**Arguments**

- `object` an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `value` a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object.

**Value**

an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `pdMat`, "matrix<-"

**Examples**

```r
r1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(r1) <- list(diag(2), 3)
```

---

**Meat**

*Tenderness of meat*

**Description**

The Meat data frame has 30 rows and 4 columns.
**Milk**

### Format

This data frame contains the following columns:

- **Storage**: an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)
- **score**: a numeric vector giving the tenderness score of beef roast.
- **Block**: an ordered factor identifying the muscle from which the roast was extracted with levels II < V < I < III < IV
- **Pair**: an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < ... < IV-1

### Details

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

### Source

---

**Milk**

### Description

The *Milk* data frame has 1337 rows and 4 columns.

### Format

This data frame contains the following columns:

- **protein**: a numeric vector giving the protein content of the milk.
- **Time**: a numeric vector giving the time since calving (weeks).
- **Cow**: an ordered factor giving a unique identifier for each cow.
- **Diet**: a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

### Details

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows’ milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

### Source

model.matrix.reStruct  reStruct Model Matrix

Description
The model matrices for each element of formula(object), calculated using data, are bound together column-wise. When multiple grouping levels are present (i.e. when length(object) > 1), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

Usage
## S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)

Arguments
- object: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- data: a data frame in which to evaluate the variables defined in formula(object).
- contrast: an optional named list specifying the contrasts to be used for representing the factor variables in data. The components names should match the names of the variables in data for which the contrasts are to be specified. The components of this list will be used as the contrasts attribute of the corresponding factor. If missing, the default contrast specification is used.
- ...: some methods for this generic require additional arguments. None are used in this method.

Value
a matrix obtained by binding together, column-wise, the model matrices for each element of formula(object).

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
- model.matrix, contrasts, reStruct, formula.reStruct

Examples
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
Muscle

Contraction of heart muscle sections

Description

The Muscle data frame has 60 rows and 3 columns.

Format

This data frame contains the following columns:

- **Strip** an ordered factor indicating the strip of muscle being measured.
- **conc** a numeric vector giving the concentration of CaCl2
- **length** a numeric vector giving the shortening of the heart muscle strip.

Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl2 solution. The muscle strips are taken from the left auricle of a rat’s heart.

Source

Names

Names Associated with an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

Usage

Names(object, ...)  
Names(object, ...) <- value

Arguments

- **object** any object for which names can be extracted and/or assigned.
- **...** some methods for this generic function require additional arguments.
- **value** names to be assigned to object.

Value

will depend on the method function used; see the appropriate documentation.
SIDE EFFECTS

On the left side of an assignment, sets the names associated with object to value, which must have an appropriate length.

Note

If names were generic, there would be no need for this generic function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Names.formula, Names.pdMat

Examples

## see the method function documentation

---

## Extract Names from a formula

**Description**

This method function returns the names of the terms corresponding to the right hand side of object (treated as a linear formula), obtained as the column names of the corresponding model.matrix.

**Usage**

```r
## S3 method for class 'formula'
Names(object, data, exclude, ...)
```

**Arguments**

- `object`: an object inheriting from class "formula".
- `data`: an optional data frame containing the variables specified in object. By default the variables are taken from the environment from which Names.formula is called.
- `exclude`: an optional character vector with names to be excluded from the returned value. Default is c("pi", ".").
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

a character vector with the column names of the model.matrix corresponding to the right hand side of object which are not listed in excluded.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

model.matrix, terms, Names

Examples

Names(distance ~ Sex * age, data = Orthodont)

pd1 <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(pd1)
Names.pdMat

Names of a pdMat Object

Description

This method function returns the first element of the Dimnames attribute of object, which contains the column names of the matrix represented by object.

Usage

```r
## S3 method for class 'pdMat'
Names(object, ...)
## S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class "pdMat", representing a positive-definite matrix.
- `value`: a character vector with the replacement values for the column and row names of the matrix represented by object. It must have length equal to the dimension of the matrix represented by `object` and, if names have been previously assigned to `object`, it must correspond to a permutation of the original names.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

If `object` has a Dimnames attribute then the first element of this attribute is returned; otherwise NULL.

SIDE EFFECTS

On the left side of an assignment, sets the Dimnames attribute of `object` to `list(value, value)`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Names, Names.pdBlocked

Examples

```r
pd1 <- pdSymm(~age, data = Orthodont)
Names(pd1)
```
Description

This method function extracts the column names of each of the positive-definite matrices represented the pdMat elements of object.

Usage

```r
## S3 method for class 'reStruct'
Names(object, ...)
## S3 replacement method for class 'reStruct'
Names(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `value`: a list of character vectors with the replacement values for the names of the individual pdMat objects that form object. It must have the same length as `object`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a list containing the column names of each of the positive-definite matrices represented by the pdMat elements of object.

SIDE EFFECTS

On the left side of an assignment, sets the Names of the pdMat elements of object to the corresponding element of value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`reStruct`, `pdMat`, `Names.pdMat`

Examples

```r
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
Names(rs1)
```
needUpdate  

Check if Update is Needed

Description

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of `object`. If this is NULL or FALSE it returns FALSE; else it returns TRUE. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage

```r
needUpdate(object)
```

Arguments

- `object` any object

Value

a logical value indicating whether `object` needs to be updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `needUpdate.modelStruct`

Examples

```r
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

needUpdate.modelStruct  

Check if a `modelStruct` Object Needs Updating

Description

This method function checks if any of the elements of `object` needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage

```r
## S3 method for class 'modelStruct'
needUpdate(object)
```
**Arguments**

object an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.

**Value**

a logical value indicating whether any element of object needs to be updated.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

needUpdate

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                   varStruct = varPower(form = ~age))
needUpdate(lms1)
```

**Nitrendipene**

*Assay of nitrendipene*

**Description**

The Nitrendipene data frame has 89 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **activity** a numeric vector
- **NIF** a numeric vector
- **Tissue** an ordered factor with levels 2 < 1 < 3 < 4
- **log.NIF** a numeric vector

**Source**

nlme

Nonlinear Mixed-Effects Models

Description

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

Usage

nlme(model, data, fixed, random, groups, start, correlation, weights, subset, method, na.action, naPattern, control, verbose)

Arguments

model a nonlinear model formula, with the response on the left of a \( \sim \) operator and an expression involving parameters and covariates on the right, or an nlsList object. If data is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function nlme.nlsList is documented separately.

data an optional data frame containing the variables named in model, fixed, random, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which nlme is called.

fixed a two-sided linear formula of the form \( f_1 + \ldots + f_n \sim x_1 + \ldots + x_m \), or a list of two-sided formulas of the form \( f_1 \sim x_1 + \ldots + x_m \), with possibly different models for different parameters. The \( f_1, \ldots, f_n \) are the names of parameters included on the right hand side of model and the \( x_1 + \ldots + x_m \) expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).

random optionally, any of the following: (i) a two-sided formula of the form \( r_1 + \ldots + r_n \sim x_1 + \ldots + x_m \mid g_1 / \ldots / g_Q \), with \( r_1, \ldots, r_n \) naming parameters included on the right hand side of model, \( x_1 + \ldots + x_m \) specifying the random-effects model for these parameters and \( g_1 / \ldots / g_Q \) the grouping structure (\( Q \) may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form \( r_1 + \ldots + r_n \sim x_1 + \ldots + x_m \), a list of two-sided formulas of the form \( r_1 \sim x_1 + \ldots + x_m \), with possibly different random-effects models for different parameters, a pdMat object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for formula(random)), or a list of pdMat objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in groups, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class groupedData, (iii) a named list of formulas, lists of formulas, or pdMat objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (iv) an reStruct object. See the documentation on pdClasses for a description of the available pdMat classes. Defaults to fixed, resulting in all fixed effects having also random effects.
groups  an optional one-sided formula of the form ~g1 (single level of nesting) or
~~g1/.../gQ (multiple levels of nesting), specifying the partitions of the data
over which the random effects vary. g1,...,gQ must evaluate to factors in
data. The order of nesting, when multiple levels are present, is taken from left
to right (i.e. g1 is the first level, g2 the second, etc.).

start  an optional numeric vector, or list of initial estimates for the fixed effects and
random effects. If declared as a numeric vector, it is converted internally to a
list with a single component fixed, given by the vector. The fixed component
is required, unless the model function inherits from class selfStart, in which
case initial values will be derived from a call to nlsList. An optional random
component is used to specify initial values for the random effects and should
consist of a matrix, or a list of matrices with length equal to the number of
grouping levels. Each matrix should have as many rows as the number of groups
at the corresponding level and as many columns as the number of random effects
in that level.

correlation  an optional corStruct object describing the within-group correlation struc-
ture. See the documentation of corClasses for a description of the available
corStruct classes. Defaults to NULL, corresponding to no within-group corre-
lations.

weights an optional varFunc object or one-sided formula describing the within-group
heteroscedasticity structure. If given as a formula, it is used as the argument
to varFixed, corresponding to fixed variance weights. See the documentation
on varClasses for a description of the available varFunc classes. Defaults to
NULL, corresponding to homoscedastic within-group errors.

subset an optional expression indicating the subset of the rows of data that should be
used in the fit. This can be a logical vector, or a numeric vector indicating which
observation numbers are to be included, or a character vector of the row names
to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-
likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

na.action a function that indicates what should happen when the data contain NAs. The
default action (na.fail) causes nlme to print an error message and terminate if
there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be re-
garded as missing.

control a list of control values for the estimation algorithm to replace the default values
returned by the function nlmeControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative
algorithm is printed. Default is FALSE.

Value

an object of class nlme representing the nonlinear mixed-effects model fit. Generic functions such
as print, plot and summary have methods to show the results of the fit. See nlmeObject for the
components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects
can be used to extract some of its components.

Note

The function does not do any scaling internally: the optimization will work best when the response
is scaled so its variance is of the order of one.

nlme.nlsList  

**NLME fit from nlsList Object**

**Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on `nlme.formula` for a description of that function.

**Usage**

```r
## S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
    subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

- `model`  
an object inheriting from class "nlsList", representing a list of nls fits with a common model.

- `data`  
this argument is included for consistency with the generic function. It is ignored in this method function.

- `fixed`  
this argument is included for consistency with the generic function. It is ignored in this method function.

- `random`  
an optional one-sided linear formula with no conditioning expression, or a `pdMat` object with a `formula` attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of `formula(fixed)`.

- `groups`  
an optional one-sided formula of the form ~g1 (single level of nesting) or ~g1/.../gQ (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. g1,...,gQ must evaluate to factors in `data`. The order of nesting, when multiple levels are present, is taken from left to right (i.e. g1 is the first level, g2 the second, etc.).

- `start`  
an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component `fixed`, given by the vector. The `fixed` component is required, unless the model function inherits from class `selfStart`, in which case initial values will be derived from a call to `nlsList`. An optional `random` component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.

- `correlation`  
an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations.
weights

weights is an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset

subset is an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method

method is a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

na.action

na.action is a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations.

naPattern

naPattern is an expression or formula object, specifying which returned values are to be regarded as missing.

control

control is a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list.

verbose

verbose is an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

Value

Value is an object of class nlme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

nlmeControl

Control Values for nlme Fit

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the nlme function.

Usage

nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
             tolerance, niterEM, pnlsTol, msTol,
             returnObject, msVerbose, msWarnNoConv,
             gradHess, apVar, .relStep, minAbsParApVar = 0.05,
             opt = c("nlminb", "nlm"), natural = TRUE, sigma = NULL, ...)

Arguments

maxIter  maximum number of iterations for the nlme optimization algorithm. Default is 50.
pnlsMaxIter  maximum number of iterations for the PNLS optimization step inside the nlme optimization. Default is 7.
msMaxIter  maximum number of iterations for nlminb (iter.max) or the nlm (iterlim, from the 10-th step) optimization step inside the nlme optimization. Default is 50 (which may be too small for e.g. for overparametrized cases).
minScale  minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.
tolerance  tolerance for the convergence criterion in the nlme algorithm. Default is 1e-6.
niterEM  number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
pnlsTol  tolerance for the convergence criterion in PNLS step. Default is 1e-3.
nlmeControl

**msTol**
tolerance for the convergence criterion in nlm, passed as the gradtol argument to the function (see documentation on nlm). Default is 1e-7.

**returnObject**
a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.

**msVerbose**
a logical value passed as the trace to nlm(...,control=list(trace = *,...)) or as argument print.level to nlm(). Default is FALSE.

**msWarnNoConv**
logical indicating if a warning should be signalled whenever the minimization by (opt) in the LME step does not converge; defaults to TRUE.

**gradHess**
a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the nlm optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE.

**apVar**
a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

**relStep**
relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3).

**minAbsParApVar**
numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

**opt**
the optimizer to be used, either "nlminb" (the default) or "nlm".

**natural**
a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

**sigma**
optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

... Further, named control arguments to be passed to nlm(...,control=list(...)) (apart from trace and eval.max mentioned above), where used (eval.max and those from abs.tol down).

**Value**
a list with components for each of the possible arguments.

**Author(s)**
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

**See Also**

**Examples**

# decrease the maximum number iterations in the ms call and # request that information on the evolution of the ms iterations be printed nlmeControl(msMaxIter = 20, msVerbose = TRUE)
nlmeObject

Fitted nlme Object

Description
An object returned by the \texttt{nlme} function, inheriting from class "\texttt{nlme}" , also inheriting from class "\texttt{lme}" , and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions \texttt{anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, summary, and update}.

Value
The following components must be included in a legitimate "\texttt{nlme}" object.

- \texttt{apVar} an approximate covariance matrix for the variance-covariance coefficients. If \texttt{apVar = FALSE} in the control values used in the call to \texttt{nlme}, this component is \texttt{NULL}.
- \texttt{call} a list containing an image of the \texttt{nlme} call that produced the object.
- \texttt{coefficients} a list with two components, \texttt{fixed} and \texttt{random}, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the \texttt{random} list, the columns refer to the random effects and the rows to the groups.
- \texttt{contrasts} a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the \texttt{nlme} model, this component will be an empty list.
- \texttt{dims} a list with basic dimensions used in the \texttt{nlme} fit, including the components \texttt{N} - the number of observations in the data, \texttt{Q} - the number of grouping levels, \texttt{qvec} - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), \texttt{ngrps} - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and \texttt{ncol} - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
- \texttt{fitted} a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
- \texttt{fixDF} a list with components \texttt{X} and \texttt{terms} specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
- \texttt{groups} a data frame with the grouping factors as columns. The grouping level increases from left to right.
- \texttt{logLik} the (restricted) log-likelihood at convergence.
- \texttt{map} a list with components \texttt{fmap}, \texttt{rmap}, \texttt{rmapRel}, and \texttt{bmap}, specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.
nlmeStruct

Method

The estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

ModelStruct

An object inheriting from class nlmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.

numIter

The number of iterations used in the iterative algorithm.

residuals

A data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.

sigma

The estimated within-group error standard deviation.

varFix

An approximate covariance matrix of the fixed effects estimates.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

nlme, nlmeStruct

nlmeStruct

Nonlinear Mixed-Effects Structure

Description

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An nlmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the nlmeStruct list.

Usage

nlmeStruct(reStruct, corStruct, varStruct)

Arguments

reStruct

A reStruct representing a random effects structure.

corStruct

An optional corStruct object, representing a correlation structure. Default is NULL.

varStruct

An optional varFunc object, representing a variance function structure. Default is NULL.

Value

A list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
nlsList

See Also
corClasses, nlme, residuals.nlmeStruct, reStruct, varFunc

Examples

nlms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())

nlsList

List of nls Objects with a Common Model

Description

Data is partitioned according to the levels of the grouping factor defined in model and individual nls fits are obtained for each data partition, using the model defined in model.

Usage

nlsList(model, data, start, control, level, subset,
       na.action = na.fail, pool = TRUE, warn.nls = NA)

## S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)

Arguments

object an object inheriting from class nlsList, representing a list of fitted nls objects.
model either a nonlinear model formula, with the response on the left of a ~ operator and an expression involving parameters, covariates, and a grouping factor separated by the | operator on the right, or a selfStart function. The method function nlsList.selfStart is documented separately.
model. changes to the model – see update.formula for details.
data a data frame in which to interpret the variables named in model.
start an optional named list with initial values for the parameters to be estimated in model. It is passed as the start argument to each nls call and is required when the nonlinear function in model does not inherit from class selfStart.
control a list of control values passed as the control argument to nls. Defaults to an empty list.
level an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlsList to print an error message and terminate if there are any incomplete observations.
pool an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for pool in calculations of standard deviations or standard errors for summaries.
warn.nls logical indicating if nls() errors (all of which are caught by tryCatch) should be signalled as a "summarizing" warning.

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Details

As nls(.) is called on each sub group, and convergence of these may be problematic, these calls happen with error catching.

Since nlme version 3.1-127 (2016-04), all the errors are caught (via tryCatch) and if present, a "summarizing" warning is stored as attribute of the resulting "nlsList" object and signalled unless suppressed by warn.nls = FALSE or currently also when warn.nls = NA (default) and getOption("show.error.messages") is false.

nlsList() originally had used try(*) (with its default silent=FALSE) and hence all errors were printed to the console unless the global option show.error.messages was set to true. This still works, but has been deprecated.

Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an nlsList object.

stopifnot(length(i.ok) > 0, !anyNA(match(c(2:4, 6:9, 12), i.ok)))
## where as (some of) the others gave errors during profile re-fitting :
str(cfm1[- i.ok])
nlsList.selfStart

nlsList Fit from a selfStart Function

Description

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a selfStarting model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

Usage

```r
## S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset,
       na.action = na.fail, pool = TRUE, warn.nls = NA)
```

Arguments

- `model`: a "selfStart" model function, which calculates initial estimates for the model parameters from `data`.
- `data`: a data frame in which to interpret the variables in `model`. Because no grouping factor can be specified in `model`, data must inherit from class "groupedData".
- `start`: an optional named list with initial values for the parameters to be estimated in `model`. It is passed as the `start` argument to each `nls` call and is required when the nonlinear function in `model` does not inherit from class `selfStart`.
- `control`: a list of control values passed as the `control` argument to `nls`. Defaults to an empty list.
- `level`: an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
- `subset`: an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (`na.fail`) causes `nlsList` to print an error message and terminate if there are any incomplete observations.
- `pool`, `warn.nls`: optional `logicals`, see `nlsList`.

Value

A list of `nls` objects with as many components as the number of groups defined by the grouping factor. A NULL value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

**Oats**

*Split-plot Experiment on Varieties of Oats*

**Description**

The Oats data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Block**: an ordered factor with levels VI < V < III < IV < II < I
- **Variety**: a factor with levels Golden Rain Marvellous Victory
- **nitro**: a numeric vector
- **yield**: a numeric vector

**Details**

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a $3 \times 4$ full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

**Orthodont**

*Growth curve data on an orthodontic measurement*

**Description**

The Orthodont data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.
Ovary

Format

This data frame contains the following columns:

- **distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.
- **age** a numeric vector of ages of the subject (yr).
- **Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.
- **Sex** a factor with levels Male and Female

Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

```

<table>
<thead>
<tr>
<th>Ovary</th>
<th>Counts of Ovarian Follicles</th>
</tr>
</thead>
</table>

Description

The Ovary data frame has 308 rows and 3 columns.

Format

This data frame contains the following columns:

- **Mare** an ordered factor indicating the mare on which the measurement is made.
- **Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.
- **follicles** the number of ovarian follicles greater than 10 mm in diameter.

Details

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.
Source

Oxboys

*Heights of Boys in Oxford*

Description
The Oxboys data frame has 234 rows and 4 columns.

Format
This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

Details
These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

Source

Oxide

*Variability in Semiconductor Manufacturing*

Description
The Oxide data frame has 72 rows and 5 columns.

Format
This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.
These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

---

### Description

Scatter plots of the values being compared are generated for each pair of coefficients in `x`. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the `trellis` function `xyplot` is used; otherwise the `trellis` function `splom` is used.

#### Usage

```r
## S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

#### Arguments

- **x**: an object of class `compareFits`.
- **subset**: an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used.
- **key**: an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (`splom` or `xyplot`). Defaults to `TRUE`.
- **...**: optional arguments passed down to the `trellis` function generating the plots.

#### Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

#### Author(s)

José Pinheiro and Douglas Bates

Examples

example(compareFits) # cF12 <- compareFits(coef(lmList(Orthodont)), .. lme(*))
pairs(cF12)

pairs.lme  Pairs Plot of an lme Object

Description

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a | operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function xyplot is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function splom is used).

Usage

## S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)

Arguments

x  an object inheriting from class "$lme", representing a fitted linear mixed-effects model.
form  an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form, and to the left of the | operator, must evaluate to a data frame with at least two columns. Default is ~ coef(.), corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting.
label  an optional character vector of labels for the variables in the pairs plot.
id  an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the 1 − value percentile of the appropriate chi-square distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.
pairs.lmList

idLabels  an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.

grid  an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

...  optional arguments passed to the Trellis plot function.

Value
	a diagnostic Trellis plot.

lme, pairs.compareFits, pairs.lmList, xyplot, splom

Examples

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)

# scatter plot of coefficients by gender, identifying unusual subjects
pairs(fm1, ~coef(.), augFrame = TRUE) | Sex, id = 0.1, adj = -0.5)

# scatter plot of estimated random effects :
pairs(fm1, ~ranef(.))
Arguments

- **x**
  - An object inheriting from class "1mList", representing a list of lm objects with a common model.

- **form**
  - An optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of Form, and to the left of the | operator, must evaluate to a data frame with at least two columns. Default is ~ coef(.), corresponding to a pairs plot of the coefficients of x.

- **label**
  - An optional character vector of labels for the variables in the pairs plot.

- **id**
  - An optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the 1 − value percentile of the appropriate chi-square distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.

- **idLabels**
  - An optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.

- **grid**
  - An optional logical value indicating whether a grid should be added to plot. Default is FALSE.

- **...**
  - Optional arguments passed to the Trellis plot function.

Value

A diagnostic Trellis plot.

```
Effect of Phenylbiguanide on Blood Pressure

Description
The PBG data frame has 60 rows and 5 columns.

Format
This data frame contains the following columns:

- **deltaBP**: a numeric vector
- **dose**: a numeric vector
- **Run**: an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1
- **Treatment**: a factor with levels MDL 72222 Placebo
- **Rabbit**: an ordered factor with levels 5 < 3 < 2 < 4 < 1

Details
Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

Source

Positive-Definite Block Diagonal Matrix

Description
This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.
Usage

pdBlocked(value, form, nam, data, pdClass)

Arguments

value an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object.

form an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.

nam an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.

pdClass an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

as.matrix.pdMat, coef.pdMat, pdClasses, matrix<-.pdMat

Examples

pd1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
    nam = list(c("A","B"), c("a1","a2","a3")))

pd1
**Description**

Standard classes of positive-definite matrices (pdMat) structures available in the nlme package.

**Value**

Available standard classes:

- `pdSymm`: general positive-definite matrix, with no additional structure
- `pdLogChol`: general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization
- `pdDiag`: diagonal
- `pdIdent`: multiple of an identity
- `pdCompSymm`: compound symmetry structure (constant diagonal and constant off-diagonal elements)
- `pdBlocked`: block-diagonal matrix, with diagonal blocks of any 'atomic' pdMat class
- `pdNatural`: general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization.

**Note**

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions `pdConstruct`, `pdMatrix` and `coef`. For examples of these functions, see the methods for classes `pdSymm` and `pdDiag`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`pdBlocked`, `pdCompSymm`, `pdDiag`, `pdFactor`, `pdIdent`, `pdMat`, `pdMatrix`, `pdNatural`, `pdSymm`, `pdLogChol`
This function is a constructor for the `pdCompSymm` class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdCompSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```r
pdCompSymm(value, form, nam, data)
```

**Arguments**

- `value` an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector of length 2. Defaults to `numeric(0)`, corresponding to an uninitialized object.
- `form` an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a `data.frame` to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.
- `nam` an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`.
- `data` an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for `factors`, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on `factors` appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

- a `pdCompSymm` object representing a positive-definite matrix with compound symmetry structure, also inheriting from class `pdMat`.

pdConstruct  
Construct pdMat Objects

Description

This function is an alternative constructor for the pdMat class associated with object and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

Usage

pdConstruct(object, value, form, nam, data, ...)

Arguments

object  
an object inheriting from class pdMat, representing a positive definite matrix.
value  
an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
form  
an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.
nam  
an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
data  
an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdMat object representing a positive-definite matrix, inheriting from the same classes as object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
See Also

pdCompSymm, pdDiag, pdIdent, pdNatural, pdSymm

Examples

```r
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

Description

This function gives an alternative constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

Usage

```r
## S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass, ...)
```

Arguments

- **object**: an object inheriting from class "pdBlocked", representing a positive definite block-diagonal matrix.
- **value**: an optional list with elements to be used as the `value` argument to other `pdMat` constructors. These include: `pdMat` objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g., all one-sided formulas, or all numeric vectors). Defaults to `numeric(0)`, corresponding to an uninitialized object.
- **form**: an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by `object`. Because factors may be present in `form`, the formulas needs to be evaluated on a data.frame to resolve the names they defines. This argument is ignored when `value` is a list of one-sided formulas. Defaults to `NULL`.
- **nam**: an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by `object`. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when `value` is a list of vector of character strings. Defaults to `NULL`.
**pdDiag**

**data**
an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

**pdClass**
an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

... some methods for this generic require additional arguments. None are used in this method.

**Value**
a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

**Author(s)**
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

```r
pd1 <- pdBlocked(list(c("A","B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

---

**Diagonal Positive-Definite Matrix**

**Description**
This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension n, it is represented by n unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**
```r
pdDiag(value, form, nam, data)
```
Arguments

value

an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to numeric(0), corresponding to an uninitialized object.

form

an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam

an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data

an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdDiag object representing a diagonal positive-definite matrix, also inheriting from class pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**pdFactor**  
*Square-Root Factor of a Positive-Definite Matrix*

**Description**

A square-root factor of the positive-definite matrix represented by object is obtained. Letting \( \Sigma \) denote a positive-definite matrix, a square-root factor of \( \Sigma \) is any square matrix \( L \) such that \( \Sigma = L' / L \). This function extracts \( L \).
Usage

pdFactor(object)

Arguments

object an object inheriting from class pdMat, representing a positive definite matrix, which must have been initialized (i.e. length(coef(object)) > 0).

Value

a vector with a square-root factor of the positive-definite matrix associated with object stacked column-wise.

Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The pdMatrix function can be used to obtain square-root factors in matrix form.

**Examples**

```r
r1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
pdFactor(r1)
```

---

**Description**

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with object is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When value is numeric(0), an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**

```r
pdIdent(value, form, nam, data)
```
**Arguments**

- **value**: an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric value. Defaults to `numeric(0)`, corresponding to an uninitialized object.

- **form**: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.

- **nam**: an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`.

- **data**: an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

A `pdIdent` object representing a multiple of the identity positive-definite matrix, also inheriting from class `pdMat`.

**pdLogChol**  
*General Positive-Definite Matrix*
Description

This function is a constructor for the pdLogChol class, representing a general positive-definite matrix. If the matrix associated with object is of dimension n, it is represented by \( n(n + 1)/2 \) unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996).

- When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a character vector, object is returned as an uninitialized pdLogChol object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions.
- If value is an initialized pdMat object, object will be constructed from as.matrix(value).
- Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

Usage

pdLogChol(value, form, nam, data)

Arguments

value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam an optional character vector specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a character vector. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Details

Internally, the pdLogChol representation of a symmetric positive definite matrix is a vector starting with the logarithms of the diagonal of the Choleski factorization of that matrix followed by its upper triangular portion.

Value

a pdLogChol object representing a general positive-definite matrix, also inheriting from class pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

pd4c[upper.tri(pd4c)]
log(diag(pd4c)) # 1 2 3

pdMat

Positive-Definite Matrix

Description

This function gives an alternative way of constructing an object inheriting from the pdMat class named in pdClass, or from data.class(object) if object inherits from pdMat, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

Usage

pdMat(value, form, nam, data, pdClass)

Arguments

value

an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.

form

an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam

an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data

an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
pdMatrix

pdClass

an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to “pdSymm”.

Value

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

**pdMatrix**

*Extract Matrix or Square-Root Factor from a pdMat Object*

**Description**

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting \( \Sigma \) denote a positive-definite matrix, a square-root factor of \( \Sigma \) is any square matrix \( L \) such that \( \Sigma = L'L \). This function extracts \( S \) or \( L \).

**Usage**

pdMatrix(object, factor)

**Arguments**

object

an object inheriting from class pdMat, representing a positive definite matrix.

factor

an optional logical value. If TRUE, a square-root factor of the positive-definite matrix represented by object is returned; else, if FALSE, the positive-definite matrix is returned. Defaults to FALSE.

**Value**

if fact is FALSE the positive-definite matrix represented by object is returned; else a square-root of the positive-definite matrix is returned.

Examples
pd1 <- pdSymm(diag(1:4))
pdMatrix(pd1)

pdMatrix.reStruct Extract Matrix or Square-Root Factor from Components of an reStruct Object

Description
This method function extracts the positive-definite matrices corresponding to the pdMat elements of object, or square-root factors of the positive-definite matrices.

Usage
## S3 method for class 'reStruct'
pdMatrix(object, factor)

Arguments
object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
factor an optional logical value. If TRUE, square-root factors of the positive-definite matrices represented by the elements of object are returned; else, if FALSE, the positive-definite matrices are returned. Defaults to FALSE.

Value
a list with components given by the positive-definite matrices corresponding to the elements of object, or square-root factors of the positive-definite matrices.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
pdMatrix(rs1)

Description

This function is a constructor for the pdNatural class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with object is of dimension n, it is represented by n(n + 1)/2 parameters. Letting \(a_{ij}\) denote the \(ij\)-th element of the underlying positive definite matrix and \(\rho_{ij} = a_{ij}/\sqrt{a_{ii}a_{jj}}\), \(i \neq j\) denote the associated "correlations", the "natural" parameters are given by \(\sqrt{a_{ii}}, i = 1, \ldots, n\) and \(\log((1 + \rho_{ij})/(1 - \rho_{ij})), i \neq j\). Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

Usage

pdNatural(value, form, nam, data)

Arguments

- **value**: an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
- **form**: an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.
- **nam**: an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
- **data**: an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
**pdSymm**

**Value**

a **pdNatural** object representing a general positive-definite matrix in natural parametrization, also inheriting from class **pdMat**.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**pdSymm**

**General Positive-Definite Matrix**

**Description**

This function is a constructor for the **pdSymm** class, representing a general positive-definite matrix. If the matrix associated with **object** is of dimension *n*, it is represented by *n*(n + 1)/2 unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When **value** is numeric(0), an uninitialized **pdMat** object, a one-sided formula, or a vector of character strings, **object** is returned as an uninitialized **pdSymm** object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the **coef** or **matrix** replacement functions. If **value** is an initialized **pdMat** object, **object** will be constructed from **as.matrix(value)**. Finally, if **value** is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```r
pdSymm(value, form, nam, data)
```

**Arguments**

- **value**: an optional initialization value, which can be any of the following: a **pdMat** object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
- **form**: an optional one-sided linear formula specifying the row/column names for the matrix represented by **object**. Because factors may be present in **form**, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when **value** is a one-sided formula. Defaults to **NULL**.
The **Phenobarb** data frame has 744 rows and 7 columns.

### Description

The Phenobarb data frame has 744 rows and 7 columns.

### Format

This data frame contains the following columns:

- **Subject**: an ordered factor identifying the infant.
- **Wt**: a numeric vector giving the birth weight of the infant (kg).
- **Apgar**: an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.
- **ApgarInd**: a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.
- **time**: a numeric vector giving the time when the sample is drawn or drug administered (hr).
- **dose**: a numeric vector giving the dose of drug administered (ug/kg).
- **conc**: a numeric vector giving the phenobarbital concentration in the serum (ug/L).

### Examples

```r
d1 <- pdSymm(diag(1:3), nam = c("A","B","C"))
d1
```
**Details**

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn (1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

**Source**

Grasela and Donn (1985), Neonatal population pharmacokinetics of phenobarbital derived from routine clinical data, *Developmental Pharmacology and Therapeutics*, 8, 374-383.

---

**Usage**

```
phenoModel(Subject, time, dose, lCl, lV)
```

**Arguments**

- **Subject**: an integer vector of subject identifiers. These should be sorted in increasing order.
- **time**: numeric. A vector of the times at which the sample was drawn or the drug administered (hr).
- **dose**: numeric. A vector of doses of drug administered (ug/kg).
- **lCl**: numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.
- **lV**: numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.

**Details**

See the details section of *Phenobarb* for a description of the model function that *phenoModel* evaluates.
Value

a numeric vector of predicted phenobarbital concentrations.

Pixel

X-ray pixel intensities over time

Description

The Pixel data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time.

Format

This data frame contains the following columns:

Dog a factor with levels 1 to 10 designating the dog on which the scan was made
Side a factor with levels L and R designating the side of the dog being scanned
day a numeric vector giving the day post injection of the contrast on which the scan was made
pixel a numeric vector of pixel intensities

Source

Examples

fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
        random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
plot.ACF

Description

An `xyplot` of the autocorrelations versus the lags, with `type = "h"`, is produced. If `alpha > 0`, curves representing the critical limits for a two-sided test of level `alpha` for the autocorrelations are added to the plot.

Usage

```r
## S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

Arguments

- `x`: An object inheriting from class `ACF`, consisting of a data frame with two columns named `lag` and `ACF`, representing the autocorrelation values and the corresponding lags.
- `alpha`: An optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level `alpha` are added to the plot. Default is 0, in which case no lines are plotted.
- `xlab, ylab`: Optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".
- `grid`: An optional logical value indicating whether a grid should be added to plot. Default is `FALSE`.
- `...`: Optional arguments passed to the `xyplot` function.

Value

An `xyplot` Trellis plot.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`ACF`, `xyplot`

Examples

```r
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```
plot.augPred

plot.augPred

Plot an augPred Object

Description
A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

Usage
```r
## S3 method for class 'augPred'
plot(x, key, grid, ...)
```

Arguments
- `x`: an object of class "augPred".
- `key`: an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE.
- `grid`: an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- `...`: optional arguments passed down to the trellis function generating the plots.

Value
A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
`augPred`, `xyplot`

Examples
```r
fm1 <- lme(Orthodont)
plot(augPred(fm1, level = 0:1, length.out = 2))
```
plot.compareFits

Plot a compareFits Object

Description

A Trellis dotplot of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

Usage

## S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)

Arguments

x
an object of class "compareFits".

subset
an optional logical or integer vector specifying which rows of x should be used in the plots. If missing, all rows are used.

key
an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (dotplot). Defaults to TRUE.

mark
an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.

...
optional arguments passed down to the trellis function generating the plots.

Value

A Trellis dotplot of the values being compared, with rows determined by the groups and panels by the coefficients.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

compareFits, pairs.compareFits, dotplot

Examples

eexample(compareFits) # cF12 <- compareFits(coef(lmList(Orthodont)), .. lme(*))
plot(cF12)
plot.gls

Plot a gls Object

Description

Diagnostic plots for the linear model fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

## S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)

Arguments

x an object inheriting from class "gls", representing a generalized least squares fitted linear model.

form an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(. , type = "p") ~ fitted(.), corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.

abline an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.

idResType an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized
residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid

an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

...

optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot.

# standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
# box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.,))
# observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))
plot.lme

Arguments

x an object inheriting from class "intervals.lmList", representing confidence intervals and estimates for the coefficients in the lm components of the lmList object used to produce x.
xlab, ylab axis labels, each with a sensible default.
strip a function or FALSE, see dotplot() from package lattice.
...
optional arguments passed to the dotplot function (see above).

Value

a Trellis plot with the confidence intervals on the coefficients of the individual lm components of the lmList that generated x.

plot.lme  Plot an lme or nls object

Description

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

## S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
plot.lme

Arguments

x
an object inheriting from class "lme", representing a fitted linear mixed-effects model, or from nls, representing an fitted nonlinear least squares model.

form
an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "p") ~ fitted(.), corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.

abline
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

idResType
an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid
an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

...
optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot.

plot(m1, distance ~ fitted(.) | Subject, abline = c(0,1))

plot.lmList  

Plot an lmList Object

Description

Diagnostic plots for the linear model fits corresponding to the x components are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

## S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)

Arguments

x  
an object inheriting from class "lmList", representing a list of lm objects with a common model.

form  
an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "pool") ~ fitted(.), corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.

abline  
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id  
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value / 2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
plot.nffGroupedData

Plot an nffGroupedData Object

Description

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function dotplot is used.

Usage

```r
## S3 method for class 'nffGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key, grid, ...)```

idLabels

an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is getGroups(x).

grid

an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

... optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lmList, predict.lm, xyplot, bwplot, histogram

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))```
Arguments

x
an object inheriting from class `nffGroupedData`, representing a `groupedData` object with a factor primary covariate and a single grouping level.

outer
an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to `TRUE`, `attr(object,"outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.

inner
an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to `TRUE`, `attr(object,"inner")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.

innerGroups
an optional one-sided formula specifying a factor to be used for grouping the levels of the `inner` covariate. Different colors, or symbols, are used for each level of the `innerGroups` factor. Default is `NULL`, meaning that no `innerGroups` covariate is present.

xlab
an optional character string with the label for the horizontal axis. Default is the elements of `attr(object,"labels")` and `attr(object,"units")` pasted together.

ylab
an optional character string with the label for the vertical axis. Default is the grouping factor name.

strip
an optional function passed as the `strip` argument to the `dotplot` function. Default is `strip.default(...,style = 1)` (see `trellis.args`).

panel
an optional function used to generate the individual panels in the Trellis display, passed as the `panel` argument to the `dotplot` function.

key
an optional logical function or function. If `TRUE` and either `inner` or `innerGroups` are non-`NULL`, a legend for the different `inner` (or `innerGroups`) levels is included at the top of the plot. If given as a function, it is passed as the key argument to the dotplot function. Default is `TRUE` is either `inner` or `innerGroups` are non-`NULL` and `FALSE` otherwise.

grid
this argument is included for consistency with the `plot.nfnGroupedData` method calling sequence. It is ignored in this method function.

... optional arguments passed to the `dotplot` function.

Value

a Trellis dot-plot of the response by group.

plot.nfnGroupedData

See Also
groupedData, dotplot

Examples

plot(Machines)
plot(Machines, inner = TRUE)

plot.nfnGroupedData  Plot an nfnGroupedData Object

Description

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function xyplot is used.

Usage

## S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
     key, grid, ...)

Arguments

x          an object inheriting from class nfnGroupedData, representing a groupedData object with a numeric primary covariate and a single grouping level.
outer      an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, attr(object,"outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.
inner      an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object,"inner") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.
ininnerGroups an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or line types, are used for each level of the innerGroups factor. Default is NULL, meaning that no innerGroups covariate is present.
xlab, ylab  optional character strings with the labels for the plot. Default is the corresponding elements of attr(object,"labels") and attr(object,"units") pasted together.
strip

an optional function passed as the strip argument to the xyplot function. Default is strip.default(...,style = 1) (see trellis.args).

aspect

an optional character string indicating the aspect ratio for the plot passed as the aspect argument to the xyplot function. Default is "xy" (see trellis.args).

panel

an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the xyplot function.

default is TRUE if innerGroups is non-NULL and FALSE otherwise.

key

an optional logical function or function. If TRUE and innerGroups is non-NULL, a legend for the different innerGroups levels is included at the top of the plot. If given as a function, it is passed as the key argument to the xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE otherwise.

grid

an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

...optional arguments passed to the xyplot function.

Value

a Trellis plot of the response versus the primary covariate.

groupedData, xyplot

Examples

# different panels per Subject
plot(Orthodont)
# different panels per gender
plot(Orthodont, outer = TRUE)

description

The groupedData object is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor, which is plotted using the appropriate plot method for groupedData objects with single level of grouping.
 Usage

## S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
     preserve, FUN, subset, key, grid, ...)

 Arguments

 x an object inheriting from class nmGroupedData, representing a groupedData object with multiple grouping factors.
collapseLevel an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
displayLevel an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when outer is missing. Default is collapseLevel.
outer an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.
inner an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object, "outer") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.
preserve an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.
FUN an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
subset an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is NULL, meaning that all levels are used.
key an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE.

grid an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

... optional arguments passed to the Trellis plot function.

Value

a Trellis display of the data collapsed over the values of the collapseLevel grouping factor and grouped according to the displayLevel grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also
groupedData, collapse.groupedData, plot.nfnGroupedData, plot.nffGroupedData

Examples

# no collapsing, panels by Dog
plot(Pixel, display = "Dog", inner = ~Side)
# collapsing by Dog, preserving day
plot(Pixel, collapse = "Dog", preserve = ~day)
**Arguments**

- **x**: an object inheriting from class "ranef.lme", representing the estimated coefficients or estimated random effects for the lme object from which it was produced.

- **form**: an optional formula specifying the desired type of plot.
  - If given as a one-sided formula, a dotplot() of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in form is returned.
  - If given as a two-sided formula (or by default, NULL), an xyplot() Trellis display of the random effect (coefficient) versus the named covariates is returned. In NULL case the row names of the random effects (coefficients) are used (as covariates).

See also ‘Details’.

- **omitFixed**: an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is TRUE.

- **level**: an optional integer value giving the level of grouping to be used for x. Only used when x is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.

- **grid**: an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is TRUE.

- **control**: an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is 0.8); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

- **xlab, ylab**: axis labels, each with a sensible default.

- **strip**: a function or FALSE, see dotplot() from package lattice.

- **...**: optional arguments passed to the Trellis dotplot function.

**Details**

If form is missing, or is given as a one-sided formula, a Trellis dot-plot (via dotplot() from pkg lattice) of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). Single factors (~g) or crossed factors (~g1*g2) are allowed. For a single factor, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula.

If form is a two-sided formula, the left hand side must be a single random effect (coefficient) and the right hand side is formed by covariates in x separated by +. An xyplot() Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (Factor or ordered) variables.
Value

A Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

ranef.lme, lme, dotplot.

Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex) # "connected" boxplots
```

Description

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right-hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

Usage

```r
# S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

Arguments

- `x`:
  An object inheriting from class "ranef.lmList", representing the estimated coefficients or estimated random effects for the lmList object from which it was produced.

- `form`:
  An optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned. Single factors (~g) or crossed factors (~g1*g2) are allowed. If given as a two-sided formula, the left-hand side must be a single random effects (coefficient) and the right-hand side is formed by covariates in `x` separated by ~. A Trellis
display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used.

grid
an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is FALSE.

control
an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is 0.8); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2,0.5,0)).

Value
a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

plot(fmlRE, form = ~ Sex)
plot(fmlRE, form = age ~ Sex)

plot.Variogram  Plot a Variogram Object

Description
an xyplot of the semi-variogram versus the distances is produced. If smooth = TRUE, a loess smoother is added to the plot. If showModel = TRUE and x includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

Usage

## S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab, ylab, type, ylim, grid, ...)
Arguments

- **x**: an object inheriting from class "Variogram", consisting of a data frame with two columns named variog and dist, representing the semi-variogram values and the corresponding distances.
- **smooth**: an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to TRUE, when showModel is FALSE.
- **showModel**: an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of x, if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present.
- **sigma**: an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn.
- **span**: an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.
- **xlab,ylab**: optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".
- **type**: an optional character indicating the type of plot. Defaults to "p".
- **ylim**: an optional numeric vector with the limits for the y-axis. Defaults to c(0,max(x$variog)).
- **grid**: an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- **...**: optional arguments passed to the Trellis xyplot function.

Value

an xyplot Trellis plot.

lmList, lm

Examples

fm1 <- lmList(Orthodont)
pooledSD(fm1)

predict.gls Predictions from a gls Object

Description

The predictions for the linear model represented by object are obtained at the covariate values defined in newdata.

Usage

## S3 method for class 'gls'
predict(object, newdata, na.action, ...)

Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted linear model.

newdata an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.

na.action a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.

... some methods for this generic require additional arguments. None are used in this method.
predict.gnls

Predictions from a gnls Object

Description
The predictions for the nonlinear model represented by object are obtained at the covariate values defined in newdata.

Usage
```r
## S3 method for class 'gnls'
predict(object, newdata, na.action, naPattern, ...)
```

Arguments
- `object`: an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned.
- `na.action`: a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- `naPattern`: an expression or formula object, specifying which returned values are to be regarded as missing.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value
a vector with the predicted values.

Examples
```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
            correlation = corAR1(form = ~ 1 | Mare))
newOvary <- data.frame(Time = c(-0.75, -0.5, 0, 0.5, 0.75))
predict(fm1, newOvary)
```
predict.lme

Predictions from an lme Object

Description

The predictions at level \( i \) are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to \( i \). The resulting values estimate the best linear unbiased predictions (BLUPs) at level \( i \). If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

Usage

```r
## S3 method for class 'lme'
predict(object, newdata, level = Q, asList = FALSE, na.action = na.fail, ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
- `level`: an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
- `asList`: an optional logical value. If TRUE and a single value is given in `level`, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of `level`.
- `na.action`: a function that indicates what should happen when `newdata` contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- `...`: some methods for this generic require additional arguments. None are used in this method.
predict.lmList

Value

if a single level of grouping is specified in level, the returned value is either a list with the predictions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

lme, fitted.lme

Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male", "Male", "Female", "Female", "Male", "Male"),
                      age = c(15, 20, 10, 12, 2, 4),
                      Subject = c("M01", "M01", "F30", "F30", "M04", "M04"))
## The 'Orthodont' data has *no* 'F30', so predict NA at level 1:
predict(fm1, newOrth, level = 0:1)
```
Predictions from an nlme Object

The predictions at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

Usage

```r
## S3 method for class 'nlme'
predict(object, newdata, level = Q, asList = FALSE,
        na.action = na.fail, naPattern = NULL, ...)
```

Arguments

- `object`: an object inheriting from class "nlme", representing a fitted nonlinear mixed-effects model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
level an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping (and is object$dims$Q).

asList an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of level.

na.action a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be regarded as missing.

... some methods for this generic require additional arguments. None are used in this method.

Value if a single level of grouping is specified in level, the returned value is either a list with the predictions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

print.summary.pdMat

p301[, "predict.Seed"] - 
p329[, "predict.Seed"]

print.summary.pdMat  Print a summary.pdMat Object

Description

The standard deviations and correlations associated with the positive-definite matrix represented by 
object (considered as a variance-covariance matrix) are printed, together with the formula and the 
grouping level associated object, if any are present.

Usage

## S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)

Arguments

x an object inheriting from class "summary.pdMat", generally resulting from applying 
summary to an object inheriting from class "pdMat".

sigma an optional numeric value used as a multiplier for the square-root factor of the 
positive-definite matrix represented by object (usually the estimated within-
group standard deviation from a mixed-effects model). Defaults to 1.

rdig an optional integer value with the number of significant digits to be used in 
printing correlations. Defaults to 3.

Level an optional character string with a description of the grouping level associated 
with object (generally corresponding to levels of grouping in a mixed-effects 
model). Defaults to NULL.

resid an optional logical value. If TRUE an extra row with the "residual" standard 
development given in sigma will be included in the output. Defaults to FALSE.

... optional arguments passed to print.default; see the documentation on that 
method function.

data = Orthodont) 
print(summary(pd1), sigma = 1.2, resid = TRUE)
**print.varFunc**  
*Print a varFunc Object*

**Description**

The class and the coefficients associated with `x` are printed.

**Usage**

```r
## S3 method for class 'varFunc'
print(x, ...)  
```

**Arguments**

- `x`  
an object inheriting from class "varFunc", representing a variance function structure.
- `...`  
optional arguments passed to `print.default`; see the documentation on that method function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`summary.varFunc`

**Examples**

```r
vf1 <- varPower(0.3, form = ~age)  
vf1 <- Initialize(vf1, Orthodont)  
print(vf1)
```

---

**qqnorm.gls**  
*Normal Plot of Residuals from a gls Object*

**Description**

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```r
## S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```
Arguments

- **y**: an object inheriting from class "gls", representing a generalized least squares fitted model.
- **form**: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form and to the left of a | operator must evaluate to a residuals vector. Default is ~ resid(., type = "p"), corresponding to a normal plot of the standardized residuals.
- **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
- **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
- **idLabels**: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
- **grid**: an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.
- **...**: optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot for assessing normality of residuals.

gls, plot.gls

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, 
correlation = corAR1(form = ~ 1 | Mare))
qqnorm(fm1, abline = c(0,1))
```
qqnorm.lme

Normal Plot of Residuals or Random Effects from an lme Object

Description
Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

Usage
### S3 method for class ‘lme’
qqnorm(y, form, abline, id, idLabels, grid, ...)

Arguments
- **y**: an object inheriting from class "lme", representing a fitted linear mixed-effects model or from class "lmList", representing a list of lm objects, or from class "lm", representing a fitted linear model, or from class "nls", representing a nonlinear least squares fitted model.
- **form**: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form and to the left of a | operator must evaluate to a residuals vector, or a random effects matrix. Default is ~ resid(.,type = "p"), corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting.
- **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
- **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
- **idLabels**: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
- **grid**: an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- **...**: optional arguments passed to the Trellis plot function.
Quinidine  

Value

a diagnostic Trellis plot for assessing normality of residuals or random effects.

lme, plot.lme

Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
## normal plot of standardized residuals by gender
qqnorm(fm1, ~ resid(., type = "p") | Sex, abline = c(0, 1))
## normal plots of random effects
qqnorm(fm1, ~ ranef(.,))
```

Quinidine Kinetics

Description

The Quinidine data frame has 1471 rows and 14 columns.

Format

This data frame contains the following columns:

- **Subject** a factor identifying the patient on whom the data were collected.
- **time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.
- **conc** a numeric vector giving the serum quinidine concentration (mg/L).
- **dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.
- **interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.
- **Age** a numeric vector giving the age of the subject on entry to the study (yr).
- **Height** a numeric vector giving the height of the subject on entry to the study (in.).
- **Weight** a numeric vector giving the body weight of the subject (kg).
- **Race** a factor with levels Caucasian, Latin, and Black identifying the race of the subject.
- **Smoke** a factor with levels no and yes giving smoking status at the time of the measurement.
- **Ethanol** a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.
- **Heart** a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.
- **Creatinine** an ordered factor with levels < 50 < = 50 indicating the creatine clearance (mg/min).
- **glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.
Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation of ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

Source

**quinModel**

*Model function for the Quinidine data*

**Description**

A model function for a model used with the Quinidine data. This function calls compiled C code.

**Usage**

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

**Arguments**

- **Subject**
  - a factor identifying the patient on whom the data were collected.

- **time**
  - a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

- **conc**
  - a numeric vector giving the serum quinidine concentration (mg/L).

- **dose**
  - a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

- **interval**
  - a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

- **lV**
  - numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.

- **lKa**
  - numeric. A vector of values of the natural log of the absorption rate constant according to Subject and time.

- **lCl**
  - numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.
Details

See the details section of Quinidine for a description of the model function that quinModel evaluates.

Value

a numeric vector of predicted quinidine concentrations.

Description

The Rail data frame has 18 rows and 2 columns.

Format

This data frame contains the following columns:

| Rail      | Evaluation of Stress in Railway Rails |

- **Rail**: an ordered factor identifying the rail on which the measurement was made.
- **travel**: a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds). The value given is the original travel time minus 36,100 nanoseconds.

Details

Devore (2000, Example 10.10, p. 427) cites data from an article in Materials Evaluation on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

random.effects  

Extract Random Effects

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

**Usage**

```r
c random.effects(object, ...)  
ranef(object, ...)
```

**Arguments**

- `object`: any fitted model object from which random effects estimates can be extracted.
- `...`: some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

**See Also**

- `ranef.lmList`
- `ranef.lme`

**Examples**

```r
## see the method function documentation
```

---

ranef.lme  

Extract lme Random Effects

**Description**

The estimated random effects at level \(i\) are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

**Usage**

```r
## S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN, standard, omitGroupingFactor, subset, ...)
```
Arguments

object  an object inheriting from class "lme", representing a fitted linear mixed-effects model.

augFrame  an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.

level  an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.

data  an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.

which  an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.

FUN  an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

standard  an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to FALSE.

omitGroupingFactor  an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset  an optional expression indicating for which rows the random effects should be extracted.

...  some methods for this generic require additional arguments. None are used in this method.

Value

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in level and, optionally, other covariates summarized over groups. The returned object inherits from classes random.effects.lme and data.frame.

\texttt{ranef.lmList}

\textit{Extract \texttt{lmList} Random Effects}

Description

The difference between the individual \texttt{lm} components coefficients and their average is calculated.

Usage

\begin{verbatim}
## S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard, 
      omitGroupingFactor, ...)
\end{verbatim}

Arguments

\begin{itemize}
\item \textbf{object} an object inheriting from class \textquote{\texttt{lmList}}, representing a list of \texttt{lm} objects with a common model.
\item \textbf{augFrame} an optional logical value. If \texttt{TRUE}, the returned data frame is augmented with variables defined in \texttt{data}; else, if \texttt{FALSE}, only the coefficients are returned. Defaults to \texttt{FALSE}.
\item \textbf{data} an optional data frame with the variables to be used for augmenting the returned data frame when \texttt{augFrame = TRUE}. Defaults to the data frame used to fit \texttt{object}.
\item \textbf{which} an optional positive integer vector specifying which columns of \texttt{data} should be used in the augmentation of the returned data frame. Defaults to all columns in \texttt{data}.
\item \textbf{FUN} an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If \texttt{FUN} is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If \texttt{FUN} is a list of functions, the names in the list should designate classes of variables in the frame such as \texttt{ordered}, \texttt{factor}, or \texttt{numeric}. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are \texttt{mean} for numeric factors, and \texttt{Mode} for both \texttt{factor} and \texttt{ordered}. The \texttt{Mode} function, defined internally in \texttt{gsummary}, returns the modal or most popular value of the variable. It is different from the \texttt{mode} function that returns the S-language mode of the variable.
\end{itemize}
an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.

omitGroupingFactor

an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the differences between the individual lm coefficients in object and their average.

RatPupWeight

The weight of rat pups

---

Description

The RatPupWeight data frame has 322 rows and 5 columns.

Format

This data frame contains the following columns:

- **weight** a numeric vector
- **sex** a factor with levels Male Female
- **Litter** an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 15 < 16 < 20 < 19 < 18 < 12
- **Lsize** a numeric vector
- **Treatment** an ordered factor with levels Control < Low < High
Recalculate Condensed Linear Model Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, modelStruct, reStruct, and varFunc.

Usage

recalc(object, conLin, ...)

Arguments

object any object which induces a recalculation of the condensed linear model object conLin.

conLin a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.

... some methods for this generic can take additional arguments.

Value

the recalculated condensed linear model object.

Note

This function is only used inside model fitting functions, such as lme and gls, that require recalculation of a condensed linear model object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

recalc.corStruct, recalc.modelStruct, recalc.reStruct, recalc.varFunc

Examples

## see the method function documentation
Description

This method function pre-multiplies the "Xy" component of conLin by the transpose square-root factor(s) of the correlation matrix (matrices) associated with object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

Usage

```r
## S3 method for class 'corStruct'
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "corStruct", representing a correlation structure.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as lme and gls, that allow correlated error terms.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

corfactor, logLik.corStruct
Recalculate for a modelStruct Object

Description

This method function recalculates the condensed linear model object using each element of object sequentially from last to first.

Usage

## S3 method for class 'modelStruct'
reCalc(object, conLin, ...)

Arguments

- **object**: an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to attr(object,"conLin").
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is generally only used inside model fitting functions, such as lme and g1s, that allow model components, such as correlated error terms and variance functions.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

reCalc.corStruct, reCalc.reStruct, reCalc.varFunc
Recalculate for an reStruct Object

Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)` is calculated and added to the `logLik` component of `conLin`. The settings attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

Usage

```r
## S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of `pdMat` objects.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the condensed linear model with its `logLik` component updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`logLik`, `lme`, `recalc`, `reStruct`

Recalculate for varFunc Object

Description

This method function pre-multiples the "Xy" component of `conLin` by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`. 
Usage

```r
## S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

Arguments

- **object**: an object inheriting from class "varFunc", representing a variance function structure.
- **conLin**: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow heteroscedastic error terms.

**Relaxin**

**Assay for Relaxin**

Description

The Relaxin data frame has 198 rows and 3 columns.

Format

This data frame contains the following columns:

- **Run**: an ordered factor with levels `5 < 8 < 9 < 3 < 4 < 2 < 7 < 1 < 6`
- **conc**: a numeric vector
- **cAMP**: a numeric vector

Source

Remifentanil

Pharmacokinetics of Remifentanil

Description

Intravenous infusion of remifentanil (a strong analgesic) in different rates over varying time periods was applied to a total of 65 patients. Concentration measurements of remifentanil were taken along with several covariates resulting in the Remifentanil data frame with 2107 rows and 12 columns.

Usage

data("Remifentanil", package = "nlme")

Format

This data frame (of class "groupedData", specifically "nfnGroupedData") contains the following columns:

- ID: numerical (patient) IDs.
- Subject: an ordered factor with 65 levels (of the IDs): 30 < 21 < 25 < 23 < 29 < ... < 36 < 6 < 5 < 10 < 9.
- Time: time from beginning of infusion in minutes (numeric).
- conc: remifentanil concentration in [ng / ml] (numeric).
- Rate: infusion rate in [µg / min].
- Amt: amount of remifentanil given in the current time interval in [µg].
- Age: age of the patient in years.
- Sex: gender of the patient, a factor with levels Female and Male.
- Ht: height of the patient in cm.
- Wt: weight of the patient in kg.
- BSA: body surface area (DuBois and DuBois 1916): \( BSA := W^{0.425} \cdot H^{0.725} \cdot 0.007184 \).
- LBM: lean body mass (James 1976), with slightly different formula for men \( LBM_m := 1.1Wt - 128(Wt/Ht)^2 \), and women \( LBM_f := 1.07Wt - 148(Wt/Ht)^2 \).

Author(s)

of this help page: Niels Hagenbuch and Martin Maechler, SfS ETH Zurich.

Examples

```r
plot(Remifentanil, type = "l", lwd = 2) # shows the 65 patients' remi profiles

## The same on log-log scale (*more* sensible for modeling?):
plot(Remifentanil, type = "l", lwd = 2, scales = list(log=TRUE))

str(Remifentanil)
summary(Remifentanil)

plot(xtabs(~Subject, Remifentanil))
summary(unclass(table(Remifentanil$Subject)))
## between 20 and 54 measurements per patient (median: 24; mean: 32.42)

## Only first measurement of each patient:
dim(Remi.1 <- Remifentanil[!duplicated(Remifentanil[,"ID"]),]) # 65 x 12

LBMfn <- function(Wt, Ht, Sex) ifelse(Sex == "Female",
   1.07 * Wt - 148*(Wt/Ht)^2,
   1.1 * Wt - 128*(Wt/Ht)^2)

## Rate: typically 3 µg / kg body weight, but:
sunflowerplot(Rate ~ Wt, Remifentanil)
abline(0,3, lty=2, col=adjustcolor("black", 0.5))
```

---

**residuals.gls**

**Extract gls Residuals**

**Description**

The residuals for the linear model represented by object are extracted.

**Usage**

```r
## S3 method for class 'gls'
residuals(object, type, ...)
```
The residuals for the linear model represented by object are extracted.

Usage

```r
## S3 method for class 'glsStruct'
residuals(object, glsFit, ...)
```

Description

The residuals for the linear model represented by object are extracted.
Arguments

object an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.

glsFit an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object,"glsFit").

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the residuals for the linear model represented by object.

Note

This method function is primarily used inside gls and residuals.gls.

residuals.gnlsStruct  Calculate gnlsStruct Residuals

Description

The residuals for the nonlinear model represented by object are extracted.

Usage

## S3 method for class 'gnlsStruct'
residuals(object, ...)

Arguments

object an object inheriting from class "gnlsStruct", representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the residuals for the nonlinear model represented by object.
Note
This method function is primarily used inside gnls and residuals.gnls.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
gnls, residuals.gnls, fitted.gnlsStruct

residuals.lme Extract lme Residuals

Description
The residuals at level \( i \) are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if type="pearson"). The fitted values at level \( i \) are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to \( i \).

Usage
## S3 method for class 'lme'
residuals(object, level = Q,
          type = c("response", "pearson", "normalized"), asList = FALSE, ...)

Arguments
object an object inheriting from class "lme", representing a fitted linear mixed-effects model.
level an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.
type an optional character string specifying the type of residuals to be used. If "response", as by default, the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided.
asList an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE.
...
some methods for this generic require additional arguments. None are used in this method.
Value

if a single level of grouping is specified in level, the returned value is either a list with the residuals split by groups (asList = TRUE) or a vector with the residuals (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the naresid method is applied.

lme, fitted.lme

Examples

```r
fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
head(residuals(fm1, level = 0:1))
summary(residuals(fm1) / residuals(fm1, type = "p")) # constant scaling factor 1.432
```

Description

The residuals at level \(i\) are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level \(i\) are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to \(i\).

Usage

```r
## S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

Arguments

- **object**: an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix \(X\) combined with a response vector \(y\), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object,"conLin").
- **lmeFit**: an optional list with components beta and b containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to attr(object,"lmeFit").
- **...**: some methods for this generic accept optional arguments.
Value

if a single level of grouping is specified in level, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the residuals at different levels.

Note

This method function is primarily used within the lme function.

residuals.lmList

Extract lmList Residuals

Description

The residuals are extracted from each lm component of object and arranged into a list with as many components as object, or combined into a single vector.

Usage

## S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)

Arguments

object an object inheriting from class "lmList", representing a list of lm objects with a common model.

subset an optional character or integer vector naming the lm components of object from which the residuals are to be extracted. Default is NULL, in which case all components are used.

type an optional character string specifying the type of residuals to be extracted. Options include "response" for the "raw" residuals (observed - fitted), "pearson" for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each lm fit, and "pooled.pearson" for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response".

asList an optional logical value. If TRUE, the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.
residuals.nlmeStruct

Value

A list with components given by the residuals of each \texttt{lm} component of \texttt{object}, or a vector with the residuals for all \texttt{lm} components of \texttt{object}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{lmList}, \texttt{fitted.lmList}

Examples

\begin{verbatim}
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
\end{verbatim}

Description

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters.

Usage

\begin{verbatim}
## S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \textbf{object} an object inheriting from class "nlmeStruct", representing a list of mixed-effects model components, such as \texttt{reStruct}, \texttt{corStruct}, and \texttt{varFunc} objects.
  \item \textbf{level} an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from \texttt{object}. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
  \item \textbf{conLin} an optional condensed linear model object, consisting of a list with components "\texttt{Xy}" corresponding to a regression matrix (X) combined with a response vector (y), and "\texttt{logLik}" corresponding to the log-likelihood of the underlying \texttt{nlme} model. Defaults to \texttt{attr(object,"conLin")}.
  \item \text{...} optional arguments to the residuals generic. Not used.
\end{itemize}

Value

If a single level of grouping is specified in \texttt{level}, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in \texttt{level}, the returned object is a matrix with columns given by the residuals at different levels.
Note

This method function is primarily used within the nlme function.

reStruct

Random Effects Structure

Description

This function is a constructor for the reStruct class, representing a random effects structure and consisting of a list of pdMat objects, plus a settings attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

Usage

reStruct(object, pdClass, REML, data)

## S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)

Arguments

object

any of the following: (i) a one-sided formula of the form ~x1+...+xn | g1/.../gm, with x1+...+xn specifying the model for the random effects and g1/.../gm the grouping structure (m may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form ~x1+...+xn | g, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form ~x1+...+xn, or a pdMat object with a formula (i.e. a non-NULL value for formula(object)), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an reStruct object.

pdClass

an optional character string with the name of the pdMat class to be used for the formulas in object. Defaults to "pdSymm" which corresponds to a general positive-definite matrix.
REML: an optional logical value. If TRUE, the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if FALSE, maximum likelihood will be used. Defaults to FALSE.

data: an optional data frame in which to evaluate the variables used in the random effects formulas in object. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying pdMat objects. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

x: an object inheriting from class reStruct to be printed.
sigma: an optional numeric value used as a multiplier for the square-root factors of the pdMat components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.

reEstimates: an optional list with the random effects estimates for each level of grouping. Only used when verbose = TRUE.

verbose: an optional logical value determining if the random effects estimates should be printed. Defaults to FALSE.

...: Optional arguments can be given to other methods for this generic. None are used in this method.

Value

an object inheriting from class reStruct, representing a random effects structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

rs1

## S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2, method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)

Description

The model object is fit to the data. Using the fitted values of the parameters, nsim new data vectors from this model are simulated. Both object and m2 are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

Usage

## S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2, method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)

Simulate Results from lme Models
simulate.lme

Arguments

object
an object inheriting from class "lme", representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to lme. This argument defines the null model.

m2
an "lme" object or a list, like object containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model object and m2 need to be specified.

seed
an optional integer that is passed to set.seed. Defaults to a random integer.

method
an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to c("REML", "ML"), in which case both methods are used.

nsim
an optional positive integer specifying the number of simulations to perform. Defaults to 1. This has changed. Previously the default was 1000.

niterEM
an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the object and m2 to each simulated set of data. Defaults to c(40, 200).

useGen
an optional logical value. If TRUE, numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the ms function. If FALSE, the default algorithm in ms for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the "pdMat" classes used in object and m2: if both are standard classes (see pdClasses) then defaults to TRUE, otherwise defaults to FALSE.

... optional additional arguments. None are used.

Value
an object of class simulate.lme with components null and alt. Each of these has components ML and/or REML which are matrices. An attribute called Random.seed contains the seed that was used for the random number generator.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples
orthSim <-
simulate.lme(list(fixed = distance ~ age, data = Orthodont,
                random = ~ 1 | Subject), nsim = 200,
                m2 = list(random = ~ age | Subject))
solve.pdMat  

Calculate Inverse of a Positive-Definite Matrix

Description

The positive-definite matrix represented by `a` is inverted and assigned to `a`.

Usage

```r
## S3 method for class 'pdMat'
solve(a, b, ...)
```

Arguments

- `a`  
an object inheriting from class "pdMat", representing a positive definite matrix.
- `b`  
this argument is only included for consistency with the generic function and is not used in this method function.
- `...`  
some methods for this generic require additional arguments. None are used in this method.

Value

a `pdMat` object similar to `a`, but with coefficients corresponding to the inverse of the positive-definite matrix represented by `a`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

pdMat

Examples

```r
pd1 <- pdCompSymm(3 * diag(3) + 1)
solve(pd1)
```

solve.reStruct  

Apply Solve to an reStruct Object

Description

Solve is applied to each `pdMat` component of `a`, which results in inverting the positive-definite matrices they represent.

Usage

```r
## S3 method for class 'reStruct'
solve(a, b, ...)
```
Arguments

- **a**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **b**: this argument is only included for consistency with the generic function and is not used in this method function.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

an reStruct object similar to a, but with the pdMat components representing the inverses of the matrices represented by the components of a.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

solve.pdMat.reStruct

Examples

```r
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
                  B = pdDiag(2 * diag(4), form = ~Educ)))
solve(rs1)
```

Soybean

*Growth of soybean plants*

Description

The Soybean data frame has 412 rows and 5 columns.

Format

This data frame contains the following columns:

- **Plot**: a factor giving a unique identifier for each plot.
- **Variety**: a factor indicating the variety: Forrest (F) or Plant Introduction #416937 (P).
- **Year**: a factor indicating the year the plot was planted.
- **Time**: a numeric vector giving the time the sample was taken (days after planting).
- **weight**: a numeric vector giving the average leaf weight per plant (g).

Details

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction #416937 (P), an experimental strain, and Forrest (F), a commercial variety.”
Source

Examples

```r
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

**splitFormula**  
*Split a Formula*

**Description**

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

**Usage**

```
splitFormula(form, sep)
```

**Arguments**

- `form`  
a formula object.

- `sep`  
an optional character string specifying the separator to be used for splitting the formula. Defaults to `/`.

**Value**

a list of formulas, corresponding to the split of `form` according to `sep`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`formula`

**Examples**

```
splitFormula(~ g1/g2/g3)
```
Spruce  

**Growth of Spruce Trees**

**Description**

The Spruce data frame has 1027 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Tree** a factor giving a unique identifier for each tree.
- **days** a numeric vector giving the number of days since the beginning of the experiment.
- **logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.
- **plot** a factor identifying the plot in which the tree was grown.

**Details**

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

**Source**

---

**summary.corStruct**  

**Summarize a corStruct Object**

**Description**

This method function prepares object to be printed using the `print.summary` method, by changing its class and adding a structName attribute to it.

**Usage**

```r
## S3 method for class 'corStruct'
summary(object, structName, ...)
```

**Arguments**

- **object** an object inheriting from class "corStruct", representing a correlation structure.
- **structName** an optional character string defining the type of correlation structure associated with object, to be used in the `print.summary` method. Defaults to `class(object)[1]`.
- **...** some methods for this generic require additional arguments. None are used in this method.
Value

an object identical to object, but with its class changed to summary.corStruct and an additional attribute structName. The returned value inherits from the same classes as object.

Author(s)

José Pinheiro and Douglas Bates

See Also

corClasses, corNatural, Initialize.corStruct, summary

Examples

cs1 <- corAR1(0.2)
summary(cs1)

summary.gls

Summarize a Generalized Least Squares gls Object

Description

Additional information about the linear model fit represented by object is extracted and included as components of object.

Usage

## S3 method for class 'gls'
summary(object, verbose, ...)

Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted linear model.
verbose an optional logical value used to control the amount of output when the object is printed. Defaults to FALSE.
... some methods for this generic require additional arguments. None are used in this method.

Value

an object inheriting from class summary.gls with all components included in object (see glsObject for a full description of the components) plus the following components:

corBeta approximate correlation matrix for the coefficients estimates
tTable a matrix with columns Value, Std. Error, t-value, and p-value representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a t approximation. Rows correspond to the different coefficients.
summary.lme

residuals if more than five observations are used in the gls fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.

AIC the Akaike Information Criterion corresponding to object.

BIC the Bayesian Information Criterion corresponding to object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
AIC, BIC, gls, summary

Examples
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, correlation = corAR1(form = ~ 1 | Mare))

coef(summary(fm1)) # "the matrix"

summary.lme Summarize an lme Object

Description
Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object has a print and a coef method, the latter returning the coefficient’s tTtable.

Usage
## S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
## S3 method for class 'summary.lme'
print(x, verbose = FALSE, ...)

Arguments
object an object inheriting from class "lme", representing a fitted linear mixed-effects model.
adjustSigma an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by \( \sqrt{n_{obs}/(n_{obs} - n_{par})} \), converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
verbose an optional logical value used to control the amount of output in the print.summary.lme method. Defaults to FALSE.
... additional optional arguments passed to methods, mainly for the print method.
x a "summary.lme" object!
Value

an object inheriting from class summary.lme with all components included in object (see `lmeObject` for a full description of the components) plus the following components:

corFixed approximate correlation matrix for the fixed effects estimates.
tTable a matrix with columns named Value, Std. Error, DF, t-value, and p-value representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects.
residuals if more than five observations are used in the lme fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.
AIC the Akaike Information Criterion corresponding to object.
BIC the Bayesian Information Criterion corresponding to object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`AIC`, `BIC`, `lme`.

Examples

(s1 <- summary(fm1))
coef(s1) # the (coef | Std.E | t | P-v ) matrix
```

summary.lmList  Summarize an lmList Object

Description

The `summary.lmList` method is applied to each lm component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

Usage

```r
## S3 method for class 'lmList'
summary(object, pool, ...)
```

Arguments

- `object` an object inheriting from class "lmList", representing a list of lm fitted objects.
- `pool` an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object,"pool")`.
- `...` some methods for this generic require additional arguments. None are used in this method.
Value

a list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of `value` are:

- **call**: a list containing an image of the `lmList` call that produced `object`.
- **coefficients**: a three dimensional array with summary information on the `lm` coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)". The third dimension is given by the coefficients names.
- **correlation**: a three dimensional array with the correlations between the individual `lm` coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by `lm` component.
- **cov.unscaled**: a three dimensional array with the unscaled variances/covariances for the individual `lm` coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by `lm` component.
- **df**: an array with the number of degrees of freedom for the model and for residuals, for each `lm` component.
- **df.residual**: the total number of degrees of freedom for residuals, corresponding to the sum of residuals `df` of all `lm` components.
- **fstatistics**: an array with the F test statistics and corresponding degrees of freedom, for each `lm` component.
- **pool**: the value of the `pool` argument to the function.
- **r.squared**: a vector with the multiple R-squared statistics for each `lm` component.
- **residuals**: a list with components given by the residuals from individual `lm` fits.
- **RSE**: the pooled estimate of the residual standard error.
- **sigma**: a vector with the residual standard error estimates for the individual `lm` fits.
- **terms**: the terms object used in fitting the individual `lm` components.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`lmList`, `summary`

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```
### summary.modelStruct

#### Summarize a modelStruct Object

**Description**

This method function applies `summary` to each element of `object`.

**Usage**

```r
## S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

- `object` an object inheriting from class "modelStruct", representing a list of model components, such as `reStruct`, `corStruct` and `varFunc` objects.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with elements given by the summarized components of `object`. The returned value is of class `summary.modelStruct`, also inheriting from the same classes as `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `summary`

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                 corStruct = corAR1(0.3))
summary(lms1)
```

### summary.nlsList

#### Summarize an nlsList Object

**Description**

The `summary` function is applied to each `nls` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.nlsList` method.

**Usage**

```r
## S3 method for class 'nlsList'
summary(object, ...)
```
Arguments

object  an object inheriting from class "nlsList", representing a list of nls fitted objects.

...  optional arguments to the summary.lmList method. One such optional argument is pool, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object,"pool").

Value

a list with summary statistics obtained by applying summary to the elements of object, inheriting from class summary.nlsList. The components of value are:

call  a list containing an image of the nlsList call that produced object.

parameters  a three dimensional array with summary information on the nls coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.

correlation  a three dimensional array with the correlations between the individual nls coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by nls component.

cov.unscaled  a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by nls component.

df  an array with the number of degrees of freedom for the model and for residuals, for each nls component.

df.residual  the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all nls components.

pool  the value of the pool argument to the function.

RSE  the pooled estimate of the residual standard error.

sigma  a vector with the residual standard error estimates for the individual lm fits.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

nlsList, summary

Examples

fm1 <- nlsList(SSasymp, Loblolly)
summary(fm1)
summarize.pdMat

 summa ry.pdMat  
 Summarize a pdMat Object

Description

Attributes structName and noCorrelation, with the values of the corresponding arguments to the method function, are appended to object and its class is changed to summary.pdMat.

Usage

```r
## S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

Arguments

- `object` an object inheriting from class "pdMat", representing a positive definite matrix.
- `structName` an optional character string with a description of the pdMat class. Default depends on the method function: "Blocked" for pdBlocked, "Compound Symmetry" for pdCompSymm, "Diagonal" for pdDiag, "Multiple of an Identity" for pdIdent, "General Positive-Definite,Natural Parametrization" for pdNatural, "General Positive-Definite" for pdSymm, and data.class(object) for pdMat.
- `noCorrelation` an optional logical value indicating whether correlations are to be printed in print.summary.pdMat. Default depends on the method function: FALSE for pdDiag and pdIdent, and TRUE for all other classes.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

an object similar to object, with additional attributes structName and noCorrelation, inheriting from class summary.pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

print.summary.pdMat, pdMat

Examples

```r
summary(pdSymm(diag(4)))
```
**summary.varFunc**  

**Summarize varFunc Object**

**Description**

A structName attribute, with the value of corresponding argument, is appended to object and its class is changed to summary.varFunc.

**Usage**

```r
## S3 method for class 'varFunc'
summary(object, structName, ...)
```

**Arguments**

- **object**: an object inheriting from class "varFunc", representing a variance function structure.
- **structName**: an optional character string with a description of the varFunc class. Default depends on the method function: "Combination of variance functions" for varComb, "Constant plus power of covariate" for varConstPower, "Exponential of variance covariate" for varExp, "Different standard deviations per stratum" for varIdent, "Power of variance covariate" for varPower, and data.class(object) for varFunc.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to object, with an additional attribute structName, inheriting from class summary.varFunc.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- varClasses, varFunc

**Examples**

```r
vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
summary(vf1)
```
Pharmacokinetics of tetracycline

Description

The Tetracycline1 data frame has 40 rows and 4 columns.

Format

This data frame contains the following columns:

- **conc**: a numeric vector
- **Time**: a numeric vector
- **Subject**: an ordered factor with levels 5 < 3 < 2 < 4 < 1
- **Formulation**: a factor with levels tetrachel tetracyn

Source

---

Pharmacokinetics of tetracycline

Description

The Tetracycline2 data frame has 40 rows and 4 columns.

Format

This data frame contains the following columns:

- **conc**: a numeric vector
- **Time**: a numeric vector
- **Subject**: an ordered factor with levels 4 < 5 < 2 < 1 < 3
- **Formulation**: a factor with levels Berkmycin tetramycin

Source

update.modelStruct  

*Update a modelStruct Object*

**Description**

This method function updates each element of object, allowing the access to data.

**Usage**

```r
## S3 method for class 'modelStruct'
update(object, data, ...)
```

**Arguments**

- `object`: an object inheriting from class "modelStruct", representing a list of model components, such as `corStruct` and `varFunc` objects.
- `data`: a data frame in which to evaluate the variables needed for updating the elements of object.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object` (same class, length, and names), but with updated elements.

**Note**

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

- `reStruct`

---

update.varFunc  

*Update varFunc Object*

**Description**

If the `formula(object)` includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.
Usage

## S3 method for class 'varFunc'
update(object, data, ...)

Arguments

object  an object inheriting from class "varFunc", representing a variance function structure.
data    a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s).
...     some methods for this generic require additional arguments. None are used in this method.

Value

if formula(object) includes a "." term, an varFunc object similar to object, but with the variance covariate reevaluated at the current fitted object value; else object is returned unchanged.

<table>
<thead>
<tr>
<th>varClasses</th>
<th>Variance Function Classes</th>
</tr>
</thead>
</table>

Description

Standard classes of variance function structures (varFunc) available in the nlme package. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

Value

Available standard classes:

- varExp: exponential of a variance covariate.
- varPower: power of a variance covariate.
- varConstPower: constant plus power of a variance covariate.
- varIdent: constant variance(s), generally used to allow different variances according to the levels of a classification factor.
- varFixed: fixed weights, determined by a variance covariate.
- varComb: combination of variance functions.
Note

Users may define their own varFunc classes by specifying a constructor function and, at a minimum, methods for the functions coef, coef<-, and initialize. For examples of these functions, see the methods for class varPower.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

varClasses, varWeights.varComb, coef.varComb

Examples

vf1 <- varComb(varIdent(form = ~1|Sex), varPower())
Description

This function is a constructor for the \texttt{varConstPower} class, representing a constant plus power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the constant plus power variance function is defined as $\sigma^2(v) = (\theta_1 + |v|^\theta_2)^2$, where $\theta_1, \theta_2$ are the variance function coefficients. When a grouping factor is present, different $\theta_1, \theta_2$ are used for each factor level.

Usage

\begin{verbatim}
\texttt{varConstPower(const, power, form, fixed)}
\end{verbatim}

Arguments

- \texttt{const, power} optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in \texttt{form}. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in \texttt{form}. If a grouping factor is present in \texttt{form} and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for \texttt{const}. Default is \texttt{numeric(0)}, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- \texttt{form} an optional one-sided formula of the form \texttt{~ v}, or \texttt{~ v | g}, specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using \texttt{"."}, representing a fitted model object from which fitted values (\texttt{fitted(.)}) and residuals (\texttt{resid(.)}) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in \texttt{form}, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the \texttt{*} operator, as in \texttt{~ v | g1 * g2 * g3}. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to \texttt{~ fitted(.)} representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- \texttt{fixed} an optional list with components \texttt{const} and/or \texttt{power}, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in \texttt{form}, the components of \texttt{fixed} must have names identifying which coefficients are to be fixed. Coefficients included in \texttt{fixed} are not allowed to vary during the optimization of an objective function. Defaults to \texttt{NULL}, corresponding to no fixed coefficients.

Value

a \texttt{varConstPower} object representing a constant plus power variance function structure, also inheriting from class \texttt{varFunc}. 
Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

VarCorr

Extract variance and correlation components

Description
This function calculates the estimated variances, standard deviations, and correlations between the
random-effects terms in a linear mixed-effects model, of class "lme", or a nonlinear mixed-effects
model, of class "nlme". The within-group error variance and standard deviation are also calculated.

Usage
VarCorr(x, sigma = 1, ...)
## S3 method for class 'lme'
VarCorr(x, sigma = x$sigma, rdig = 3, ...)

## S3 method for class 'pdMat'
VarCorr(x, sigma = 1, rdig = 3, ...)
## S3 method for class 'pdBlocked'
VarCorr(x, sigma = 1, rdig = 3, ...)

Arguments
x a fitted model object, usually an object inheriting from class "lme".
sigma an optional numeric value used as a multiplier for the standard deviations. The
default is x$sigma or 1 depending on class(x).
rdig an optional integer value specifying the number of digits used to represent cor-
relation estimates. Default is 3.
... further optional arguments passed to other methods (none for the methods doc-
umented here).

Value
a matrix with the estimated variances, standard deviations, and correlations for the random effects.
The first two columns, named Variance and StdDev, give, respectively, the variance and the stan-
ard deviations. If there are correlation components in the random effects model, the third column,
named Corr, and the remaining unnamed columns give the estimated correlations among random
effects within the same level of grouping. The within-group error variance and standard deviation
are included as the last row in the matrix.
Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)
```

---

**varExp**

---

**Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the exponential variance function is defined as $\sigma^2(v) = \exp(2\theta v)$, where $\theta$ is the variance function coefficient. When a grouping factor is present, a different $\theta$ is used for each factor level.

**Usage**

```
varExp(value, form, fixed)
```

**Arguments**

- `value` an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- `form` an optional one-sided formula of the form $\sim v$, or $\sim v | g$, specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, like in $\sim v | g1 * g2 * g3$. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group
the observations. Defaults to ~ fitted(.) representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

fixed
an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in form, fixed must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.

Value
a varExp object representing an exponential variance function structure, also inheriting from class varFunc.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also
varClasses, varWeights.varFunc, coef.varExp

Examples
vf1 <- varExp(0.2, form = ~age|Sex)

Description
This function is a constructor for the varFixed class, representing a variance function with fixed variances. Letting $v$ denote the variance covariate defined in value, the variance function $\sigma^2(v)$ for this class is $\sigma^2(v) = |v|$. The variance covariate $v$ is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

Usage
varFixed(value)

Arguments
value
a one-sided formula of the form ~ v specifying a variance covariate v. Grouping factors are ignored.

Value
a varFixed object representing a fixed variance function structure, also inheriting from class varFunc.
Description

If object is a one-sided formula, it is used as the argument to varFixed and the resulting object is returned. Else, if object inherits from class varFunc, it is returned unchanged.

Usage

varFunc(object)

Arguments

object either an one-sided formula specifying a variance covariate, or an object inher-

Value

an object from class varFunc, representing a variance function structure.

summary.varFunc, varFixed, varWeights.varFunc, coef.varFunc

Examples

ev1 <- varFixed(~age)
varIdent

Constant Variance Function

Description
This function is a constructor for the varIdent class, representing a constant variance function structure. If no grouping factor is present in form, the variance function is constant and equal to one, and no coefficients required to represent it. When form includes a grouping factor with \( M > 1 \) levels, the variance function allows \( M \) different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only \( M - 1 \) coefficients are needed to represent the variance function. By default, if the elements in value are unnamed, the first group level is taken as the reference level.

Usage

\texttt{varIdent(value, form, fixed)}

Arguments

\begin{itemize}
\item \texttt{value} an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in form, this argument is ignored, as the resulting variance function contains no coefficients. If value has length one, its value is repeated for all coefficients in the variance function. If value has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is \texttt{numeric(0)}, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).
\item \texttt{form} an optional one-sided formula of the form \( \sim v \), or \( \sim v \mid g \), specifying a variance covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in form, a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the \( * \) operator, like in \( \sim v \mid g1 \ast g2 \ast g3 \). In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to \( \sim 1 \).
\item \texttt{fixed} an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in \texttt{fixed} are not allowed to vary during the optimization of an objective function. Defaults to \texttt{NULL}, corresponding to no fixed coefficients.
\end{itemize}

Value

a \texttt{varIdent} object representing a constant variance function structure, also inheriting from class \texttt{varFunc}.

Variogram

Calculate Semi-variogram

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include default, gls and lme. See the appropriate method documentation for a description of the arguments.

Usage

Variogram(object, distance, ...)

Arguments

object

a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.

distance

a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs (1,2), (1,3),..., (n-1,n), with n representing the length of object, and must have length n(n-1)/2.

...

some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Variogram.corExp

## Calculate Semi-variogram for a corExp Object

### Description
This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

### Usage
```r
## S3 method for class 'corExp'
Variogram(object, distance, sig2, length.out, ...)
```

### Arguments
- `object`:
  - an object inheriting from class "corExp", representing an exponential spatial correlation structure.
- `distance`:
  - an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to `NULL`, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used.
- `sig2`:
  - an optional numeric value representing the process variance. Defaults to 1.
- `length.out`:
  - an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to 50.
- `...`:
  - some methods for this generic require additional arguments. None are used in this method.

### Value
A data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

### Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### Examples
```r
stopifnot(require("stats", quietly = TRUE))
cs1 <- corExp(3, form = ~ Time | Rat)
cs1 <- Initialize(cs1, BodyWeight)
Variogram(cs1)[1:10,]
```
Variogram.corGaus  

Calculate Semi-variogram for a corGaus Object

Description

This method function calculates the semi-variogram values corresponding to the Gaussian correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

```r
## S3 method for class 'corGaus'
Variogram(object, distance, sig2, length.out, ...)
```

Arguments

- `object`: an object inheriting from class "corGaus", representing an Gaussian spatial correlation structure.
- `distance`: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to `NULL`, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used.
- `sig2`: an optional numeric value representing the process variance. Defaults to 1.
- `length.out`: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to 50.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

Calculate Semi-variogram for a corLin Object

Description

This method function calculates the semi-variogram values corresponding to the Linear correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

## S3 method for class 'corLin'
Variogram(object, distance, sig2, length.out, ...)

Arguments

object an object inheriting from class "corLin", representing an Linear spatial correlation structure.
distance an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
sig2 an optional numeric value representing the process variance. Defaults to 1.
length.out an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
... some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.default

Variogram.default

Calculate Semi-variogram

Description

This method function calculates the semi-variogram for an arbitrary vector object, according to the distances in distance. For each pair of elements \( x, y \) in object, the corresponding semi-variogram is \((x - y)^2/2\). The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

Usage

## Default S3 method:
Variogram(object, distance, ...)

Arguments

object

a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.

distance

a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs \((1,2),(1,3),...,(n-1,n)\), with \(n\) representing the length of object, and must have length \(n(n-1)/2\).

...

some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.gls

Calculate Semi-variogram for Residuals from a gls Object

Description

This method function calculates the semi-variogram for the residuals from a gls fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

## S3 method for class 'gls'
Variogram(object, distance, form, resType, data, 
   na.action, maxDist, length.out, collapse, nint, breaks, 
   robust, metric, ...)

Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted model.
distance an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.
form an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a | operator in form). Default is ~1, implying that the observation order within the groups is used to obtain the distances.
resType an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
data an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.
na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
maxDist an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.
length.out  an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse  an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint  an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust  an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks  an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

...  some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

Variogram.lme

Calculate Semi-variogram for Residuals from an lme Object

Description

This method function calculates the semi-variogram for the within-group residuals from an lme fit. The semi-variogram values are calculated for pairs of residuals within the same group. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

```r
## S3 method for class 'lme'
Variogram(object, distance, form, resType, data, na.action, maxDist, length.out, collapse, nint, breaks, robust, metric, ...)
```

Arguments

- **object**: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- **distance**: an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.
- **form**: an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a | operator in form). Default is ~1, implying that the observation order within the groups is used to obtain the distances.
- **resType**: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- **data**: an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.
- **na.action**: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
Variogram.lme

maxDist an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

length.out an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

... some methods for this generic require additional arguments. None are used in this method.

Value

da data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

lme, Variogram, Variogram.default, Variogram.gls, plot.Variogram
Examples

```r
fm1 <- lme(weight ~ Time * Diet, data=BodyWeight, ~ Time | Rat)
Variogram(fm1, form = ~ Time | Rat, nint = 10, robust = TRUE)
```

### Description

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting \( v \) denote the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the power variance function is defined as \( \sigma^2(v) = |v|^2^{\theta} \), where \( \theta \) is the variance function coefficient. When a grouping factor is present, a different \( \theta \) is used for each factor level.

### Usage

```r
varPower(value, form, fixed)
```

### Arguments

- **value**: an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- **form**: an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using `"."`, representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, like in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- **fixed**: an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

### Value

A `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

---

**Examples**

```r
fm1 <- lme(weight ~ Time * Diet, data=BodyWeight, ~ Time | Rat)
Variogram(fm1, form = ~ Time | Rat, nint = 10, robust = TRUE)
```
Extract Variance Function Weights

Description
The inverse of the standard deviations corresponding to the variance function structure represented by object are returned.

Usage
varWeights(object)

Arguments
object an object inheriting from class varFunc, representing a variance function structure.

Value
if object has a weights attribute, its value is returned; else NULL is returned.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

varWeights(vf1)[1:10]

vf1 <- varPower(form=~age)
vf1 <- Initialize(vf1, Orthodont) coef(vf1) <- 0.3
varWeights(vf1)[1:10]
Description
If object includes a varStruct component, the inverse of the standard deviations of the variance function structure represented by the corresponding varFunc object are returned; else, a vector of ones of length equal to the number of observations in the data frame used to fit the associated linear model is returned.

Usage
## S3 method for class 'glsStruct'
varWeights(object)

Arguments
object an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.

Value
if object includes a varStruct component, a vector with the corresponding variance weights; else, or a vector of ones.

Wheat Yield Trials

Description

The Wheat2 data frame has 224 rows and 5 columns.

Format

This data frame contains the following columns:

- **Block** an ordered factor with levels 4 < 2 < 3 < 1
- **variety** a factor with levels ARAPAHOE BRULE BUCKSKIN CENTURA CENTURK78 CHEYENNE CODY COLT GAGE HOMESTEAD KS831374 LANCER LANCOTA NE83404 NE83406 NE83407 NE83432 NE83498 NE83T12 NE84557 NE85556 NE85623 NE86482 NE86501 NE86503 NE86507 NE86509 NE86527 NE86582 NE86606 NE86607 NE86T666 NE87403 NE87408 NE87409 NE87446 NE87451 NE87457 NE87463 NE87499 NE87512 NE87513 NE87522 NE875622 NE87612 NE87613 NE87615 NE87619 NE87627 NORKAN REDLAND ROUGHRIDER SCOUT66 SIOUXLAND TAM107 TAM200 VONA
- **yield** a numeric vector
- **latitude** a numeric vector
- **longitude** a numeric vector

Source

Description

This method function extracts sub-matrices from the positive-definite matrix represented by \( x \).

Usage

```r
## S3 method for class 'pdMat'
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat'
x[i, j] <- value
```

Arguments

- **\( x \)**: an object inheriting from class "pdMat" representing a positive-definite matrix.
- **\( i, j \)**: optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by object. When \( i \) (\( j \)) is omitted, all rows (columns) are extracted.
- **drop**: a logical value. If TRUE, single rows or columns are converted to vectors. If FALSE the returned value retains its matrix representation.
- **value**: a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by \( x \).

Value

If \( i \) and \( j \) are identical, the returned value will be \( \text{pdMat} \) object with the same class as \( x \). Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

class.ind

Generates Class Indicator Matrix from a Factor

Description

Generates a class indicator function from a given factor.

Usage

class.ind(cl)

Arguments

cl  factor or vector of classes for cases.

Value

a matrix which is zero except for the column corresponding to the class.

References

Examples

# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[[1:n] + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}
multinom

**Fit Multinomial Log-linear Models**

**Description**

Fits multinomial log-linear models via neural networks.

**Usage**

```r
multinom(formula, data, weights, subset, na.action,
          contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
          model = FALSE, ...
)
```

**Arguments**

- `formula` a formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor or a matrix with \( K \) columns, which will be interpreted as counts for each of \( K \) classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with \( K \) columns if the response is either a matrix with \( K \) columns or a factor with \( K \geq 2 \) classes, or a numeric vector for a response factor with 2 levels. See the documentation of `formula()` for other details.

- `data` an optional data frame in which to interpret the variables occurring in `formula`.

- `weights` optional case weights in fitting.

- `subset` expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

- `na.action` a function to filter missing data.

- `contrasts` a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

- `Hess` logical for whether the Hessian (the observed/expected information matrix) should be returned.

- `summ` integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same \( X \) and different \( Y \), which changes the baseline for the deviance.

- `censored` If \( Y \) is a matrix with \( K \) columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.

- `model` logical. If true, the model frame is saved as component `model` of the returned object.

- `...` additional arguments for `nnet`

**Details**

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to \([0,1]\) or the fit will be slow or may not converge at all.
Value

A nnet object with additional components:

- **deviance**: the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood.
- **edf**: the (effective) number of degrees of freedom used by the model.
- **AIC**: the AIC for this fit.
- **Hessian** (if Hess is true).
- **model** (if model is true).

References

See Also

nnet

Examples

```r
oc <- options(contrasts = c("contr.treatment", "contr.poly"))
library(MASS)
example(birthwt)
(bwt.mu <- multinom(low ~ ., bwt))
options(oc)
```

---

nnet  

**Fit Neural Networks**

Description

Fit single-hidden-layer neural network, possibly with skip-layer connections.

Usage

```r
nnet(x, ...)
```

## S3 method for class 'formula'
```
nnet(formula, data, weights, ..., 
    subset, na.action, contrasts = NULL)
```

## Default S3 method:
```
nnet(x, y, weights, size, Wts, mask, 
    linout = FALSE, entropy = FALSE, softmax = FALSE, 
    censored = FALSE, skip = FALSE, rang = 0.7, decay = 0, 
    maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000, 
    abstol = 1.0e-4, reltol = 1.0e-8, ...)
```
Arguments

**formula**  A formula of the form `class ~ x1 + x2 + ...`

**x**  matrix or data frame of x values for examples.

**y**  matrix or data frame of target values for examples.

**weights**  (case) weights for each example – if missing defaults to 1.

**size**  number of units in the hidden layer. Can be zero if there are skip-layer units.

**data**  Data frame from which variables specified in formula are preferentially to be taken.

**subset**  An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

**na.action**  A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)

**contrasts**  a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

**Wts**  initial parameter vector. If missing chosen at random.

**mask**  logical vector indicating which parameters should be optimized (default all).

**linout**  switch for linear output units. Default logistic output units.

**entropy**  switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.

**softmax**  switch for softmax (log-linear model) and maximum conditional likelihood fitting. linout, entropy, softmax and censored are mutually exclusive.

**censored**  A variant on softmax, in which non-zero targets mean possible classes. Thus for softmax a row of `(0, 1, 1)` means one example each of classes 2 and 3, but for censored it means one example whose class is only known to be 2 or 3.

**skip**  switch to add skip-layer connections from input to output.

**rang**  Initial random weights on `[-rang, rang]`. Value about 0.5 unless the inputs are large, in which case it should be chosen so that `rang * max(|x|)` is about 1.

**decay**  parameter for weight decay. Default 0.

**maxit**  maximum number of iterations. Default 100.

**Hess**  If true, the Hessian of the measure of fit at the best set of weights found is returned as component `Hessian`.

**trace**  switch for tracing optimization. Default TRUE.

**MaxNWts**  The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing `MaxNWts` will probably allow fits that are very slow and time-consuming.

**abstol**  Stop if the fit criterion falls below `abstol`, indicating an essentially perfect fit.

**reltol**  Stop if the optimizer is unable to reduce the fit criterion by a factor of at least `1 - reltol`.

... arguments passed to or from other methods.
Details

If the response in formula is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to nnet.default.

Optimization is done via the BFGS method of optim.

Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

- wts: the best set of weights found
- value: value of fitting criterion plus weight decay term.
- fitted.values: the fitted values for the training data.
- residuals: the residuals for the training data.
- convergence: 1 if the maximum number of iterations was reached, otherwise 0.

table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
nnetHess  Evaluates Hessian for a Neural Network

Description
Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument Hess=TRUE to nnet or via vcov.multinom.

Usage
nnetHess(net, x, y, weights)

Arguments
- net: object of class nnet as returned by nnet.
- x: training data.
- y: classes for training data.
- weights: the (case) weights used in the nnet fit.

Value
square symmetric matrix of the Hessian evaluated at the weights stored in the net.

predict.nnet

Predict New Examples by a Trained Neural Net

Description

Predict new examples by a trained neural net.

Usage

## S3 method for class 'nnet'
predict(object, newdata, type = c("raw", "class"), ...)

Arguments

object an object of class nnet as returned by nnet.
newdata matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case.
type Type of output
... arguments passed to or from other methods.

Details

This function is a method for the generic function predict() for class "nnet". It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.nnet(x) regardless of the class of the object.

Value

If type = "raw", the matrix of values returned by the trained network; if type = "class", the corresponding class (which is probably only useful if the net was generated by nnet.formula).

which.is.max

Find Maximum Position in Vector

Description

Find the maximum position in a vector, breaking ties at random.

Usage

which.is.max(x)

Arguments

x

a vector

Details

Ties are broken at random.

Value

index of a maximal value.

car.test.frame  Automobile Data from 'Consumer Reports' 1990

**Description**

The `car.test.frame` data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in `cu.summary`.

**Usage**

`car.test.frame`

**Format**

This data frame contains the following columns:

- **Price**: a numeric vector giving the list price in US dollars of a standard model
- **Country of origin**: a factor with levels 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'
- **Reliability**: a numeric vector coded 1 to 5.
- **Mileage**: fuel consumption miles per US gallon, as tested.
- **Type**: a factor with levels Compact Large Medium Small Sporty Van
- **Weight**: kerb weight in pounds.
- **Disp.**: the engine capacity (displacement) in litres.
- **HP**: the net horsepower of the vehicle.

**Source**

---
See Also
car90, cu.summary

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

Description

Usage
data(car90)

Format

The data frame contains the following columns

- **Country**  a factor giving the country in which the car was manufactured
- **Disp**  engine displacement in cubic inches
- **Disp2**  engine displacement in liters
- **Eng.Rev**  engine revolutions per mile, or engine speed at 60 mph
- **Front.Hd**  distance between the car’s head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU
- **Frt.Leg.Room**  maximum front leg room, in inches, as measured by CU
- **Frt.Shld**  front shoulder room, in inches, as measured by CU
- **Gear.Ratio**  the overall gear ratio, high gear, for manual transmission
- **Gear2**  the overall gear ratio, high gear, for automatic transmission
- **HP**  net horsepower
- **HP.revs**  the red line—the maximum safe engine speed in rpm
- **Height**  height of car, in inches, as supplied by manufacturer
- **Length**  overall length, in inches, as supplied by manufacturer
- **Luggage**  luggage space
- **Mileage**  a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.
- **Model2**  alternate name, if the car was sold under two labels
- **Price**  list price with standard equipment, in dollars
- **Rear.Hd**  distance between the car’s head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU
- **Rear.Seating**  rear fore-and-aft seating room, in inches, as measured by CU
RearShld  rear shoulder room, in inches, as measured by CU

Reliability  an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better': contains NAs.

Rim  factor giving the rim size

Sratio.m  Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

Sratio.p  Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

Steering  steering type offered: manual, power, or both

Tank  fuel refill capacity in gallons

Tires  factor giving tire size

Trans1 manual transmission, a factor with levels '', 'man.4', 'man.5' and 'man.6'

Trans2 automatic transmission, a factor with levels '', 'auto.3', 'auto.4', and 'auto.CVT'. No car is missing both the manual and automatic transmission variables, but several had both as options

Turning  the radius of the turning circle in feet

Type  a factor giving the general type of car. The levels are: ‘Small’, ‘Sporty’, ‘Compact’, ‘Medium’, ‘Large’, ‘Van’

Weight  an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

Wheel.base  length of wheelbase, in inches, as supplied by manufacturer

Width  width of car, in inches, as supplied by manufacturer

Source

This is derived (with permission) from the data set car.all in S-PLUS, but with some further clean up of variable names and definitions.

car.test.frame, cu.summary for extracts from other versions of the dataset.

Examples

data(car90)
plot(car90$Price/1000, car90$Weight,
   xlab = "Price (thousands)", ylab = "Weight (lbs)"
mlowess <- function(x, y, ...) {
  keep <- !(is.na(x) | is.na(y))
  lowess(x[keep], y[keep], ...)
}
with(car90, lines(mlowess(Price/1000, Weight, f = 0.5)))
The `cu.summary` data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

### Usage

cu.summary

### Format

This data frame contains the following columns:

- **Price**: a numeric vector giving the list price in US dollars of a standard model
- **Country**: a factor with levels 'Brazil', 'England', 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'
- **Reliability**: an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better'
- **Mileage**: fuel consumption miles per US gallon, as tested.
- **Type**: a factor with levels Compact Large Medium Small Sporty Van

### Examples

```r
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```
The kyphosis data frame has 81 rows and 4 columns, representing data on children who have had corrective spinal surgery.

This data frame contains the following columns:

- **Kyphosis**: A factor with levels `absent` and `present` indicating if a kyphosis (a type of deformation) was present after the operation.
- **Age**: In months
- **Number**: The number of vertebrae involved
- **Start**: The number of the first (topmost) vertebra operated on.

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

This function provides labels for the branches of an `rpart` tree.

```r
## S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```
Arguments

object: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

digits: the number of digits to be used for numeric values. All of the rpart functions that call labels explicitly set this value, with options("digits") as the default.

minlength: the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than 1, the abbreviate function is used, passed the minlength argument.

pretty: an argument included for compatibility with the tree package: pretty = 0 implies minlength = 0L, pretty = NULL implies minlength = 1L, and pretty = TRUE implies minlength = 4L.

collapse: logical. The returned set of labels is always of the same length as the number of nodes in the tree. If collapse = TRUE (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node. If FALSE, the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes.

...: optional arguments to abbreviate.

Value

Vector of split labels (collapse = TRUE) or matrix of left and right splits (collapse = FALSE) for the supplied rpart object. This function is called by printing methods for rpart and is not intended to be called directly by the users.

See Also

abbreviate

Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

Usage

meanvar(tree, ...)

## S3 method for class 'rpart'
meanvar(tree, xlab = "ave(y)", ylab = "ave(deviance)", ...)
Arguments

- **tree**: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
- **xlab**: x-axis label for the plot.
- **ylab**: y-axis label for the plot.
- **...**: additional graphical parameters may be supplied as arguments to this function.

Value

an invisible list containing the following vectors is returned.

- **x**: fitted value at terminal nodes (yval).
- **y**: deviance of node divided by number of observations at node.
- **label**: node number.

Side Effects

a plot is put on the current graphics device.

See Also

plot.rpart.

Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')
```

---

**na.rpart**

Handles Missing Values in an Rpart Object

Description

Handles missing values in an "rpart" object.

Usage

```r
na.rpart(x)
```

Arguments

- **x**: a model frame.

Details

Default function that handles missing values when calling the function rpart.

It omits cases where part of the response is missing or all the explanatory variables are missing.
path.rpart

Follow Paths to Selected Nodes of an Rpart Object

Description
Returns a names list where each element contains the splits on the path from the root to the selected nodes.

Usage
path.rpart(tree, nodes, pretty = 0, print.it = TRUE)

Arguments
- tree: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
- nodes: an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.
- pretty: an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A NULL, the default, signifies using elements of letters to represent the different factor levels.
- print.it: Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if nodes argument is supplied.

Details
The function has a required argument as an rpart object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

Value
A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

Graphical Interaction
A dendrogram of the rpart object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

References
This function was modified from path.tree in S.

Examples

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, node = c(11, 22))
```

---

**plot.rpart**  
*Plot an Rpart Object*

**Description**

Plots an rpart object on the current graphics device.

**Usage**

```r
## S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace, margin = 0, minbranch = 0.3, ...)
```

**Arguments**

- `x`: a fitted object of class "rpart", containing a classification, regression, or rate tree.
- `uniform`: if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
- `branch`: controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
- `compress`: if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes uniform=TRUE; surprisingly, the result is usually an improvement even when that is not the case.
- `nspace`: the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of `branch`.
- `margin`: an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
- `minbranch`: set the minimum length for a branch to minbranch times the average branch length. This parameter is ignored if uniform=TRUE. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
- `...`: arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.
plotcp

Plot a Complexity Parameter Table for an Rpart Fit

Value
The coordinates of the nodes are returned as a list, with components x and y.

Side Effects
An unlabeled plot is produced on the current graphics device: one being opened if needed.

In order to build up a plot in the usual S style, e.g., a separate text command for adding labels, some extra information about the plot needs to be retained. This is kept in an environment in the package.

See Also
rpart, text.rpart

Examples
fit <- rpart(Price ~ Mileage + Type + Country, data = cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)

plotcp(x, minline = TRUE, lty = 3, col = 1,
upper = c("size", "splits", "none"), ...)

Arguments
x an object of class "rpart"
minline whether a horizontal line is drawn 1SE above the minimum of the curve.
lty line type for this line
col colour for this line
upper what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing.
... additional plotting parameters

Details
The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of \( cp \) for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by \( \text{rpart} \). The \( \text{cptable} \) in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of \( cp \) for pruning is often the leftmost value for which the mean lies below the horizontal line.
Value

None.

Side Effects

A plot is produced on the current graphical device.

See Also

rpart, printcp, rpart.object

Description

Generates a PostScript presentation plot of an rpart object.

Usage

post(tree, ...)

## S3 method for class 'rpart'
post(tree, title.,
    filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
    digits = getOption("digits") - 2, pretty = TRUE,
    use.n = TRUE, horizontal = TRUE, ...)

Arguments

tree fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

title. a title which appears at the top of the plot. By default, the name of the rpart endpoint is printed out.

filename ASCII file to contain the output. By default, the name of the file is the name of the object given by rpart (with the suffix .ps added). If filename = "", the plot appears on the current graphical device.

digits number of significant digits to include in numerical data.

pretty an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation.

use.n Logical. If TRUE (default), adds to label (#events level1/\#events level2/etc. for method class, n for method anova, and #events/n for methods poisson and exp).

horizontal Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape.

... other arguments to the postscript function.
Details

The plot created uses the functions `plot.rpart` and `text.rpart` (with the fancy option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

Side Effects

A plot of `rpart` is created using the postscript driver, or the current device if `filename = ""`.

See Also

`plot.rpart`, `rpart`, `text.rpart`, `abbreviate`

Examples

```r
## Not run:
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "")  # display tree on active device
    # now construct postscript version on file "pretty.ps"
    # with no title
post(z.auto, file = "pretty.ps", title = "")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
## End(Not run)
```

predict.rpart

Predictions from a Fitted Rpart Object

Description

Returns a vector of predicted responses from a fitted `rpart` object.

Usage

```r
## S3 method for class 'rpart'
predict(object, newdata, 
type = c("vector", "prob", "class", "matrix"),
na.action = na.pass, ...)
```

Arguments

- `object`: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `newdata`: data frame containing the values at which predictions are required. The predictors referred to in the right side of `formula(object)` must be present by name in `newdata`. If missing, the fitted values are returned.
- `type`: character string denoting the type of predicted value returned. If the `rpart` object is a classification tree, then the default is to return prob predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of `tree`). Otherwise, a vector result is returned.
na.action a function to determine what should be done with missing values in newdata.
The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are \texttt{na.omit} and \texttt{na.fail}.

... further arguments passed to or from other methods.

Details

This function is a method for the generic function predict for class "rpart". It can be invoked by calling predict for an object of the appropriate class, or directly by calling \texttt{predict.rpart} regardless of the class of the object.

Value

A new object is obtained by dropping \texttt{newdata} down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and \texttt{frame$yval} at the node is the prediction.

If \texttt{type = "vector"}:
vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If \texttt{type = "prob"}:
(for a classification tree) a matrix of class probabilities.

If \texttt{type = "matrix"}:
a matrix of the full responses (\texttt{frame$yval2} if this exists, otherwise \texttt{frame$yval}). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of at least the predicted class, the class counts at that node in the fitted tree, and the class probabilities (some versions of \texttt{rpart} may contain further columns).

If \texttt{type = "class"}:
(for a classification tree) a factor of classifications based on the responses.

## End(Not run)
prune.rpart  

Cost-complexity Pruning of an Rpart Object

Description

Determines a nested sequence of subtrees of the supplied rpart object by recursively snipping off the least important splits, based on the complexity parameter (cp).

Usage

prune(tree, ...)

## S3 method for class 'rpart'
prune(tree, cp, ...)

Arguments

tree  
fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

 cp  
Complexity parameter to which the rpart object will be trimmed.

...  
further arguments passed to or from other methods.

Value

A new rpart object that is trimmed to the value cp.

See Also

rpart

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) #plot smaller rpart object

residuals.rpart  

Residuals From a Fitted Rpart Object

Description

Method for residuals for an rpart object.

Usage

## S3 method for class 'rpart'
residuals(object, type = c("usual", "pearson", "deviance"), ...)

Arguments

object  fitted model object of class "rpart".

Arguments

type  Indicates the type of residual desired.

For regression or anova trees all three residual definitions reduce to \( y - \text{fitted} \). This is the residual returned for user method trees as well.

For classification trees the usual residuals are the misclassification losses \( L(\text{actual}, \text{predicted}) \) where \( L \) is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The pearson residual is \( (1 - \text{fitted})/\sqrt{\text{fitted}(1-\text{fitted})} \) and the deviance residual is \( \sqrt{-\text{min twice logarithm of fitted}} \).

For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The pearson and deviance residuals are as defined in McCullagh and Nelder.

...  further arguments passed to or from other methods.

Value

Vector of residuals of type type from a fitted rpart object.

References

Examples

```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel, 
data = solder.balance, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

rpart  Recursive Partitioning and Regression Trees

Description

Fit a rpart model

Usage

rpart(formula, data, weights, subset, na.action = na.rpart, method, 
model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)

Arguments

formula  a formula, with a response but no interaction terms. If this a a data frame, that is taken as the model frame (see model.frame).

data  an optional data frame in which to interpret the variables named in the formula.

weights  optional case weights.

subset  optional expression saying that only a subset of the rows of the data should be used in the fit.
na.action  the default action deletes all observations for which y is missing, but keeps those in which one or more predictors are missing.

method  one of "anova", "poisson", "class" or "exp". If method is missing then the routine tries to make an intelligent guess. If y is a survival object, then method = "exp" is assumed, if y has 2 columns then method = "poisson" is assumed, if y is a factor then method = "class" is assumed, otherwise method = "anova" is assumed. It is wisest to specify the method directly, especially as more criteria may added to the function in future.

Alternatively, method can be a list of functions named init, split and eval. Examples are given in the file ‘tests/usersplits.R’ in the sources, and in the vignettes ‘User Written Split Functions’.

model  if logical: keep a copy of the model frame in the result? If the input value for model is a model frame (likely from an earlier call to the rpart function), then this frame is used rather than constructing new data.

x  keep a copy of the x matrix in the result.

y  keep a copy of the dependent variable in the result. If missing and model is supplied this defaults to FALSE.

parms  optional parameters for the splitting function.

Anova splitting has no parameters.

Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1.

Exponential splitting has the same parameter as Poisson.

For classification splitting, the list can contain any of: the vector of prior probabilities (component prior), the loss matrix (component loss) or the splitting index (component split). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be gini or information. The default priors are proportional to the data counts, the losses default to 1, and the split defaults to gini.

control  a list of options that control details of the rpart algorithm. See rpart.control.

cost  a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.

...  arguments to rpart.control may also be specified in the call to rpart. They are checked against the list of valid arguments.

Details

This differs from the tree function in S mainly in its handling of surrogate variables. In most details it follows Breiman et. al (1984) quite closely. R package tree provides a re-implementation of tree.

Value

An object of class rpart. See rpart.object.

References

rpart.control

Control for Rpart Fits

Description

Various parameters that control aspects of the rpart fit.

Usage

rpart.control(minsplit = 20, minbucket = round(minsplit/3), cp = 0.01,
maxcompete = 4, maxsurrogate = 5, usesurrogate = 2, xval = 10,
surrogatestyle = 0, maxdepth = 30, ...)

Arguments

minsplt the minimum number of observations that must exist in a node in order for a
split to be attempted.

minbucket the minimum number of observations in any terminal <leaf> node. If only
one of minbucket or minsplit is specified, the code either sets minsplit to
minbucket*3 or minbucket to minsplit/3, as appropriate.

cp complexity parameter. Any split that does not decrease the overall lack of fit by
a factor of cp is not attempted. For instance, with anova splitting, this means
that the overall R-squared must increase by cp at each step. The main role of
this parameter is to save computing time by pruning off splits that are obviously
not worthwhile. Essentially, the user informs the program that any split which
does not improve the fit by cp will likely be pruned off by cross-validation, and
that hence the program need not pursue it.

maxcompete the number of competitor splits retained in the output. It is useful to know not
just which split was chosen, but which variable came in second, third, etc.

maxsurrogate the number of surrogate splits retained in the output. If this is set to zero the
compute time will be reduced, since approximately half of the computational
time (other than setup) is used in the search for surrogate splits.

Examples

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
parms = list(prior = c(.65,.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
rpart.exp

usesurrogate: how to use surrogates in the splitting process. 0 means display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1 means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value 2, if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of tree, and 2 to the recommendations of Breiman et al (1984).

xval: number of cross-validations.
surrogatestyle: controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.

maxdepth: Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 rpart will give nonsense results on 32-bit machines.

Value
A list containing the options.

See Also
rpart

rpart.exp(y, offset, parms, wt)

Arguments
y: the response, which will be of class Surv
offset: optional offset
parms: parameters controlling the fit. This is a list with components shrink and method. The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root.
wt: case weights, if present

Description
This function does the initialization step for rpart, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

Usage
rpart.exp(y, offset, parms, wt)
**Value**

a list with the necessary initialization components

**Author(s)**

Terry Therneau

**See Also**

`rpart`

---

**rpart.object**

*Recursive Partitioning and Regression Trees Object*

---

**Description**

These are objects representing fitted `rpart` trees.

**Value**

- `frame`: data frame with one row for each node in the tree. The row names of `frame` contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of `frame` include `var`, a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level "<leaf>"), `n`, the number of observations reaching the node, `wt`, the sum of case weights for observations reaching the node, `dev`, the deviance of the node, `yval`, the fitted value of the response at the node, and `splits`, a two column matrix of left and right split labels for each node. Also included in the frame are `complexity`, the complexity parameter at which this split will collapse, `ncompete`, the number of competitor splits recorded, and `nsurrogate`, the number of surrogate splits recorded.

Extra response information which may be present is in `yval2`, which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node, the class probabilities and the 'node probability' (classification trees).

- `where`: an integer vector of the same length as the number of observations in the root node, containing the row number of `frame` corresponding to the leaf node that each observation falls into.

- `call`: an image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say `update(tree)`.

- `terms`: an object of class c("terms","formula") (see `terms.object`) summarizing the formula. Used by various methods, but typically not of direct relevance to users.

- `splits`: a numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are count, the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), `ncat`,
the number of categories or levels for the variable (+/-1 for a continuous variable), improve, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and index, the numeric split point. The last column adj gives the adjusted concordance for surrogate splits. For a factor, the index column contains the row number of the csplit matrix. For a continuous variable, the sign of ncat determines whether the subset x < cutpoint or x > cutpoint is sent to the left.

csplit an integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the index column of the splits matrix. The columns record 1 if that level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree (or not defined for the factor).

method character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).

cptable a matrix of information on the optimal prunings based on a complexity parameter.

variable.importance a named numeric vector giving the importance of each variable. (Only present if there are any splits.) When printed by summary.rpart these are rescaled to add to 100.

numresp integer number of responses; the number of levels for a factor response.

parms, control a record of the arguments supplied, which defaults filled in.

functions the summary, print and text functions for method used.

ordered a named logical vector recording for each variable if it was an ordered factor.

na.action (where relevant) information returned by model.frame on the special handling of NAs derived from the na.action argument.

There may be attributes "xlevels" and "levels" recording the levels of any factor splitting variables and of a factor response respectively.

Optional components include the model frame (model), the matrix of predictors (x) and the response variable (y) used to construct the rpart object.

Structure

The following components must be included in a legitimate rpart object.

See Also

rpart.

rsq.rpart

Plots the Approximate R-Square for the Different Splits

Description

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.
Usage
rsq.rpart(x)

Arguments
x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

Side Effects
Two plots are produced.

Note
The labels are only appropriate for the "anova" method.

Examples
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)

snip.rpart Snip Subtrees of an Rpart Object

Description
Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the toss argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

Usage
snip.rpart(x, toss)

Arguments
x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
toss an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

Details
A dendrogram of rpart is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting rpart object.

See the documentation for the specific graphics device for details on graphical input techniques.
Value
A `rpart` object containing the nodes that remain after specified or selected subtrees have been snipped off.

Warning
Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

See Also
`plot.rpart`

Examples
```r
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree
# can also interactively select the node using the mouse in the
# graphics window
## End(Not run)
```

`solder.balance`  
**Soldering of Components on Printed-Circuit Boards**

Description
The `solder.balance` data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

The `solder` data frame is the full version of the data with 900 rows. It is located in both the `rpart` and the `survival` packages.

Usage
`solder`

Format
This data frame contains the following columns:

- **Opening**  
  A factor with levels `L`, `M` and `S` indicating the amount of clearance around the mounting pad.

- **Solder**  
  A factor with levels `Thick` and `Thin` giving the thickness of the solder used.

- **Mask**  
  A factor with levels `A1.5`, `A3`, `B3` and `B6` indicating the type and thickness of mask used.

- **PadType**  
  A factor with levels `D4`, `D6`, `D7`, `L4`, `L6`, `L7`, `L8`, `L9`, `W4` and `W9` giving the size and geometry of the mounting pad.

- **Panel 1:3**  
  Indicating the panel on a board being tested.

- **skips**  
  A numeric vector giving the number of visible solder skips.
stagec

Source

Examples
```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
             data = solder.balance, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

**stagec**

**Stage C Prostate Cancer**

Description
A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

Usage
data(stagec)

Format
A data frame with 146 observations on the following 8 variables.

- `pgtime` Time to progression or last follow-up (years)
- `pgstat` 1 = progression observed, 0 = censored
- `age` age in years
- `eet` early endocrine therapy, 1 = no, 2 = yes
- `g2` percent of cells in G2 phase, as found by flow cytometry
- `grade` grade of the tumor, Farrow system
- `gleason` grade of the tumor, Gleason system
- `ploidy` the ploidy status of the tumor, from flow cytometry. Values are ‘diploid’, ‘tetraploid’, and ‘aneuploid’

Details
A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

Examples
```r
require(survival)
rpart(Surv(pgtime, pgstat) ~ ., stagec)
```
**summary.rpart**

*Summarize a Fitted Rpart Object*

**Description**

Returns a detailed listing of a fitted `rpart` object.

**Usage**

```r
## S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```

**Arguments**

- `object` fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `digits` Number of significant digits to be used in the result.
- `cp` trim nodes with a complexity of less than `cp` from the listing.
- `file` write the output to a given file name. (Full listings of a tree are often quite long).
- `...` arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `summary` for class "rpart". It can be invoked by calling `summary` for an object of the appropriate class, or directly by calling `summary.rpart` regardless of the class of the object.

It prints the call, the table shown by `printcp`, the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

**See Also**

`summary`, `rpart.object`, `printcp`.

**Examples**

```r
## a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

## a classification tree with multiple variables and surrogate splits.
some الطب (Kyphosis ~ Age + Number + Start, data = kyphosis))
```
**text.rpart**

Place Text on a Dendrogram Plot

**Description**

Labels the current plot of the tree dendrogram with text.

**Usage**

```r
## S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
     pretty = NULL, digits = getOption("digits") - 3, use.n = FALSE,
     fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
     minlength = 1L, ...)  
```

**Arguments**

- `x`: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `splits`: logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split.
- `label`: For compatibility with `rpart2`, ignored in this version (with a warning).
- `FUN`: the name of a labeling function, e.g. `text`.
- `all`: Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes.
- `minlength`: the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', ..., Larger values use abbreviations of the label names. See the `labels.rpart` function for details.
- `pretty`: an alternative to the `minlength` argument, see `labels.rpart`.
- `digits`: number of significant digits to include in numerical labels.
- `use.n`: Logical. If TRUE, adds to label (#events level1/ #events level2/etc. for class, n for anova, and #events/n for poisson and exp).
- `fancy`: Logical. If TRUE, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by `yval`. The edges connecting the nodes are labeled by left and right splits.
- `fwidth`: Relates to option `fancy` and the width of the ellipses and rectangles. If `fwidth < 1` then it is a scaling factor (default = 0.8). If `fwidth > 1` then it represents the number of character widths (for current graphical device) to use.
- `fheight`: Relates to option `fancy` and the height of the ellipses and rectangles. If `fheight <1` then it is a scaling factor (default = 0.8). If `fheight > 1` then it represents the number of character heights (for current graphical device) to use.
- `bg`: The color used to paint the background to annotations if `fancy = TRUE`.
- `...`: Graphical parameters may also be supplied as arguments to this function (see `par`). As labels often extend outside the plot region it can be helpful to specify `xpd = TRUE`. 
Side Effects

the current plot of a tree dendrogram is labeled.

text, plot.rpart, rpart, labels.rpart, abbreviate

Examples

freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)

xpred.rpart

Return Cross-Validated Predictions

Description

Gives the predicted values for an rpart fit, under cross validation, for a set of complexity parameter values.

Usage

xpred.rpart(fit, xval = 10, cp, return.all = FALSE)

Arguments

fit a object of class "rpart".
xval number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups.
cp the desired list of complexity values. By default it is taken from the cptable component of the fit.
return.all if FALSE return only the first element of the prediction

Details

Complexity penalties are actually ranges, not values. If the cp values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for cp in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.

Value

A matrix with one row for each observation and one column for each complexity value. If return.all is TRUE and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; result[1, ,] will be the matrix of predicted classes, result[2, ,] the matrix of class 1 probabilities, etc.

The spatial package

### anova.trls  
*Anova tables for fitted trend surface objects*

#### Description
Compute analysis of variance tables for one or more fitted trend surface model objects; where `anova.trls` is called with multiple objects, it passes on the arguments to `anovalist.trls`.

#### Usage
```r
## S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

#### Arguments
- `object`: A fitted trend surface model object from `surf.ls`
- `...`: Further objects of the same kind

#### Value
`anova.trls` and `anovalist.trls` return objects corresponding to their printed tabular output.

#### References

#### See Also

summary(topo4)

---

correlogram

Compute Spatial Correlograms

Description

Compute spatial correlograms of spatial data or residuals.

Usage

correlogram(krig, nint, plotit = TRUE, ...)

Arguments

- **krig**: trend-surface or kriging object with columns x, y, and z
- **nint**: number of bins used
- **plotit**: logical for plotting
- **...**: parameters for the plot

Details

Divides range of data into nint bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

Value

x and y coordinates of the correlogram, and cnt, the number of pairs averaged per bin.

Side Effects

Plots the correlogram if plotit = TRUE.

References

variogram
expcov

Examples

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
correlogram(topo.kr, 25)
d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```

---

**expcov**

Spatial Covariance Functions

Description

Spatial covariance functions for use with `surf.gls`.

Usage

```r
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

Arguments

- `r`: vector of distances at which to evaluate the covariance
- `d`: range parameter
- `alpha`: proportion of nugget effect
- `se`: standard deviation at distance zero
- `D`: dimension of spheres.

Value

vector of covariance values.

lines(d, expcov(d, 0.7))
```
**Kaver**  
*Average K-functions from Simulations*

**Description**

Forms the average of a series of (usually simulated) K-functions.

**Usage**

```r
Kaver(fs, nsim, ...)
```

**Arguments**

- `fs` full scale for K-fn
- `nsim` number of simulations
- `...` arguments to simulate one point process object

**Value**

list with components `x` and `y` of the average K-fn on L-scale.

**References**

**See Also**

lines(lims$x,lims$upper, lty=2, col="green")
lines(Kaver(10,25,Strauss(69,0.5,3.5)), col="red")
```
Kenvl

**Compute Envelope and Average of Simulations of K-fns**

**Description**

Computes envelope (upper and lower limits) and average of simulations of K-fns

**Usage**

Kenvl(fs, nsim, ...)

**Arguments**

- **fs**: full scale for K-fn
- **nsim**: number of simulations
- **...**: arguments to produce one simulation

**Value**

List with components

- **x**: distances
- **lower**: min of K-fns
- **upper**: max of K-fns
- **aver**: average of K-fns

**References**

**See Also**

lines(Kaver(10,25,Strauss(69,0.5,3.5)), col="red")
Compute \( K \)-fn of a Point Pattern

**Description**

Actually computes \( L = \sqrt{K/\pi} \).

**Usage**

\[
\text{Kfn}(pp, fs, k=100)
\]

**Arguments**

- **pp**: a list such as a pp object, including components \( x \) and \( y \)
- **fs**: full scale of the plot
- **k**: number of regularly spaced distances in \((0, fs)\)

**Details**

relies on the domain \( D \) having been set by \texttt{ppinit} or \texttt{ppregion}.

**Value**

A list with components

- **x**: vector of distances
- **y**: vector of \( L \)-fn values
- **k**: number of distances returned – may be less than \( k \) if \( fs \) is too large
- **dmin**: minimum distance between pair of points
- **lm**: maximum deviation from \( L(t) = t \)

**References**

ppregion

Read a Point Process Object from a File

Description
Read a file in standard format and create a point process object.

Usage
\[
\text{ppinit(file)}
\]

Arguments
\[
\begin{align*}
\text{file} & \quad \text{string giving file name}
\end{align*}
\]

Details
The file should contain
- the number of points
- a header (ignored)
- \(x_l\) \(x_u\) \(y_l\) \(y_u\) \(scale\)
- \(x\) \(y\) (repeated \(n\) times)

Value
class "pp" object with components \(x, y, x_l, x_u, y_l, y_u\)
Side Effects

Calls \texttt{ppregion} to set the domain.

References

Examples

\begin{verbatim}
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
\end{verbatim}

\begin{verbatim}
pplik(pines, 0.7)
\end{verbatim}

\textbf{Description}

Pseudo-likelihood estimation of a Strauss spatial point process.

\textbf{Usage}

\begin{verbatim}
pplik(pp, R, ng=50, trace=FALSE)
\end{verbatim}

\textbf{Arguments}

\begin{verbatim}
pp a \texttt{pp} object
R the fixed parameter R
ng use a ng x ng grid with border R in the domain for numerical integration.
trace logical? Should function evaluations be printed?
\end{verbatim}

\textbf{Value}

estimate for \(c\) in the interval \([0, 1]\).

\textbf{Examples}

\begin{verbatim}
pines <- ppinit("pines.dat")
pplik(pines, 0.7)
\end{verbatim}
**ppregion**

*Set Domain for Spatial Point Pattern Analyses*

**Description**

Sets the rectangular domain \((x_l, x_u) \times (y_l, y_u)\).

**Usage**

```r
ppregion(xl = 0, xu = 1, yl = 0, yu = 1)
```

**Arguments**

- `xl`: Either `xl` or a list containing components `x1, xu, y1, yu` (such as a point-process object)
- `xu`
- `yl`
- `yu`

**Value**

none

**Side Effects**

initializes variables in the C subroutines.

**References**

**See Also**

`ppinit, ppgetregion`

---

**predict.trls**

*Predict method for trend surface fits*

**Description**

Predicted values based on trend surface model object

**Usage**

```r
## S3 method for class 'trls'
predict(object, x, y, ...)
```
prmat

Evaluate Kriging Surface over a Grid

Description

Evaluate Kriging surface over a grid.

Usage

prmat(obj, x1, xu, y1, yu, n)

Arguments

obj  object returned by surf.gls
x1   limits of the rectangle for grid
xu   y1   yu   n

References

Examples

data(topo, package="MASS")
topo2 <- surf.ls(2, topo)
topo4 <- surf.ls(4, topo)
x <- c(1.78, 2.21)
y <- c(6.15, 6.15)
z2 <- predict(topo2, x, y)
z4 <- predict(topo4, x, y)
cat("2nd order predictions:", z2, "\n4th order predictions:", z4, "\n")
Value

list with components \( x \), \( y \) and \( z \) suitable for contour and image.

References

See Also

`surf.gls`, `trmat`, `semat`

Examples

data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))

---

**Psim**  
*Simulate Binomial Spatial Point Process*

Description

Simulate Binomial spatial point process.

Usage

`Psim(n)`

Arguments

- `n` number of points

Details

relies on the region being set by `ppinit` or `ppregion`.

Value

list of vectors of \( x \) and \( y \) coordinates.

Side Effects

uses the random number generator.

References

semat

**Evaluate Kriging Standard Error of Prediction over a Grid**

**Description**

Evaluate Kriging standard error of prediction over a grid.

**Usage**

```r
semat(obj, xl, xu, yl, yu, n, se)
```

**Arguments**

- `obj`: object returned by `surf.gls`
- `xl`: limits of the rectangle for grid
- `xu`
- `yl`
- `yu`
- `n`: use n x n grid within the rectangle
- `se`: standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied.

**Value**

list with components `x`, `y` and `z` suitable for `contour` and `image`.

**References**

**See Also**

`surf.gls`, `trmat`, `prmat`
SSI

Simulates Sequential Spatial Inhibition Point Process

Description
Simulates SSI (sequential spatial inhibition) point process.

Usage
SSI(n, r)

Arguments
n  number of points
r  inhibition distance

Details
uses the region set by ppinit or ppregion.

Value
list of vectors of x and y coordinates

Side Effects
uses the random number generator.

Warnings
will never return if r is too large and it cannot place n points.

References

See Also
Psim, Strauss
Examples

```r
towns <- ppinit("towns.dat")
par(pty = "s")
plot(Kfn(towns, 10), type = "b", xlab = "distance", ylab = "L(t)"
lines(Kaver(10, 25, SSI(69, 1.2)))
```

**Strauss**

*Simulates Strauss Spatial Point Process*

**Description**

Simulates Strauss spatial point process.

**Usage**

```r
Strauss(n, c=0, r)
```

**Arguments**

- `n`: number of points
- `c`: parameter c in [0, 1]. c = 0 corresponds to complete inhibition at distances up to r.
- `r`: inhibition distance

**Details**

Uses spatial birth-and-death process for 4n steps, or for 40n steps starting from a binomial pattern on the first call from an other function. Uses the region set by ppinit or ppregion.

**Value**

list of vectors of x and y coordinates

**Side Effects**

uses the random number generator

**References**

**See Also**

*Psim, SSI*

**Examples**

```r
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)"
lines(Kaver(10, 25, Strauss(69,0.5,3.5)))
```
**surf.gls**

*Fits a Trend Surface by Generalized Least-squares*

**Description**

Fits a trend surface by generalized least-squares.

**Usage**

```
surf.gls(np, covmod, x, y, z, nx = 1000, ...)
```

**Arguments**

- `np`: degree of polynomial surface
- `covmod`: function to evaluate covariance or correlation function
- `x`: x coordinates or a data frame with columns `x`, `y`, `z`
- `y`: y coordinates
- `z`: z coordinates. Will supersede `x$z`
- `nx`: Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object.
- `...`: parameters for `covmod`

**Value**

list with components

- `beta`: the coefficients
- `x`
- `y`
- `z` and others for internal use only.

**References**

**See Also**

topo.kr <- surf.gls(2, expcov, topo, d=0.7)
trsurf <- trmat(topo.kr, 0, 6.5, 0, 6.5, 50)
eqscplot(trsurf, type = "n")
contour(trsurf, add = TRUE)

prsrf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
```

surf.ls

Fits a Trend Surface by Least-squares

Description

Fits a trend surface by least-squares.

Usage

surf.ls(np, x, y, z)

Arguments

np             degree of polynomial surface
x             x coordinates or a data frame with columns x, y, z
y             y coordinates
z             z coordinates. Will supersede x$z

Value

list with components

beta             the coefficients
x
y
z             and others for internal use only.

title(xlab= "Circle radius proportional to Cook’s influence statistic")
```

trls.influence  
Regression diagnostics for trend surfaces

Description

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

Usage

```r
trls.influence(object)
```

Arguments

- `object, x`: Fitted trend surface model from `surf.ls`
- `div`: scaling factor for influence circle radii in `plot.trls`
- `add`: add influence plot to existing graphics if TRUE
- `border, col, pch, cex, ...`: additional graphical parameters

Value

- `trls.influence` returns a list with components:
  - `r`: raw residuals as given by `residuals.trls`
  - `hii`: diagonal elements of the Hat matrix
  - `stresid`: standardised residuals
  - `Di`: Cook’s statistic

data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
trsurf <- trmat(topo.kr, 0, 6.5, 0, 6.5, 50)

variogram(topo.kr, 25)
```

---

**Description**

Compute spatial (semi-)variogram of spatial data or residuals.

**Usage**

```r
variogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

- `krig`: trend-surface or kriging object with columns `x`, `y`, and `z`
- `nint`: number of bins used
- `plotit`: logical for plotting
- `...`: parameters for the plot

**Details**

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

**Value**

- `x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

**Side Effects**

Plots the variogram if `plotit = TRUE`

**References**

variogram
Chapter 29

The survival package

aareg

Aalen’s additive regression model for censored data

Description

Returns an object of class "aareg" that represents an Aalen model.

Usage

aareg(formula, data, weights, subset, na.action,
qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
test = c('aalen', 'variance', 'nrisk'),
model=FALSE, x=FALSE, y=FALSE)

Arguments

formula a formula object, with the response on the left of a ‘~’ operator and the terms, separated by + operators, on the right. The response must be a Surv object. Due to a particular computational approach that is used, the model MUST include an intercept term. If "-1" is used in the model formula the program will ignore it.
data data frame in which to interpret the variables named in the formula, subset, and weights arguments. This may also be a single number to handle some special cases – see below for details. If data is missing, the variables in the model formula should be in the search path.
weights vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of weights must be the same as the number of observations. The weights must be nonnegative and it is recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the subset argument instead of zero weights.
subset expression specifying which subset of observations should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default.
na.action  a function to filter missing data. This is applied to the model.frame after any subset argument has been applied. The default is na.fail, which returns an error if any missing values are found. An alternative is na.exclude, which deletes observations that contain one or more missing values.

qr_tol  tolerance for detection of singularity in the QR decomposition

n_min  minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when n is small and the calculations can become numerically unstable.

dfbeta  should the array of dfbeta residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a cluster term in the model formula.

taper  allows for a smoothed variance estimate. Var(x), where x is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point t, it is computed over all subjects who are still at risk at time t. The tape argument allows smoothing these estimates, for example taper=(1:4)/4 would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model.

test  selects the weighting to be used, for computing an overall “average” coefficient vector over time and the subsequent test for equality to zero.

model, x, y  should copies of the model frame, the x matrix of predictors, or the response vector y be included in the saved result.

Details

The Aalen model assumes that the cumulative hazard H(t) for a subject can be expressed as a(t) + X B(t), where a(t) is a time-dependent intercept term, X is the vector of covariates for the subject (possibly time-dependent), and B(t) is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to B at time t is based on the subjects still at risk at time t. The tolerance and/or n_min parameters may act to truncate the estimate before the last death. The taper argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when n is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

Value

an object of class "aareg" representing the fit, with the following components:

n  vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation

times  vector of sorted event times, which may contain duplicates

nrisk  vector containing the number of subjects at risk, of the same length as times

coef  matrix of coefficients, with one row per event and one column per covariate

test.statistic  the value of the test statistic, a vector with one element per covariate

test.var  variance-covariance matrix for the test

test  the type of test; a copy of the test argument above

tweight  matrix of weights used in the computation, one row per event

call  a copy of the call that produced this result

## aeqSurv

Adjudicate near ties in a Surv object

### Description

The check for tied survival times can fail due to floating point imprecision, which can make actual ties appear to be distinct values. Routines that depend on correct identification of ties pairs will then give incorrect results, e.g., a Cox model. This function rectifies these.

### Usage

```r
aeqSurv(x, tolerance = sqrt(.Machine$double.eps))
```

### Arguments

- `x` a Surv object
- `tolerance` the tolerance used to detect values that will be considered equal

### Details

This routine is called by both `survfit` and `coxph` to deal with the issue of ties that get incorrectly broken due to floating point imprecision. See the short vignette on tied times for a simple example. Use the `timefix` argument of `survfit` or `coxph.control` to control the option if desired.

The rule for ‘equality’ is identical to that used by the `all.equal` routine. Pairs of values that are within round off error of each other are replaced by the smaller value. An error message is generated if this process causes a 0 length time interval to be created.

### Value

- a Surv object identical to the original, but with ties restored.

### Author(s)

Terry Therneau

### See Also

- `survfit`, `coxph.control`
Cox model fitting functions

Description
These are the functions called by coxph that do the actual computation. In certain situations, e.g., a simulation, it may be advantageous to call these directly rather than the usual coxph call using a model formula.

Usage
agreg.fit(x, y, strata, offset, init, control, weights, method, rownames, resid=TRUE)
coxph.fit(x, y, strata, offset, init, control, weights, method, rownames, resid=TRUE)

Arguments
- **x**: Matrix of predictors. This should not include an intercept.
- **y**: a Surv object containing either 2 columns (coxph.fit) or 3 columns (agreg.fit).
- **strata**: a vector containing the stratification, or NULL
- **offset**: optional offset vector
- **init**: initial values for the coefficients
- **control**: the result of a call to coxph.control
- **weights**: optional vector of weights
- **method**: method for handling ties, one of "breslow" or "efron"
- **rownames**: this is only needed for a NULL model, in which case it contains the rownames (if any) of the original data.
- **resid**: compute and return residuals.

Details
This routine does no checking that arguments are the proper length or type. Only use it if you know what you are doing!

The resid and concordance arguments will save some compute time for calling routines that only need the likelihood, the generation of a permutation distribution for instance.

Value
a list containing results of the fit

Author(s)
Terry Therneau

coxph
**aml**  
*Acute Myelogenous Leukemia survival data*

**Description**  
Survival in patients with Acute Myelogenous Leukemia. The question at the time was whether the standard course of chemotherapy should be extended (‘maintainance’) for additional cycles.

**Usage**

```r
aml
leukemia
```

**Format**

- **time**: survival or censoring time
- **status**: censoring status
- **x**: maintenance chemotherapy given? (factor)

**Source**

---

**anova.coxph**  
*Analysis of Deviance for a Cox model.*

**Description**

Compute an analysis of deviance table for one or more Cox model fits.

**Usage**

```r
# S3 method for class 'coxph'
anova(object, ..., test = 'Chisq')
```

**Arguments**

- **object**: An object of class `coxph`
- **...**: Further `coxph` objects
- **test**: a character string. The appropriate test is a chisquare, all other choices result in no test being done.
Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model log-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of partial-likelihood values does not make sense, and anova will refuse to print results. If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models by anova or will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

See Also

coxph, anova.

Examples

```r
fit <- coxph(Surv(futime, fustat) ~ resid.ds * rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds + rx + ecog.ps, data=ovarian)
anova(fit2, fit)
```

attrassign

Create new-style "assign" attribute

Description

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

Usage

```r
## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm'
attrassign(object,...)
```
Arguments

- **object**: model matrix or linear model object
- **tt**: terms object
- **...**: ignored

Details

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact form for `assign`, a vector (0, 1, 2, 3, 3, 3); which can be read as “the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3”.

The alternate (S-Plus default) form is a list

```
$(Intercept) 1
$age 2
$sex 3
$factor(ph.ecog) 4 5 6
```

Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

See Also

- `terms`
- `model.matrix`

Examples

```r
formula <- Surv(time, status) ~ factor(ph.ecog)
tt <- terms(formula)
mf <- model.frame(tt, data = lung)
mm <- model.matrix(tt, mf)
## a few rows of data
mm[1:3,]
## old-style assign attribute
attr(mm, "assign")
## alternate style assign attribute
attrassign(mm, tt)
```
basehaz

Alias for the survfit function

Description

Compute the predicted survival curve for a Cox model.

Usage

basehaz(fit, centered=TRUE)

Arguments

fit a coxph fit
centered if TRUE return data from a predicted survival curve at the mean values of the covariates fit$mean, if FALSE return a prediction for all covariates equal to zero.

Details

This function is simply an alias for survfit, which does the actual work and has a richer set of options. The alias exists only because some users look for predicted survival estimates under this name.

The function returns a data frame containing the time, cumhaz and optionally the strata (if the fitted Cox model used a strata statement), which are copied the survfit result. If there are factor variables in the model, then the default predictions at the "mean" are meaningless since they do not correspond to any possible subject; correct results require use of the newdata argument of survfit. Results for all covariates =0 are normally only of use as a building block for further calculations.

Value

a data frame with variable names of hazard, time and optionally strata. The first is actually the cumulative hazard.

See Also

survfit.coxph

bladder

Bladder Cancer Recurrences
**Description**

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo, and only the first four recurrences for any patient. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects: all those with follow-up beyond their 4th recurrence. This “follow-up” is a side effect of throwing away all events after the fourth while retaining the last follow-up time variable from the original data. The bladder2 data set found here does not make this mistake, but some analyses in the literature have done so; it results in the addition of a small amount of immortal time bias and shrinks the fitted coefficients towards zero.

Source

cch  Fits proportional hazards regression model to case-cohort data

Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

Usage

cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size, method =c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"), robust=FALSE)

Arguments

formula A formula object that must have a Surv object as the response. The Surv object must be of type "right", or of type "counting".
subcoh Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If data is a data frame then subcoh may be a one-sided formula.
id Vector of unique identifiers, or formula specifying such a vector.
stratum A vector of stratum indicators or a formula specifying such a vector
cohort.size Vector with size of each stratum original cohort from which subcohort was sampled
data An optional data frame in which to interpret the variables occurring in the formula.
method Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".
robust For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I
Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The data argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

ccoef
regression coefficients.

naive.var
Self-Prentice model based variance-covariance matrix.

var
Lin-Ying empirical variance-covariance matrix.

cgd  Chronic Granulotamous Disease data

Description

Data are from a placebo controlled trial of gamma interferon in chronic granulotomous disease (CGD). Contains the data on time to serious infections observed through end of study for each patient.

Usage

cgd

Format

  id  subject identification number

  center  enrolling center
random date of randomization
treatment placebo or gamma interferon
sex sex
age age in years, at study entry
height height in cm at study entry
weight weight in kg at study entry
inherit pattern of inheritance
steroids use of steroids at study entry, 1=yes
propylac use of prophylactic antibiotics at study entry
hos.cat a categorization of the centers into 4 groups
tstart, tstop start and end of each time interval
status 1 = the interval ends with an infection
enum observation number within subject

Details

The cgdθ data set is in the form found in the references, with one line per patient and no recoding of the variables. The cgd data set (this one) has been cast into (start, stop] format with one line per event, and covariates such as center recoded as factors to include meaningful labels.

cipoisson

Confidence limits for the Poisson

Description

Confidence interval calculation for Poisson rates.

Usage

cipoisson(k, time = 1, p = 0.95, method = c("exact", "anscombe"))

Arguments

k  Number of successes
time  Total time on trial
p  Probability level for the (two-sided) interval
method  The method for computing the interval.
Details

The likelihood method is based on equation 10.10 of Feller, which relates poisson probabilities to tail area of the gamma distribution. The Anscombe approximation is based on the fact that \( \sqrt{k + 3/8} \) has a nearly constant variance of \( 1/4 \), along with a continuity correction.

There are many other proposed intervals: Patil and Kulkarni list and evaluate 19 different suggestions from the literature. The exact intervals can be overly broad for very small values of \( k \), many of the other approaches try to shrink the lengths, with varying success.

Value

a vector, matrix, or array. If both \( k \) and \( time \) are single values the result is a vector of length 2 containing the lower an upper limits. If either or both are vectors the result is a matrix with two columns. If \( k \) is a matrix or array, the result will be an array with one more dimension; in this case the dimensions and dimnames (if any) of \( k \) are preserved.

clogit

Conditional logistic regression

Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form case.status~exposure+strata(matched.set). The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.
Usage

clogit(formula, data, weights, subset, na.action,
    method=c("exact", "approximate", "efron", "breslow"),
    ...)  

Arguments

  formula  Model formula
  data     data frame
  weights  optional, names the variable containing case weights
  subset   optional, subset the data
  na.action optional na.action argument. By default the global option na.action is used.
  method   use the correct (exact) calculation in the conditional likelihood or one of the approximations
  ...      optional arguments, which will be passed to coxph.control

Details

It turns out that the loglikelihood for a conditional logistic regression model = \loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this 'trick' rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is 20!/(10! 10!) = 184756 terms. Gail et al describe a fast recursion method which partly ameliorates this; it was incorporated into version 2.36-11 of the survival package. The computation remains infeasible for very large groups of ties, say 100 ties out of 500 subjects, and may even lead to integer overflow for the subscripts – in this latter case the routine will refuse to undertake the task. The Efron approximation is normally a sufficiently accurate substitute.

Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, in which case all of the approximations for ties lead to exactly the same result. The 'approximate' option maps to the Breslow approximation for the Cox model, for historical reasons.

Case weights are not allowed when the exact option is used, as the likelihood is not defined for fractional weights. Even with integer case weights it is not clear how they should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine in this case.

Value

An object of class "clogit", which is a wrapper for a "coxph" object.

## Not run: clogit(case ~ spontaneous + induced + strata(stratum), data=infert)

# A multinomial response recoded to use clogit
# The revised data set has one copy per possible outcome level, with new
# variable tocc = target occupation for this copy, and case = whether
# that is the actual outcome for each subject.
# See the reference below for the data.
resp <- levels(logan$occupation)
N <- nrow(logan)
indx <- rep(1:N, length(resp))
logan2 <- data.frame(logan[indx,],
                    id = indx,
                    tocc = factor(rep(resp, each=N)))
logan2$case <- (logan2$occupation == logan2$tocc)
clogit(case ~ tocc + tocc:education + strata(id), logan2)

cluster

Identify clusters.

Description

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. This style is now discouraged, use the cluster option instead.

Usage

ccluster(x)

Arguments

x

A character, factor, or numeric variable.

Details

The function's only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the "working independence" variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don't mix.
Value

See Also

coxph, survreg

Examples

marginal.model <- coxph(Surv(time, status) ~ rx, data= rats, cluster=litter, subset=(sex=='f'))
frailty.model <- coxph(Surv(time, status) ~ rx + frailty(litter), rats, subset=(sex=='f'))

Description

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death.

Usage

colon

Format

id: id
study: 1 for all patients
rx: Treatment - Observation, Lev(amisole), Lev(amisole)+5-FU
sex: 1=male
age: in years
obstruct: obstruction of colon by tumour
perfor: perforation of colon
adhere: adherence to nearby organs
nodes: number of lymph nodes with detectable cancer
time: days until event or censoring
status: censoring status
differ: differentiation of tumour (1=well, 2=moderate, 3=poor)
extent: Extent of local spread (1=submucosa, 2=muscle, 3=serosa, 4=contiguous structures)
surg: time from surgery to registration (0=short, 1=long)
node4: more than 4 positive lymph nodes
etype: event type: 1=recurrence, 2=death
Note
The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).
Peter Higgins has pointed out a data inconsistency, revealed by `table(colon$nodes, colon$node4)`. We don’t know which of the two variables is actually correct so have elected not to ‘fix’ it. (Real data has warts, why not have some in the example data too?)

References

concordance

Compute the concordance statistic for data or a model

Description
The concordance statistic compute the agreement between an observed response and a predictor. It is closely related to Kendall’s tau-a and tau-b, Goodman’s gamma, and Somers’ d, all of which can also be calculated from the results of this function.

Usage
concordance(object, ...) # S3 method for class 'formula'
concordance(object, data, weights, subset, na.action, cluster, ymin, ymax, timewt= c("n", "S", "S/G", "n/G", "n/G2", "I"), influence=0, ranks = FALSE, reverse=FALSE, timefix=TRUE, keepstrata=10, ...)
concordance(object, ..., newdata, cluster, ymin, ymax, influence=0, ranks=FALSE, timefix=TRUE, keepstrata=10)
concordance(object, ..., newdata, cluster, ymin, ymax, timewt= c("n", "S", "S/G", "n/G", "n/G2", "I"), influence=0, ranks=FALSE, timefix=FALSE, keepstrata=10)
# S3 method for class 'survreg'
concordance(object, ..., newdata, cluster, ymin, ymax,
  timewt= c("n", "S", "S/G", "n/G", "n/G2", "I"), influence=0,
  ranks=FALSE, timefix=FALSE, keepstrata=10)

Arguments

object  a fitted model or a formula. The formula should be of the form y ~ x or y ~ x + strata(z) with a single numeric or survival response and a single predictor. Counts of concordant, discordant and tied pairs are computed separately per stratum, and then added.
data  a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument. Only applicable if object is a formula.
weights  optional vector of case weights. Only applicable if object is a formula.
subset  expression indicating which subset of the rows of data should be used in the fit. Only applicable if object is a formula.
na.action  a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action. Only applicable if object is a formula.
...  multiple fitted models are allowed. Only applicable if object is a model object.
newdata  optional, a new data frame in which to evaluate (but not refit) the models
cluster  optional grouping vector for calculating the robust variance
ymin, ymax  compute the concordance over the restricted range ymin <= y <= ymax. (For survival data this is a time range.)
timewt  the weighting to be applied. The overall statistic is a weighted mean over event times.
influence  1= return the dfbeta vector, 2= return the full influence matrix, 3 = return both
ranks  if TRUE, return a data frame containing the individual ranks that make up the overall score.
reverse  if TRUE then assume that larger x values predict smaller response values y; a proportional hazards model is the common example of this.
timefix  if the response is a Surv object, correct for possible rounding error; otherwise this argument has no effect. See the vignette on tied times for more explanation. For the coxph and survreg methods this issue will have already been addressed in the parent routine, so should not be revisited.
keepstrata  either TRUE, FALSE, or an integer value. Computations are always done within stratum, then added. If the total number of strata greater than keepstrata, or keepstrata=FALSE, those subtotals are not kept in the output.

Details

At each event time, compute the rank of the subject who had the event as compared to all others with a longer survival, where the rank is value between 0 and 1. The concordance is a weighted mean of these values, determined by the timewt option. For uncensored data each unique response value is compared to all those which are larger.

Using the default value for timewt, this gives the area under the receiver operating curve (AUC) for a binary response, Harrell’s c-statistic when the response is a survival time, and (d+1)/2 when y is continuous, where d is Somers’ d.
When the number of strata is very large, such as in a conditional logistic regression for instance (clogit function), a much faster computation is available when the individual strata results are not retained. In the more general case the keepstrata = 10 default simply keeps the printout manageable.

Value

An object of class concordance containing the following components:

- **concordance**: the estimated concordance value or values
- **count**: a vector containing the number of concordant pairs, discordant, tied on x but not y, tied on y but not x, and tied on both x and y
- **n**: the number of observations
- **var**: a vector containing the estimated variance of the concordance based on the infinitesimal jackknife (IJ) method. If there are multiple models it contains the estimated variance/covariance matrix.
- **cvar**: a vector containing the estimated variance(s) of the concordance values, based on the variance formula for the associated score test from a proportional hazards model. (This was the primary variance used in the survConcordance function.)
- **dfbeta**: optional, the vector of leverage estimates for the concordance
- **influence**: optional, the matrix of leverage values for each of the counts, one row per observation
- **ranks**: optional, a data frame containing the Somers’ d rank at each event time, along with the time weight, case weight of the observation with an event, and variance (contribution to the proportional hazards model information matrix). A weighted mean of the ranks equals Somer’s d.

coxph

Examples

```r
fit1 <- coxph(Surv(ptime, pstat) ~ age + sex + mspike, mgus2)
concordance(fit1, timewt="n")
# logistic regression
fit2 <- glm(pstat ~ age + sex + mspike, binomial, data= mgus2)
concordance(fit2)  # equal to the AUC
```
Description

This is the working routine behind the concordance function. It is not meant to be called by users, but is available for other packages to use. Input arguments, for instance, are assumed to all be the correct length and type, and missing values are not allowed: the calling routine is responsible for these things.

Usage

concordancefit(y, x, strata, weights, ymin = NULL, ymax = NULL, timewt = c("n", "S", "S/G", "n/G", "n/G2", "I"), cluster, influence = 0, ranks = FALSE, reverse = FALSE, timefix = TRUE, keepstrata=10)

Arguments

y
  the response. It can be numeric, factor, or a Surv object
x
  the predictor, a numeric vector
strata
  optional numeric vector that stratifies the data
weights
  options vector of case weights
ymin, ymax
  restrict the comparison to response values in this range
timewt
  the time weighting to be used
cluster, influence, ranks, reverse, timefix
  see the help for the concordance function
keepstrata
  either TRUE, FALSE, or an integer value. Computations are always done within stratum, then added. If the total number of strata greater than keepstrata, or keepstrata=FALSE, those subtotals are not kept in the output.

Value

a list containing the results

Author(s)

Terry Therneau

See Also

concordance
Description

Test the proportional hazards assumption for a Cox regression model fit (coxph).

Usage

```r
cox.zph(fit, transform="km", terms=TRUE, singledf=FALSE, global=TRUE)
```

Arguments

- `fit`: the result of fitting a Cox regression model, using the `coxph` or `coxme` functions.
- `transform`: a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument.
- `terms`: if TRUE, do a test for each term in the model rather than for each separate covariate. For a factor variable with k levels, for instance, this would lead to a k-1 degree of freedom test. The plot for such variables will be a single curve evaluating the linear predictor over time.
- `singedf`: use a single degree of freedom test for terms that have multiple coefficients, i.e., the test that corresponds most closely to the plot. If `terms=FALSE` this argument has no effect.
- `global`: should a global chi-square test be done, in addition to the per-variable or per-term tests tests.

Details

The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in coxph. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient $\beta(t)$. If the proportional hazards assumption holds then the true $\beta(t)$ function would be a horizontal line. The table component provides the results of a formal score test for slope=0, a linear fit to the plot would approximate the test.

Random effects terms such a frailty or random effects in a `coxme` model are not checked for proportional hazards, rather they are treated as a fixed offset in model.

If the model contains strata by covariate interactions, then the y matrix may contain structural zeros, i.e., deaths (rows) that had no role in estimation of a given coefficient (column). These are marked as NA. If an entire row is NA, for instance after subscripting a `cox.zph` object, that row is removed.

Value

an object of class "cox.zph", with components:

- `table`: a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain a score test of for addition of the time-dependent term, the degrees of freedom, and the two-sided p-value.
- `x`: the transformed time axis.
time  the untransformed time values; there is one entry for each event time in the data
strata for a stratified coxph model, the stratum of each of the events
y the matrix of scaled Schoenfeld residuals. There will be one column per term
or per variable (depending on the terms option above), and one row per event.
The row labels are a rounded form of the original times.
var a variance matrix for the covariates, used to create an approximate standard error
band for plots
transform the transform of time that was used
call the calling sequence for the routine.

Note
In versions of the package before survival3.0 the function computed a fast approximation to the
score test. Later versions compute the actual score test.

print(temp) # display the results
plot(temp)  # plot curves

coxph  Fit Proportional Hazards Regression Model

Description
Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata,
multiple events per subject, and other extensions are incorporated using the counting process for-
mulation of Andersen and Gill.

Usage
coxph(formula, data=, weights, subset,
na.action, init, control,
ties=c("efron","breslow","exact"),
singular.ok=TRUE, robust,
model=FALSE, x=FALSE, y=TRUE, tt, method=ties,
id, cluster, istate, statedata, ...)
Arguments

**formula**
a formula object, with the response on the left of a ~ operator, and the terms on the right. The response must be a survival object as returned by the `Surv` function.

**data**
a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument.

**weights**
vector of case weights, see the note below. For a thorough discussion of these see the book by Therneau and Grambsch.

**subset**
expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.

**na.action**
a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is `options()`$na.action.

**init**
vector of initial values of the iteration. Default initial value is zero for all variables.

**control**
Object of class `coxph.control` specifying iteration limit and other control options. Default is `coxph.control(...)`.  

**ties**
a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, it is more accurate when dealing with tied death times, and is as efficient computationally. The “exact partial likelihood” is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values. See further below.

**singular.ok**
logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.

**robust**
should a robust variance be computed. The default is TRUE if: there is a cluster argument, there are case weights that are not 0 or 1, or there are id values with more than one event.

**id**
optional variable name that identifies subjects. Only necessary when a subject can have multiple rows in the data, and there is more than one event type. This variable will normally be found in data.

**cluster**
optional variable which clusters the observations, for the purposes of a robust variance. If present, it implies robust. This variable will normally be found in data.

**istate**
optional variable giving the current state at the start each interval. This variable will normally be found in data.

**statedata**
optional data set used to describe multistate models.

**model**
logical value: if TRUE, the model frame is returned in component model.

**x**
logical value: if TRUE, the x matrix is returned in component x.

**y**
logical value: if TRUE, the response vector is returned in component y.

**tt**
optional list of time-transform functions.

**method**
alternate name for the `ties` argument.

**...**
Other arguments will be passed to `coxph.control`
**Details**

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation (start, stop).

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. However, arguments to offset are not scaled since there are situations where a large offset value is purposefully used. In general, however, users should not avoid very large numeric values for an offset due to possible loss of precision in the estimates.

**Value**

An object of class `coxph` representing the fit. See `coxph.object` for details.

**Side Effects**

Depending on the call, the `predict`, `residuals`, and `survfit` routines may need to reconstruct the x matrix created by `coxph`. It is possible for this to fail, as in the example below in which the predict function is unable to find `tform`.

```r
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the `model=TRUE` option to the `coxph` call to obviate the need for reconstruction, at the expense of a larger fit object.

**Case weights**

Case weights are treated as replication weights, i.e., a case weight of 2 is equivalent to having 2 copies of that subject’s observation. When computers were much smaller grouping like subjects together was a common trick to used to conserve memory. Setting all weights to 2 for instance will give the same coefficient estimate but halve the variance. When the Efron approximation for ties (default) is employed replication of the data will not give exactly the same coefficients as the weights option, and in this case the weighted fit is arguably the correct one.

When the model includes a `cluster` term or the `robust=TRUE` option the computed variance treats any weights as sampling weights; setting all weights to 2 will in this case give the same variance as weights of 1.

**Special terms**

There are three special terms that may be used in the model equation. A `strata` term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The `cluster` term is used to compute a robust variance for the model. The term `+ cluster(id)` where each value of `id` is unique is equivalent to specifying the `robust=TRUE` argument. If `id` is not unique, it is assumed that it identifies clusters of correlated observations. The robust estimate arises from many different arguments and thus has had many labels. It is variously known as the Huber sandwich estimator, White’s estimate (linear models/econometrics), the Horvitz-Thompson estimate (survey sampling), the working independence variance (generalized estimating equations), the infinitesimal jackknife, and the Wei, Lin, Weissfeld (WLW) estimate.
A time-transform term allows variables to vary dynamically in time. In this case the tt argument will be a function or a list of functions (if there are more than one tt() term in the model) giving the appropriate transform. See the examples below.

One user mistake that has recently arisen is to slavishly follow the advice of some coding guides and prepend survival:: onto everthing, including the special terms, e.g.,

```r
survival::coxph(survival::Surv(time,status) ~ age +
survival::cluster(inst),data=lung)
```

First, this is unnecessary: arguments within the coxph call will be evaluated within the survival namespace, so another package's Surv or cluster function would not be noticed. (Full qualification of the coxph call itself may be protective, however.) Second, and more importantly, the call just above will not give the correct answer. The specials are recognized by their name, and 'survival::cluster' is not the same as 'cluster'; the above model would treat inst as an ordinary variable. A similar issue arises from using stats::offset as a term, in either survival or glm models.

Convergence

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to exp becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Most often number 1 is the first to occur.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic = coefficient/se(coefficient) is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

Ties

There are three possible choices for handling tied event times. The Breslow approximation is the easiest to program and hence became the first option coded for almost all computer routines. It then ended up as the default option when other options were added in order to "maintain backwards compatibility". The Efron option is more accurate if there are a large number of ties, and it is the default option here. In practice the number of ties is usually small, in which case all the methods are statistically indistinguishable.

Using the "exact partial likelihood" approach the Cox partial likelihood is equivalent to that for matched logistic regression. (The clogit function uses the coxph code to do the fit.) It is technically appropriate when the time scale is discrete and has only a few unique values, and some packages refer to this as the "discrete" option. There is also an "exact marginal likelihood" due to Prentice which is not implemented here.

The calculation of the exact partial likelihood is numerically intense. Say for instance 180 subjects are at risk on day 7 of which 15 had an event; then the code needs to compute sums over all 180-choose-15 > 10^43 different possible subsets of size 15. There is an efficient recursive algorithm for this task, but even with this the computation can be insufferably long. With (start, stop) data it is much worse since the recursion needs to start anew for each unique start time.

A separate issue is that of artificial ties due to floating-point imprecision. See the vignette on this topic for a full explanation or the timefix option in coxph.control. Users may need to add timefix=FALSE for simulated data sets.

Penalized regression

coxph can maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression (ridge), smoothing splines (pspline), and frailty models (frailty).
coxph.control

Ancillary arguments for controlling coxph fits

Description

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to coxph.
coxph.control

Usage

coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75, 
iter.max = 20, toler.inf = sqrt(eps), outer.max = 10, timefix=TRUE)

Arguments

eps
  Iteration continues until the relative change in the log partial likelihood is less
  than eps, or the absolute change is less than sqrt(eps). Must be positive.

toler.chol
  Tolerance for detection of singularity during a Cholesky decomposition of the
  variance matrix, i.e., for detecting a redundant predictor variable.

iter.max
  Maximum number of iterations to attempt for convergence.

toler.inf
  Tolerance criteria for the warning message about a possible infinite coefficient
  value.

outer.max
  For a penalized coxph model, e.g. with pspline terms, there is an outer loop of
  iteration to determine the penalty parameters; maximum number of iterations
  for this outer loop.

timefix
  Resolve any near ties in the time variables.

Details

The convergence tolerances are a balance. Users think they want THE maximum point of the like-
lihood surface, and for well behaved data sets where this is quadratic near the max a high accuracy
is fairly inexpensive: the number of correct digits approximately doubles with each iteration. Con-
versely, a drop of .0001 from the maximum in any given direction will be correspond to only about
1/20 of a standard error change in the coefficient. Statistically, more precision than this is straining
at a gnat. Based on this the author originally had set the tolerance to 1e-5, but relented in the face
of multiple "why is the answer different than package X" queries.

Asking for results that are too close to machine precision (double.eps) is a fool’s errand; a reason-
able criteria is often the square root of that precision. The Cholesky decompostion needs to be held
higher standard than the overall convergence criterion, however. The toler.chol value
controls a warning message; if it is too small incorrect warnings can appear, if too large some actual
cases of an infinite coefficient will not be detected.

The most difficult cases are data sets where the MLE coefficient is infinite; an example is a data
set where at each death time, it was the subject with the largest covariate value who perished. In
that situation the coefficient increases at each iteration while the log-likelihood asymptotes to a
maximum. As iteration proceeds there is a race condition condition for three endpoint: exp(coef)
overflows, the Hessian matrix become singular, or the change in loglik is small enough to satisfy
the convergence criterion. The first two are difficult to anticipate and lead to numeric difficulties,
which is another argument for moderation in the choice of eps.

See the vignette "Roundoff error and tied times" for a more detailed explanation of the timefix
option. In short, when time intervals are created via subtraction then two time intervals that are
actually identical can appear to be different due to floating point round off error, which in turn can
make coxph and survfit results dependent on things such as the order in which operations were
done or the particular computer that they were run on. Such cases are unfortunately not rare in
practice. The timefix=TRUE option adds logic similar to all.equal to ensure reliable results. In
analysis of simulated data sets, however, where often by definition there can be no duplicates, the
option will often need to be set to FALSE to avoid spurious merging of close numeric values.

Value

a list containing the values of each of the above constants
**Description**

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

**Usage**

```r
coxph.detail(object, riskmat=FALSE)
```

**Arguments**

- `object`: a Cox model object, i.e., the result of `coxph`.
- `riskmat`: include the at-risk indicator matrix in the output?

**Details**

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

**Value**

A list with components:

- `time`: the vector of unique event times.
- `nevent`: the number of events at each of these time points.
- `means`: a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights `exp(x %*% fit$coef)`.
- `nrisk`: number of subjects at risk.
- `score`: the contribution to the score vector (first derivative of the log partial likelihood) at each time point.
- `imat`: the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.
- `hazard`: the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses `object$mean` as the future subject.
- `varhaz`: the variance of the hazard increment.
- `x, y`: copies of the input data.
- `strata`: only present for a stratified Cox model, this is a table giving the number of time points of component `time` that were contributed by each of the strata.
- `riskmat`: a matrix with one row for each time and one column for each observation containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point.
See Also

coxph, residuals.coxph

Examples

```r
fit <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
# There is one Schoenfeld residual for each unique death. It is a
# vector (covariates for the subject who died) - (weighted mean covariate
# vector at that time). The weighted mean is defined over the subjects
# still at risk, with exp(X beta) as the weight.

events <- fit$y[,2]==1
etime <- fit$y[events,1]  # the event times --- may have duplicates
indx <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

---

**coxph.object**

*Proportional Hazards Regression Object*

**Description**

This class of objects is returned by the `coxph` class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions `print`, `summary`, `residuals`, `predict` and `survfit`.

**Arguments**

- **coefficients**: the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.
- **var**: the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.
- **naive.var**: this component will be present only if the `robust` option was true. If so, the `var` component will contain the robust estimate of variance, and this component will contain the ordinary estimate.
- **loglik**: a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.
- **score**: value of the efficient score test, at the initial value of the coefficients.
- **rscore**: the robust log-rank statistic, if a robust variance was requested.
- **wald.test**: the Wald test of whether the final coefficients differ from the initial values.
- **iter**: number of iterations used.
- **linear.predictors**: the vector of linear predictors, one per subject. Note that this vector has been centered, see `predict.coxph` for more details.
- **residuals**: the martingale residuals.
- **means**: vector of column means of the X matrix. Subsequent survival curves are adjusted to this value.
- **n**: the number of observations used in the fit.
The objects will also contain the following, for documentation see the \texttt{lm} object: \texttt{terms}, \texttt{assign}, \texttt{formula}, \texttt{call}, and, optionally, \texttt{x}, \texttt{y}, and/or \texttt{frame}.

\section*{Components}

The following components must be included in a legitimate \texttt{coxph} object.

\section*{See Also}

\texttt{coxph, coxph.detail, cox.zph, residuals.coxph, survfit, survreg}.

\texttt{coxph.wtest} \hspace{1cm} \textit{Compute a quadratic form}

\subsection*{Description}

This function is used internally by several survival routines. It computes a simple quadratic form, while properly dealing with missings.

\subsection*{Usage}

\texttt{coxph.wtest(var, b, toler.chol = 1e-09)}

\subsection*{Arguments}

\begin{itemize}
  \item \texttt{var} \hspace{1cm} variance matrix
  \item \texttt{b} \hspace{1cm} vector
  \item \texttt{toler.chol} \hspace{1cm} tolerance for the internal cholesky decomposition
\end{itemize}
Details

Compute $b^T V^{-1} b$. Equivalent to $\text{sum}(b \ast \text{solve}(V,b))$, except for the case of redundant covariates in the original model, which lead to NA values in $V$ and $b$.

Value

a real number

Author(s)

Terry Therneau

---

coxsurv.fit  A direct interface to the ‘computational engine’ of survfit.coxph

Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a ‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

Usage

```r
coxsurv.fit(ctype, stype, se.fit, varmat, cluster, 
y, x, wt, risk, position, strata, oldid, 
y2, x2, risk2, strata2, id2, unlist=TRUE)
```

Arguments

- **stype**: survival curve computation: 1=direct, 2=exp(-cumulative hazard)
- **ctype**: cumulative hazard computation: 1=Breslow, 2=Efron
- **se.fit**: if TRUE, compute standard errors
- **varmat**: the variance matrix of the coefficients
- **cluster**: vector to control robust variance
- **y**: the response variable used in the Cox model. (Missing values removed of course.)
- **x**: covariate matrix used in the Cox model
- **wt**: weight vector for the Cox model. If the model was unweighted use a vector of 1s.
- **risk**: the risk score $\exp(X \beta + \text{offset})$ from the fitted Cox model.
- **position**: optional argument controlling what is counted as ‘censored’. Due to time dependent covariates, for instance, a subject might have start, stop times of (1,5)(5,30)(30,100). Times 5 and 30 are not ‘real’ censorings. Position is 1 for a real start, 2 for an actual end, 3 for both, 0 for neither.
- **strata**: strata variable used in the Cox model. This will be a factor.
- **oldid**: identifier for subjects with multiple rows in the original data.
- **y2, x2, risk2, strata2**: variables for the hypothetical subjects, for which prediction is desired.
optional; if present and not NULL this should be a vector of identifiers of length \( nrow(x2) \). A non-null value signifies that \( x2 \) contains time dependent covariates, in which case this identifies which rows of \( x2 \) go with each subject.

unlist  
if FALSE the result will be a list with one element for each strata. Otherwise the strata are “unpacked” into the form found in a \texttt{survfit} object.

Value 

a list containing nearly all the components of a \texttt{survfit} object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a \texttt{coxph} object), and the class.

Note 
The source code for for both this function and \texttt{survfit.coxph} is written using noweb. For complete documentation see the \texttt{inst/sourcecode.pdf} file.

\texttt{survfit.coxph}

diabetic  
\textit{Ddiabetic retinopathy}

Description 

Partial results from a trial of laser coagulation for the treatment of diabetic retinopathy.

Usage 

data("diabetic")

Format 

A data frame with 394 observations on the following 8 variables.

\begin{verbatim}
id  subject id
laser  laser type: xenon or argon
age  age at diagnosis
eye  a factor with levels of left right
trt  treatment: 0 = no treatment, 1= laser
risk  risk group of 6-12
time  time to event or last follow-up
status  status of 0= censored or 1 = visual loss
\end{verbatim}
Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are therefore the actual time to blindness in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

References

Huster, Brookmeyer and Self, Biometrics, 1989.

Examples

```r
# juvenile diabetes is defined as and age less than 20
juvenile <- 1*(diabetic$age < 20)
coxph(Surv(time, status) ~ trt + juvenile, cluster= id, 
    data= diabetic)
```

```

dsurvreg

Distributions available in survreg.

Description

Density, cumulative distribution function, quantile function and random generation for the set of distributions supported by the `survreg` function.

Usage

dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qusurfreg(p, mean, scale=1, distribution='weibull', parms)
rsurvreg(n, mean, scale=1, distribution='weibull', parms)

Arguments

x vector of quantiles. Missing values (NAs) are allowed.
q vector of quantiles. Missing values (NAs) are allowed.
p vector of probabilities. Missing values (NAs) are allowed.
n number of random deviates to produce
mean vector of linear predictors for the model. This is replicated to be the same length as p, q or n.
scale vector of (positive) scale factors. This is replicated to be the same length as p, q or n.
distribution character string giving the name of the distribution. This must be one of the elements of survreg.distributions
parms optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.
Details

Elements of q or p that are missing will cause the corresponding elements of the result to be missing.

The location and scale values are as they would be for survreg. The label "mean" was an unfortunate choice (made in mimicry of qnorm); since almost none of these distributions are symmetric it will not actually be a mean, but corresponds instead to the linear predictor of a fitted model. Translation to the usual parameterization found in a textbook is not always obvious. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting \( F(t) = 1 - \exp[-(at)^p] \) be the cumulative distribution of the Weibull using a standard parameterization in terms of \( a \) and \( p \), the survreg location corresponds to \(-\log(a)\) and the scale to \(1/p\) (Kalbfleisch and Prentice, section 2.2.2).

Value
density (dsurvreg), probability (psurvreg), quantile (qsurvreg), or for the requested distribution with mean and scale parameters mean and sd.

# Hazard function for a Weibull distribution
x <- seq(.1, 3, length=30)
haz <- dsurvreg(x, 2, 3)/(1-psurvreg(x, 2, 3))
```

```
## Not run:
plot(x, haz, log='xy', ylab="Hazard") #line with slope (1/scale -1)
```

```r
```

Description

The Fine-Gray model can be fit by first creating a special data set, and then fitting a weighted Cox model to the result. This routine creates the data set.
Usage

finegray(formula, data, weights, subset, na.action= na.pass, etype, prefix="fg", count, id, timefix=TRUE)

Arguments

- **formula**: a standard model formula, with survival on the left and covariates on the right.
- **data**: an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model.
- **weights**: optional vector of observation weights
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options.
- **etype**: the event type for which a data set will be generated. The default is to use whichever is listed first in the multi-state survival object.
- **prefix**: the routine will add 4 variables to the data set: a start and end time for each interval, status, and a weight for the interval. The default names of these are "fgstart", "fgstop", "fgstatus", and "fgwt"; the prefix argument determines the initial portion of the new names.
- **count**: a variable name in the output data set for an optional variable that will contain the the replication count for each row of the input data. If a row is expanded into multiple lines it will contain 1, 2, etc.
- **id**: optional, the variable name in the data set which identifies subjects.
- **timefix**: process times through the aeqSurv function to eliminate potential roundoff issues.

Details

The function expects a multi-state survival expression or variable as the left hand side of the formula, e.g. `Surv(atime, astat)` where `astat` is a factor whose first level represents censoring and remaining levels are states. The output data set will contain simple survival data (status = 0 or 1) for a single endpoint of interest. In the output data set subjects who did not experience the event of interest become censored subjects whose times are artificially extended over multiple intervals, with a decreasing case weight from interval to interval. The output data set will normally contain many more rows than the input.

Time dependent covariates are allowed, but not (currently) delayed entry. If there are time dependent covariates, e.g., the input data set had `Surv(entry, exit, stat)` as the left hand side, then an `id` statement is required. The program does data checks in this case, and needs to know which rows belong to each subject.

See the competing risks vignette for more details.

Value

- a data frame

Author(s)

- Terry Therneau

adata <- finegray(Surv(etime, event) ~ . + strata(sex),
                 data=mgus2, na.action=na.pass)

flchain

Assay of serum free light chain for 7874 subjects.

Description

This is a stratified random sample containing 1/2 of the subjects from a study of the relationship between serum free light chain (FLC) and mortality. The original sample contains samples on approximately 2/3 of the residents of Olmsted County aged 50 or greater.

Usage

data(flchain)

Format

A data frame with 7874 persons containing the following variables.

age  age in years
sex  F=female, M=male
sample.yr the calendar year in which a blood sample was obtained
kappa serum free light chain, kappa portion
lambda serum free light chain, lambda portion
flc.grp the FLC group for the subject, as used in the original analysis
creatinine serum creatinine
mgus 1 if the subject had been diagnosed with monoclonal gammapathy (MGUS)

futime days from enrollment until death. Note that there are 3 subjects whose sample was obtained on their death date.

death 0=alive at last contact date, 1=dead

chapter for those who died, a grouping of their primary cause of death by chapter headings of the International Code of Diseases ICD-9

Details

In 1995 Dr. Robert Kyle embarked on a study to determine the prevalence of monoclonal gammapathy of undetermined significance (MGUS) in Olmsted County, Minnesota, a condition which is normally only found by chance from a test (serum electrophoresis) which is ordered for other causes. Later work suggested that one component of immunoglobulin production, the serum free light chain, might be a possible marker for immune disregulation. In 2010 Dr. Angela Dispenzieri and colleagues assayed FLC levels on those samples from the original study for which they had patient permission and from which sufficient material remained for further testing. They found that elevated FLC levels were indeed associated with higher death rates.

Patients were recruited when they came to the clinic for other appointments, with a final random sample of those who had not yet had a visit since the study began. An interesting side question is whether there are differences between early, mid, and late recruits.

This data set contains an age and sex stratified random sample that includes 7874 of the original 15759 subjects. The original subject identifiers and dates have been removed to protect patient identity. Subsampling was done to further protect this information.

Source

The primary investigator (A Dispenzieri) and statistician (T Therneau) for the study.

Examples

data(flchain)
age.grp <- cut(flchain$age, c(49,54, 59,64, 69,74,79, 89, 110), labels= paste(c(50,55,60,65,70,75,80,90), c(54,59,64,69,74,79,89,100), sep='-'))
table(flchain$sex, age.grp)
The frailty function allows one to add a simple random effects term to a Cox or survreg model.

### Usage

```r
frailty(x, distribution="gamma", ...)  
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05,  
              method = c("em","aic", "df", "fixed"), ...)  
frailty.gaussian(x, sparse = (nclass > 5), theta, df,  
                 method =c("reml","aic", "df", "fixed"), ...)  
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,  
          method = c("aic", "df", "fixed"), ...)  
```

### Arguments

- **x**: the variable to be entered as a random effect. It is always treated as a factor.
- **distribution**: either the gamma, gaussian or t distribution may be specified. The routines frailty.gamma, frailty.gaussian and frailty.t do the actual work.
- **...**: Arguments for specific distribution, including (but not limited to)
- **sparse**: cutoff for using a sparse coding of the data matrix. If the total number of levels of `x` is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership.
- **theta**: if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies `method="Var fixed"`.
- **df**: if specified, this fixes the degrees of freedom for the random effect. Specifying this implies `method="Var df"`. Only one of `theta` or `df` should be specified.
- **method**: the method used to select a solution for `theta`, the variance of the random effect. The `fixed` corresponds to a user-specified value, and no iteration is done. The `df` selects the variance such that the degrees of freedom for the random effect matches a user specified value. The `aic` method seeks to maximize Akaike’s information criteria $2*(\text{partial likelihood} - \text{df})$. The `em` and `reml` methods are specific to Cox models with gamma and gaussian random effects, respectively. Please see further discussion below.
- **tdf**: the degrees of freedom for the t-distribution.
- **eps**: convergence criteria for the iteration on `theta`. 

---

**Description**

The frailty function allows one to add a simple random effects term to a Cox or survreg model.
frailty

Details

The frailty plugs into the general penalized modeling framework provided by the coxph and survreg routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a gamma frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a gaussian frailty. Both of these are specific to the Cox model. Use of gamma/ml or gaussian/reml with survreg does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as frailty or pspline, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a frailty term implies a mixed effects model and use of a cluster term implies a GEE approach; these cannot be mixed.

The coxme package has superseded this method. It is faster, more stable, and more flexible.

Value

this function is used in the model statement of either coxph or survreg. It’s results are used internally.

is.ratetable  
Verify that an object is of class ratetable.

Description
The function verifies not only the class attribute, but the structure of the object.

Usage
is.ratetable(x, verbose=FALSE)

Arguments
x  
the object to be verified.

verbose  
if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which x fails to be a proper ratetable object.

Details
Rate tables are used by the pyears and survexp functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the verbose option can help in creating a new rate table.

Value
returns TRUE if x is a ratetable, and FALSE or a description if it is not.

See Also
pyears, survexp.

Examples
is.ratetable(survexp.us)  # True
is.ratetable(cancer)  # False

kidney  
Kidney catheter data

Description
Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

Format
levels.Surv

patient: id
time: time
status: event status
age: in years
sex: 1=male, 2=female
disease: disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail: frailty estimate from original paper

Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

Source

Examples

```r
kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time,status) ~ age + sex + disease + frailty(id, dist='gauss'), kidney)
```

---

**levels.Surv**

*Return the states of a multi-state Surv object*

**Description**

For a multi-state Surv object, this will return the names of the states.

**Usage**

```r
## S3 method for class 'Surv'
levels(x)
```

**Arguments**

- `x` a Surv object

**Value**

for a multi-state Surv object, the vector of state names (excluding censoring); or NULL for an ordinary Surv object
Examples

```r
y1 <- Surv(c(1,5, 9, 17,21, 30),
           factor(c(0, 1, 2,1,0,2), 0:2, c("censored", "progression", "death")))
levels(y1)

y2 <- Surv(1:6, rep(0:1, 3))
y2
levels(y2)
```

---

**lines.survfit**

*Add Lines or Points to a Survival Plot*

Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with `plot.survfit`.

Usage

```r
## S3 method for class 'survfit'
lines(x, type="s", pch=3, col=1, lty=1, lwd=1, cex=1, mark.time=FALSE,
      fun, conf.int=FALSE, conf.times, conf.cap=.005, conf.offset=.012,
      conf.type = c("log", "log-log", "plain", "logit", "arcsin"),
      mark, noplot="(s0)", cumhaz= FALSE, ...)

## S3 method for class 'survexp'
lines(x, type="l", ...)

## S3 method for class 'survfit'
points(x, fun, censor=FALSE, col=1, pch, noplot="(s0)", cumhaz=FALSE, ...)
```

Arguments

- `x`: a survival object, generated from the `survfit` or `survexp` functions.
- `type`: the line type, as described in `lines`. The default is a step function for `survfit` objects, and a connected line for `survexp` objects. All other arguments for `lines.survexp` are identical to those for `lines.survfit`.
- `col`, `lty`, `lwd`, `cex`: vectors giving the mark symbol, color, line type, line width and character size for the added curves. Of this set only color is applicable to `points`.
- `pch`: plotting characters for points, in the style of `matplot`, i.e., either a single string of characters of which the first will be used for the first curve, etc; or a vector of characters or integers, one element per curve.
- `mark`: a historical alias for `pch`.
- `censor`: should censoring times be displayed for the `points` function?
- `...`: other graphical parameters
- `mark.time`: controls the labeling of the curves. If `FALSE`, no labeling is done. If `TRUE`, then curves are marked at each censoring time. If `mark.time` is a numeric vector, then curves are marked at the specified time points.
fun
an arbitrary function defining a transformation of the survival curve. For example fun=log is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the log=T option, "event" plots cumulative events (f(y) = 1-y), "cumhaz" plots the cumulative hazard function (f(y) = -log(y)) and "cloglog" creates a complimentary log-log survival plot (f(y) = log(-log(y))) along with log scale for the x-axis.

conf.int
if TRUE, confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot. A numeric value, e.g. conf.int = .90, can be used to

conf.times
optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.

conf.cap
width of the horizontal cap on top of the confidence bars; only used if conf.times is used. A value of 1 is the width of the plot region.

conf.offset
the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve’s bars are offset by this amount from the prior curve’s bars, if it is a vector the values are used directly.

conf.type
One of "plain", "log" (the default), "log-log", "logit", or "none". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve +-k *se(curve), where k is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option bases the intervals on the log hazard or log(-log(survival)), and the logit option on log(survival/(1-survival)).

noplot
for multi-state models, curves with this label will not be plotted. The default corresponds to an unspecified state.

cumhaz
plot the cumulative hazard, rather than the survival or probability in state.

Details
When the survfit function creates a multi-state survival curve the resulting object has class ‘survfitms’. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

Value
a list with components x and y, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

Side Effects
one or more curves are added to the current plot.

**Data from the 1972-78 GSS data used by Logan**

**Description**

Intergenerational occupational mobility data with covariates.

**Usage**

data(logan)

**Format**

A data frame with 838 observations on the following 4 variables.

- `occupation` subject’s occupation, a factor with levels `farm`, `operatives`, `craftsmen`, `sales`, and `professional`
- `focc` father’s occupation
- `education` total years of schooling, 0 to 20
- `race` levels of non-black and black

General Social Survey data, see the web site for detailed information on the variables. [http://www3.norc.org/GSS+Website](http://www3.norc.org/GSS+Website).

**References**

Description

The logLik function for survival models

Usage

```r
## S3 method for class 'coxph'
logLik(object, ...)
## S3 method for class 'survreg'
logLik(object, ...)
```

Arguments

- `object`: the result of a coxph or survreg fit
- `...`: optional arguments for other instances of the method

Details

The logLik function is used by summary functions in R such as AIC. For a Cox model, this method returns the partial likelihood. The number of degrees of freedom (df) used by the fit and the effective number of observations (nobs) are added as attributes. Per Raftery and others, the effective number of observations is the taken to be the number of events in the data set.

For a survreg model the proper value for the effective number of observations is still an open question (at least to this author). For right censored data the approach of logLik.coxph is the most sensible, but for interval censored observations the result is unclear. The code currently does not add a `nobs` attribute.

Value

an object of class logLik

Author(s)

Terry Therneau

logLik
**Description**

Survival in patients with advanced lung cancer from the North Central Cancer Treatment Group. Performance scores rate how well the patient can perform usual daily activities.

**Usage**

- **lun**
- **cancer**

**Format**

- **inst:** Institution code
- **time:** Survival time in days
- **status:** censoring status 1=censored, 2=dead
- **age:** Age in years
- **sex:** Male=1 Female=2
- **ph.ecog:** ECOG performance score as rated by the physician. 0=asymptomatic, 1= symptomomatic but completely ambulatory, 2= in bed <50% of the day, 3= in bed >50% of the day but not bedbound, 4 = bedbound
- **ph.karno:** Karnofsky performance score (bad=0-good=100) rated by physician
- **pat.karno:** Karnofsky performance score as rated by patient
- **meal.cal:** Calories consumed at meals
- **wt.loss:** Weight loss in last six months

**Note**

The use of 1/2 for alive/dead instead of the usual 0/1 is a historical footnote. For data contained on punch cards, IBM 360 Fortran treated blank as a zero, which led to a policy within the section of Biostatistics to never use "0" as a data value since one could not distinguish it from a missing value. The policy became a habit, as is often the case; and the 1/2 coding endured long beyond the demise of punch cards and Fortran.

Description

Natural history of 241 subjects with monoclonal gammopathy of undetermined significance (MGUS).

Usage

\textit{mgus}
\textit{mgus1}

Format

\textit{mgus}: A data frame with 241 observations on the following 12 variables.

- id: subject id
- age: age in years at the detection of MGUS
- sex: male or female
- dxyr: year of diagnosis
- pcdx: for subjects who progress to a plasma cell malignancy
  
  the subtype of malignancy: multiple myeloma (MM) is the most common, followed by amyloidosis (AM), macroglobulinemia (MA), and other lymphoproliferative disorders (LP)
- pctime: days from MGUS until diagnosis of a plasma cell malignancy
- futime: days from diagnosis to last follow-up
- death: 1= follow-up is until death
- alb: albumin level at MGUS diagnosis
- creat: creatinine at MGUS diagnosis
- hgb: hemoglobin at MGUS diagnosis
- mspike: size of the monoclonal protein spike at diagnosis

\textit{mgus1}: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

- start, stop: sequential intervals of time for each subject
- status: =1 if the interval ends in an event
- event: a factor containing the event type: censor, death, or plasma cell malignancy
- enum: event number for each subject: 1 or 2

Details

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about $10^6$ different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undetermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural
history of such subjects. Due to the diligence of the principle investigator 0 subjects have been lost to follow-up.

Three subjects had MGUS detected on the day of death. In data set mgus1 these subjects have the time to MGUS coded as .5 day before the death in order to avoid tied times.

These data sets were updated in Jan 2015 to correct some small errors.

Source

Mayo Clinic data courtesy of Dr. Robert Kyle.

References

Examples

# Create the competing risk curves for time to first of death or PCM
sfit <- survfit(Surv(start, stop, event) ~ sex, mgus1, id=id, subset=(enum==1))
print(sfit) # the order of printout is the order in which they plot

plot(sfit, xscale=365.25, lty=c(2,2,1,1), col=c(1,2,1,2),
     xlab="Years after MGUS detection", ylab="Proportion")
legend(0, .8, c("Death/male", "Death/female", "PCM/male", "PCM/female"),
     lty=c(1,1,2,2), col=c(2,1,2,1), bty='n')

title("Curves for the first of plasma cell malignancy or death")
# The plot shows that males have a higher death rate than females (no
# surprise) but their rates of conversion to PCM are essentially the same.
Details

This is an extension of the study found in the mgus data set, containing enrollment through 1994 and follow-up through 1999.

Source

Mayo Clinic data courtesy of Dr. Robert Kyle. All patient identifiers have been removed, age rounded to the nearest year, and follow-up times rounded to the nearest month.

References

Description

Recreate the model frame of a coxph fit.

Usage

```r
## S3 method for class 'coxph'
model.frame(formula, ...)
```

Arguments

- `formula`: the result of a coxph fit
- `...`: other arguments to `model.frame`

Details

For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like `residual` that need to recreate the data set from a model in order to do further calculations.

Value

the model frame used in the original fit, or a parallel one for new data.
Description
Reconstruct the model matrix for a cox model.

Usage

```r
## S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg =
object$contrasts, ...)
```

Arguments

- `object`: the result of a coxph model
- `data`: optional, a data frame from which to obtain the data
- `contrast.arg`: optional, a contrasts object describing how factors should be coded
- `...`: other possible argument to `model.frame`

Details
When there is a data argument this function differs from most of the other `model.matrix` methods in that the response variable for the original formula is *not* required to be in the data.

If the data frame contains a `terms` attribute then it is assumed to be the result of a call to `model.frame`, otherwise a call to `model.frame` is applied with the data as an argument.

Value
The model matrix for the fit

Author(s)
Terry Therneau

`model.matrix`
```r
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung, 
             x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

### myeloid

**Acute myeloid leukemia**

### Description

This simulated data set is based on a trial in acute myeloid leukemia.

### Format

A data frame with 646 observations on the following 9 variables.

- **id**  subject identifier, 1-646
- **trt**  treatment arm A or B
- **sex**  f=female, m=male
- **futime** time to death or last follow-up
- **death** 1 if futime is a death, 0 for censoring
- **txtime** time to hematropic stem cell transplant
- **crtime** time to complete response
- **rltime** time to relapse of disease

### Details

This data set is used to illustrate multi-state survival curves. The correlation between within-subject event times strongly resembles that from an actual trial, but none of the actual data values are from that source.

### References

### Examples

```r
coxph(Surv(futime, death) ~ trt, data=myeloid)
# See the mstate vignette for a more complete analysis
```
**nafld**

*Non-alcohol fatty liver disease*

**Description**

Data sets containing the data from a population study of non-alcoholic fatty liver disease (NAFLD). Subjects with the condition and a set of matched control subjects were followed forward for metabolic conditions, cardiac endpoints, and death.

**Usage**

nafld1

nafld2

nafld3

**Format**

nafld1 is a data frame with 17549 observations on the following 10 variables.

- **id** subject identifier
- **age** age at entry to the study
- **male** 0=female, 1=male
- **weight** weight in kg
- **height** height in cm
- **bmi** body mass index
- **case.id** the id of the NAFLD case to whom this subject is matched
- **futime** time to death or last follow-up
- **status** 0= alive at last follow-up, 1=dead

nafld2 is a data frame with 400123 observations and 4 variables containing laboratory data

- **id** subject identifier
- **days** days since index date
- **test** the type of value recorded
- **value** the numeric value

nafld3 is a data frame with 34340 observations and 3 variables containing outcomes

- **id** subject identifier
- **days** days since index date
- **event** the endpoint that occurred
Details

The primary reference for the NAFLD study is Allen (2018). The incidence of non-alcoholic fatty liver disease (NAFLD) has been rising rapidly in the last decade and it is now one of the main drivers of hepatology practice Tapper 2018. It is essentially the presence of excess fat in the liver, and parallels the ongoing obesity epidemic. Approximately 20-25% of NAFLD patients will develop the inflammatory state of non-alcoholic steatohepatitis (NASH), leading to fibrosis and eventual end-stage liver disease. NAFLD can be accurately diagnosed by MRI methods, but NASH diagnosis currently requires a biopsy.

The current study constructed a population cohort of all adult NAFLD subjects from 1997 to 2014 along with 4 potential controls for each case. To protect patient confidentiality all time intervals are in days since the index date; none of the dates from the original data were retained. Subject age is their integer age at the index date, and the subject identifier is an arbitrary integer. As a final protection, we include only a 90% random sample of the data. As a consequence analyses results will not exactly match the original paper.

There are 3 data sets: naf1d1 contains baseline data and has one observation per subject, naf1d2 has one observation for each (time dependent) continuous measurement, and naf1d3 has one observation for each yes/no outcome that occurred.

Source

Data obtained from the author.

References

neardate

Find the index of the closest value in data set 2, for each entry in data set one.

Description

A common task in medical work is to find the closest lab value to some index date, for each subject.

Usage

neardate(id1, id2, y1, y2, best = c("after", "prior"), nomatch = NA_integer_)

Arguments

id1 vector of subject identifiers for the index group
id2 vector of identifiers for the reference group
y1 normally a vector of dates for the index group, but any orderable data type is allowed
y2 reference set of dates
best if best='prior' find the index of the first y2 value less than or equal to the target y1 value, for each subject. If best='after' find the first y2 value which is greater than or equal to the target y1 value, for each subject.

nomatch the value to return for items without a match

Details

This routine is closely related to match and to findInterval, the first of which finds exact matches and the second closest matches. This finds the closest matching date within sets of exactly matching identifiers. Closest date matching is often needed in clinical studies. For example data set 1 might contain the subject identifier and the date of some procedure and data set set 2 has the dates and values for laboratory tests, and the query is to find the first test value after the intervention but no closer than 7 days.

The id1 and id2 arguments are similar to match in that we are searching for instances of id1 that will be found in id2, and the result is the same length as id1. However, instead of returning the first match with id2 this routine returns the one that best matches with respect to y1.

The y1 and y2 arguments need not be dates, the function works for any data type such that the expression c(y1,y2) gives a sensible, sortable result. Be careful about matching Date and DateTime values and the impact of time zones, however, see as.POSIXct. If y1 and y2 are not of the same class the user is on their own. Since there exist pairs of unmatched data types where the result could be sensible, the routine will in this case proceed under the assumption that “the user knows what they are doing”. Caveat emptor.

Value

the index of the matching observations in the second data set, or the nomatch value for no successful match

Author(s)

Terry Therneau

nwtco

Data from the National Wilm's Tumor Study

Description

Measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

Usage

nwtco

Format

A data frame with 4028 observations on the following 9 variables.

seqno  id number
instit  Histology from local institution
histol  Histology from central lab
stage  Disease stage
study  study
rel  indicator for relapse
edrel  time to relapse
age  age in months
in.subcohort  Included in the subcohort for the example in the paper

References

Examples

*Mayo Clinic Primary Biliary Cirrhosis Data*

**Description**

This data is from the Mayo Clinic trial in primary biliary cirrhosis (PBC) of the liver conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.
Usage

pbc

Format

age: in years
albumin: serum albumin (g/dl)
alk.phos: alkaline phosphotase (U/liter)
ascites: presence of ascites
ast: aspartate aminotransferase, once called SGOT (U/ml)
bili: serum bilirubin (mg/dl)
chol: serum cholesterol (mg/dl)
copper: urine copper (ug/day)
edema: 0 no edema, 0.5 untreated or successfully treated
       1 edema despite diuretic therapy
hepato: presence of hepatomegaly or enlarged liver
id: case number
platelet: platelet count
protetime: standardised blood clotting time
sex: m/f
spiders: blood vessel malformations in the skin
stage: histologic stage of disease (needs biopsy)
status: status at endpoint, 0/1/2 for censored, transplant, dead
time: number of days between registration and the earlier of death,
       transplantation, or study analysis in July, 1986
trt: 1/2/NA for D-penicillmain, placebo, not randomised
trig: triglycerides (mg/dl)

pbcseq

Description

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.
The primary PBC data set contains only baseline measurements of the laboratory parameters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

Usage

pbc

Format

id: case number
age: in years
sex: m/f
trt: 1/2/NA for D-penicillmain, placebo, not randomised
time: number of days between registration and the earlier of death, transplantation, or study analysis in July, 1986
status: status at endpoint, 0/1/2 for censored, transplant, dead
day: number of days between enrollment and this visit date
all measurements below refer to this date
albumin: serum albumin (mg/dl)
alk.phos: alkaline phosphotase (U/liter)
ascites: presence of ascites
ast: aspartate aminotransferase, once called SGOT (U/ml)
bili: serum bilirunbin (mg/dl)
chol: serum cholesterol (mg/dl)
copper: urine copper (ug/day)
edema: 0 no edema, 0.5 untreated or successfully treated
1 edema despite diuretic therapy
hepato: presence of hepatomegaly or enlarged liver
platelet: platelet count

plot.aareg

Plot an aareg object.

Description

Plot the estimated coefficient function(s) from a fit of Aalen’s additive regression model.

Usage

## S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', ...)

Arguments

x the result of a call to the aareg function
se if TRUE, standard error bands are included on the plot
maxtime upper limit for the x-axis.
type graphical parameter for the type of line, default is "steps".
... other graphical parameters such as line type, color, or axis labels.

Side Effects

A plot is produced on the current graphical device.

References

plot.cox.zph

Graphical Test of Proportional Hazards

Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

Usage

```r
## S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var,
     xlab="Time", ylab, lty=1:2, col=1, lwd=1, ...)
```

Arguments

- `x`: result of the `cox.zph` function.
- `resid`: a logical value, if TRUE the residuals are included on the plot, as well as the smooth fit.
- `se`: a logical value, if TRUE, confidence bands at two standard errors will be added.
- `df`: the degrees of freedom for the fitted natural spline, df=2 leads to a linear fit.
- `nsmo`: number of points to use for the lines
- `var`: the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below.
- `xlab`: label for the x-axis of the plot
- `ylab`: optional label for the y-axis of the plot. If missing a default label is provided. This can be a vector of labels.
- `lty`, `col`, `lwd`: line type, color, and line width for the overlaid curve. Each of these can be a vector of length 2, in which case the second element is used for the confidence interval.
- `...`: additional graphical arguments passed to the `plot` function.

Side Effects

a plot is produced on the current graphics device.

title(main="VA Lung Study")

plot.survfit

Plot method for survfit objects

Description

A plot of survival curves is produced, one curve for each strata. The log=T option does extra work to avoid log(0), and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

Curves are plotted in the same order as they are listed by print (which gives a 1 line summary of each). This will be the order in which col, lty, etc are used.

Usage

## S3 method for class 'survfit'
plot(x, conf.int=, mark.time=FALSE,
pch=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
xlim, ylim, xmax, fun,
xlab="", ylab="", xaxs="r", conf.times, conf.cap=.005,
conf.offset=.012,
conf.type = c("log", "log-log", "plain", "logit", "arcsin"),
mark, noplot="(s0)", cumhaz=FALSE,
firstx, ymin, ...)

Arguments

x an object of class survfit, usually returned by the survfit function.
conf.int determines whether pointwise confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata, using 95% confidence intervals. Alternatively, this can be a numeric value giving the desired confidence level.
mark.time controls the labeling of the curves. If set to FALSE, no labeling is done. If TRUE, then curves are marked at each censoring time. If mark is a numeric vector then curves are marked at the specified time points.
pch vector of characters which will be used to label the curves. The points help file contains examples of the possible marks. A single string such as "abcd" is treated as a vector c("a", "b", "c", "d"). The vector is reused cyclically if it is shorter than the number of curves. If it is present this implies mark.time = TRUE.
col a vector of integers specifying colors for each curve. The default value is 1.
lty a vector of integers specifying line types for each curve. The default value is 1.
\texttt{lwd} a vector of numeric values for line widths. The default value is 1.
\texttt{cex} a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.
\texttt{log} a logical value, if TRUE the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.
\texttt{xscale} a numeric value used like \texttt{yscale} for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.
\texttt{yscale} a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with \texttt{lines(surv.exp(\ldots))}, say, will perform as it did without the \texttt{yscale} argument.
\texttt{xlim, ylim} optional limits for the plotting region.
\texttt{xmax} the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the \texttt{xlim} graphical parameter, warning messages about out of bounds points are not generated.
\texttt{fun} an arbitrary function defining a transformation of the survival curve. For example \texttt{fun=log} is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values), and \texttt{fun=sqrt} would generate a curve on square root scale. Five often used transformations can be specified with a character argument instead: "S" gives the usual survival curve, "log" is the same as using the \texttt{log=T} option, "event" or "F" plots the empirical CDF \( F(t) = 1 - S(t) \) (\( f(y) = 1-y \)), "cumhaz" plots the cumulative hazard function (see details), and "cloglog" creates a complimentary log-log survival plot (\( f(y) = \log(-\log(y)) \) along with log scale for the x-axis). The terms "identity" and "surv" are allowed as synonyms for \texttt{type=\"S\"}. 
\texttt{xlab} label given to the x-axis.
\texttt{ylab} label given to the y-axis.
\texttt{xaxs} either "S" for a survival curve or a standard x axis style as listed in \texttt{par}; "r" (regular) is the R default. Survival curves have historically been displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally. The "S" style is becoming increasingly less common, however.
\texttt{conf.times} optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.
\texttt{conf.cap} width of the horizontal cap on top of the confidence bars; only used if \texttt{conf.times} is used. A value of 1 is the width of the plot region.
\texttt{conf.offset} the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve’s bars are offset by this amount from the prior curve’s bars, if it is a vector the values are used directly.
\texttt{conf.type} One of "plain", "log" (the default), "log-log" or "logit". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals \( \pm k \times \text{se(curve)} \), where \( k \) is determined from \texttt{conf.int}. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log
option bases the intervals on the log hazard or log(-log(survival)), and the logit option on log(survival/(1-survival)).

mark  a historical alias for pch
noplot  for multi-state models, curves with this label will not be plotted. (Also see the istate0 argument in survcheck.)
cumhaz  plot the cumulative hazard rather than the probability in state or survival
ymin  this will normally be given as part of the ylim argument
firstx  this will normally be given as part of the xlim argument.
...  other arguments that will be passed forward to the underlying plot method, such as xlab or ylab.

Details
If the object contains a cumulative hazard curve, then fun = 'cumhaz' will plot that curve, otherwise it will plot -log(S) as an approximation. Theoretically, S = \log(-\Lambda) where S is the survival and \Lambda is the cumulative hazard. The same relationship holds for estimates of S and \Lambda only in special cases, but the approximation is often close.

When the survfit function creates a multi-state survival curve the resulting object also has class 'survfitms'. Competing risk curves are a common case. In this situation the fun argument is ignored.

When the conf.times argument is used, the confidence bars are offset by conf.offset units to avoid overlap. The bar on each curve are the confidence interval for the time point at which the bar is drawn, i.e., different time points for each curve. If curves are steep at that point, the visual impact can sometimes substantially differ for positive and negative values of conf.offset.

Value
a list with components x and y, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

Note
In prior versions the behavior of xscale and yscale differed: the first changed the scale both for the plot and for all subsequent actions such as adding a legend, whereas yscale affected only the axis label. This was normalized in version 2-36.4, and both parameters now only affect the labeling.

title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsv2, lty=2:3, fun="cumhaz",
xlab="Months", ylab="Cumulative Hazard")
Description

Compute fitted values and regression terms for a model fitted by `coxph`

Usage

```r
## S3 method for class 'coxph'
predict(object, newdata,
    type=c("lp", "risk", "expected", "terms", "survival"),
    se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
    reference=c("strata", "sample"), ...)
```

Arguments

- `object`: the results of a coxph fit.
- `newdata`: Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit. When coxph has been called with a formula argument created in another context, i.e., coxph has been called within another function and the formula was passed as an argument to that function, there can be problems finding the data set. See the note below.
- `type`: the type of predicted value. Choices are the linear predictor ("lp"), the risk score \( \exp(lp) \) ("risk"), the expected number of events given the covariates and follow-up time ("expected"), and the terms of the linear predictor ("terms"). The survival probability for a subject is equal to \( \exp(-expected) \).
- `se.fit`: if TRUE, pointwise standard errors are produced for the predictions.
- `na.action`: applies only when the `newdata` argument is present, and defines the missing value action for the new data. The default is to include all observations. When there is no newdata, then the behavior of missing is dictated by the `na.action` option of the original fit.
- `terms`: if type="terms", this argument can be used to specify which terms should be included; the default is all.
- `collapse`: optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation.
- `reference`: reference for centering predictions, see details below
- `...`: For future methods

Details

The Cox model is a relative risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The primary underlying reason is statistical: a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Using the `reference="strata"` option causes this to be true for predictions as well. (There have been occasional requests for `reference="zero"`, i.e., a hypothetical subject with
all covariates equal to zero, in order to match certain other packages’ results. The issue is that the results are often silly, e.g., risk relative to a subject with height, weight, or blood pressure of zero.) When the results of predict are used in further calculations it may be desirable to use a fixed reference level. Use of reference="sample" will use the overall means, and agrees with the linear.predictors component of the coxph object (which uses the overall mean for backwards compatibility with older code). Predictions of type="terms" are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference. Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the reference option has no effect on these. These values depend on the follow-up time for the future subjects as well as covariates so the newdata argument needs to include both the right and left hand side variables from the formula. (The status variable will not be used, but is required since the underlying code needs to reconstruct the entire formula.) Models that contain a frailty term are a special case: due to the technical difficulty, when there is a newdata argument the predictions will always be for a random effect of zero.

Value

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the se.fit option is TRUE.

Note

Some predictions can be obtained directly from the coxph object, and for others it is necessary for the routine to have the entirety of the original data set, e.g., for type = terms or if standard errors are requested. This extra information is saved in the coxph object if model=TRUE, if not the original data is reconstructed. If it is known that such residuals will be required overall execution will be slightly faster if the model information is saved.

In some cases the reconstruction can fail. The most common is when coxph has been called inside another function and the formula was passed as one of the arguments to that enclosing function. Another is when the data set has changed between the original call and the time of the prediction call. In each of these the simple solution is to add model=TRUE to the original coxph call.

pzero <- function(fit)
  predict(fit, reference="sample") + sum(coef(fit) * fit$means, na.rm=TRUE)
predict.survreg

Predicted Values for a 'survreg' Object

Description

Predicted values for a survreg object

Usage

## S3 method for class 'survreg'
predict(object, newdata,
type=c("response", "link", "lp", "linear", "terms", "quantile", "uquantile"),
se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)

Arguments

object result of a model fit using the survreg function.
newdata data for prediction. If absent predictions are for the subjects used in the original fit.
type the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical.
se.fit if TRUE, include the standard errors of the prediction in the result.
terms subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.
p vector of percentiles. This is used only for quantile predictions.
na.action applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations.
...

Value

a vector or matrix of predicted values.

Examples

# Draw figure 1 from Escobar and Meeker, 1992.
fit <- survreg(Surv(time, status) ~ age + I(age^2), data=stanford2, dist="lognormal")
with(stanford2, plot(age, time, xlab="Age", ylab="Days", xlim=c(0,65), ylim=c(.1, 10^5), log="y", type="n")
with(stanford2, points(age, time, pch=c(2,4)[status+1], cex=.7))

pred <- predict(fit, newdata=list(age=1:65), type="quantile", p=c(.1, .5, .9))

matlines(1:65, pred, lty=c(2,1,2), col=1)

# Predicted Weibull survival curve for a lung cancer subject with ECOG score of 2
lfit <- survreg(Surv(time, status) ~ ph.ecog, data=lung)

pct <- 1:98/100 # The 100th percentile of predicted survival is at +infinity
ptime <- predict(lfit, newdata=data.frame(ph.ecog=2), type="quantile", p=pct, se=TRUE)

matplot(cbind(ptime$fit, ptime$fit + 2*ptime$se.fit, ptime$fit - 2*ptime$se.fit)/30.5, 1-pct, xlab="Months", ylab="Survival", type='l', lty=c(1,2,2), col=1)

print.aareg

Print an aareg object

Description

Print out a fit of Aalen’s additive regression model

Usage

## S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"), scale=1,...)

Arguments

x the result of a call to the aareg function
maxtime the upper time point to be used in the test for non-zero slope
test the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point.
scale scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10^-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
...

Details

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last ‘tail’ is excluded.
Value

the calling argument is returned.

Side Effects

the results of the fit are displayed.

print.summary.coxph

Print method for summary.coxph objects

Description

Produces a printed summary of a fitted coxph model

Usage

## S3 method for class 'summary.coxph'
print(x, digits=max(getOption("digits") - 3, 3),
      signif.stars = getOption("show.signif.stars"), expand=FALSE, ...)

Arguments

x the result of a call to summary.coxph
digits significant digits to print
signif.stars Show stars to highlight small p-values
expand if the summary is for a multi-state coxph fit, print the results in an expanded format.
... For future methods
print.summary.survexp    Print Survexp Summary

Description
Prints the results of summary.survexp

Usage
## S3 method for class 'summary.survexp'
print(x, digits = max(options()$digits - 4, 3), ...)

Arguments
x an object of class summary.survexp.
digits the number of digits to use in printing the result.
... for future methods

Value
x, with the invisible flag set to prevent further printing.

Author(s)
Terry Therneau

link{summary.survexp}, survexp

# print.summary.survfit  Print Survfit Summary

Description
Prints the result of summary.survfit.

Usage
## S3 method for class 'summary.survfit'
print(x, digits = max(options()$digits-4, 3), ...)

Arguments
x an object of class "summary.survfit", which is the result of the summary.survfit function.
digits the number of digits to use in printing the numbers.
... for future methods
Value

x, with the invisible flag set to prevent printing.

Side Effects

prints the summary created by `summary.survfit`.

See Also

`options`, `print`, `summary.survfit`.

print.survfit

Print a Short Summary of a Survival Curve

Description

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

Usage

```r
## S3 method for class 'survfit'
print(x, scale=1, digits = max(options()$digits - 4,3),
    print.rmean=getOption("survfit.print.rmean"),
    rmean = getOption("survfit.rmean"),...)
```

Arguments

- **x**: the result of a call to the `survfit` function.
- **scale**: a numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, scale=365 would scale the printout to years.
- **digits**: Number of digits to print
- **print.rmean**, **rmean**: Options for computation and display of the restricted mean.
- **...**: for future results

Details

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches to resolve this, which are selected by the `rmean` option. The first is to set the upper limit to a constant, e.g., `rmean=365`. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are "none" (no estimate), "common" and "individual". The "common" option uses the maximum time for all curves in the object as a common upper limit for the auc calculation. For the "individual"options the mean is computed as the area under each curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatibility, as this estimate was the default (only) one in earlier
pspline

Specify a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplification, they refer to the result as a p-spline.

Usage

```r
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
       Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, combine, ...)
```

```r
psplineinverse(x)
```
Arguments

x  for psline: a covariate vector. The function does not apply to factor variables.
    For psplineinverse x will be the result of a pspline call.

df  the desired degrees of freedom. One of the arguments df or theta must be
given, but not both. If df=0, then the AIC = (loglik -df) is used to choose an
"optimal" degrees of freedom. If AIC is chosen, then an optional argument
'caic=T' can be used to specify the corrected AIC of Hurvich et. al.

theta  roughness penalty for the fit. It is a monotone function of the degrees of freedom,
    with theta=1 corresponding to a linear fit and theta=0 to an unconstrained fit of
    nterm degrees of freedom.

nterm  number of splines in the basis

degree  degree of splines

eps  accuracy for df

method  the method for choosing the tuning parameter theta. If theta is given, then
    'fixed' is assumed. If the degrees of freedom is given, then 'df' is assumed.
    If method='aic' then the degrees of freedom is chosen automatically using
    Akaike's information criterion.

...  optional arguments to the control function

Boundary.knots  the spline is linear beyond the boundary knots. These default to the range of the
    data.

intercept  if TRUE, the basis functions include the intercept.

penalty  if FALSE a large number of attributes having to do with penalized fits are ex-
    cluded. This is useful to create a pspline basis matrix for other uses.

combine  an optional vector of increasing integers. If two adjacent values of combine are
    equal, then the corresponding coefficients of the fit are forced to be equal. This
    is useful for monotone fits, see the vignette for more details.

Value

Object of class pspline, coxph.penalty containing the spline basis, with the appropriate attributes
    to be recognized as a penalized term by the coxph or survreg functions.

For psplineinverse the original x vector is reconstructed.

### pyears

<table>
<thead>
<tr>
<th>pyears</th>
<th>Person Years</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

**Usage**

```r
pyears(formula, data, weights, subset, na.action, rmap, ratetable, scale=365.25, expect=c('event', 'pyears'), model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

**Arguments**

- `formula`: a formula object. The response variable will be a vector of follow-up times for each subject, or a `Surv` object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by `+` operators (exactly as in `survfit`), time-dependent grouping variables such as `age` (specified with `tcut`), and optionally a `ratetable` term. This latter matches each subject to his/her expected cohort.
- `data`: a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.
- `weights`: case weights.
- `subset`: expression saying that only a subset of the rows of the data should be used in the fit.
- `na.action`: a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is `options()$na.action`.
- `rmap`: an optional list that maps data set names to the ratetable names. See the details section below.
- `ratetable`: a table of event rates, such as `survexp.uswhite`.
- `scale`: a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.
- `expect`: should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.
- `data.frame`: return a data frame rather than a set of arrays.
- `model, x, y`: If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.
Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```r
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt), ratetable=survexp.us)
```

the natural unit of the ratetable is hazard per day, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The ratetable being used may have different variable names than the user’s data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary(survcsv.us)` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The `sex` variable is not mapped, therefore the code assumes that it exists in `mydata` in the correct format. (Note: for factors such as `sex`, the program will match on any unique abbreviation, ignoring case.)

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that `age` is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0, 2, 10, 25, 100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The `print` routine, therefore, is designed to give only a summary of the table.

Value

A list with components:

- `pyears` an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation.
- `n` an array containing the number of subjects who contribute time to each cell of the `pyears` array.
- `event` an array containing the observed number of events. This will be present only if the response variable is a `Surv` object.
- `expected` an array containing the expected number of events (or person years if `expect` ="pyears"). This will be present only if there was a `ratetable` term.
- `data` if the `data.frame` option was set, a data frame containing the variables `n`, `event`, `pyears` and `event` that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays.
- `offtable` the number of person-years of exposure in the cohort that was not part of any cell in the `pyears` array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table.
- `tcut` whether the call included any time-dependent cutpoints.
- `summary` a summary of the rate-table matching. This is also useful as an error check.
Quantiles from a survfit object

Description

Retrieve quantiles and confidence intervals for them from a survfit object.
Usage

```r
## S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
    tolerance= sqrt(.Machine$double.eps), ...)
## S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
    tolerance= sqrt(.Machine$double.eps), ...)
```

Arguments

- `x`: a result of the `survfit` function
- `probs`: numeric vector of probabilities with values in [0,1]
- `conf.int`: should lower and upper confidence limits be returned?
- `tolerance`: tolerance for checking that the survival curve exactly equals one of the quantiles
- `...`: optional arguments for other methods

Details

The kth quantile for a survival curve \( S(t) \) is the location at which a horizontal line at height \( p=1-k \) intersects the plot of \( S(t) \). Since \( S(t) \) is a step function, it is possible for the curve to have a horizontal segment at exactly 1-k, in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to 1-k, then that quantile is undefined.

In order to be consistent with other quantile functions, the argument `prob` of this function applies to the cumulative distribution function \( F(t) = 1 - S(t) \).

Confidence limits for the values are based on the intersection of the horizontal line at 1-k with the upper and lower limits for the survival curve. Hence confidence limits use the same p-value as was in effect when the curve was created, and will differ depending on the `conf.type` option of `survfit`. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.

When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is \((19/20)(18/19)(17/18) \ldots (10/11) = 10/20\), but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than `tolerance` is considered to be an exact match.

Value

The quantiles will be a vector if the `survfit` object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components `quantile`, `lower`, and `upper`, otherwise it is the vector or matrix of quantiles.

description

Description
Description of the rate tables used by expected survival routines.

Details
A rate table contains event rates per unit time for some particular endpoint. Death rates are the most
common use, the survexp.us table, for instance, contains death rates for the United States by year
of age, sex, and calendar year.
A rate table is structured as a multi-way array with the following attributes:

**dim** the dimensions of the array

**dimnames** a named list of dimnames. The names are used to match user data to the dimensions,
e.g., see the rmap argument in the pyears example. If a dimension is categorical, such as sex
in survexp.us, then the dimname itself is matched against user’s data values. The matching
ignores case and allows abbreviations, e.g., “M”, “Male”, and “m” all successfully match the
survexp.us dimname of sex=c("male","female").

**type** a vector giving the type of each dimension, which will be 1= categorical, 2= continuous, 3=
date, 4= calendar year of a US rate table. If type is 3 or 4, then the corresponding cutpoints
must be one of the calendar date types: Date, POSIXt, date, or chron. This allows the code to
properly match user data to the ratetable. (The published US decennial rate tables’ definition
is that a subject does not begin to experience a new years’ death rate on Jan 1, but rather
on their next birthday. The actual impact of this delay on any given subjects’ calculation is
neglible, but the code has always tried to be correct.)

**cutpoints** a list with one element per dimension. If type=1 then the corresponding list element
should be NULL, otherwise it should be a vector of length dim[i] containing the starting
point of the interval to which the corresponding row/col of the array applies. Cutpoints must
be in the same units as the underlying table, e.g., the survexp.us table contains death rates
per day, so the age cutpoint vector contains age in days while year contains a vector of Dates.
Cutpoints do not need to be evenly spaced: the survexp.us table, for instance, originally had
age divided up as 0-1 days, 1-7 days, 7-28 days, 28 days - 1 year, 2, 3,…119 years. (Changes
in the source of the tables made it difficult to continue splitting out the first year.)
an optional summarization function. If present, it will be called with a numeric matrix that has one column per dimension and one row per observation. The function returns a character string giving a summary of the data. This is used by some routines to print an informative message, and provides one way to inform users of a data mistake, e.g., if the printout states that all subjects are between 0.14 and 0.23 years old it is likely that the user’s age variable was in years when it should have been in days.

dimid optional attribute containing the names of the dimnames. If the dimnames list itself has names, this attribute will be ignored.

ratetableDate Convert date objects to ratetable form

Description

This method converts dates from various forms into the internal form used in ratetable objects.

Usage

ratetableDate(x)

Arguments

x a date. The function currently has methods for Date, date, POSIXt, timeDate, and chron objects.

Details

This function is useful for those who create new ratetables, but is normally invisible to users. It is used internally by the survexp and pyears functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

Value

a numeric vector, the number of days since 1/1/1960.

Author(s)

Terry Therneau

See Also

pyears, survexp
Description

Census data sets for the expected survival and person years functions.

Details

- **survexp.us** total United States population, by age and sex, 1940 to 2012.
- **survexp.usr** United States population, by age, sex and race, 1940 to 2014. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.
- **survexp.mn** total Minnesota population, by age and sex, 1970 to 2013.

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as $-\log(1 - q)/365.25$ where $q$ is the 1 year probability of death as reported in the original tables from the US Census. For age 25 in 1970, for instance, $p = 1 - q$ is is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day for computational convenience.

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard R arrays. See the help page for `ratetable` for details.

All numeric dimensions of a rate table must be in the same units. The `survexp.us` rate table contains daily hazard rates, the age cutpoints are in days, and the calendar year cutpoints are a Date.

Rats

Rat treatment data from Mantel et al.

Description

Rat treatment data from Mantel et al. Three rats were chosen from each of 100 litters, one of which was treated with a drug, and then all followed for tumor incidence.

Usage

- rats

Format
litter: litter number from 1 to 100
rx: treatment, (1=drug, 0=control)
time: time to tumor or last follow-up
status: event status, 1=tumor and 0=censored
sex: male or female

Note
Since only 2/150 of the male rats have a tumor, most analyses use only females (odd numbered litters), e.g. Lee et al.

Source

References

rats2  Rat data from Gail et al.

Description
48 rats were injected with a carcinogen, and then randomized to either drug or placebo. The number of tumors ranges from 0 to 13; all rats were censored at 6 months after randomization.

Usage
rats2

Format
rat: id
trt: treatment, (1=drug, 0=control)
observation: within rat
start: entry time
stop: exit time
status: event status, 1=tumor, 0=censored
reliability

Source

---

reliability  

Reliability data sets

Description

A set of data for simple reliability analyses, taken from the book by Meeker and Escobar.

Details

- **capacitor**: Data from a factorial experiment on the life of glass capacitors as a function of voltage and operating temperature. There were 8 capacitors at each combination of temperature and voltage. Testing at each combination was terminated after the fourth failure.
  - **temperature**: temperature in degrees Celsius
  - **voltage**: applied voltage
  - **time**: time to failure
  - **status**: 1=failed, 0=censored
- **cracks**: Data on the time until the development of cracks in a set of 167 identical turbine parts. The parts were inspected at 8 selected times.
  - **day**: time of inspection
  - **fail**: number of fans found to have cracks, at this inspection
- **Data set genfan**: Time to failure of 70 diesel engine fans.
  - **hours**: hours of service
  - **status**: 1=failure, 0=censored
- **Data set ifluid**: A data frame with two variables describing the time to electrical breakdown of an insulating fluid.
  - **time**: hours to breakdown
  - **voltage**: test voltage in kV
- **Data set imotor**: Breakdown of motor insulation as a function of temperature.
  - **temp**: temperature of the test
  - **time**: time to failure or censoring
  - **status**: 0=censored, 1=failed
- **Data set turbine**: Each of 432 turbine wheels was inspected once to determine whether a crack had developed in the wheel or not.
  - **hours**: time of inspection (100s of hours)
  - **inspected**: number that were inspected
  - **failed**: number that failed
- **Data set valveSeat**: Time to replacement of valve seats for 41 diesel engines. More than one seat may be replaced at a particular service, leading to duplicate times in the data set. The final inspection time for each engine will have status=0.
  - **id**: engine identifier
  - **time**: time of the inspection, in days
  - **status**: 1=replacement occurred, 0= not

survreg(Surv(time, status) ~ temperature + voltage, capacitor)

residuals.coxph  Calculate Residuals for a 'coxph' Fit

Description

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

Usage

## S3 method for class 'coxph'
residuals(object, 
  type=c("martingale", "deviance", "score", "schoenfeld", 
         "dfbeta", "dfbetas", "scaledsch", "partial"), 
  collapse=FALSE, weighted=FALSE, ...)

## S3 method for class 'coxph.null'
residuals(object, 
  type=c("martingale", "deviance", "score", "schoenfeld"), 
  collapse=FALSE, weighted=FALSE, ...)

Arguments

object  an object inheriting from class coxph, representing a fitted Cox regression model. Typically this is the output from the coxph function.

type    character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required.
collapse vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then collapse=c(1,1,1,2,3,3,4,4,4,4) could be used to obtain per subject rather than per observation residuals.
weighted if TRUE and the model was fit with case weights, then the weighted residuals are returned.
...     other unused arguments
Value

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute strata is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the cox.zph function.

The score residuals are each individual’s contribution to the score vector. Two transformations of this are often more useful: dfbeta is the approximate change in the coefficient vector if that observation were dropped, and dfbetas is the approximate change in the coefficients, scaled by the standard error for the coefficients.

NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

fit <- coxph(Surv(start, stop, event) ~ (age + surgery)* transplant,
             data=heart)
 mresid <- resid(fit, collapse=heart$id)

residuals.survreg  Compute Residuals for 'survreg' Objects

Description

This is a method for the function residuals for objects inheriting from class survreg.

Usage

## S3 method for class 'survreg'
residuals(object, type=c("response", "deviance","dfbeta","dfbetas",
                          "working","ldcase","ldresp","ldshape","matrix"), rsigma=TRUE,
collapse=FALSE, weighted=FALSE, ...)
Arguments

- **object**: an object inheriting from class `survreg`.
- **type**: type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", and "matrix".
- **rsigma**: include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).
- **collapse**: optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.
- **weighted**: give weighted residuals? Normally residuals are unweighted.
- **...**: other unused arguments

Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the ith row gives the approximate change in the coefficients due to the addition of subject i. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let $L$ be the log-likelihood, $p$ be the linear predictor $X\beta$, and $s \equiv \log(\sigma)$. Then the 6 columns of the matrix are $L$, $dL/dp$, $\partial^2 L/\partial p^2$, $dL/ds$, $\partial^2 L/\partial s^2$ and $\partial^2 L/\partial p \partial s$. Diagnostics based on these quantities are discussed in the book and article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (ldcase), the response value (ldresp), and the shape.

For a transformed distribution such as the log-normal or Weibull, matrix residuals are based on the log-likelihood of the transformed data log(y). For a monotone function $f$ the density of $f(X)$ is the density of $X$ divided by the derivative of $f$ (the Jacobian), so subtract log(derivative) from each uncensored observation's loglik value in order to match the loglik component of the result. The other columns of the matrix residual are unchanged by the transformation.

```
Description

A trial of laser coagulation as a treatment to delay diabetic retinopathy.

Usage

data("retinopathy")

Format

A data frame with 394 observations on the following 9 variables.

id  numeric subject id
laser type of laser used: xenon argon
eye which eye was treated: right left
age age at diagnosis of diabetes
type type of diabetes: juvenile adult, (diagnosis before age 20)
trt 0 = control eye, 1 = treated eye
futime time to loss of vision or last follow-up
status 0 = censored, 1 = loss of vision in this eye
risk a risk score for the eye. This high risk subset is defined as a score of 6 or greater in at least one eye.

Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment, and has two observations in the data set. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are the actual time to vision loss in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

Examples

coxph(Surv(futime, status) ~ type + trt, cluster= id, retinopathy)
rhDNase  

**rhDNASE data set**

**Description**

Results of a randomized trial of rhDNase for the treatment of cystic fibrosis.

**Format**

A data frame with 767 observations on the following 8 variables.

- id: subject id
- inst: enrolling institution
- trt: treatment arm: 0=placebo, 1= rhDNase
- entry.dt: date of entry into the study
- end.dt: date of last follow-up
- fev: forced expiratory volume at enrollment, a measure of lung capacity
- ivstart: days from enrollment to the start of IV antibiotics
- ivstop: days from enrollment to the cessation of IV antibiotics

**Details**

In patients with cystic fibrosis, extracellular DNA is released by leukocytes that accumulate in the airways in response to chronic bacterial infection. This excess DNA thickens the mucus, which then cannot be cleared from the lung by the cilia. The accumulation leads to exacerbations of respiratory symptoms and progressive deterioration of lung function. At the time of this study more than 90% of cystic fibrosis patients eventually died of lung disease.

Deoxyribonuclease I (DNase I) is a human enzyme normally present in the mucus of human lungs that digests extracellular DNA. Genentech, Inc. cloned a highly purified recombinant DNase I (rhDNase or Pulmozyme) which when delivered to the lungs in an aerosolized form cuts extracellular DNA, reducing the viscoelasticity of airway secretions and improving clearance. In 1992 the company conducted a randomized double-blind trial comparing rhDNase to placebo. Patients were then monitored for pulmonary exacerbations, along with measures of lung volume and flow. The primary endpoint was the time until first pulmonary exacerbation; however, data on all exacerbations were collected for 169 days.

The definition of an exacerbation was an infection that required the use of intravenous (IV) antibiotics. Subjects had 0–5 such episodes during the trial, those with more than one have multiple rows in the data set, those with none have NA for the IV start and end times. A few subjects were infected at the time of enrollment, subject 173 for instance has a first infection interval of -21 to 7. We do not count this first infection as an "event", and the subject first enters the risk set at day 7. Subjects who have an event are not considered to be at risk for another event during the course of antibiotics, nor for an additional 6 days after they end. (If the symptoms reappear immediately after cessation then from a medical standpoint this would not be a new infection.)

This data set reproduces the data in Therneau and Grambsch, is does not exactly reproduce those in Therneau and Hamilton due to data set updates.
ridge

Examples

# Build the start-stop data set for analysis, and
# replicate line 2 of table 8.13
first <- subset(rhDNase, !duplicated(id)) # first row for each subject
dnase <- tmerge(first, first, id=id, tstop=as.numeric(end.dt-entry.dt))

# Subjects whose fu ended during the 6 day window are the reason for
# this next line
temp.end <- with(rhDNase, pmin(ivstop+6, end.dt-entry.dt))
dnase <- tmerge(dnase, rhDNase, id=id,
              infect=event(ivstart),
              end = event(temp.end))
# toss out the non-at-risk intervals, and extra variables
# 3 subjects had an event on their last day of fu, infect=1 and end=1
dnase <- subset(dnase, (infect==1 | end==0), c(id:trt, fev:infect))
agfit <- coxph(Surv(tstart, tstop, infect) ~ trt + fev, cluster=id,
               data=dnase)

ridge

Ridge regression

Description

When used in a coxph or survreg model formula, specifies a ridge regression term. The likelihood is penalized by \( \theta/2 \) time the sum of squared coefficients. If \( \text{scale}=T \) the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If \( \text{df} \) is specified then \( \theta \) is chosen based on an approximate degrees of freedom.

Usage

ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)

Arguments

... predictors to be ridged
theta penalty is \( \theta/2 \) time sum of squared coefficients
df Approximate degrees of freedom
esps Accuracy required for df
scale Scale variables before applying penalty?

Value

An object of class coxph.penalty containing the data and control functions.
Note

If the expression `ridge(x1, x2, x3, ...)` is too many characters long then the internal `terms()` function will add newlines to the variable name and then the `coxph` routine simply gets lost. (Some labels will have the newline and some won’t.) One solution is to bundle all of the variables into a single matrix and use that matrix as the argument to `ridge` so as to shorten the call, e.g. `mdata$many <- as.matrix(mydata[, 5:53])`.

1fit1 <- survreg(Surv(time, status) ~ age + ridge(ph.ecog, theta=5), cancer)
1fit2 <- survreg(Surv(time, status) ~ sex + ridge(age, ph.ecog, theta=1), cancer)
1fit3 <- survreg(Surv(time, status) ~ sex + age + ph.ecog, cancer)
```

solder

Data from a soldering experiment

Description

In 1988 an experiment was designed and implemented at one of AT&T’s factories to investigate alternatives in the “wave soldering” procedure for mounting electronic components to printed circuit boards. The experiment varied a number of factors relevant to the process. The response, measured by eye, is the number of visible solder skips.

Usage

data("solder")

Format

A data frame with 900 observations on the following 6 variables.

- **Opening** the amount of clearance around the mounting pad (3 levels)
- **Solder** the amount of solder (Thick or Thin)
- **Mask** type and thickness of the material used for the solder mask (A1.5, A3, A6, B3, B6)
- **PadType** the geometry and size of the mounting pad (10 levels)
- **Panel** each board was divided into 3 panels
- **skips** the number of skips
Details
This data set is used as a detailed example in chapter 1 of Chambers and Hastie. Observations 1-360 and 541-900 form a balanced design of 3*2*10*3=180 observations for four of the pad types (A1.5, A3, B3, B6), while rows 361-540 match 3 of the 6 Solder*Opening combinations with pad type A6 and the other 3 with pad type A3.

References

Examples
data(solder)
# The balanced subset used by Chambers and Hastie
# contains the first 180 of each mask and deletes mask A6.
index <- 1 + (1:nrow(solder)) - match(solder$Mask, solder$Mask)
solder.balance <- droplevels(subset(solder, Mask != "A6" & index <= 180))

Description
This contains the Stanford Heart Transplant data in a different format. The main data set is in heart.

Usage
stanford2

Format
id: ID number
time: survival or censoring time
status: censoring status
age: in years
t5: T5 mismatch score

Source

predict.survreg, heart
statefig

Draw a state space figure.

Description

For multi-state survival models it is useful to have a figure that shows the states and the possible transitions between them. This function creates a simple "box and arrows" figure. It's goal was simplicity.

Usage

```
statefig(layout, connect, margin = 0.03, box = TRUE, cex = 1, col = 1, lwd=1, lty=1, bcol=col, acol=col, alwd=lwd, alty=lty, offset=0)
```

Arguments

- **layout**: describes the layout of the boxes on the page. See the detailed description below.
- **connect**: a square matrix with one row for each state. If `connect[i,j] != 0` then an arrow is drawn from state i to state j. The row names of the matrix are used as the labels for the states.
- **margin**: the fraction of white space between the label and the surrounding box, and between the box and the arrows, as a function of the plot region size.
- **box**: should boxes be drawn? TRUE or FALSE.
- **cex, col, lty, lwd**: default graphical parameters used for the text and boxes. The last 3 can be a vector of values.
- **bcol**: color for the box, if it differs from that used for the text.
- **acol, alwd, alty**: color, line type and line width for the arrows.
- **offset**: used to slight offset the arrows between two boxes x and y if there is a transition in both directions. The default of 0 leads to a double headed arrow in this case – to arrows are drawn but they coincide. A positive value causes each arrow to shift to the left, from the view of someone standing at the foot of a arrow and looking towards the arrowhead, a negative offset shifts to the right. A value of 1 corresponds to the size of the plotting region.

Details

The arguments for color, line type and line width can all be vectors, in which case they are recycled as needed. Boxes and text are drawn in the order of the rownames of `connect`, and arrows are drawn in the usual R matrix order.

The layout argument is normally a vector of integers, e.g., the vector (1, 3, 2) describes a layout with 3 columns. The first has a single state, the second column has 3 states and the third has 2. The coordinates of the plotting region are 0 to 1 for both x and y. Within a column the centers of the boxes are evenly spaced, with 1/2 a space between the boxes and the margin, e.g., 4 boxes would be at 1/8, 3/8, 5/8 and 7/8. If layout were a 1 column matrix with values of (1, 3, 2) then the layout will have three rows with 1, 3, and 2 boxes per row, respectively. Alternatively, the user can supply a 2 column matrix that directly gives the centers.
The values of the connect matrix should be 0 for pairs of states that do not have a transition and values between 0 and 2 for those that do. States are connected by an arc that passes through the centers of the two boxes and a third point that is between them. Specifically, consider a line segment joining the two centers and erect a second segment at right angles to the midpoint of length $d$ times the distance from center to midpoint. The arc passes through this point. A value of $d=0$ gives a straight line, $d=1$ a right hand half circle centered on the midpoint and $d=-1$ a left hand half circle. The connect matrix contains values of $d+1$ with $-1 < d < 1$.

The connecting arrow are drawn from (center of box 1 + offset) to (center of box 2 + offset), where the the amount of offset (white space) is determined by the box and margin parameters. If a pair of states are too close together this can result in an arrow that points the wrong way.

**Value**

a matrix containing the centers of the boxes, with the invisible attribute set.

**Note**

The goal of this function is to make “good enough” figures as simply as possible, and thereby to encourage users to draw them. The layout argument was inspired by the diagram package, which can draw more complex and well decorated figures, e.g., many different shapes, shading, multiple types of connecting lines, etc., but at the price of greater complexity.

Because curved lines are drawn as a set of short line segments, line types have almost no effect for that case.

**Author(s)**

Terry Therneau

**Examples**

```
# Draw a simple competing risks figure
states <- c("Entry", "Complete response", "Relapse", "Death")
connect <- matrix(0, 4, 4, dimnames=list(states, states))
connect[1, -1] <- c(1.1, 1, 0.9)
statefig(c(1, 3), connect)
```

---

**strata**

*Identify Stratification Variables*

**Description**

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

**Usage**

```
strata(..., na.group=FALSE, shortlabel, sep=' ', '')
```
Arguments

... any number of variables. All must be the same length.

na.group a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.

shortlabel if TRUE omit variable names from resulting factor labels. The default action is to omit the names if all of the arguments are factors, and none of them was named.

sep the character used to separate groups, in the created label

Details

When used outside of a coxph formula the result of the function is essentially identical to the interaction function, though the labels from strata are often more verbose.

Value

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

See Also

coxph, interaction

Examples

a <- factor(rep(1:3,4), labels=c("low", "medium", "high"))
b <- factor(rep(1:4,3))
levels(strata(b))
levels(strata(a,b,shortlabel=TRUE))
coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)

summary.aareg Summarize an aareg fit

Description

Creates the overall test statistics for an Aalen additive regression model

Usage

## S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)

Arguments

object the result of a call to the aareg function

maxtime truncate the input to the model at time "maxtime"

test the relative time weights that will be used to compute the test

scale scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10^-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.

... for future methods
**Details**

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The `maxtime` parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in lieu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.

**Value**

A list is returned with the following components:

- `table`: A matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, its standard error, the z-score and a p-value.
- `test`: The time weighting used for computing the test statistics.
- `test.statistic`: The vector of test statistics.
- `test.var`: The model-based variance matrix for the test statistic.
- `test.var2`: Optionally, a robust variance matrix for the test statistic.
- `chisq`: The overall test (ignoring the intercept term) for significance of any variable.
- `n`: A vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times.

### summary.coxph

**Summary method for Cox models**

**Description**

Produces a summary of a fitted coxph model

**Usage**

```r
## S3 method for class 'coxph'
summary(object, conf.int=0.95, scale=1,...)
```

**Arguments**

- `object`: the result of a coxph fit
- `conf.int`: level for computation of the confidence intervals. If set to FALSE no confidence intervals are printed
- `scale`: vector of scale factors for the coefficients, defaults to 1. The printed coefficients, se, and confidence intervals will be associated with one scale unit.
- `...`: for future methods

**Value**

An object of class `summary.coxph`, with components:

- `n, nevent`: number of observations and number of events, respectively, in the fit
- `loglik`: the log partial likelihood at the initial and final values
- `coefficients`: a matrix with one row for each coefficient, and columns containing the coefficient, the hazard ratio exp(coef), standard error, Wald statistic, and P value.
- `conf.int`: a matrix with one row for each coefficient, containing the confidence limits for exp(coef)
- `logtest, sctest, waldtest`: the overall likelihood ratio, score, and Wald test statistics for the model
- `concordance`: the concordance statistic and its standard error
- `used.robust`: whether an asymptotic or robust variance was used
- `rsq`: an approximate R^2 based on Nagelkerke (Biometrika 1991).
- `fail`: a message, if the underlying coxph call failed
- `call`: a copy of the call
- `na.action`: information on missing values
Note

The pseudo r-squared of Nagelkirke is attractive because it is simple, but further work has shown that it has poor properties and it is now deprecated. The value is no longer printed by default, and will eventually be removed from the object.

See Also

coxph, print.coxph

Examples

```r
fit <- coxph(Surv(time, status) ~ age + sex, lung)
summary(fit)
```

Description

Create a printable table of a person-years result.

Usage

```r
## S3 method for class 'pyears'
summary(object, header = TRUE, call = header, n = TRUE,
event = TRUE, pyears = TRUE, expected = TRUE, rate = FALSE, rr =expected,
ci.r = FALSE, ci.rr = FALSE, totals=FALSE, legend = TRUE, vline = FALSE,
vertical= TRUE, nastring=".", conf.level = 0.95,
scale = 1, ...)```

Arguments

- `object` a pyears object
- `header` print out a header giving the total number of observations, events, person-years, and total time (if any) omitted from the table
- `call` print out a copy of the call
- `n, event, pyyears, expected` logical arguments: should these elements be printed in the table?
- `rate, ci.r` logical arguments: should the incidence rate and/or its confidence interval be given in the table?
- `rr, ci.rr` logical arguments: should the hazard ratio and/or its confidence interval be given in the table?
- `totals` should row and column totals be added?
- `legend` should a legend be included in the printout?
- `vline` should vertical lines be included in the printed tables?
- `vertical` when there is only a single predictor, should the table be printed with the predictor on the left (vertical=TRUE) or across the top (vertical=FALSE)?
nastring: what to use for missing values in the table. Some of these are structural, e.g.,
risk ratios for a cell with no follow-up time.
conf.level: confidence level for any confidence intervals
scale: a scaling factor for printed rates
... optional arguments which will be passed to the format function; common
choices would be digits=2 or nsmall=1.

Details

The pyears function is often used to create initial descriptions of a survival or time-to-event vari-
able; the type of material that is often found in “table 1” of a paper. The summary routine prints
this information out using one of pandoc table styles. A primary reason for choosing this style is
that Rstudio is then able to automatically render the results in multiple formats: html, rtf, latex, etc.
If the pyears call has only a single covariate then the table will have that covariate as one margin
and the statistics of interest as the other. If the pyears call has two predictors then those two
predictors are used as margins of the table, while each cell of the table contains the statistics of
interest as multiple rows within the cell. If there are more than two predictors then multiple tables
are produced, in the same order as the standard R printout for an array.
The "N" entry of a pyears object is the number of observations which contributed to a particular cell.
When the original call includes tcut objects then a single observation may contribute to multiple
cells.

Value

a copy of the object

Notes

The pandoc system has four table types: with or without vertical bars, and with single or multiple
rows of data in each cell. This routine produces all 4 styles depending on options, but currently not
all of them are recognized by the Rstudio-pandoc pipeline. (And we don’t yet see why.)

cipoisson, pyears, format

summary.survexp

Summary function for a survexp object

Description

Returns a list containing the values of the survival at specified times.

Usage

## S3 method for class 'survexp'
summary(object, times, scale = 1, ...)

Arguments

- **object**: the result of a call to the `survexp` function
- **times**: vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed.
- **scale**: numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, `scale = 365.25` would scale the output to years.
- **...**: For future methods

Details

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

Value

A list with the following components:

- **surv**: the estimate of survival at time t.
- **time**: the timepoints on the curve.
- **n.risk**: In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation.

Author(s)

Terry Therneau

- `survexp`

---

**summary.survfit**  
*Summary of a Survival Curve*

Description

Returns a list containing the survival curve, confidence limits for the curve, and other information.

Usage

```r
## S3 method for class 'survfit'
summary(object, times, censored=FALSE, scale=1,
         extend=FALSE, rmean=getOption('survfit.rmean'), ...)```
Arguments

- **object**: the result of a call to the `survfit` function.
- **times**: vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If `censored=T`, the default `times` vector contains all the unique times in `fit`, otherwise the default `times` vector uses only the event (death) times.
- **censored**: logical value: should the censoring times be included in the output? This is ignored if the `times` argument is present.
- **scale**: numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, `scale = 365.25` would scale the output to years.
- **extend**: logical value: if `TRUE`, prints information for all specified `times`, even if there are no subjects left at the end of the specified `times`. This is only used if the `times` argument is present.
- **rmean**: Show restricted mean: see `print.survfit` for details
- **...**: for future methods

Value

A list with the following components:

- **surv**: the estimate of survival at time t+0.
- **time**: the timepoints on the curve.
- **n.risk**: the number of subjects at risk at time t-0 (but see the comments on weights in the `survfit` help file).
- **n.event**: if the `times` argument is missing, then this column is the number of events that occurred at time t. Otherwise, it is the cumulative number of events that have occurred since the last time listed until time t+0.
- **n.entered**: This is present only for counting process survival data. If the `times` argument is missing, this column is the number of subjects that entered at time t. Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time t.
- **n.exit.censored**: if the `times` argument is missing, this column is the number of subjects that left without an event at time t. Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time t+0. This is only present for counting process survival data.
- **std.err**: the standard error of the survival value.
- **conf.int**: level of confidence for the confidence intervals of survival.
- **lower**: lower confidence limits for the curve.
- **upper**: upper confidence limits for the curve.
- **strata**: indicates stratification of curve estimation. If `strata` is not NULL, there are multiple curves in the result and the `surv`, `time`, `n.risk`, etc. vectors will contain multiple curves, pasted end to end. The levels of `strata` (a factor) are the labels for the curves.
- **call**: the statement used to create the `fit` object.
- **na.action**: same as for `fit`, if present.
- **table**: table of information that is returned from `print.survfit` function.
- **type**: type of data censoring. Passed through from the `fit` object.
**Surv**

**Details**

This routine has two uses: printing out a survival curve at specified time points (often yearly), or extracting the values at specified time points for further processing. In the first case we normally want `extend=FALSE`, i.e., don’t print out data past the end of the curve. If the `times` option only contains values beyond the last point in the curve then there is nothing to print and an error message will result. For the second usage we almost always want `extend=TRUE`, so that the results will have a predictable length.

**See Also**

`survfit`, `print.summary.survfit`

**Examples**

```r
summary( survfit( Surv(futime, fustat)~1, data=ovarian))
summary( survfit( Surv(futime, fustat)~rx, data=ovarian))
```

---

**Surv**

**Create a Survival Object**

**Description**

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

**Usage**

```r
Surv(time, time2, event, type=c("right", "left", "interval", "counting", "interval2", "mstate"), origin=0)
is.Surv(x)
```

**Arguments**

- `time` for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.
- `event` The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. For multiple endpoint data the event variable will be a factor, whose first level is treated as censoring. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event.
- `time2` ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, ([start,end]). For counting process data, event indicates whether an event occurred at the end of the interval.
- `type` character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", "interval2" or "mstate".

---
for counting process data, the hazard function origin. This option was intended
to be used in conjunction with a model containing time dependent strata in order
to align the subjects properly when they cross over from one strata to another,
but it has rarely proven useful.

\( x \)  
any R object.

**Details**

When the type argument is missing the code assumes a type based on the following rules:

- If there are two unnamed arguments, they will match \( \text{time} \) and \( \text{event} \) in that order. If there
  are three unnamed arguments they match \( \text{time} \), \( \text{time2} \) and \( \text{event} \).
- If the event variable is a factor then type \( \text{mstate} \) is assumed. Otherwise type \( \text{right} \) if there is
  no \( \text{time2} \) argument, and type \( \text{counting} \) if there is.

As a consequence the type argument will normally be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level
of the factor is taken to represent censoring and remaining ones a transition to the given state. (If
the status variable is a factor then \( \text{mstate} \) is assumed.)

Interval censored data can be represented in two ways. For the first use \( \text{type = "interval"} \) and the
codes shown above. In that usage the value of the \( \text{time2} \) argument is ignored unless \( \text{event}=3 \).
The second approach is to think of each observation as a time interval with \((-\infty, t) \) for left censored,
\((t, \infty) \) for right censored, \((t_0, t) \) for exact and \((t_1, t_2) \) for an interval. This is the approach used
for type \( = \text{interval2} \). Infinite values can be represented either by actual infinity \((\text{Inf}) \) or NA. The
second form has proven to be the more useful one.

Presently, the only methods allowing interval censored data are the parametric models computed by
\text{survreg} and survival curves computed by \text{survfit}; for both of these, the distinction between open
and closed intervals is unimportant. The distinction is important for counting process data and the
Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for censored data via the condition
\( \text{if (max(status)==2)} \). If 1/2 coding is used and all the subjects are censored, it will
guess wrong. In any questionable case it is safer to use logical coding, e.g., \( \text{Surv(time, status==3)} \)
would indicate that ‘3’ is the code for an event. For multi-state survival the status variable will be a
factor, whose first level is assumed to correspond to censoring.

\text{Surv} objects can be subscripted either as a vector, e.g. \( x[1:3] \) using a single subscript, in which
case the \( \text{drop} \) argument is ignored and the result will be a survival object; or as a matrix by using two
subscripts. If the second subscript is missing and \( \text{drop}=\text{F} \) (the default), the result of the subscripting
will be a \text{Surv} object, e.g., \( x[1:3,,\text{drop=}\text{F}] \), otherwise the result will be a matrix (or vector), in
accordance with the default behavior for subscripting matrices.

**Value**

An object of class \text{Surv}. There are methods for \text{print}, \text{is.na}, and subscripting survival objects.
\text{Surv} objects are implemented as a matrix of 2 or 3 columns that has further attributes. These
include the type (left censored, right censored, counting process, etc.) and labels for the states
for multi-state objects. Any attributes of the input arguments are also preserved in \text{inputAttributes}.
This may be useful for other packages that have attached further information to data items such as
labels; none of the routines in the survival package make use of these values, however.

In the case of \text{is.Surv}, a logical value \text{TRUE} if \( x \) inherits from class "\text{Surv}"; otherwise an \text{FALSE}. 
Note

The use of 1/2 coding for status is an interesting historical artifact. For data contained on punch cards, IBM 360 Fortran treated blank as a zero, which led to a policy within the Mayo Clinic section of Biostatistics to never use "0" as a data value since one could not distinguish it from a missing value. Policy became habit, as is often the case, and the use of 1/2 coding for alive/dead endured long after the demise of the punch cards that had sired the practice. At the time Surv was written many Mayo data sets still used this convention, e.g., the 1994 lung data set found in the package.

tail(x, ...)

## S3 method for class 'Surv'
unique(x, ...)

### Arguments

- **x**: a Surv object
- **probs**: a vector of probabilities
- **na.rm**: remove missing values from the calculation
- **value**: a character vector of up to the same length as x, or NULL
- **...**: other arguments to the method

### Details

These functions extend the standard methods to Surv objects. The arguments and results from these are mostly as expected, with the following further details:

- The `as.character` function uses "5+" for right censored at time 5, "5-" for left censored at time 5, "[2,7]" for an observation that was interval censored between 2 and 7, "(1,6]" for a counting process data denoting an observation which was at risk from time 1 to 6, with an event at time 6, and "(1,6+)" for an observation over the same interval but not ending with and event. For a multi-state survival object the type of event is appended to the event time using ":type".
- The print and format methods make use of `as.character`.
- The `as.numeric` and `as.integer` methods perform these actions on the survival times, but do not affect the censoring indicator.
- The `as.matrix` and `t` methods return a matrix
• The length of a Surv object is the number of survival times it contains, not the number of items required to encode it, e.g., \( x \leftarrow \text{Surv}(1:4, 5:9, c(1, 8, 1, 0)) \); length(x) has a value of 4. Likewise names(x) will be NULL or a vector of length 4. (For technical reasons, any names are actually stored in the rownames attribute of the object.)

• For a multi-state survival object levels returns the names of the endpoints, otherwise it is NULL.

• The median, quantile and plot methods first construct a survival curve using survfit, then apply the appropriate method to that curve.

• The concatenation method c() is asymmetric, its first argument determines the execution path. For instance c(Surv(1:4), Surv(5:6)) will concatenate the two objects, c(Surv(1:4), 5:6) will give an error, and c(5:6, Surv(1:4)) is equivalent to c(5:6, as.vector(Surv(1:4))).

Surv

---

**Surv2**

Create a survival object

Description

Create a survival object from a timeline style data set. This will almost always be the response variable in a formula.

Usage

Surv2(time, event)

Arguments

time a timeline variable, such as age, time from enrollment, date, etc.

event the outcome at that time. This can be a 0/1 variable, TRUE/FALSE, or a factor. If the latter, the first level of the factor corresponds to ‘no event was observed at this time’.

Details

When used in a coxph or survfit model, Surv2 acts as a trigger to internally convert a timeline style data set into counting process style data, which is then acted on by the routine.

Value

An object of class Surv2. There are methods for print, is.na and subscripting.

See Also

coxph, survfit
Surv2data

Convert data from timecourse to (time1,time2) style

Description

The multi-state survival functions coxph and survfit allow for two forms of input data. This routine converts between them. The function is normally called behind the scenes when Surv2 is as the response.

Usage

Surv2data(formula, data, subset, id)

Arguments

formula  a model formula
data      a data frame
subset   optional, selects rows of the data to be retained
id       a variable that identified multiple rows for the same subject, normally found in the referenced data set

Details

For timeline style data, each row is uniquely identified by an (identifier, time) pair. The time could be a date, time from entry to a study, age, etc. (there may often be more than one time variable). The identifier and time cannot be missing. The remaining covariates represent values that were observed at that time point. Often, a given covariate is observed at only a subset of times and is missing at others. At the time of death, in particular, often only the identifier, time, and status indicator are known.

In the resulting data set missing covariates are replaced by their last known value, and the response y will be a Surv(time1, time2, endpoint) object.

Value

a list with elements

mf           an updated model frame (fewer rows, unchanged columns)
S2.y         the constructed response variable
S2.state     the current state for each of the rows
survcheck

Checks of a survival data set

Description

Perform a set of consistency checks on survival data

Usage

survcheck(formula, data, subset, na.action, id, istate, istate0="(s0)",
timefix=TRUE,...)

Arguments

formula a model formula with a Surv object as the response
data data frame in which to find the id, istate and formula variables
subset expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
na.action a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action.
id an identifier that labels unique subjects
istate an optional vector giving the current state at the start of each interval
istate0 default label for the initial state of each subject (at their first interval) when istate is missing
timefix process times through the aeqSurv function to eliminate potential roundoff issues.
... other arguments, which are ignored (but won’t give an error if someone added weights for instance)

Details

This routine will examine a multi-state data set for consistency of the data. The basic rules are that if a subject is at risk they have to be somewhere, can not be two states at once, and should make sensible transitions from state to state. It reports the number of instances of the following conditions:

overlap two observations for the same subject that overlap in time, e.g. intervals of (0, 100) and (90, 120). If y is simple (time, status) survival observation intervals implicitly start at 0, so in that case any duplicate identifiers will generate an overlap.

jump a hole in a subject’s timeline, where they are in one state at the end of the prior interval, but a new state in the at the start subsequent interval.

gap one or more gaps in a subject’s timeline; they are presumably in the same state at their return as when they left.

teleport two adjacent intervals for a subject, with the first interval ending in one state and the subsequent interval starting in another. They have instantaneously changed states with experiencing a transition.

The total number of occurrences of each is present in the flags vector. Optional components give the location and identifiers of the flagged observations.
survConcordance

Value

a list with components

- **states**: the vector of possible states
- **transitions**: a matrix giving the count of transitions from one state to another
- **statecount**: table of the number of visits per state, e.g., 18 subjects had 2 visits to the “infection” state
- **flags**: a vector giving the counts of each check
- **istate**: a copy of the istate vector, if it was supplied; otherwise a constructed istate that satisfies all the checks
- **overlap**: a list with the row number and id of overlaps (not present if there are no overlaps)
- **gaps**: a list with the row number and id of gaps (not present if there are no gaps)
- **teleport**: a list with the row number and id of inconsistent rows (not present if there are none)
- **jumps**: a list with the row number and id of jumps (not present if there are no jumps)

Note

For data sets with time-dependent covariates, a given subject will often have intermediate rows with a status of ‘no event at this time’. (numeric value of 0). For instance a subject who started in state 1 at time 0, transitioned to state 2 at time 10, had a covariate x change from 135 to 156 at time 20, and a final transition to state 3 at time 30. The response would be Surv(c(0,10,20),c(10,20,30),c(2,0,3)): the status variable records changes in state, and there was no change at time 20. The istate variable would be (1, 2, 2); it contains the current state, and so the value is unchanged when status = censored.

Thus, when there are intermediate observations istate is not simply a lagged version of the status, and may be more challenging to create. One approach is to let survcheck do the work: call it with an istate argument that is correct for the first row of each subject, or no istate argument at all, and then insert the returned value into ones data frame.

---

survConcordance

*Compute a concordance measure.*

Description

This function computes the concordance between a right-censored survival time and a single continuous covariate

Usage

```r
survConcordance(formula, data, weights, subset, na.action)
survConcordance.fit(y, x, strata, weight)
```
Arguments

- **formula**: a formula with a survival time on the left and a single covariate on the right, along with an optional `strata()` term. The left hand term can also be a numeric vector.
- **data**: a data frame
- **weights, subset, na.action**: as for `coxph`
- **x, y, strata, weight**: predictor, response, strata, and weight vectors for the direct call

Details

The `survConcordance` function computes the result but does no data checking whatsoever. It is intended as a hook for other packages that wish to compute concordance, and the data has already been assembled and verified.

Concordance is defined as $\Pr(\text{agreement})$ for any two randomly chosen observations, where in this case agreement means that the observation with the shorter survival time of the two also has the larger risk score. The predictor (or risk score) will often be the result of a Cox model or other regression.

For continuous covariates concordance is equivalent to Kendall’s tau, and for logistic regression is equivalent to the area under the ROC curve. A value of 1 signifies perfect agreement, .6-.7 is a common result for survival data, .5 is an agreement that is no better than chance, and .3-.4 is the performance of some stock market analysts.

The computation involves all $n(n-1)/2$ pairs of data points in the sample. For survival data, however, some of the pairs are incomparable. For instance a pair of times (5+, 8), the first being a censored value. We do not know whether the first survival time is greater than or less than the second. Among observations that are comparable, pairs may also be tied on survival time (but only if both are uncensored) or on the predictor. The final concordance is $(\text{agree} + \text{tied}/2)/(\text{agree} + \text{disagree} + \text{tied})$.

There is, unfortunately, one aspect of the formula above that is unclear. Should the count of ties include observations that are tied on survival time $y$, tied on the predictor $x$, or both? By default the concordance only counts ties in $x$, treating tied survival times as incomparable; this agrees with the AUC calculation used in logistic regression. The Goodman-Kruskal Gamma statistic is $(\text{agree} - \text{disagree})/(\text{agree} + \text{disagree})$, ignoring ties. It ranges from -1 to +1 similar to a correlation coefficient. Kendall’s tau uses ties of both types. All of the components are returned in the result, however, so people can compute other combinations if interested. (If two observations have the same survival and the same $x$, they are counted in the tied survival time category).

The algorithm is based on a balanced binary tree, which allows the computation to be done in $O(n \log n)$ time.

Value

- an object containing the concordance, followed by the number of pairs that agree, disagree, are tied, and are not comparable.

See Also

- `concordance`
**survdiff**

---

### Test Survival Curve Differences

**Description**

Tests if there is a difference between two or more survival curves using the $G^p$ family of tests, or for a single curve against a known alternative.

**Usage**

```r
survdiff(formula, data, subset, na.action, rho=0, timefix=TRUE)
```

**Arguments**

- `formula` a formula expression as for other survival models, of the form `Surv(time,status) ~ predictors`. For a one-sample test, the predictors must consist of a single `offset(sp)` term, where `sp` is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A `strata` term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `strata` function with its `na.group=T` argument.

- `data` an optional data frame in which to interpret the variables occurring in the formula.

- `subset` expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.

- `na.action` a missing-data filter function. This is applied to the `model.frame` after any subset argument has been used. Default is `options()$na.action`.

- `rho` a scalar parameter that controls the type of test.

- `timefix` process times through the `aeqSurv` function to eliminate potential roundoff issues.

**Value**

A list with components:

- `n` the number of subjects in each group.

- `obs` the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum.

- `exp` the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum.

- `chisq` the chisquare statistic for a test of equality.

- `var` the variance matrix of the test.

- `strata` optionally, the number of subjects contained in each stratum.
METHOD

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of \( S(t)^\rho \), where \( S(t) \) is the Kaplan-Meier estimate of survival. With \( \rho = 0 \) this is the log-rank or Mantel-Haenszel test, and with \( \rho = 1 \) it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the factor function with its exclude argument.

References

Examples

```r
## Two-sample test
survdiff(Surv(futime, fustat) ~ rx, data=ovarian)

## Stratified 7-sample test
survdiff(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on US mortality tables
expect <- survexp(futime ~ 1, data=jasa, cohort=FALSE,
                 rmap=list(age=(accept.dt - birth.dt), sex=1, year=accept.dt),
                 ratetable=survexp.us)

## actual survival is much worse (no surprise)
survdiff(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

Description

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

Usage

```r
survexp(formula, data, weights, subset, na.action, rmap, times,
        method=c("ederer", "hakulinen", "conditional", "individual.h",
                 "individual.s"),
        cohort=TRUE, conditional=FALSE,
        ratetable=survexp.us, scale=1,
        se.fit, model=FALSE, x=FALSE, y=FALSE)
```
Arguments

formula formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the + operator (as in survfit), and is often ~1, i.e., expected survival for the entire group.

data data frame in which to interpret the variables named in the formula, subset and weights arguments.

weights case weights. This is most useful when conditional survival for a known population is desired, e.g., the data set would contain all unique age/sex combinations and the weights would be the proportion of each.

subset expression indicating a subset of the rows of data to be used in the fit.

na.action function to filter missing data. This is applied to the model frame after subset has been applied. Default is options()$na.action.

rmap an optional list that maps data set names to the ratetable names. See the details section below.

times vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of times supplied in the response value of the formula.

method computational method for the creating the survival curves. The individual option does not create a curve, rather it retrieves the predicted survival individual.s or cumulative hazard individual.h for each subject. The default is to use method='ederer' if the formula has no response, and method='hakulinen' otherwise.

cohort logical value. This argument has been superseded by the method argument. To maintain backwards compatibility, if it is present and FALSE, it implies method='individual.s'.

conditional logical value. This argument has been superseded by the method argument. To maintain backwards compatibility, if it is present and TRUE it implies method='conditional'.

ratetable a table of event rates, such as survexp.mn, or a fitted Cox model. Note the survival:: prefix in the default argument is present to avoid the (rare) case of a user who expects the default table but just happens to have an object named ”survexp.us” in their own directory.

scale numeric value to scale the results. If ratetable is in units/day, scale = 365.25 causes the output to be reported in years.

se.fit compute the standard error of the predicted survival. This argument is currently ignored. Standard errors are not a defined concept for population rate tables (they are treated as coming from a complete census), and for Cox models the calculation is hard. Despite good intentions standard errors for this latter case have not been coded and validated.

model,x,y flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.

Details

Individual expected survival is usually used in models or testing, to ‘correct’ for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study,
sex and actual survival time are all known for a group of subjects. The \texttt{survexp.us} population tables contain expected death rates based on calendar year, sex and age. Then

\begin{verbatim}
haz <- survexp(fu.time ~ 1, data=mydata,  
  rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),  
  method='individual.h')
\end{verbatim}

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable \texttt{fu.time}) This probability can be used as a rescaled time value in models:

\begin{verbatim}
glm(status ~ 1 + offset(log(haz)), family=poisson)  
glm(status ~ x + offset(log(haz)), family=poisson)
\end{verbatim}

In the first model, a test for intercept=0 is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable \texttt{x} after adjustment for age and sex.

The ratetable being used may have different variable names than the user’s data set, this is dealt with by the \texttt{rmap} argument. The rate table for the above calculation was \texttt{survexp.us}, a call to \texttt{summary(survexp.us)} reveals that it expects to have variables \texttt{age = age in days}, \texttt{sex}, and \texttt{year = the date of study entry}, we create them in the \texttt{rmap} line. The sex variable was not mapped, therefore the function assumes that it exists in \texttt{mydata} in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored, for this case no response variable is required in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

\textbf{Value}

if \texttt{cohort=TRUE} an object of class \texttt{survexp}, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time. The cohort survival is the hypothetical survival for a cohort of subjects enrolled from the population at large, but matching the data set on the factors found in the rate table.

\textbf{References}

survexp.fit

Compute Expected Survival

Description
Compute expected survival times.

Usage
survexp.fit(group, x, y, times, death, ratetable)

Arguments
- **group**: if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer.
- **x**: A matrix whose columns match the dimensions of the ratetable, in the correct order.
- **y**: the follow up time for each subject.
- **times**: the vector of times at which a result will be computed.
- **death**: a logical value, if TRUE the conditional survival is computed, if FALSE the cohort survival is computed. See survexp for more details.
- **ratetable**: a rate table, such as survexp.uswhite.
survexp.object

Details

For conditional survival \( y \) must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate \( \text{times} \) should be a superset of \( y \), so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the \( \text{times} \) spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are > .99.

For a subgroup of size 1 and \( \text{times} > y \), the conditional method reduces to \( \exp(-h) \) where \( h \) is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

Value

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

Warning

Most users will call the higher level routine \( \text{survexp} \). Consequently, this function has very few error checks on its input arguments.

See Also

\( \text{survexp, survexp.us} \).

survexp.object  Expected Survival Curve Object

Description

This class of objects is returned by the \( \text{survexp} \) class of functions to represent a fitted survival curve.

Objects of this class have methods for \text{summary}, and inherit the \text{print, plot, points and lines} methods from \text{survfit}.

Arguments

- \text{surv}  \( \) the estimate of survival at time \( t+0 \). This may be a vector or a matrix.
- \text{n.risk}  \( \) the number of subjects who contribute at this time.
- \text{time}  \( \) the time points at which the curve has a step.
- \text{std.err}  \( \) the standard error of the cumulative hazard or -log(survival).
- \text{strata}  \( \) if there are multiple curves, this component gives the number of elements of the \text{time} etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
- \text{method}  \( \) the estimation method used. One of "Ederer", "Hakulinen", or "conditional".
- \text{na.action}  \( \) the returned value from the \text{na.action} function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.
- \text{call}  \( \) an image of the call that produced the object.
Structure

The following components must be included in a legitimate survfit object.

Subscripts

Survexp objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves.

Details

In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk printed here is the number of those hypothetical subject who are still part of the calculation. In particular, for the Ederer method all hypotheticals are retained for all time, so n.risk will be a constant.

See Also

plot.survfit, summary.survexp, print.survfit, survexp.
Value

An object of class `survfit` containing one or more survival curves.

Note

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., `survfit(Surv(time,status))`, in which case the formula argument is not actually a formula. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

Author(s)

Terry Therneau

---

**survfit.coxph**

*Compute a Survival Curve from a Cox model*

Description

Computes the predicted survivor function for a Cox proportional hazards model.

Usage

```r
## S3 method for class 'coxph'
survfit(formula, newdata, 
       se.fit=TRUE, conf.int=.95, individual=FALSE, stype=2, ctype, 
       conf.type=c("log","log-log","plain","none", "logit", "arcsin"), 
       censor=TRUE, start.time, id, influence=FALSE, 
       na.action=na.pass, type, ...)
```

Arguments

- `formula`: A coxph object.
- `newdata`: a data frame with the same variable names as those that appear in the coxph formula. It is also valid to use a vector, if the data frame would consist of a single row.
  - The curve(s) produced will be representative of a cohort whose covariates correspond to the values in `newdata`. Default is the mean of the covariates used in the coxph fit.
- `se.fit`: a logical value indicating whether standard errors should be computed. Default is TRUE.
- `conf.int`: the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.
- `individual`: depreicated argument, replaced by the general `id`
**survfit.coxph**

**stype**
computation of the survival curve, 1=direct, 2=exponential of the cumulative hazard.

**ctype**
whether the cumulative hazard computation should have a correction for ties, 1=no, 2=yes.

**conf.type**
One of "none", "plain", "log" (the default), "log-log" or "logit". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve + k * se(curve), where k is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option uses the log hazard or log(-log(survival)), and the logit log(survival/(1-survival)).

**censor**
if FALSE time points at which there are no events (only censoring) are not included in the result.

**id**
optional variable name of subject identifiers. If this is present, it will be search for in the newdata data frame. Each group of rows in newdata with the same subject id represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the coxph fit had strata then that must also be specified in newdata. If newid is not present, then each individual row of newdata is presumed to represent a distinct subject.

**start.time**
optional starting time, a single numeric value. If present the returned curve contains survival after start.time conditional on surviving to start.time.

**influence**
option to return the influence values

**na.action**
the na.action to be used on the newdata argument

**type**
older argument that encompassed stype and ctype, now deprecated

... for future methods

**Details**

This routine produces survival curves based on a coxph model fit. The ctype option found in survfit.formula is not present, it instead follows from the choice of the ties option in the coxph call. Likewise the choice between a model based and robust variance estimate for the curve will mirror the choice made in the coxph call. The cluster and influence options are only relevant for the robust variance. A id statement in the original call causes subjects that have multiple lines in the original data to be correctly identified. (This calculation needs both the original data and the new data.)

If the newdata argument is missing, then a curve is produced for a single "pseudo" subject with covariate values equal to the means of the data set. The resulting curve(s) almost never make sense, but The default remains due to an unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about equal numbers of observations for each. The "mean" covariate level will be 0.5 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with age*sex. The "mean" value for the age:sex interaction term will be about 30, a value that does not occur in the data. Users are strongly advised to use the newdata argument.

When the original model contains time-dependent covariates, then the path of that covariate through time needs to be specified in order to obtain a predicted curve. This requires newdata to contain multiple lines for each hypothetical subject which gives the covariate values, time interval, and strata for each line (a subject can change strata), along with an id variable which demarks which
survfit.coxph

rows belong to each subject. The time interval must have the same (start, stop, status) variables as the original model: although the status variable is not used and thus can be set to a dummy value of 0 or 1, it is necessary for the response to be recognized as a Surv object. Last, although predictions with a time-dependent covariate path can be useful, it is very easy to create a prediction that is senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When a model contains strata but no time-dependent covariates the user of this routine has a choice. If newdata argument does not contain strata variables then the returned object will be a matrix of survival curves with one row for each strata in the model and one column for each row in newdata. (This is the historical behavior of the routine.) If newdata does contain strata variables, then the result will contain one curve per row of newdata, based on the indicated stratum of the original model. In the rare case of a model with strata by covariate interactions the strata variable must be included in newdata, the routine does not allow it to be omitted (predictions become too confusing). (Note that the model Surv(time, status) ~ age*strata(sex) expands internally to strata(sex) + age:sex; the sex variable is needed for the second term of the model.)

See survfit for more details about the counts (number of events, number at risk, etc.)

Value

an object of class "survfit". See survfit.object for details. Methods defined for survfit objects are print, plot, lines, and points.

Notes

If the following pair of lines is used inside of another function then the model=TRUE argument must be added to the coxph call: fit <- coxph(...); survfit(fit). This is a consequence of the non-standard evaluation process used by the model.frame function when a formula is involved.

Survival Curve for Censored Data

Computes an estimate of a survival curve for censored data using the Aalen-Johansen estimator. For ordinary (single event) survival this reduces to the Kaplan-Meier estimate.

The function `survfit` takes the following arguments:

- **formula**: a formula object, which must have a `Surv` object as the response on the left of the `~` operator and, if desired, terms separated by `+` operators on the right. One of the terms may be a `strata` object. For a single survival curve the right hand side should be `~ 1`.
- **data**: a data frame in which to interpret the variables named in the formula, subset and weights arguments.
- **weights**: The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the subset argument.
- **subset**: expression saying that only a subset of the rows of the data should be used in the fit.
- **na.action**: a missing-data filter function, applied to the model frame, after any subset argument has been used. Default is `options()$na.action`.
- **stype**: the method to be used estimation of the survival curve: 1 = direct, 2 = exp(cumulative hazard).
- **ctype**: the method to be used for estimation of the cumulative hazard: 1 = Nelson-Aalen formula, 2 = Fleming-Harrington correction for tied events.
- **id**: identifies individual subjects, when a given person can have multiple lines of data.
- **cluster**: used to group observations for the infinitesimal jackknife variance estimate, defaults to the value of id.
- **robust**: logical, should the function compute a robust variance. For multi-state survival curves this is true by default. For single state data see details, below.
- **istate**: for multi-state models, identifies the initial state of each subject or observation.
- **timefix**: process times through the `aeqSurv` function to eliminate potential roundoff issues.
- **etype**: a variable giving the type of event. This has been superseded by multi-state `Surv` objects and is deprecated; see example below.
- **error**: this argument is no longer used.
The following additional arguments are passed to internal functions called by `survfit`.

- **se.fit** logical value, default is TRUE. If FALSE then standard error computations are omitted.
- **conf.type** One of "none", "plain", "log" (the default), "log-log" or "logit". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals $\text{curve} \pm k \times \text{se}($curve$)$, where $k$ is determined from `conf.int`. The log option calculates intervals based on the cumulative hazard or $\log(\text{survival})$. The log-log option bases the intervals on the log hazard or $\log(-\log(\text{survival}))$, and the logit option on $\log(\text{survival}/(1-\text{survival}))$.
- **conf.lower** a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are "usual" (unmodified), "peto", and "modified". The modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor $m/n$, where $n$ is the number currently at risk and $m$ is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.
- **start.time** numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to `start.time`.
- **conf.int** the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.
- **se.fit** a logical value indicating whether standard errors should be computed. Default is TRUE.
- **influence** a logical value indicating whether to return the infinitesimal jackknife (influence) values for each subject. These contain the values of the derivative of each value with respect to the case weights of each subject $i$: $\partial p/\partial w_i$, evaluated at the vector of weights. The resulting object will contain `influence.surv` and `influence.chaz` components. Alternatively, options of `influence=1` or `influence=2` will return values for only the survival or hazard curves, respectively.
- **p0** this applies only to multi-state curves. An optional vector giving the initial probability across the states. If this is missing, then $p0$ is estimated using the frequency of the starting states of all observations at risk at `start.time`, or if that is not specified, at the time of the first event.
- **type** an older argument that combined stype and ctype, now deprecated. Legal values were "kaplan-meier" which is equivalent to stype=1,ctype=1. "fleming-harrington" which is equivalent to stype=2,ctype=1, and "fh2" which is equivalent to stype=2,ctype=2.

Details

If there is a data argument, then variables in the formula, codeweights, subset, id, cluster and istate arguments will be searched for in that data set.
The routine returns both an estimated probability in state and an estimated cumulative hazard estimate. The cumulative hazard estimate is the Nelson-Aalen (NA) estimate or the Fleming-Harrington (FH) estimate, the latter includes a correction for tied event times. The estimated probability in state can estimated either using the exponential of the cumulative hazard, or as a direct estimate using the Aalen-Johansen approach. For single state data the AJ estimate reduces to the Kaplan-Meier and the probability in state to the survival curve; for competing risks data the AJ reduces to the cumulative incidence (CI) estimator. For backward compatibility the type argument can be used instead.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. Currently this algorithm is very slow, only a survival curve is produced, and it does not support a robust variance.

Robust variance: If a robust is TRUE, or for multi-state curves, then the standard errors of the results will be based on an infinitesimal jackknife (IJ) estimate, otherwise the standard model based estimate will be used. For single state curves, the default for robust will be TRUE if one of: there is a cluster argument, there are non-integer weights, or there is an id statement and at least one of the id values has multiple events, and FALSE otherwise. The default represents our best guess about when one would most often desire a robust variance. When there are non-integer case weights and (time1, time2) survival data the routine is at an impasse: a robust variance likely is called for, but requires either an id or cluster information to be done correctly; it will default to robust=FALSE.

With the IJ estimate, the leverage values themselves can be returned as arrays with dimensions: number of subjects, number of unique times, and for a multi-state model, the number of unique states. Be forewarned that these arrays can be huge. If there is a cluster argument this first dimension will be the number of clusters and the variance will be a grouped IJ estimate; this can be an important tool for reducing the size. A numeric value for the influence argument allows finer control: 0= return neither (same as FALSE), 1= return the influence array for probability in state, 2= return the influence array for the cumulative hazard, 3= both (same as TRUE).

Value

an object of class "survfit". See survfit.object for details. Methods defined for survfit objects are print, plot, lines, and points.

survfit.matrix

Create Aalen-Johansen estimates of multi-state survival from a matrix of hazards.

Description

This allows one to create the Aalen-Johansen estimate of P, a matrix with one column per state and one row per time, starting with the individual hazard estimates. Each row of P will sum to 1. Note that this routine has been superseded by the use of multi-state Cox models, and will eventually be removed.

Usage

## S3 method for class 'matrix'
survfit(formula, p0, method = c("discrete", "matexp"),
       start.time, ...)

Arguments

- `formula`: a matrix of lists, each element of which is either NULL or a survival curve object.
- `p0`: the initial state vector. The names of this vector are used as the names of the states in the output object. If there are multiple curves then p0 can be a matrix with one row per curve.
- `method`: use a product of discrete hazards, or a product of matrix exponentials. See details below.
- `start.time`: optional; start the calculations at a given starting point
- `...`: further arguments used by other survfit methods

Details

On input the matrix should contain a set of predicted curves for each possible transition, and NULL in other positions. Each of the predictions will have been obtained from the relevant Cox model. This approach for multistate curves is easy to use but has some caveats. First, the input curves must be consistent. The routine checks as best it can, but can easily be fooled. For instance, if one were to fit two Cox models, obtain predictions for males and females from one, and for treatment A and B from the other, this routine will create two curves but they are not meaningful. A second issue is that standard errors are not produced.

The names of the resulting states are taken from the names of the vector of initial state probabilities. If they are missing, then the dimnames of the input matrix are used, and lacking that the labels '1', '2', etc. are used.

For the usual Aalen-Johansen estimator the multiplier at each event time is the matrix of hazards H (also written as I + dA). When using predicted survival curves from a Cox model, however, it is possible to get predicted hazards that are greater than 1, which leads to probabilities less than 0. If the method argument is not supplied and the input curves are derived from a Cox model this routine instead uses the approximation expm(H-I) as the multiplier, which always gives valid probabilities. (This is also the standard approach for ordinary survival curves from a Cox model.)
survfit.object

Value

a survfitms object

Note

The R syntax for creating a matrix of lists is very fussy.

survfit.object

Survival Curve Object

Description

This class of objects is returned by the survfit class of functions to represent a fitted survival curve. For a multi-state model the object has class c('survfitms', 'survfit').

Objects of this class have methods for the functions print, summary, plot, points and lines. The print.survfit method does more computation than is typical for a print method and is documented on a separate page.

Arguments

n total number of subjects in each curve.
time the time points at which the curve has a step.
n.risk the number of subjects at risk at t.
n.event the number of events that occur at time t.
**n.enter** for counting process data only, the number of subjects that enter at time t.

**n.censor** for counting process data only, the number of subjects who exit the risk set, without an event, at time t. (For right censored data, this number can be computed from the successive values of the number at risk).

**surv** the estimate of survival at time \( t+0 \). This may be a vector or a matrix. The latter occurs when a set of survival curves is created from a single Cox model, in which case there is one column for each covariate set.

**pstate** a multi-state survival will have the pstate component instead of surv. It will be a matrix containing the estimated probability of each state at each time, one column per state.

**std.err** for a survival curve this contains standard error of the cumulative hazard or -log(survival), for a multi-state curve it contains the standard error of prev. This difference is a reflection of the fact that each is the natural calculation for that case.

**cumhaz hazard** optional. Contains the cumulative hazard for each possible transition.

**strata** if there are multiple curves, this component gives the number of elements of the time vector corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.

**upper** optional upper confidence limit for the survival curve or pstate

**lower** options lower confidence limit for the survival curve or pstate

**start.time, p0, sp0** see details below

**newdata** for survival curves from a fitted model, this contains the covariate values for the curves

**n.all** the total number of observations that were available. For counting process data, and any time that the start.time argument was used, not all may have been used in creating the curve, in which case this value will be larger than n above. The print and plot routines in the package do no use this value, it is for information only.

**conf.type** the approximation used to compute the confidence limits.

**conf.int** the level of the confidence limits, e.g. 90 or 95%.

**transitions** for multi-state data, the total number of transitions of each type.

**na.action** the returned value from the na.action function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.

**call** an image of the call that produced the object.

**type** type of survival censoring.

**influence.p, influence.c** optional influence matrices for the pstate (or surv) and for the cumhaz estimates. A list with one element per stratum, each element of the list is an array indexed by subject, time, state.

**version** the version of the object. Will be missing, 2, or 3

**Structure**

The following components must be included in a legitimate survfit or survfitms object.
Subscripts

Survfit objects can be subscripted. This is often used to plot a subset of the curves, for instance. From the user’s point of view the survfit object appears to be a vector, matrix, or array of curves. The first dimension is always the underlying number of curves or “strata”; for multi-state models the state is always the last dimension. Predicted curves from a Cox model can have a second dimension which is the number of different covariate prediction vectors.

Details

The survfit object has evolved over time: when first created there was no thought of multi-state models for instance. This evolution has almost entirely been accomplished by the addition of new elements. One change in survival version 3 is the addition of a survfitconf routine which will compute confidence intervals for a survfit object. This allows the computation of CI intervals to be deferred until later, if desired, rather than making them a permanent part of the object. Later iterations of the base routines may omit the confidence intervals.

The survfit object starts at the first observation time, but survival curves are normally plotted from time 0. A helper routine survfit0 can be used to add this first time point and align the data.

See Also

plot.survfit, summary.survfit, print.survfit, survfit, survfit0

survfit0

Convert the format of a survfit object.

Description

Add the point for a starting time (time 0) to a survfit object’s elements. This is useful for plotting.

Usage

survfit0(x, start.time=0)

Arguments

x a survfit object

start.time the desired starting time; see details below.

Details

Survival curves are traditionally plotted forward from time 0, but since the true starting time is not known as a part of the data, the survfit routine does not include a time 0 value in the resulting object. Someone might look at cumulative mortgage defaults versus calendar year, for instance, with the ‘time’ value a Date object. The plotted curve probably should not start at 0 = 1970/01/01. (One could certainly argue that this behavior is overly pedantic, but the decision was made over 20 years ago and it is far too late to change it now.)

This is a utility function used by plot.survfit and summary.survfit. If the original survfit call included a start.time argument then that will be used as the starting point, otherwise the default is 0. It may be useful to others, so was exported.
survfitcoxph.fit

A direct interface to the 'computational engine' of survfit.coxph

Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a 'data' level rather than a 'user' level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

Usage

survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype, vartype, varmat, id, y2, strata2, unlist=TRUE)

Arguments

y the response variable used in the Cox model. (Missing values removed of course.)
x covariate matrix used in the Cox model
wt weight vector for the Cox model. If the model was unweighted use a vector of 1s.
x2 matrix describing the hypothetical subjects for which a curve is desired. Must have the same number of columns as x.
risk the risk score exp(X beta) from the fitted Cox model. If the model had an offset, include it in the argument to exp.
newrisk risk scores for the hypothetical subjects
strata strata variable used in the Cox model. This will be a factor.
se.fit if TRUE the standard errors of the curve(s) are returned
survtype 1=Kalbfleisch-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for 'exact', N-A for 'breslow' and Efron for 'efron'.
vartype 1=Greenwood, 2=Aalen, 3=Efron
varmat the variance matrix of the coefficients
id optional; if present and not NULL this should be a vector of identifiers of length nrow(x2). A mon-null value signifies that x2 contains time dependent covariates, in which case this identifies which rows of x2 go with each subject.
y2 survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of x2. Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however.
strata2 vector of strata indicators for x2. This must be a factor.
unlist if FALSE the result will be a list with one element for each strata. Otherwise the strata are "unpacked" into the form found in a survfit object.
survobrien

Value

A list containing nearly all the components of a survfit object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a coxph object), and the class.

Note

The source code for both this function and survfit.coxph is written using noweb. For complete documentation see the inst/sourcecode.pdf file.

survfit.coxph

survobrien O'Brien's Test for Association of a Single Variable with Survival

Description

Peter O’Brien’s test for association of a single variable with survival. This test is proposed in Biometrics, June 1978.

Usage

survobrien(formula, data, subset, na.action, transform)

Arguments

formula A valid formula for a cox model.
data A data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument.
subset Expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
na.action A missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action.
transform The transformation function to be applied at each time point. The default is O’Brien’s suggestion logit(tr) where tr = (rank(x) - 1/2)/ length(x) is the rank shifted to the range 0-1 and logit(x) = log(x/(1-x)) is the logit transform.

Value

A new data frame. The response variables will be column names returned by the Surv function, i.e., “time” and “status” for simple survival data, or “start”, “stop”, “status” for counting process data. Each individual event time is identified by the value of the variable .strata.. Other variables retain their original names. If a predictor variable is a factor or is protected with I(), it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows that the original data, approximately the original number of rows * number of deaths/2.
Method

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O'Brien's method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

Note

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that strategy does not work if the original formula has a strata statement. This new data set will be the same size, but the coxph routine will process it slightly faster.

`survdiff`

Examples

```r
xx <- survobrien(Surv(futime, fustat) ~ age + factor(rx) + I(ecog.ps),
                 data=ovarian)
coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
```

survreg

Regression for a Parametric Survival Model

Description

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

Usage

```r
survreg(formula, data, weights, subset,
         na.action, dist="weibull", init=NULL, scale=0,
         control,parms=NULL,model=FALSE, x=FALSE,
         y=TRUE, robust=FALSE, cluster, score=FALSE, ...)
```
survreg

Arguments

formula
a formula expression as for other regression models. The response is usually a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details.
data
a data frame in which to interpret the variables named in the formula, weights or the subset arguments.
weights
optional vector of case weights
subset
subset of the observations to be used in the fit
na.action
a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is options()$na.action.
dist
assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from survreg.distributions. These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in survreg.distributions.
parms
a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.
init
optional vector of initial values for the parameters.
scale
optional fixed value for the scale. If set to <=0 then the scale is estimated.
control
a list of control values, in the format produced by survreg.control. The default value is survreg.control()
model,x,y
flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.
score
return the score vector. (This is expected to be zero upon successful convergence.)
robust
Use robust sandwich error instead of the asymptotic formula. Defaults to TRUE if there is a cluster argument.
cluster
Optional variable that identifies groups of subjects, used in computing the robust variance. Like model variables, this is searched for in the dataset pointed to by the data argument.
...
other arguments which will be passed to survreg.control.

Details

All the distributions are cast into a location-scale framework, based on chapter 2.2 of Kalbfleisch and Prentice. The resulting parameterization of the distributions is sometimes (e.g. gaussian) identical to the usual form found in statistics textbooks, but other times (e.g. Weibull) it is not. See the book for detailed formulas.

Value

an object of class survreg is returned.

Examples

# Fit an exponential model: the two fits are the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist="weibull",
        scale=1)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian,
        dist="exponential")

# # A model with different baseline survival shapes for two groups, i.e.,
# two different scale parameters
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

# There are multiple ways to parameterize a Weibull distribution. The survreg
# function embeds it in a general location-scale family, which is a
# different parameterization than the rweibull function, and often leads
# to confusion.
# survreg's scale = 1/(rweibull shape)
# survreg's intercept = log(rweibull scale)
# For the log-likelihood all parameterizations lead to the same value.
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")

# Economists fit a model called 'tobit regression', which is a standard
# linear regression with Gaussian errors, and left censored data.
tobinf <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
                  data=tobin, dist='gaussian')

survreg.control

Package options for survreg and coxph

Description

This functions checks and packages the fitting options for survreg.

Usage

survreg.control(maxiter=30, rel.tolerance=1e-09,
                toler.chol=1e-10, iter.max, debug=0, outer.max=10)

Arguments

maxiter  maximum number of iterations
rel.tolerance relative tolerance to declare convergence
toler.chol Tolerance to declare Cholesky decomposition singular
iter.max same as maxiter
depug print debugging information
outer.max maximum number of outer iterations for choosing penalty parameters
Value

A list with the same elements as the input

descriptions

Parametric Survival Distributions

Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf \( F \) and density \( f \) of a canonical member of the family.

Usage

survreg.distributions

Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

- **name**: name of distribution
- **variance**: function(parms) returning the variance (currently unused)
- **init(x,weights,...)**: Function returning an initial estimate of the mean and variance (used for initial values in the iteration)
- **density(x,parms)**: Function returning a matrix with columns \( F, 1 - F, f, f'/f, \) and \( f''/f \)
- **quantile(p,parms)**: Quantile function
- **scale**: Optional fixed value for scale parameter
- **parms**: Vector of default values and names for any additional parameters
- **deviance(y,scale,parms)**: Function returning the deviance for a saturated model; used only for deviance residuals.

and to define one distribution in terms of another

- **name**: name of distribution
- **dist**: name of parent distribution
- **trans**: transformation (eg log)
- **dtrans**: derivative of transformation
- **itrans**: inverse of transformation
- **scale**: Optional fixed value for scale parameter

Details

There are four basic distributions: extreme, gaussian, logistic and t. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf
survreg.distributions

is

\[ F = 1 - e^{-et}. \]

When the logarithm of survival time has one of the first three distributions we obtain respectively weibull, lognormal, and loglogistic. The location-scale parameterization of a Weibull distribution found in survreg is not the same as the parameterization of rweibull.

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of survreg.distributions with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying survreg.distributions a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

                 c(median(x), mad(x)),
                 density= function(x, parms) {
                 temp <- 1/(1 + x^2)
                 cbind(.5 + atan(x)/pi, .5* atan(-x)/pi,
                       temp/pi, -2 *x*temp, 2*temp*(4*x^2*temp -1))
                 },
                 quantile= function(p, parms) tan((p-.5)*pi),
                 deviance= function(...) stop('deviance residuals not defined')
                 )
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)
survreg.object

Parametric Survival Model Object

Description

This class of objects is returned by the survreg function to represent a fitted parametric survival model. Objects of this class have methods for the functions print, summary, predict, and residuals.

COMPONENTS

The following components must be included in a legitimate survreg object.

coefficients the coefficients of the linear.predictors, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

icoef coefficients of the baseline model, which will contain the intercept and log(scale), or multiple scale factors for a stratified model.

var the variance-covariance matrix for the parameters, including the log(scale) parameter(s).

loglik a vector of length 2, containing the log-likelihood for the baseline and full models.

iter the number of iterations required

linear.predictors the linear predictor for each subject.

df the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

scale the scale factor(s), with length equal to the number of strata.

idf degrees of freedom for the initial model.

means a vector of the column means of the coefficient matrix.

dist the distribution used in the fit.

weights included for a weighted fit.

The object will also have the following components found in other model results (some are optional): linear.predictors, weights, x, y, model, call, terms and formula. See lm.

survregDtest

Verify a survreg distribution

Description
This routine is called by survreg to verify that a distribution object is valid.

Usage
survregDtest(dlist, verbose = F)

Arguments
dlist
the list describing a survival distribution
verbose
return a simple TRUE/FALSE from the test for validity (the default), or a ver-
bose description of any flaws.

Details
If the survreg function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

Value
TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
        temp/pi, -2 +x*temp, 2*temp^2*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)

survregDtest(mycauchy, TRUE)
survSplit

Split a survival data set at specified times

Description

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in 'counting process' format, with a start time, stop time, and event status for each record.

Usage

survSplit(formula, data, subset, na.action=na.pass, cut, start="tstart", id, zero=0, episode, end="tstop", event="event")

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>formula</td>
<td>a model formula</td>
</tr>
<tr>
<td>data</td>
<td>a data frame</td>
</tr>
<tr>
<td>subset, na.action</td>
<td>rows of the data to be retained</td>
</tr>
<tr>
<td>cut</td>
<td>the vector of timepoints to cut at</td>
</tr>
<tr>
<td>start</td>
<td>character string with the name of a start time variable (will be created if needed)</td>
</tr>
<tr>
<td>id</td>
<td>character string with the name of new id variable to create (optional). This can be useful if the data set does not already contain an identifier.</td>
</tr>
<tr>
<td>zero</td>
<td>If start doesn’t already exist, this is the time that the original records start.</td>
</tr>
<tr>

<td>character string with the name of new episode variable (optional)</td>
</tr>
<tr>
<td>end</td>
<td>character string with the name of event time variable</td>
</tr>
<tr>
<td>event</td>
<td>character string with the name of censoring indicator</td>
</tr>
</tbody>
</table>

Details

Each interval in the original data is cut at the given points; if an original row were (15, 60] with a cut vector of (10,30, 40) the resulting data set would have intervals of (15,30], (30,40] and (40, 60].

Each row in the final data set will lie completely within one of the cut intervals. Which interval for each row of the output is shown by the episode variable, where 1= less than the first cutpoint, 2= between the first and the second, etc. For the example above the values would be 2, 3, and 4.

The routine is called with a formula as the first argument. The right hand side of the formula can be used to delimit variables that should be retained; normally one will use ~ as a shorthand to retain them all. The routine will try to retain variable names, e.g. Surv(adam,joe,fred)~. will result in a data set with those same variable names for tstart, end, and event options rather than the defaults. Any user specified values for these options will be used if they are present, of course. However, the routine is not sophisticated; it only does this substitution for simple names. A call of Surv(time,stat==2) for instance will not retain "stat" as the name of the event variable.

Rows of data with a missing time or status are copied across unchanged, unless the na.action argument is changed from its default value of na.pass. But in the latter case any row that is missing for any variable will be removed, which is rarely what is desired.
Value

New, longer, data frame.

Surv, cut, reshape

Examples

```r
fit1 <- coxph(Surv(time, status) ~ karno + age + trt, veteran)
plot(cox.zph(fit1)[1])
# a cox.zph plot of the data suggests that the effect of Karnofsky score
# begins to diminish by 60 days and has faded away by 120 days.
# Fit a model with separate coefficients for the three intervals.
#
vet2 <- survSplit(Surv(time, status) ~., veteran,
                      cut=c(60, 120), episode = "timegroup")
fit2 <- coxph(Surv(tstart, time, status) ~ karno* strata(timegroup) +
                  age + trt, data= vet2)
c(overall= coef(fit1)[1],
   t0_60 = coef(fit2)[1],
   t60_120= sum(coef(fit2)[c(1,4)]),
   t120 = sum(coef(fit2)[c(1,5)]))
```

Description

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

Usage

```r
tcut(x, breaks, labels, scale=1)
## S3 method for class 'tcut'
levels(x)
```

Arguments

- `x` numeric/date variable
- `breaks` breaks between categories, which are right-continuous
- `labels` labels for categories
- `scale` Multiply `x` and `breaks` by this.

Value

An object of class `tcut`

    labels=c('0-18', paste(18:30, 19:31, sep='-')))temps.yr <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700 #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
py1

tmerge

Time based merge for survival data

Description

A common task in survival analysis is the creation of start,stop data sets which have multiple intervals for each subject, along with the covariate values that apply over that interval. This function aids in the creation of such data sets.

Usage

tmerge(data1, data2, id,..., tstart, tstop, options)

Arguments

data1 the primary data set, to which new variables and/or observation will be added
data2 second data set in which all the other arguments will be found
id subject identifier
... operations that add new variables or intervals, see below
tstart optional variable to define the valid time range for each subject, only used on an initial call
tstop optional variable to define the valid time range for each subject, only used on an initial call
options a list of options. Valid ones are idname, tstartname, tstopname, delay, na.rm, and tdcstart. See the explanation below.

Details

The program is often run in multiple passes, the first of which defines the basic structure, and subsequent ones that add new variables to that structure. For a more complete explanation of how this routine works refer to the vignette on time-dependent variables.

There are 4 types of operational arguments: a time dependent covariate (tdc), cumulative count (cumtdc), event (event) or cumulative event (cumevent). Time dependent covariates change their values before an event, events are outcomes.
newname = tdc(y, x) A new time dependent covariate variable will created. The argument y is assumed to be on the scale of the start and end time, and each instance describes the occurrence of a "condition" at that time. The second argument x is optional. In the case where x is missing the count variable starts at 0 for each subject and becomes 1 at the time of the event. If x is present the value of the time dependent covariate is initialized to the tdcstart option and is reset to the value of x at each observation. If the option na.rm=TRUE missing values of x are first removed, i.e., the update will not create missing values.

newname = cumtdc(y,x) Similar to tdc, except that the event count is accumulated over time for each subject.

newname = event(y,x) Mark an event at time y. In the usual case that x is missing the new 0/1 variable will be similar to the 0/1 status variable of a survival time.

newname = cumevent(y,x) Cumulative events.

The function adds three new variables to the output data set: tstart, tstop, and id. The options argument can be used to change these names. If data1 contains the tstart variable then that is used as the starting point for the created time intervals, otherwise the initial interval for each id will begin at 0 by default. This will lead to an invalid interval and subsequent error if say a death time were <= 0.

The na.rm option affects creation of time-dependent covariates. Should a data row in data2 that has a missing value for the variable be ignored (na.rm=FALSE, default) or should it generate an observation with a value of NA? The default value leads to "last value carried forward" behavior. The delay option causes a time-dependent covariate’s new value to be delayed, see the vignette for an example.

Value

a data frame with two extra attributes tname and tcount. The first contains the names of the key variables; it’s persistence from call to call allows the user to avoid constantly reentering the options argument. The tcount variable contains counts of the match types. New time values that occur before the first interval for a subject are "early", those after the last interval for a subject are "late", and those that fall into a gap are of type "gap". All these are are considered to be outside the specified time frame for the given subject. An event of this type will be discarded. A time-dependent covariate value will be applied to later intervals but will not generate a new time point in the output.

The most common type will usually be "within", for those new times that fall inside an existing interval and cause it to be split into two. Observations that fall exactly on the edge of an interval but within the (min, max] time for a subject are counted as being on a "leading" edge, "trailing" edge or "boundary". The first corresponds for instance to an occurrence at 17 for someone with an intervals of (0,15] and (17, 35]. A tdc at time 17 will affect this interval but an event at 17 would be ignored. An event occurrence at 15 would count in the (0,15] interval. The last case is where the main data set has touching intervals for a subject, e.g. (17, 28] and (28,35] and a new occurrence lands at the join. Events will go to the earlier interval and counts to the latter one. A last column shows the number of additions where the id and time point were identical. When this occurs, the tdc and event operators will use the final value in the data (last edit wins), but ignoring missing, while cumtdc and cumevent operators add up the values.

These extra attributes are ephemeral and will be discarded if the dataframe is modified. This is intentional, since they will become invalid if for instance a subset were selected.

Examples

# The pbc data set contains baseline data and follow-up status
# for a set of subjects with primary biliary cirrhosis, while the
# pbcseq data set contains repeated laboratory values for those
# subjects.
# The first data set contains data on 312 subjects in a clinical trial plus
# 106 that agreed to be followed off protocol, the second data set has data
# only on the trial subjects.

```r
temp <- subset(pbc, id <= 312, select=c(id:sex, stage)) # baseline data
pbc2 <- tmerge(temp, temp, id=id, endpt = event(time, status))
pbc2 <- tmerge(pbc2, pbcseq, id=id, ascites = tdc(day, ascites),
               bili = tdc(day, bili), albumin = tdc(day, albumin),
               protime = tdc(day, protime), alk.phos = tdc(day, alk.phos))

fit <- coxph(Surv(tstart, tstop, endpt==2) ~ protime + log(bili), data=pbc2)
```

tobin

Tobin’s Tobit data

Description

Economists fit a parametric censored data model called the ‘tobit’. These data are from Tobin’s original paper.

Usage
tobin

Format

A data frame with 20 observations on the following 3 variables.

durable Durable goods purchase
age Age in years
quant Liquidity ratio (x 1000)

Source

Examples

```r
tfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
               data=tobin, dist='gaussian')
predict(tfit,type="response")
```
**Description**

Subjects on a liver transplant waiting list from 1990-1999, and their disposition: received a transplant, died while waiting, withdrew from the list, or censored.

**Usage**

data("transplant")

**Format**

A data frame with 815 (transplant) or 861 (transplant2) observations on the following 6 variables.

- **age**: age at addition to the waiting list
- **sex**: m or f
- **abo**: blood type: A, B, AB or 0
- **year**: year in which they entered the waiting list
- **futime**: time from entry to final disposition
- **event**: final disposition: censored, death, ltx or withdraw
- **creat**: serum creatinine
- **bili**: serum bilirubin
- **inr**: International Normalized Ratio, a measure of the blood’s clotting ability
- **meld**: calculated MELD score
- **diag**: primary diagnosis: alcoholic liver disease, cholestatic liver disease, hepatitis B, hepatitis C, or other

**Details**

This represents the transplant experience in a particular region, over a time period in which liver transplant became much more widely recognized as a viable treatment modality. The number of liver transplants rises over the period, but the number of subjects added to the liver transplant waiting list grew much faster. Important questions addressed by the data are the change in waiting time, who waits, and whether there was an consequent increase in deaths while on the list.

Blood type is an important consideration. Donor livers from subjects with blood type O can be used by patients with A, B, AB or 0 blood types, whereas an AB liver can only be used by an AB recipient. Thus type O subjects on the waiting list are at a disadvantage, since the pool of competitors is larger for type O donor livers.

This data is of historical interest and provides a useful example of competing risks, but it has little relevance to current practice. Liver allocation policies have evolved and now depend directly on each individual patient’s risk and need, assessments of which are regularly updated while a patient is on the waiting list. The overall organ shortage remains acute, however.

The `transplant` data set was a version used early in the analysis, `transplant2` has several additions and corrections, and was the final data set and matches the paper.

udca

Data from a trial of ursodeoxycholic acid

Description

Data from a trial of ursodeoxycholic acid (UDCA) in patients with primary biliary cirrhosis (PBC).

Usage

data("udca")

Format

A data frame with 170 observations on the following 15 variables.

id subject identifier
trt treatment of 0=placebo, 1=UDCA
entry.dt date of entry into the study
last.dt date of last on-study visit
stage stage of disease
bili bilirubin value at entry
riskscore the Mayo PBC risk score at entry
death.dt date of death
tx.dt date of liver transplant
hprogress.dt date of histologic progression
varices.dt appearance of esophageal varices
ascites.dt appearance of ascites
enceph.dt appearance of encephalopathy
double.dt doubling of initial bilirubin
worsen.dt worsening of symptoms by two stages
Details

This data set is used in the Therneau and Grambsch. The udca1 data set contains the baseline variables along with the time until the first endpoint (any of death, transplant, . . . , worsening). The udca2 data set treats all of the endpoints as parallel events and has a stratum for each.

References

Examples

data(udca)
# values found in table 8.3 of the book
fit1 <- coxph(Surv(futime, status) ~ trt + log(bili) + stage, 
      cluster = id, data=udca1)
fit2 <- coxph(Surv(futime, status) ~ trt + log(bili) + stage + 
      strata(endpoint), cluster=id, data=udca2)

untangle.specials

Help Process the ‘specials’ Argument of the ‘terms’ Function.

Description

Given a terms structure and a desired special name, this returns an index appropriate for subscripting the terms structure and another appropriate for the data frame.

Usage

untangle.specials(tt, special, order=1)

Arguments

tt a terms object.
special the name of a special function, presumably used in the terms object.
order the order of the desired terms. If set to 2, interactions with the special function will be included.

Value

a list with two components:

vars a vector of variable names, as would be found in the data frame, of the specials.
terms a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special.
Examples

```r
formula <- Surv(tt, ss) ~ x + z * strata(id)
# the specials attribute
attr(tms, "specials")
# main effects
untangle.specials(tms, "strata")
# and interactions
untangle.specials(tms, "strata", order = 1:2)
```

---

**uspop2**

*Projected US Population*

---

**Description**

US population by age and sex, for 2000 through 2020

**Usage**

```r
data(uspop2)
```

**Format**

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

**Details**

This data is often used as a "standardized" population for epidemiology studies.

**Source**

**See Also**

`uspop`

**Examples**

```r
us50 <- uspop2[51:101, , "2000"]  # US 2000 population, 50 and over
age <- as.integer(dimnames(us50)[[1]])
smat <- model.matrix(~ factor(floor(age/5)) - 1)
ustot <- t(smat) %*% us50  # totals by 5 year age groups
temp <- c(50, 55, 60, 65, 70, 75, 80, 85, 90, 95)
dimnames(ustot) <- list(c(paste(temp, temp+4, sep="-"), "100+"),
c("male", "female"))
```
vcov.coxph  Variance-covariance matrix

Description

Extract and return the variance-covariance matrix.

Usage

```r
## S3 method for class 'coxph'
vcov(object, complete=TRUE, ...)
## S3 method for class 'survreg'
vcov(object, complete=TRUE, ...)
```

Arguments

- `object` a fitted model object
- `complete` logical indicating if the full variance-covariance matrix should be returned. This has an effect only for an over-determined fit where some of the coefficients are undefined, and coef(object) contains corresponding NA values. If complete=TRUE the returned matrix will have row/column for each coefficient, if FALSE it will contain rows/columns corresponding to the non-missing coefficients. The coef() function has a similiar complete argument.
- `...` additional arguments for method functions

Details

For the coxph and survreg functions the returned matrix is a particular generalized inverse: the row and column corresponding to any NA coefficients will be zero. This is a side effect of the generalized cholesky decomposition used in the underlying computation.

Value

a matrix

veteran  Veterans' Administration Lung Cancer study

Description

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

Usage

veteran

Format
xtfrm.Surv

trt: 1=standard 2=test
celltype: 1=squamous, 2=smallcell, 3=adenocarcinoma, 4=large
time: survival time
status: censoring status
karno: Karnofsky performance score (100=good)
diagtime: months from diagnosis to randomisation
age: in years
prior: prior therapy 0=no, 10=yes

Source

xtfrm.Surv Sorting order for Surv objects

Description
Sort survival objects into a partial order, which is the same one used internally for many of the calculations.

Usage
## S3 method for class 'Surv'
xtfrm(x)

Arguments
x a Surv object

Details
This creates a partial ordering of survival objects. The result is sorted in time order, for tied pairs of times right censored events come after observed events (censor after death), and left censored events are sorted before observed events. For counting process data (tstart, tstop, status) the ordering is by stop time, status, and start time, again with censoring last. Interval censored data is sorted using the midpoint of each interval.

The xtfrm routine is used internally by order and sort, so these results carry over to those routines.

Value
a vector of integers which will have the same sort order as x.

Author(s)
Terry Therneau
The many options and details of this function are best described in a vignette on population prediction.
**Value**

an object of class `yates` with components of

- **estimate**: a data frame with one row for each level of the term, and columns containing the level, the mean population predicted value (mppv) and its standard deviation.
- **tests**: a matrix giving the test statistics
- **mvar**: the full variance-covariance matrix of the mppv values
- **summary**: optional: any further summary if the values provided by the prediction method.

**Author(s)**

Terry Therneau

**Examples**

```r
fit1 <- lm(skips ~ Solder*Opening + Mask, data = solder)
yates(fit1, ~Opening, population = "factorial")

fit2 <- coxph(Surv(time, status) ~ factor(ph.ecog)*sex + age, lung)
yates(fit2, ~ ph.ecog, predict="risk") # hazard ratio
```

**Description**

This is a method which is called by the `yates` function, in order to setup the code to handle a particular model type. Methods for glm, coxph, and default are part of the survival package.

**Usage**

```r
yates_setup(fit, ...)
```

**Arguments**

- **fit**: a fitted model object
- **...**: optional arguments for some methods

**Details**

If the predicted value should be the linear predictor, the function should return NULL. The `yates` routine has particularly efficient code for this case. Otherwise it should return a prediction function or a list of two elements containing the prediction function and a summary function. The prediction function will be passed the linear predictor as a single argument and should return a vector of predicted values.

**Note**

See the vignette on population prediction for more details.
yates_setup
