1. `+-base::try(EXPR)
2. | \-base::tryCatch(...)
3. | \-base::tryCatchList(expr, classes, parentenv, handlers)
4. | \-base::tryCatchOne(expr, names, parentenv, handlers[[1L]])
5. | \-base::doTryCatch(return(expr), name, parentenv, handler)
6. \-EXPR

Lines 2 to 5 are intervening call frames, the last of which finally triggered evaluation of `EXPR`. Setting `filter.callframes` to `TRUE` simplifies the profiler output by removing all sibling nodes of intervening frames.

The same kind of call frame filtering is applied with `eval()` frames. When you call `eval()`, two frames are pushed on the stack to ensure a continuity between frames. Say we have these definitions:

```r
calling <- function() evaluator(quote(called()), environment())
evaluator <- function(expr, env) eval(expr, env)
called <- function() EXPR()
calling()
calls called()
in its own environment, via `eval()`. The latter is called indirectly through `evaluator()`. The net effect of this code is identical to just calling `called()` directly, without the intermediaries. However, the full call stack looks like this:
```

1. calling()
2. \-evaluator(quote(called()), environment())
3. \-base::eval(expr, env)
4. \-base::eval(expr, env)
5. \-called()
6. \-EXPR()

When call frame filtering is turned on, the true calling environment of `called()` is looked up, and the filtered call stack looks like this:

1. calling()
5. \-called()
6. \-EXPR()

If the calling environment is not on the stack, the function called by `eval()` becomes a root node. Say we have:
calling <- function() evaluator(quote(called()), new.env())

With call frame filtering we then get the following filtered call stack:

5. called()
6. \-EXPR()

**Note**

**On Unix-alikes:** Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with ‘--disable-R-profiling’ to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use Rprof in an executable built for C-level profiling.

**On Windows:** filename can be a UTF-8-encoded filepath that cannot be translated to the current locale.

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The numfiles and bufsize arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when Rprof(NULL) is called to finish profiling.

**See Also**

The chapter on “Tidying and profiling R code” in ‘Writing R Extensions’ (see the ‘doc/manual’ subdirectory of the R source tree).

summaryRprof to analyse the output file.

tracemem, Rprofmem for other ways to track memory use.

**Examples**

```r
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
## ...
## Now post-process the output as described in Details

## End(Not run)
```

---

**Rprofmem**

*Enable Profiling of R’s Memory Use*

**Description**

Enable or disable reporting of memory allocation in R.
Usage

Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)

Arguments

filename The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append logical: should the file be over-written or appended to?
threshold numeric: allocations on R’s "large vector" heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.
Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.
The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. (It is enabled in a standard Windows build of R.)
The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.
tracemem traces duplications of specific objects.
The "Writing R Extensions" manual section on "Tidying and profiling R code"

Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
**Description**

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

**Usage**

```
Rscript [options] [-e expr [-e expr2 ...] | file] [args]
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details.</td>
</tr>
<tr>
<td>expr, expr2</td>
<td>R expression(s), properly quoted.</td>
</tr>
<tr>
<td>file</td>
<td>the name of a file containing R commands. ‘-’ indicates ‘stdin’.</td>
</tr>
<tr>
<td>args</td>
<td>arguments to be passed to the script in file or expressions supplied via ‘-e’.</td>
</tr>
</tbody>
</table>

**Details**

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--no-echo --no-restore’ are always supplied; these imply ‘--no-save’. Arguments that contain spaces cannot be specified directly on the ‘#!’ line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the ‘#!’ line. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used; see the examples.

The prescribed order of arguments is important: e.g. ‘--verbose’ specified after ‘-e’ will be part of args and passed to the expression; the same will happen to ‘-e’ specified after file.

Additional options accepted as part of options (before file or ‘-e’) are

‘--verbose’ gives details of what Rscript is doing.

‘--default-packages=list’ where list is a comma-separated list of package names or NULL. Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup.

Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If ‘--default-packages’ is not used, then Rscript checks the environment variable R_SCRIPT_DEFAULT_PACKAGES. If this is set, then it takes precedence over R_DEFAULT_PACKAGES.

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable RHOME.

stdin() refers to the input file, and file("stdin") to the stdin file stream of the process.
Note

Rscript is only supported on systems with the execv system call.

Examples

## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

# Get the same initial packages in the same order as default R:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()'

## example #! script for a Unix-alike
## (arguments given on the #! line end up as [options] to Rscript, while
## arguments passed to the #! script end up as [args], so available to
## commandArgs())
#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)

RShowDoc  Show R Manuals and Other Documentation

Description

Utility function to find and display R documentation.

Usage

RShowDoc(what, type = c("pdf", "html", "txt"), package)

Arguments

what a character string: see ‘Details’.
type an optional character string giving the preferred format. Can be abbreviated.
package an optional character string specifying the name of a package within which to look for documentation.

Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘R_HOME/doc’.

Only on Windows, the R for Windows FAQ is specified by rw-FAQ.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).
RSiteSearch

Value

A invisible character string given the path to the file found.

See Also

For displaying regular help files, help (or ?) and help.start.

For type = "txt", file.show is used. vignettes are nicely viewed via RShowDoc(*, package=).

Examples

RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")

RSiteSearch

Search for Key Words or Phrases in Documentation

Description

Search for key words or phrases in various documentation, such as R manuals, help pages of base and CRAN packages, vignettes, task views and others, using the search engine at https://search.r-project.org and view them in a web browser.

Usage

RSiteSearch(string,
  restrict = c("functions", "descriptions", "news", "Rfunctions",
    "Rmanuals", "READMEs", "views", "vignettes"),
  format,
  sortby = c("score", "date:late", "date:early", "subject",
    "subject:descending", "size", "size:descending"),
  matchesPerPage = 20,
  words = c("all", "any"))

Arguments

string A character string specifying word(s) or phrase(s) to search. If the words are to be searched as one entity, enclose them either in (escaped) quotes or in braces.

restrict A character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: functions for help pages of CRAN packages, descriptions for extended descriptions of CRAN packages, news for package NEWS, RFunctions for help pages of R base packages, Rmanuals for R manuals, READMEs for README files of CRAN packages, views for task views, vignettes for package vignettes.

format deprecated.
sortby character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for captions in alphabetical order, subject:descending for reverse alphabetical order, size or size:descending for size.)

matchesPerPage How many items to show per page.

words Show results matching all words/phrases (default) or any of them.

Details

This function is designed to work with the search site at https://search.r-project.org.
Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron and Gennadiy Starostin

See Also

help.search, help.start for local searches.
browseURL for how the help file is displayed.

Examples

# need Internet connection
## for phrase searching you may use (escaped) double quotes or brackets
RSiteSearch("(logistic regression) \"glm object\")
RSiteSearch("logistic regression")

## Search in vignettes and help files of R base packages
## store the query string:
fullquery <- RSiteSearch("lattice", restrict = c("vignettes","Rfunctions"))
fullquery # a string of 112 characters

---

rtags An Etags-like Tagging Utility for R

Description

rtags provides etags-like indexing capabilities for R code, using R’s own parser.
Usage

rtags(path = ".", pattern = "\.\.[RrSs]\$", recursive = FALSE,
src = list.files(path = path, pattern = pattern, full.names = TRUE, recursive = recursive),
keep.re = NULL, ofile = ",", append = FALSE, verbose = getOption("verbose"),
type = c("etags", "ctags"))

Arguments

path, pattern, recursive
Arguments passed on to list.files to determine the files to be tagged. By default, these are all files with extension .R, .r, .S, and .s in the current directory. These arguments are ignored if src is specified.

src
A vector of file names to be indexed.

keep.re
A regular expression further restricting src (the files to be indexed). For example, specifying keep.re = "/R/[^/]*/\/.R$" will only retain files with extension .R inside a directory named R.

ofile
Passed on to cat as the file argument; typically the output file where the tags will be written ("TAGS" or "tags" by convention). By default, the output is written to the R console (unless redirected).

append
Logical, indicating whether the output should overwrite an existing file, or append to it.

verbose
Logical. If TRUE, file names are echoed to the R console as they are processed.

type
Character string specifying whether emacs style ("etags") or vi style ("ctags") tags are to be generated.

Details

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style ctags format and the emacs-style etags format. Tag files in these formats are usually generated by the ctags and etags utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The rtags function is intended to be a tagging utility for R code. It parses R code files (using R’s parser) and produces tags in both etags and ctags formats. The support for vi-style ctags is rudimentary, and was adapted from a patch by Neal Fultz; see PR#17214.

It may be more convenient to use the command-line wrapper script R CMD rtags.

Rtangle

R Driver for Stangle

Description

A driver for Stangle that extracts R code chunks. Notably all RtangleSetup() arguments may be used as arguments in the Stangle() call.

Usage

Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE, split = FALSE, quiet = FALSE, drop.evalFALSE = FALSE, ...)

Arguments

file name of Sweave source file. See the description of the corresponding argument of Sweave.
syntax an object of class SweaveSyntax.
output name of output file used unless split = TRUE: see ‘Details’.
annotate a logical or function. When true, as by default, code chunks are separated by comment lines specifying the names and line numbers of the code chunks. If FALSE the decorating comments are omitted. Alternatively, annotate may be a function, see section ‘Chunk annotation’.
split split output into a file for each code chunk?
quiet logical to suppress all progress messages.
drop.evalFALSE logical; When false, as by default, all chunks with option eval = FALSE are commented out in the output; otherwise (drop.evalFALSE = TRUE) they are omitted entirely.
...
additional named arguments setting defaults for further options listed in ‘Supported Options’.

Examples

## Not run:
rtags("/path/to/src/repository",
      pattern = "\.[.]\.|\.[RrSs]$",
      keep.re = "\/[R/",
      verbose = TRUE,
      ofile = "TAGS",
      append = FALSE,
      recursive = TRUE)

## End(Not run)
Details

Unless split = TRUE, the default name of the output file is basename(file) with an extension corresponding to the Sweave syntax (e.g., 'Rnw', 'Stex') replaced by 'R'. File names "stdout" and "stderr" are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the 'engine' (default '.R').

Note that this driver does more than simply extract the code chunks verbatim, because chunks may re-use earlier chunks.

Chunk annotation (annotate)

By default annotate = TRUE, the annotation is of one of the forms

```
###################################################
### code chunk number 3: viewport
###################################################
```

```
###################################################
### code chunk number 18: grid.Rnw:647-648
###################################################
```

```
###################################################
### code chunk number 19: trellisdata (eval = FALSE)
###################################################
```

using either the chunk label (if present, i.e., when specified in the source) or the file name and line numbers.

annotate may be a function with formal arguments (options, chunk, output), e.g. to produce less dominant chunk annotations; see Rtangle()$runcode how it is called instead of the default.

Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

- **engine:** character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **keep.source:** logical (TRUE). If keep.source == TRUE the original source is copied to the file. Otherwise, deparsed source is output.
- **eval:** logical (TRUE). If FALSE, the code chunk is copied across but commented out.
- **prefix** Used if split = TRUE. See prefix.string.
- **prefix.string:** a character string, default is the name of the source file (without extension). Used if split = TRUE as the prefix for the filename if the chunk has no label, or if it has a label and prefix = TRUE. Note that this is used as part of filenames, so needs to be portable.
- **show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

\texttt{Sweave}, \texttt{RweaveLatex}

Examples

\begin{verbatim}
nmRnw <- "example-1.Rnw"
exfile <- system.file("Sweave", nmRnw, package = "utils")
## Create R source file
Stangle(exfile)
nmR <- sub("Rnw$", "R", nmRnw) # the (default) R output file name
if(interactive()) file.show("example-1.R")

## Smaller R source file with custom annotation:
my.Ann <- function(options, chunk, output) {
  cat("### chunk #", options$chunknr, ": ",
      if(!is.null(ol <- options$label)) ol else .RtangleCodeLabel(chunk),
      if(!options$eval) " (eval = FALSE)"", ",
      file = output, sep = "")
}
Stangle(exfile, annotate = my.Ann)
if(interactive()) file.show("example-1.R")

Stangle(exfile, annotate = my.Ann, drop.evalFALSE=TRUE)
if(interactive()) file.show("example-1.R")
\end{verbatim}

\begin{description}
\item[RweaveLatex] \textit{R/LaTeX Driver for Sweave}
\end{description}

Description

A driver for \texttt{Sweave} that translates \texttt{R} code chunks in \LaTeX{} files by “running them”, i.e., \texttt{parse()} and \texttt{eval()} each.

Usage

\begin{verbatim}
RweaveLatex()
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
                 debug = FALSE, stylepath, ...)
\end{verbatim}

Arguments

\begin{description}
\item[file] Name of Sweave source file. See the description of the corresponding argument of \texttt{Sweave}.
\item[syntax] An object of class \texttt{SweaveSyntax}.
\item[output] Name of output file. The default is to remove extension \texttt{.nw}, \texttt{.Rnw} or \texttt{.Snw} and to add extension \texttt{.tex}. Any directory paths in \texttt{file} are also removed such that the output is created in the current working directory.
\item[quiet] If \texttt{TRUE} all progress messages are suppressed.
\end{description}
debug
stylepath

If TRUE, input and output of all code chunks is copied to the console.

See ‘Details’.

... named values for the options listed in ‘Supported Options’.

Details

The \LaTeX file generated needs to contain the line ‘\usepackage{Sweave}’, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the \RweaveLaTeX driver as last line before the ‘\begin{document}’ statement. If stylepath = TRUE, a hard-coded path to the file ‘Sweave.sty’ in the \R installation is set in place of Sweave. The hard-coded path makes the \LaTeX file less portable, but avoids the problem of installing the current version of ‘Sweave.sty’ to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for stylepath is now taken from the environment variable \texttt{SWEAVE\_STYLEPATH\_DEFAULT}, or is FALSE if that is unset or empty. If set, it should be exactly TRUE or FALSE: any other values are taken as FALSE.

The simplest way for frequent Sweave users to ensure that ‘Sweave.sty’ is in the TeX input path is to add ‘\texttt{R\_HOME/share/texmf}’ as a ‘texmf tree’ (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, ‘Sweave.sty’ loads the ‘graphicx’ \LaTeX package and sets the width of all included graphics to: ‘\texttt{\setkeys{Gin}{width=0.8\textwidth}}’.

This setting (defined in the ‘graphicx’ package) affects the width size option passed to the ‘\includegraphics{}’ directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.

Thus, for example, you may set width=3 in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to ‘0.8\textwidth’ and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the ‘\texttt{\setkeys{Gin}{width=\ldots}}’ directive in your ‘.Rnw’ file after the ‘\begin{document}’ directive and changing the width option value as you prefer, using standard \LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a ‘\usepackage[nogin]{Sweave}’ directive in your preamble. In this case, no size-scaling options will be passed to the ‘\includegraphics{}’ directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

‘Sweave.sty’ also supports the ‘[nofontenc]’ option, which skips the default inclusion of ‘\usepackage[T1]{fontenc}’ for pdiTEx processing.

It also supports the ‘[inconsolata]’ option, to render monospaced text in inconsolata, the font used by default for \R help pages.

The use of fancy quotes (see sQuote) can cause problems when setting \R output in non-UTF-8 locales (note that pdiTEx assumes UTF-8 by default since 2018). Either set options(useFancyQuotes = FALSE) or arrange that \LaTeX is aware of the encoding used (in \texttt{R < 4.2.0}, Windows users needed a ‘\texttt{\usepackage[cp1252]{inputenc}}’ declaration or similar, see \texttt{l10n\_info()}) and ensure that typewriter fonts containing directional quotes are used.

Some \LaTeX graphics drivers do not include ‘.png’ or ‘.jpg’ in the list of known extensions. To enable them, add something like ‘\texttt{\DeclareGraphicsExtensions{.png,.pdf,.jpg}}’ to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are
TRUE both files will be produced by Sweave, and their order in the ‘DeclareGraphicsExtensions’ list determines which will be used by pdflatex.

Supported Options

RweaveLatex supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from Sweave through ... but not when used in the header of a code chunk.

**engine:** character string ("R"). Only chunks with engine equal to "R" or "S" are processed.

**echo:** logical (TRUE). Include R code in the output file?

**keep.source:** logical (TRUE). When echoing, if TRUE the original source is copied to the file. Otherwise, deparsed source is echoed.

**eval:** logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text nor graphical output produced.

**results:** character string ("verbatim"). If "verbatim", the output of R commands is included in the verbatim-like ‘Soutput’ environment. If "tex", the output is taken to be already proper \LaTeX{} markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.

**print:** logical (FALSE). If TRUE, this forces auto-printing of all expressions.

**term:** logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit print or similar statements.

**split:** logical (FALSE). If TRUE, text output is written to separate files for each code chunk.

**strip.white:** character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.

A ‘blank line’ is one that is empty or includes only whitespace (spaces and tabs).

Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

**prefix:** logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the prefix.string option: otherwise only unlabelled chunks use the prefix.

**prefix.string:** a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

**include:** logical (TRUE), indicating whether input statements for text output (if split = TRUE) and ‘\includegraphics’ statements for figures should be auto-generated. Use include = FALSE if the output should appear in a different place than the code chunk (by placing the input line manually).

**fig:** logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

**eps:** logical (FALSE), indicating whether EPS figures should be generated. Ignored if fig = FALSE.

**pdf:** logical (TRUE), indicating whether PDF figures should be generated. Ignored if fig = FALSE.

**pdf.version, pdf.encoding, pdf.compress:** passed to pdf to set the version, encoding and compression (or not). Defaults taken from pdf.options().

**png:** logical (FALSE), indicating whether PNG figures should be generated. Ignored if fig = FALSE. Only available in R \geq 2.13.0.
**jpeg**: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if \( \text{fig} = \) FALSE. Only available in \( R \geq 2.13.0 \).

**grdevice**: character (NULL); see section ‘Custom Graphics Devices’. Ignored if \( \text{fig} = \) FALSE. Only available in \( R \geq 2.13.0 \).

**width**: numeric (6), width of figures in inches. See ‘Details’.

**height**: numeric (6), height of figures in inches. See ‘Details’.

**resolution**: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

**concordance**: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

**figs.only**: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a ‘\$SweaveOpts{}’ line in the document. For unknown options, their type is set at first use.

### Custom Graphics Devices

If option `grdevice` is supplied for a code chunk with both `fig` and `eval` true, the following call is made

```r
get(options$grdevice, envir = .GlobalEnv)(name =, width =,
                     height =, options)
```

which should open a graphics device. The chunk’s code is then evaluated and `dev.off` is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```r
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
  grDevices::png(filename = paste(name, "png", sep = ","),
                 width = width, height = height, res = 100,
                 units = "in", type = "quartz", bg = "transparent")
@
```

Alternatively for \( R \geq 3.4.0 \), if the function exists in a package (rather than the .GlobalEnv) it can be used by setting `grdevice = "pkg::my.Swd"` (or with ‘::’ instead of ‘::’ if the function is not exported).

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for `dev.off` can be provided as a function with suffix `.off`, e.g. `my.Swd.off()` or `pkg::my.Swd.off()`, respectively.
Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each logical option of a code chunk (echo, print, ...) a hook can be specified, which is executed if and only if the respective option is `TRUE`. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as list(fig = foo), and foo is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called clean that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.

Rwin configuration

R for Windows Configuration

Description

The file 'Rconsole' configures the R GUI (Rgui) console under MS Windows and `loadRconsole(*` loads a new configuration.

The file 'Rdevga' configures the graphics devices windows, win.graph, win.metafile and win.print, as well as the bitmap devices bmp, jpeg, png and tiff (which use for type = "windows" use windows internally).

Usage

`loadRconsole(file)`

Arguments

file The file from which to load a new 'Rconsole' configuration. By default a file dialog is used to select a file.

Details

There are system copies of these files in '{R_HOME}\etc'. Users can have personal copies of the files: these are looked for in the location given by the environment variable R_USER. The system files are read only if a corresponding personal file is not found.

If the environment variable R_USER is not set, the R system sets it to HOME if that is set (stripping any trailing slash), otherwise to the Windows 'personal' directory, otherwise to {HOMEDRIVE}{HOMEPATH} if HOMEDRIVE and HOMEDRIVE are both set otherwise to the working directory. This is as described in the file 'rw-FAQ'.

Rwin configuration

R for Windows Configuration
Value

Each of the files contains details in its comments of how to set the values.

At the time of writing ‘Rdevga’ configured the mapping of font numbers to fonts, and ‘Rconsole’ configured the appearance (single or multiple document interface, toolbar, statusbar on MDI), size, font and colours of the GUI console, and whether resizing the console sets `options("width")`.

The file ‘Rconsole’ also configures the internal pager. This shares the font and colours of the console, but can be sized separately.

‘Rconsole’ can also set the initial positions of the console and the graphics device, as well as the size and position of the MDI workspace in MDI mode.

`loadRconsole` is called for its side effect of loading new defaults. It returns no useful value.

Chinese/Japanese/Korean

Users of these languages will need to select a suitable font for the console (perhaps MS Mincho) and for the graphics device (although the default Arial has many East Asian characters). It is essential that the font selected for the console has double-width East Asian characters – many monospaced fonts do not.

Note

The GUI preferences item on the Edit menu brings up an dialog box which can be used to edit the console settings, and to save them to a file.

This is only available on Windows.

windows

Examples

```r
if(.Platform$OS.type == "windows") withAutoprint({
    ruser <- Sys.getenv("R_USER")
    cat("\n\nLocation for personal configuration files is\nR_USER = " ,
    ruser, "\n\n", sep = " ")
    ## see if there are personal configuration files
    file.exists(file.path(ruser, c("Rconsole", "Rdevga")))
    ## show the configuration files used
    showConfig <- function(file)
    {
        ruser <- Sys.getenv("R_USER")
        path <- file.path(ruser, file)
        if(!file.exists(path)) path <- file.path(R.home(), "etc", file)
        file.show(path, header = path)
    }
    showConfig("Rconsole")
})
```
savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

loadhistory(file = "\.Rhistory")
savehistory(file = "\.Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
  prefix = "##------ ", suffix = " ------##",
  quiet = FALSE)

Arguments

file
max.show
reverse
pattern
...
stamp
prefix
suffix
quiet

Arguments to be passed to grep when doing the matching.

Description

There are several history mechanisms available for the different R consoles, which work in similar
but not identical ways. Notably, there are different implementations for Unix and Windows.

Windows: The functions described here work in Rgui and interactive Rterm but not in batch use
of Rterm nor in embedded/DCOM versions.

Unix-alikes: The functions described here work under the readline command-line interface but
may not otherwise (for example, in batch use or in an embedded application). Note that R can
be built without readline.

R.app, the console on macOS, has a separate and largely incompatible history mechanism,
which by default uses a file ‘.Rapp.history’ and saves up to 250 entries. These functions
are not currently implemented there.
The (readline on Unix-alikes) history mechanism is controlled by two environment variables: 
R_HISTSIZE controls the number of lines that are saved (default 512), and R_HISTFILE (default 
`.Rhistory`) sets the filename used for the loading/saving of history if requested at the begin-
ning/end of a session (but not the default for loadhistory/savehistory). There is no limit on the 
number of lines of history retained during a session, so setting R_HISTSIZE to a large value has no 
penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the 
use of `Sys.setenv`.

On Unix-alikes: Note that readline history library saves files with permission 0600, that is with 
read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the 
console. On platforms that do not support a history mechanism only the console message is printed.

**Note**

If you want to save the history at the end of (almost) every interactive session (even those in which 
you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

**Examples**

```r
## Not run:
## Save the history in the home directory: note that it is not 
## (by default) read from there but from the current directory
.Last <- function()
  if(interactive()) try(savehistory("~/.Rhistory"))

## End(Not run)
```

---

**select.list**

**Select Items from a List**

Select item(s) from a character vector.

**Usage**

```
select.list(choices, preselect = NULL, multiple = FALSE, 
            title = NULL, graphics = getOption("menu.graphics"))
```

**Arguments**

- `choices`: a character vector of items.
- `preselect`: a character vector, or NULL. If non-null and if the string(s) appear in the list, the 
  item(s) are selected initially.
- `multiple`: logical: can more than one item be selected?
- `title`: optional character string for window title, or NULL for no title.
- `graphics`: logical: should a graphical widget be used?
Details

The normal default is graphics = TRUE.

On Windows, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. If multiple is true, further items can be selected or deselected by holding the control key down whilst selecting, and shift-clicking can be used to select ranges. Normal termination is via the ‘OK’ button or by hitting Enter or double-clicking an item. Selection can be aborted via the ‘Cancel’ button or pressing Escape.

Under the macOS GUI, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If graphics is FALSE or no graphical widget is available it displays a text list from which the user can choose by number(s). The multiple = FALSE case uses menu. Preselection is only supported for multiple = TRUE, where it is indicated by a "+" preceding the item.

It is an error to use select.list in a non-interactive session.

Value

A character vector of selected items. If multiple is false and no item was selected (or Cancel was used), "" is returned. If multiple is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

menu, tk_select.list for a graphical version using Tcl/Tk.

Examples

## Not run:
select.list(sort(.packages(all.available = TRUE)))
## End(Not run)

Description

Print version information about R, the OS and attached or loaded packages.

Usage

sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE,
     RNG = !identical(x$RNGkind, .RNGdefaults), ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE,
        RNG = !identical(object$RNGkind, .RNGdefaults), ...)
osVersion
Arguments

package a character vector naming installed packages, or NULL (the default) meaning all attached packages.
x an object of class "sessionInfo".
locale an object of class "sessionInfo".
RNG show information on RNGkind()? Defaults to true iff it differs from the R version's default, i.e., RNGversion(*)
... currently not used.

Value

sessionInfo() returns an object of class "sessionInfo" which has print and toLatex methods. This is a list with components

R.version a list, the result of calling R.Version().
platform a character string describing the platform R was built under. Where sub-architectures are in use this is of the form 'platform/sub-arch (nn-bit)'.
running a character string (or possibly NULL), the same as osVersion, see below.
RNGkind a character vector, the result of calling RNGkind().
matprod a character string, the result of callinggetOption("matprod").
BLAS a character string, the result of calling extSoftVersion()["BLAS"].
LAPACK a character string, the result of callingLa_library().
locale a character string, the result of callingSys.getlocale().
basePkgs a character vector of base packages which are attached.
otherPkgs (not always present): a character vector of other attached packages.
loadedOnly (not always present): a named list of the results of callingpackageDescriptionon packages whose namespaces are loaded but are not attached.

osVersion

osVersion is a character string (or possibly NULL on bizarre platforms) describing the OS and version which it is running under (as distinct from built under). This attempts to name a Linux distribution and give the OS name on an Apple Mac.

It is the same as sessionInfo()$running and created when loading theutilspackage.

Windows may report unexpected versions: see the help for win.version.

How OSes identify themselves and their versions can be arcane: where possible osVersion (and hence sessionInfo()$running) uses a human-readable form.

Where R was compiled under macOS 10.x (as the CRAN Intel distributions have been) but running under ‘Big Sur’ or later, macOS reports itself as ‘10.16’ (which R recognizes as ‘Big Sur/Monterey’) and not ‘11.x’ or ‘12.x’.

Note

The information on ‘loaded’ packages and namespaces is the current version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.
See Also

**R.version**

Examples

```r
sI <- sessionInfo()
sI
# The same, showing the RNGkind, but not the locale :
print(sI, RNG = TRUE, locale = FALSE)
toLatex(sI, locale = FALSE) # shortest; possibly desirable at end of report
```

---

**setRepositories**  
*Select Package Repositories*

Description

Interact with the user to choose the package repositories to be used.

Usage

```r
setRepositories(graphics = getOption("menu.graphics"),
    ind = NULL, addURLs = character())
```

Arguments

- `graphics`  
  Logical. If true, use a graphical list: on Windows or macOS GUI use a list box, and on a Unix-alike if `tcltk` and an X server are available, use Tk widget. Otherwise use a text menu.

- `ind`  
  NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for `graphics = FALSE`.

- `addURLs`  
  A character vector of additional URLs: it is often helpful to use a named vector.

Details

The default list of known repositories is stored in the file `R_HOME/etc/repositories`. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable `R_REPOSITORIES`, or if this is unset or does not exist, in `HOME/.R/repositories`, which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`, e.g. via `chooseBioCmirror` — the default value is “https://bioconductor.org”.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g., only source packages or not macOS binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type "both" is equivalent to "source".)

Repository "CRAN" is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.
Value

This function is invoked mainly for its side effect of updating options("repos"). It returns (invisibly) the previous repos options setting (as a list with component repos) or NULL if no changes were applied.

Note

This does not set the list of repositories at startup: to do so set options(repos =) in a start up file (see help topic Startup).

See Also

chooseCRANmirror, chooseBioCmirror, install.packages.

Examples

## Not run:
setRepositories(addURLs =
c(CRANxtras = "https://www.stats.ox.ac.uk/pub/RWin"))
## End(Not run)

---

**setWindowTitle**

*Set the Window Title or the Statusbar of the RGui in Windows*

Description

Set or get the title of the R (i.e. RGui) window which will appear in the task bar, or set the statusbar (if in use).

Usage

```
setWindowTitle(suffix, title = paste(getIdentification(), suffix))
getWindowTitle()
getIdentification()
setStatusBar(text)
```

Arguments

- `suffix`: a character string to form part of the title
- `title`: a character string forming the complete new title
- `text`: a character string of up to 255 characters, to be displayed in the status bar.
Details

setWindowTitle appends suffix to the normal window identification (RGui, R Console or Rterm). Use suffix = "" to reset the title.

getWindowTitle gets the current title.

This sets the title of the frame in MDI mode, the title of the console for RGui --sdi, and the title of the window from which it was launched for Rterm. It has no effect in embedded uses of R.

getIdentification returns the normal window identification.

setStatusBar sets the text in the statusbar of an MDI frame: if this is not currently shown it is selected and shown.

Value

The first three functions return a length 1 character vector.

setWindowTitle returns the previous window title (invisibly).

getWindowTitle and getIdentification return the current window title and the normal window identification, respectively.

Note

These functions are only available on Windows and only make sense when using the Rgui. E.g., in Rterm (and hence in ESS) the title is not visible (but can be set and gotten), and in a version of RStudio it has been "", invariably.

Examples

if(.Platform$OS.type == "windows") withAutoprint({
  ## show the current working directory in the title, saving the old one
  oldtitle <- setWindowTitle(getwd())
  Sys.sleep(0.5)
  ## reset the title
  setWindowTitle(""")
  Sys.sleep(0.5)
  ## restore the original title
  setWindowTitle(title = oldtitle)
})

---

SHLIB

Build Shared Object/DLL for Dynamic Loading

Description

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using dyn.load or library.dynam.

Usage

R CMD SHLIB [options] [-o dllname] files
Arguments

files a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.

dllname the full name of the shared object/DLL to be built, including the extension (typically '.so' on Unix systems, and '.dll' on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file.

options Further options to control the processing. Use R CMD SHLIB --help for a current list.

Details

R CMD SHLIB is the mechanism used by INSTALL to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add cpp flags and to add libraries to the link step) and for details of some of its quirks.

Items in files with extensions ‘.c’, ‘.cpp’, ‘.cc’, ‘.C’, ‘.f’, ‘.f90’, ‘.f95’, ‘.m’ (ObjC), ‘.M’ and ‘.mm’ (ObjC++) are regarded as source files, and those with extension ‘.o’ as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on macOS.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option ‘-n’ (also known as ‘--dry-run’) will show the commands that would be run without actually executing them.

Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also

COMPILE, dyn.load, library.dynam.

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on ‘Customizing compilation’ in the former.

Examples

## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

## End(Not run)
shortPathName

Express File Paths in Short Form on Windows

Description

Convert file paths to the short form. This is an interface to the Windows API call GetShortPathNameW.

Usage

shortPathName(path)

Arguments

path character vector of file paths.

Details

For most file systems, the short form is the ‘DOS’ form with 8+3 path components and no spaces, and this used to be guaranteed. But some file systems on recent versions of Windows do not have short path names when the long-name path will be returned instead.

Value

A character vector. The path separator will be \. If a file path does not exist, the supplied path will be returned with slashes replaced by backslashes.

Note

This is only available on Windows.

See Also

normalizePath.

Examples

if(.Platform$OS.type == "windows") withAutoprint({
  cat(shortPathName(c(R.home(), tempdir())), sep = "\n")
})
Description

These functions extract information from source references.

Usage

```r
getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
getSrcref(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
                first = TRUE)
```

Arguments

- `x` An object (typically a function) containing source references.
- `full.names` Whether to include the full path in the filename result.
- `unique` Whether to list only unique filenames/directories.
- `which` Which part of a source reference to extract. Can be abbreviated.
- `first` Whether to show the first (or last) location of the object.

Details

Each statement of a function will have its own source reference if the "keep.source" option is TRUE. These functions retrieve all of them.

The components are as follows:

- **line** The line number where the object starts or ends.
- **column** The column number where the object starts or ends. Horizontal tabs are converted to spaces.
- **byte** As for "column", but counting bytes, which may differ in case of multibyte characters (and horizontal tabs).
- **parse** As for "line", but this ignores #line directives.

Value

- `getSrcFilename` and `getSrcDirectory` return character vectors holding the filename/directory.
- `getSrcref` returns a list of "srcref" objects or NULL if there are none.
- `getSrcLocation` returns an integer vector of the requested type of locations.

See Also

- `srcref`, `getParseData`
Examples

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved
getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

**stack**  
**Stack or Unstack Vectors from a Data Frame or List**

**Description**
Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

**Usage**

```r
stack(x, ...)  
## Default S3 method:
stack(x, drop=FALSE, ...)
## S3 method for class 'data.frame'
stack(x, select, drop=FALSE, ...)

unstack(x, ...)
## Default S3 method:
unstack(x, form, ...)
## S3 method for class 'data.frame'
unstack(x, form, ...)
```

**Arguments**

- `x`: a list or data frame to be stacked or unstacked.
- `select`: an expression, indicating which variable(s) to select from a data frame.
- `form`: a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to `formula(x)` in the data frame method for `unstack`.
- `drop`: Whether to drop the unused levels from the “ind” column of the return value.
- `...`: further arguments passed to or from other methods.

**Details**
The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to vectors (as determined by `is.vector`); non-vector columns (e.g., factors) will be ignored with a warning. Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.
These functions are generic: the supplied methods handle data frames and objects coercible to lists by `as.list`.

**Value**
unstack produces a list of columns according to the formula `form`. If all the columns have the same length, the resulting list is coerced to a data frame.

stack produces a data frame with two columns:

- **values**: the result of concatenating the selected vectors in `x`.
- **ind**: a factor indicating from which vector in `x` the observation originated.

**Author(s)**
Douglas Bates

**See Also**
`lm`, `reshape`

**Examples**

```r
require(stats)
formula(PlantGrowth)  # check the default formula
pg <- unstack(PlantGrowth)  # unstack according to this formula
pg
stack(pg)  # now put it back together
stack(pg, select = -ctrl)  # omitting one vector
```

---

### str

**Compactly Display the Structure of an Arbitrary R Object**

**Description**
Compact display the internal structure of an R object, a diagnostic function and an alternative to `summary` (and to some extent, `dput`). Ideally, only one line for each 'basic' structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls `args` for (non-primitive) function objects.

strOptions() is a convenience function for setting options(str = .), see the examples.

**Usage**

```r
str(object, ...)
```

### S3 method for class 'data.frame'

```r
str(object, ...)
```

### Default S3 method:

```r
str(object, max.level = NA,
    vec.len = strO$vec.len, digits.d = strO$digits.d,
    nchar.max = 128, give.attr = TRUE,
```
drop.deparse.attr = str$drop.deparse.attr,
give.head = TRUE, give.length = give.head,
width = getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
collapse = "."),
comp.str = "+", no.list = FALSE, envir = baseenv(),
strict.width = str$strict.width,
formatNum = str$formatNum, list.len = str$list.len,
deparse.lines = str$deparse.lines, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
list.len = 99, deparse.lines = NULL,
drop.deparse.attr = TRUE,
formatNum = function(x, ...)
  format(x, trim = TRUE, drop0trailing = TRUE, ...))

Arguments

object any R object about which you want to have some information.
max.level maximal level of nesting which is applied for displaying nested structures, e.g.,
a list containing sub lists. Default NA: Display all nesting levels.
vec.len numeric (>= 0) indicating how many ‘first few’ elements are displayed of each
vector. The number is multiplied by different factors (from .5 to 3) depending
on the kind of vector. Defaults to the vec.len component of option "str" (see
options) which defaults to 4.
digits.d number of digits for numerical components (as for print). Defaults to the
digits.d component of option "str" which defaults to 3.
nchar.max maximal number of characters to show for character strings. Longer strings
are truncated, see longch example below.
give.attr logical; if TRUE (default), show attributes as sub structures.
drop.deparse.attr logical; if TRUE (default), deparse(control = <S>) will not have
"showAttributes" in <S>. Used to be hard coded to FALSE and hence
can be set via strOptions() for back compatibility.
give.length logical; if TRUE (default), indicate length (as [1:...]).
give.head logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as
<type>[1:...]).
width the page width to be used. The default is the currently active
options("width"); note that this has only a weak effect, unless strict.width
is not "no".
nest.lev current nesting level in the recursive calls to str.
indent.str the indentation string to use.
comp.str string to be used for separating list components.
nol.list logical; if true, no ‘list of’ nor the class are printed.
envir the environment to be used for promise (see delayedAssign) objects only.
strict.width string indicating if the width argument’s specification should be followed
strictly, one of the values c("no", "cut", "wrap"). which can be abbreviated.
Defaults to the strict.width component of option "str" (see options)
str which defaults to "no" for back compatibility reasons; "wrap" uses `strwrap(*)`, width = width) whereas "cut" cuts directly to width. Note that a small `vec.length` may be better than setting `strict.width = "wrap"`.

formatNum a function such as `format` for formatting numeric vectors. It defaults to the `formatNum` component of option "str", see "Usage" of `strOptions()` above, which is almost back compatible to R <= 2.7.x, however, using `formatC` may be slightly better.

list.len numeric; maximum number of list elements to display within a level.

deparse.lines numeric or NULL as by default, determining the nlines argument to `deparse()` when object is a call. When NULL, the nchar.max and width arguments are used to determine a smart default.

... potential further arguments (required for Method/Generic reasons).

Value

str does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Note

See the extensive annotated ‘Examples’ below.

The default method tries to “work always", but needs to make some assumptions for the case when object has a class but no own str() method which is the typical case: There it relies on "[" and "[[" subsetting methods to be compatible with `length()`). When this is not the case, or when `is.list(object)` is TRUE, but `length(object)` differs from `length(unclass(object))` it treats it as “irregular" and reports the contents of `unclass(object)` as “hidden list’.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

See Also

`ls.str` for listing objects with their structure; `summary`, `args`.

Examples

```r
require(stats); require(grDevices); require(graphics)
## The following examples show some 'str' capabilities
str(1:12)
str(ls)
str(args) #-- more useful than args(args) !
str(freeny)
str(.Machine)
str(.Machine, digits.d = 20) # extra digits for identification of binary numbers
str( lsfit(1:9, 1:9))
str( lsfit(1:9, 1:9), max.level = 1)
str( lsfit(1:9, 1:9), width = 60, strict.width = "cut")
str( lsfit(1:9, 1:9), width = 60, strict.width = "wrap")
opt <- options(); str(opt) # save first;
    # otherwise internal options() is used.
need.dev <-
    !exists(".Device") || is.null(.Device) || .Device == "null device"
```
\begin{verbatim}
( if(need.dev) postscript()
   str(par())
   if(need.dev) graphics.off()
)
ch <- letters[1:12]; is.na(ch) <- 3:5
str(ch) # character NA

str(list(a = "A", L = as.list(1:100)), list.len = 9)
## ------------
## " .. [list output truncated] "
## Long strings, 'nchar.max'; 'strict.width' :
str(longch <- paste(rep(letters,100), collapse = ""))
str(longch)
str(longch, nchar.max = 52)
str(longch, strict.width = "wrap")

## Multibyte characters in strings (in multibyte locales):
oloc <- Sys.getlocale("LC_CTYPE")
mbyte.lc <- if(.Platform$OS.type == "windows")
   "English_United States.28605" else "en_GB.UTF-8"
try(Sys.setlocale("LC_CTYPE", mbyte.lc))
## Truncation behavior (<-> correct width measurement) for "long" non-ASCII:
idx <- c(65313:65338, 65345:65350)
fwch <- intToUtf8(idx) # full width character string: each has width 2
c.fw = nchar(fwch), w.fw = nchar(fwch, "w"))
stopifnot(unname(ncc) == c(64,64, 32, 64))
## nchar.max: 1st line needs an increase of 2 in order to see 1 (in UTF-8!):
invisible(lapply(60:66, function(N) str(fwch, nchar.max = N)))
invisible(lapply(60:66, function(N) str( ch , nchar.max = N))) # "1 is 1" here
## revert locale to previous:
Sys.setlocale("LC_CTYPE", oloc)

## Settings for narrow transcript :
op <- options(width = 60, str = strOptions(strict.width = "wrap"))

   -sum(dpois(y, lambda=ymax/(1+x/xh), log=TRUE))
fit <- mle(ll)
str(fit)
\end{verbatim}
strcapture

Capture String Tokens into a data.frame

Description

Given a character vector and a regular expression containing capture expressions, strcapture will extract the captured tokens into a tabular data structure, such as a data.frame, the type and structure of which is specified by a prototype object. The assumption is that the same number of tokens are captured from every input string.

Usage

strcapture(pattern, x, proto, perl = FALSE, useBytes = FALSE)

Arguments

pattern  The regular expression with the capture expressions.
x        A character vector in which to capture the tokens.
proto    A data.frame or S4 object that behaves like one. See details.
perl,useBytes Arguments passed to regexec.

Details

The proto argument is typically a data.frame, with a column corresponding to each capture expression, in order. The captured character vector is coerced to the type of the column, and the column names are carried over to the return value. Any data in the prototype are ignored. See the examples.

Value

A tabular data structure of the same type as proto, so typically a data.frame, containing a column for each capture expression. The column types and names are inherited from proto. Cases in x that do not match pattern have NA in every column.

See Also

regexec and regmatches for related low-level utilities.

Examples

x <- "chr1:1-1000"
pattern <- "(.\?):[[:digit:]+]-[[:digit:]+]"
proto <- data.frame(chr=character(), start=integer(), end=integer())
strcapture(pattern, x, proto)
summaryRprof  

**Summarise Output of R Sampling Profiler**

**Description**

Summarise the output of the `Rprof` function to show the amount of time used by different R functions.

**Usage**

```r
summaryRprof(filename = "Rprof.out", chunksize = 5000,
             memory = c("none", "both", "tseries", "stats"),
             lines = c("hide", "show", "both"),
             index = 2, diff = TRUE, exclude = NULL,
             basenames = 1)
```

**Arguments**

- `filename`: Name of a file produced by `Rprof()`.
- `chunksize`: Number of lines to read at a time.
- `memory`: Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated.
- `lines`: Summaries for line information. See ‘Line profiling’ below. Can be abbreviated.
- `index`: How to summarize the stack trace for memory information. See ‘Details’ below.
- `diff`: If TRUE memory summaries use change in memory rather than current memory.
- `exclude`: Functions to exclude when summarizing the stack trace for memory summaries.
- `basenames`: Number of components of the path to filenames to display.

**Details**

This function provides the analysis code for `Rprof` files used by `R CMD Rprof`.

As the profiling output file could be larger than available memory, it is read in blocks of `chunksize` lines. Increasing `chunksize` will make the function run faster if sufficient memory is available.

**Value**

If `memory = "none"` and `lines = "hide"`, a list with components

- `by.self`: A data frame of timings sorted by ‘self’ time.
- `by.total`: A data frame of timings sorted by ‘total’ time.
- `sample.interval`: The sampling interval.
- `sampling.time`: Total time of profiling run.

The first two components have columns ‘self.time’, ‘self.pct’, ‘total.time’ and ‘total.pct’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If `lines = "show"`, an additional component is added to the list:
by.line

A data frame of timings sorted by source location.

If memory = "both" the same list but with memory consumption in Mb in addition to the timings.

If memory = "tseries" a data frame giving memory statistics over time. Memory usage is in bytes.

If memory = "stats" a by object giving memory statistics by function. Memory usage is in bytes.

If no events were recorded, a zero-row data frame is returned.

Memory profiling

Options other than memory = "none" apply only to files produced by Rprof(memory.profiling = TRUE).

When called with memory.profiling = TRUE, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from malloc), memory in nodes on the R heap. It also records the number of calls to the internal function duplicate in the time interval. duplicate is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With memory = "both" the change in total memory (truncated at zero) is reported in addition to timing data.

With memory = "tseries" or memory = "stats" the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With memory = "tseries" the index is used to construct labels and may be a vector to give multiple sets of labels. With memory = "stats" the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both memory = "tseries" and memory = "stats" the argument diff = TRUE asks for summaries of the increase in memory use over the sampling interval and diff = FALSE asks for the memory use at the end of the interval.

Line profiling

If the code being run has source reference information retained (via keep.source = TRUE in source or KeepSource = TRUE in a package 'DESCRIPTION' file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the lines parameter can enable the display.

If lines = "show", line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If lines = "both", line locations will be mixed with function names in a combined display.

See Also

The chapter on 'Tidying and profiling R code' in 'Writing R Extensions' (see the 'doc/manual' subdirectory of the R source tree).

Rprof

tracemem traces copying of an object via the C function duplicate.

Rprofmem is a non-sampling memory-use profiler.

https://developer.r-project.org/memory-profiling.html
Examples

```r
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
exaMple(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)
## End(Not run)
```

Sweave

Automatic Generation of Reports

Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.

Usage

```r
Sweave(file, driver = RweaveLatex(),
syntax =getOption("SweaveSyntax"), encoding = "", ...)
```

```r
Stangle(file, driver = Rtangle(),
syntax =getOption("SweaveSyntax"), encoding = "", ...)
```

Arguments

- **file**: Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches `file`.
- **driver**: the actual workhorse, (a function returning) a named list of five functions; for details, see Section 5 of the ‘Sweave User Manual’ available as vignette("Sweave").
- **syntax**: NULL or an object of class "SweaveSyntax" or a character string with its name. See the section ‘Syntax Definition’.
- **encoding**: The default encoding to assume for `file`.
- **...**: further arguments passed to the driver’s setup function. See `RweaveLatexSetup` and `RtangleSetup`, respectively, for the arguments of the default drivers.

Details

An Sweave source file contains both text in a markup language (like \LaTeX) and R (or S) code. The code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an \texttt{R} source file that can be run using \texttt{source}. (Code inside \texttt{\Sexpr{}} statements is ignored by Stangle.)
Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used and are provided by various contributed packages.

Environment variable SWEAVE_OPTIONS can be used to override the initial options set by the driver: it should be a comma-separated set of key=value items, as would be used in a '\SweaveOpts' statement in a document.

If the encoding is unspecified (the default), non-ASCII source files must contain a line of the form

\usepackage[foo]{inputenc}

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or a comment line

%%SweaveUTF8

to declare UTF-8 input (the default encoding assumed by pdfTeX since 2018), or they will give an error. Re-encoding can be turned off completely with argument encoding = "bytes".

Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a \LaTeX-style syntax can be used. (See the user manual for further details.)

If syntax = NULL (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects SweaveSyntaxNoweb (with extension = "[.]\[rsRS\]nw$") and SweaveSyntaxLatex (with extension = "[.]\[rsRS\]tex$") are supplied, but users or packages can supply others with names matching the pattern SweaveSyntax.*.

Author(s)

Friedrich Leisch and R-core.

Examples

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask = FALSE)
options(device.ask.default = FALSE)
## create a LaTeX file - in the current working directory, getwd():
Sweave(testfile)

## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")

## or outside R by
##
## R CMD texi2pdf Sweave-test-1.tex
## on Unix-alikes which sets the appropriate TEXINPUTS path.
##
## On Windows,
## Rcmd texify --pdf Sweave-test-1.tex
## if MiKTeX is available.

## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")

---

**SweaveSyntConv**

*Convert Sweave Syntax*

**Description**

This function converts the syntax of files in Sweave format to another Sweave syntax definition.

**Usage**

SweaveSyntConv(file, syntax, output = NULL)

**Arguments**

- `file` Name of Sweave source file.
- `syntax` An object of class `SweaveSyntax` or a character string with its name giving the target syntax to which the file is converted.
- `output` Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in `file` are also removed such that the output is created in the current working directory.

**Author(s)**

Friedrich Leisch

**See Also**

'Sweave User Manual', a vignette in the **utils** package.

*RweaveLatex*, *Rtangle*
**Examples**

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

```r
## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)
## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```
drives can be included in filepaths). Rtools 4 and earlier included a tar which used ‘--force-local’, but Rtools 4.2 includes original GNU tar, which does not use it by default.

A convenient and robust way to set options for GNU tar is via environment variable TAR_OPTIONS. Appending ‘--force-local’ to TAR does not work with GNU tar due to restrictions on how some options can be mixed. The tar available on Windows 10 (libarchive’s bsdtar) supports drive letters by default. It does not support the ‘--force-local’, but ignores TAR_OPTIONS.

For GNU tar, ‘--format=ustar’ forces a more portable format. (The default is set at compilation and will be shown at the end of the output from tar --help: for version 1.30 ‘out-of-the-box’ it is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=posix’ which is the same as pax – it was never part of the POSIX standard for tar and should not be used.) For libarchive’s bsdtar, ‘--format=ustar’ is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU tar or libarchive tar (aka bsdtar).

Note that files = ‘.’ will usually not work with an external tar as that would expand the list of files after tarfile is created. (It does work with the default internal method.)

Value

The return code from system or 0 for the internal version, invisibly.

Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of pax, and in any case many common implementations diverged from the former standard.

Many R platforms use a version of GNU tar, but the behaviour seems to be changed with each version. macOS >= 10.6, FreeBSD and Windows 10 use bsdtar from the libarchive project (but for macOS a version from 2017 or earlier, 2010 for High Sierra), and commercial Unixes will have their own versions. bsdtar is available for many other platforms: macOS up to at least 10.9 had GNU tar as gnutar and other platforms, e.g. Solaris, have it as gtar: on a Unix-alike configure will try gnutar and gtar before tar.

Known problems arise from

• The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recent tar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by untar).

Most formats do not record the encoding of file paths.

• (File) links. tar was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but bsdtar ignores it. The internal method uses the GNU extension, with a warning.
• Header fields, in particular the padding to be used when fields are not full or not used. POSIX
did define the correct behaviour but commonly used implementations did (and still do) not
comply.

• File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and
symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks
of nuls), unlike GNU tar which by default pads with ‘\0’ to a multiple of 20 blocks (10KB).
Implementations which pad differ on whether the block padding should occur before or after com-
pression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with
higher resolution it is conventional to discard fractional seconds.

Compression

When an external tar command is used, compressing the tar archive requires that tar supports
the ‘-z’, ‘-j’ or ‘-J’ flag, and may require the appropriate command (gzip, bzip2 or xz) to be
available. For GNU tar, further compression programs can be specified by e.g. extra_flags =
"-I lz4". Some versions of bsd.tar accept options such as ‘--lz4’, ‘--lzop’ and ‘--lrzip’ or an
external compressor via --use-compress-program lz4: these could be supplied in extra_flags.

NetBSD prior to 8.0 used flag ‘--xz’ rather than ‘-J’, so this should be used via extra_flags =
"--xz" rather than compression = "xz". The commands from OpenBSD and the Heirloom Toolch-
est are not documented to support xz.

The tar programs in commercial Unixen such as AIX and Solaris do not support compression.

Note

For users of macOS. Apple’s file systems have a legacy concept of ‘resource forks’ dating from
classic Mac OS and rarely used nowadays. Apple’s version of tar stores these as separate files in
the tarball with names prefixed by ‘. _’, and unpacks such files into resource forks (if possible):
other ways of unpacking (including untar in R) unpack them as separate files.

When argument tar is set to the command tar on macOS, environment variable
COPYFILE_DISABLE=1 is set, which for the system version of tar prevents these separate files being
included in the tarball.

utility pax handles tar formats.

untar.
toBibtex(object, ...)  
toLatex(object, ...)  
## S3 method for class 'Bibtex'  
print(x, prefix = "", ...)  
## S3 method for class 'Latex'  
print(x, prefix = "", ...)  

Arguments  
object: object of a class for which a toBibtex or toLatex method exists.  
x: object of class "Bibtex" or "Latex".  
prefix: a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation.  
... in the print methods, passed to writeLines.

Details  
Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

citEntry and sessionInfo for examples

txtProgressBar(min = 0, max = 1, initial = 0, char = ",", width = NA, title, label, style = 1, file = "")  
getTxtProgressBar(pb)  
setTxtProgressBar(pb, value, title = NULL, label = NULL)  
## S3 method for class 'txtProgressBar'  
close(con, ...)
Arguments

- **min, max**: (finite) numeric values for the extremes of the progress bar. Must have \( \text{min} < \text{max} \).
- **initial, value**: initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.
- **char**: the character (or character string) to form the progress bar. Must have non-zero display width.
- **width**: the width of the progress bar, as a multiple of the width of **char**. If **NA**, the default, the number of characters is that which fits into `getOption("width")`.
- **style**: the 'style' of the bar – see ‘Details’.
- **file**: an open connection object or "" which indicates the console: `stderr()` might be useful here.
- **pb, con**: an object of class "txtProgressBar".
- **title, label**: ignored, for compatibility with other progress bars.
- **...**: for consistency with the generic.

Details

txtProgressBar will display a progress bar on the \( \text{R} \) console (or a connection) via a text representation.

setTxtProgressBar will update the value. Missing (**NA**) and out-of-range values of **value** will be (silently) ignored. (Such values of **initial** cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character. **style = 1** and **style = 2** just shows a line of **char**. They differ in that **style = 2** redraws the line each time, which is useful if other code might be writing to the \( \text{R} \) console. **style = 3** marks the end of the range by | and gives a percentage to the right of the bar.

Value

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

Note

Using **style 2 or 3** or reducing the value with **style = 1** uses ‘\r’ to return to the left margin – the interpretation of carriage return is up to the terminal or console in which \( \text{R} \) is running, and this is liable to produce ugly output on a connection other than a terminal, including when `stdout()` is redirected to a file.

See Also

- **winProgressBar** (Windows only), **tkProgressBar** (Unix-alike platforms).
Examples

```r
# slow
testit <- function(x = sort(runif(20)), ...) {
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
testit(char = '\u27a4')
```

type.convert

Convert Data to Appropriate Type

Description

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

Usage

```r
type.convert(x, ...)
## Default S3 method:
type.convert(x, na.strings = "NA", as.is, dec = ".",
            numerals = c("allow.loss", "warn.loss", "no.loss"), ...)
## S3 method for class 'data.frame'
type.convert(x, ...)
## S3 method for class 'list'
type.convert(x, ...)
```

Arguments

- `x` a vector, matrix, array, data frame, or list.
- `na.strings` a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- `as.is` whether to store strings as plain character. When false (was default before R 4.0.0), convert character vectors to factors. See ‘Details’.
- `dec` the character to be assumed for decimal points.
- `numerals` string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when `x` has more digits than can be stored in a double. Can be abbreviated. Possible values are `numerals = "allow.loss"`, **default**: the conversion happens with some accuracy loss. This was the behavior of R versions 3.0.3 and earlier, and the default from 3.1.1 onwards.
- `numerals = "warn.loss"`: a warning about accuracy loss is signalled and the conversion happens as with `numerals = "allow.loss"`. 
- `numerals = "no.loss"`: `x` is not converted to a number, but to a factor or character, depending on `as.is`. This was the behavior of R version 3.1.0.
- ... arguments to be passed to or from methods.
type.convert

Details

This helper function is used by read.table. When the data object x is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and when additionally as.is = FALSE (no longer the default!), converts a character vector to factor. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

Vectors containing just F, T, FALSE, TRUE and values from na.strings are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from na.strings are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see NumericConstants), or NaN, Inf or infinity (ignoring case) or values from na.strings are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings or (for as.is = FALSE) factors.

Since this is a helper function, the caller should always pass an appropriate value of as.is.

Value

An object like x but using another storage mode when appropriate.

Author(s)

R Core, with a contribution by Arni Magnusson

See Also

read.table, class, storage.mode.

Examples

```r
## Numeric to integer
class(rivers)
x <- type.convert(rivers, as.is = TRUE)
class(x)

## Convert many columns
auto <- type.convert(mtcars, as.is = TRUE)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones, as.is = TRUE)
storage.mode(WorldPhones)
storage.mode(phones)

## Factor or character
chr <- c("A", "B", "B", "A")
fac <- factor(c("A", "B", "B", "A"))
type.convert(chr, as.is = FALSE) # -> factor
type.convert(fac, as.is = FALSE) # -> factor
type.convert(chr, as.is = TRUE) # -> character
type.convert(fac, as.is = TRUE) # -> character
```
untar  

Extract or List Tar Archives

Description

Extract files from or list the contents of a tar archive.

Usage

```r
untar(tarfile, files = NULL, list = FALSE, exdir = ".", compressed = NA, extras = NULL, verbose = FALSE, restore_times = TRUE, support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE), tar = Sys.getenv("TAR"))
```

Arguments

- **tarfile**  
  The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary reads. For a compressed tarfile, and if a connection is to be used, that should be created by `gzfile(.)` (or `gzcon(.)`) which currently only works for "gzip", whereas `gzfile()` works for all compressions available in `tar()`.

- **files**  
  A character vector of recorded filepaths to be extracted: the default is to extract all files.

- **list**  
  If TRUE, list the files (the equivalent of `tar -tf`). Otherwise extract the files (the equivalent of `tar -xf`).

- **exdir**  
  The directory to extract files to (the equivalent of `tar -C`). It will be created if necessary.

- **compressed**  
  (Deprecated in favour of auto-detection, used only for an external tar command.) Logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression, and NA (the default) indicates that the type is to be inferred from the file header. The external command may ignore the selected compression type but detect a type automatically.

- **extras**  
  NULL or a character string: further command-line flags such as ‘-p’ to be passed to an external tar program.

- **verbose**  
  logical: if true echo the command used for an external tar program.

- **restore_times**  
  logical. If true (default) restore file modification times. If false, the equivalent of the ‘-m’ flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded. Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).

- **support_old_tars**  
  logical. If false (the default), the external tar command is assumed to be able handle compressed tarfiles and if compressed does not specify it, to automatically detect the type of compression. (The major implementations have done so since 2009; for GNU tar since version 1.22.)
If true, the R code calls an appropriate decompressor and pipes the output to tar, for compressed = NA examining the tarfile header to determine the type of compression.

tar

character string: the path to the command to be used or "internal". If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces.

Details

This is either a wrapper for a tar command or for an internal implementation written in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (except on Windows, when tar.exe is tried first).

Unless otherwise stated three types of compression of the tar file are supported: gzip, bzip2 and xz.

What options are supported will depend on the tar implementation used: the "internal" one is intended to provide support for most in a platform-independent way.

GNU tar: Modern GNU tar versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for xz compression.

On a Unix-alike, configure will set environment variable TAR, preferring GNU tar if found.

bsdtar: macOS 10.6 and later (and FreeBSD and some other OSes) have a tar from the libarchive project which detects all three forms of compression automagically (even if undocumented in macOS).

NetBSD: It is undocumented if NetBSD’s tar can detect compression automagically: for versions before 8 the flag for xz compression was ‘--xz’ not ‘-J’. So support_old_tars = TRUE is recommended (or use bsdtar if installed).

OpenBSD: OpenBSD’s tar does not detect compression automagically. It has no support for xz beyond reporting that the file is xz-compressed. So support_old_tars = TRUE is recommended.

Heirloom Toolchest: This tar does automagically detect gzip and bzip2 compression (undocumented) but has no support for xz compression.

Older support: Environment variable R_GZIPCMD gives the command to decompress gzip files, and R_BZIPCMD for bzip2 files. (On Unix-alikes these are set at installation if found.) xz is used if available: if not decompression is expected to fail.

Arguments compressed, extras and verbose are only used when an external tar is used.

Some external tar commands will detect some of lrzip, lzma, lz4, lzop and zstd compression in addition to gzip, bzip2 and xz. (For some external tar commands, compressed tarfiles can only be read if the appropriate utility program is available.) For GNU tar, further (de)compression programs can be specified by e.g. extras = "-I lz4". For bsdtar this could be extras = "--use-compress-program lz4". Most commands will detect (the nowadays rarely seen) ‘.tar.Z’ archives compressed by compress.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses gzfile to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some tar implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the USTAR/POSIX, GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.
You may see warnings from the internal implementation such as

```r
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a `tar` program that handles it, and look carefully at the resulting files. There may also be the warning

```r
using pax extended headers
```

This indicates that additional information may have been discarded, such as ACLs, encodings .... The former standards only supported ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

The internal implementation does not special-case ‘resource forks’ in macOS: that system’s `tar` command does. This may lead to unexpected files with names with prefix ‘._’.

**Value**

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive. Otherwise the return code from `system` with an external `tar` or `0L`, invisibly.

**See Also**

tar, unzip.

### unzip

**Extract or List Zip Archives**

**Description**

Extract files from or list a zip archive.

**Usage**

```r
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)
```

**Arguments**

- `zipfile`  The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.
- `files`    A character vector of recorded filepaths to be extracted: the default is to extract all files.
- `list`     If `TRUE`, list the files and extract none. The equivalent of `unzip -l`.
- `overwrite` If `TRUE`, overwrite existing files (the equivalent of `unzip -o`), otherwise ignore such files (the equivalent of `unzip -n`).
update.packages

junkpaths If TRUE, use only the basename of the stored filepath when extracting. The equivalent of `unzip -j`.

exdir The directory to extract files to (the equivalent of `unzip -d`). It will be created if necessary.

unzip The method to be used. An alternative is to use `getOption("unzip")`, which on a Unix-alike may be set to the path to a `unzip` program.

setTimes logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.)

Value

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class "POSIXct").

Otherwise for the "internal" method, a character vector of the filepaths extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows’ users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in `zip 3.8`: for that use `unzip = "unzip"` with `unzip 6.00` or later. It does have some support for bzip2 compression and > 2GB zip files (but not >= 4GB files pre-compression contained in a zip file: like many builds of `unzip` it may truncate these, in R’s case with a warning if possible).

If `unzip` specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be `NA` or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from `unzip 6.00`).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses zlib and is in particular based on the contributed ‘minizip’ application in the zlib sources (from https://zlib.net/) by Gilles Vollant.

See Also

`unz` to read a single component from a zip file.
`zip` for packing, i.e., the “inverse” of `unzip()`: further `untar` and `tar`, the corresponding pair for (un)packing tar archives (“tarballs”) such as R source packages.

update.packages  Compare Installed Packages with CRAN-like Repositories

Description

`old.packages` indicates packages which have a (suitable) later version on the repositories whereas `update.packages` offers to download and install such packages.

`new.packages` looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.
Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  method, instlib = NULL,
  ask = TRUE, available = NULL,
  oldPkgs = NULL, ..., checkBuilt = FALSE,
  type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  instPkgs = installed.packages(lib.loc = lib.loc, ...),
  method, available = NULL, checkBuilt = FALSE, ...
  type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  instPkgs = installed.packages(lib.loc = lib.loc, ...),
  method, available = NULL, ask = FALSE, ...
  type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos. Incompatible with type = "both".
method Download method, see download.file. Unused if a non-NULL available is supplied.
instlib character string giving the library directory where to install the packages.
ask logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. The latter value only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE. ask does not control questions asked before installing packages from source via type = "both" (see option "install.packages.compile.from.source").
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages. Incompatible with type = "both".
checkBuilt If TRUE, a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be 'old'.
oldPkgs if specified as non-NULL, update.packages() only considers these packages for updating. This may be a character vector of package names or a matrix as returned by old.packages.
instPkgs by default all installed packages, installed.packages(lib.loc = lib.loc). A subset can be specified; currently this must be in the same (character matrix) format as returned by installed.packages().
Arguments such as destdir and dependencies to be passed to `install.packages` and ignore_repo_cache, max_repo_cache_age and noCache to `available.packages` or `installed.packages`.

type character, indicating the type of package to download and install. See `install.packages`.

Details

`old.packages` compares the information from `available.packages` with that from instPkgs (computed by `installed.packages` by default) and reports installed packages that have newer versions on the repositories or, if checkBuilt = TRUE, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If ask != FALSE it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If ask = TRUE (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `instlib` if specified).

For how the list of suitable available packages is determined see `available.packages`. `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

Value

`update.packages` returns NULL invisibly.

For `old.packages`, NULL or a matrix with one row per package, row names the package names and column names “Package”, “LibPath”, “Installed” (the version), “Built” (the version built under), “ReposVer” and “Repository”.

For `new.packages` a character vector of package names, after any selected via ask have been installed.

Warning

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

See Also

`install.packages`, `available.packages`, `download.packages`, `installed.packages`, `contrib.url`.

The options listed for `install.packages` under options.

See `download.file` for how to handle proxies and other options to monitor file transfers.

The ‘R Installation and Administration’ manual for how to set up a repository.
url.show  

Display a Text URL

Description

Extension of file.show to display text files from a remote server.

Usage

```
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```

Arguments

- `url`: The URL to read from.
- `title`: Title for the browser.
- `file`: File to copy to.
- `delete.file`: Delete the file afterwards?
- `method`: File transfer method: see `download.file`
- `...`: Arguments to pass to `file.show`.

Note

Since this is for text files, it will convert to CRLF line endings on Windows.

See Also

`url`, `file.show`, `download.file`

Examples

```
## Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")
```

URLencode  

Encode or Decode (partial) URLs

Description

Functions to percent-encode or decode characters in URLs.

Usage

```
URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)
```

Arguments

- `URL`: a character vector.
- `reserved`: logical: should ‘reserved’ characters be encoded? See ‘Details’.
- `repeated`: logical: should apparently already-encoded URLs be encoded again?

Details

Characters in a URL other than the English alphanumeric characters and ‘-_.~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’. In addition, ‘! $ & ’ ( ) * + , ; = : ? @ # [ ] ‘ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLencode is to leave them alone, which is appropriate for ‘file:///’ URLs, but probably not for ‘http://’ ones.

An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.

Value

A character vector.

References

Examples

(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted

## both functions support character vectors of length > 1
y <- URLdecode(URLencode(c("url with space", "another one")))

Description

(Currently none)

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

Deprecated, Defunct
Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like \( \mathbb{R} \) object.

Usage

\[
\text{View}(x, \text{title})
\]

Arguments

- \( x \): an \( \mathbb{R} \) object which can be coerced to a data frame with non-zero numbers of rows and columns.
- \( \text{title} \): title for viewer window. Defaults to name of \( x \) prefixed by \text{Data:}.

Details

Object \( x \) is coerced (if possible) to a data frame, then columns are converted to character using \text{format.data.frame}. The object is then viewed in a spreadsheet-like data viewer, a read-only version of \text{data.entry}.

If there are row names on the data frame that are not \( 1: \text{nr} \), they are displayed in a separate first column called \( \text{row.names} \).

Objects with zero columns or zero rows are not accepted.

On Unix-alikes, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

On Windows, the array of cells can be navigated via the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see \text{Rconsole}), but adjusted downwards to show a whole number of rows and columns.

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

\text{edit.data.frame, data.entry}. 
vignette

View, List or Get R Source of Package Vignettes

Description

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

Usage

vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)
## S3 method for class 'vignette'
edit(name, ...)

Arguments

topic a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

package a character vector with the names of packages to search through, or NULL in which ‘all’ packages (as defined by argument all) are searched.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.

all logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.

x, name object of class vignette.

... ignored by the print method, passed on to file.edit by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it.

On Unix-alikes, The program specified by the pdfviewer option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class “packageIQR”.

See Also

browseVignettes for an HTML-based vignette browser; RShowDoc(<basename>, package = "<pkg>") displays a “rendered” vignette (pdf or html).
Examples

```r
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## The grid intro vignette -- open it
## Not run: vignette("grid") # calling print()
## The same (conditional on existence of the vignette).
## Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
  ## Not run: v1 # calling print(.)
  str(v1)
  ## Now let us have a closer look at the code

## Not run: edit(v1) # e.g., to send lines ...
}# if( has vignette "installed")
## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
  ## vignette("rotated")
  ## The same, but without searching for it:
  vignette("rotated", package = "grid")
}
```

### Description

Collect errors (class "error", typically from `tryCatch`) from a list `x` into a "summary warning", by default produce a `warning` and keep that message as "warningMsg" attribute.

### Usage

```r
warnErrList(x, warn = TRUE, errValue = NULL)
```

### Arguments

- **x**: a `list`, typically from applying models to a list of data (sub)sets, e.g., using `tryCatch(*, error = identity)`.
- **warn**: logical indicating if `warning()` should be called.
- **errValue**: the value with which errors should be replaced.

### Value

A `list` of the same length and names as the `x` argument, with the error components replaced by `errValue`, `NULL` by default, and summarized in the "warningMsg" attribute.
See Also

The `warnErrList()` utility has been used in `lmList()` and `nlsList()` in recommended package `nlme` forever.

Examples

```r
## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[,"Chick"])
sapply(ChWtgrps, nrow)# typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
                                 lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :
## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
                                 lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
                                 lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
  , identical(nl3[-1], nlis3[-1])
  , is.null(nl3[[1]])
)

## With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
data(Soybean, package="nlme")
  attr(Soybean, "formula") #=> weight ~ Time | Plot => split by "Plot":
L <- lapply(split(Soybean, Soybean[,"Plot"]),
            function(DD) tryCatch(error = identity,
              nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
Lw <- warnErrList(L)
} # if <nlme>
```

---

**winDialog**

**Dialog Boxes under Windows**

### Description

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

### Usage

```r
winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
          message)

winDialogString(message, default)
```
Arguments

- **type** character. The type of dialog box. It will have the buttons implied by its name.
- **message** character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R).
- **default** character. The default string.

Value

For **winDialog** a character string giving the name of the button pressed (in capitals) or NULL (invisibly) if the user had no choice.

For **winDialogString** a string giving the contents of the text box when Ok was pressed, or NULL if Cancel was pressed.

Note

The standard keyboard accelerators work with these dialog boxes: where appropriate Return accepts the default action, Esc cancels and the underlined initial letter (Y or N) can be used.

These functions are only available on Windows.

See Also

- **winMenuAdd**
- **file.choose** to select a file
- **package windlgs** in the package source distribution for ways to program dialogs in C in the GraphApp toolkit.

Examples

```r
## Not run: winDialog("yesno", "Is it OK to delete file blah")
```

---

**Description**

Get the self-reported Microsoft Windows version number.

**Usage**

```r
win.version()
```

**Details**

`win.version` is an auxiliary function for `sessionInfo` and `bug.report`.

**Value**

A character string describing the version of Windows reported to be in use.
**Note**

This function is only available on Microsoft Windows.

The result is based on the Windows `GetVersionEx` API function, which for recent versions of Windows reports the compatibility version, and not necessarily the actual version (hence 8.1 and 10 may be reported as 8). If the API call reports 8, this function returns >= 8.

**Examples**

```r
if(.Platform$OS.type == "windows")
  print(win.version())
```

---

**User Menus under MS Windows (Rgui)**

**Description**

Enables users to add, delete and program menus for the Rgui in MS Windows.

**Usage**

- `winMenuAdd(menuname)`
- `winMenuAddItem(menuname, itemname, action)`
- `winMenuDel(menuname)`
- `winMenuDelItem(menuname, itemname)`
- `winMenuNames()`
- `winMenuItems(menuname)`

**Arguments**

- `menuname` a character string naming a menu.
- `itemname` a character string naming a menu item on an existing menu.
- `action` a character string describing the action when that menu is selected, or "enable" or "disable".

**Details**

User menus are added to the right of existing menus, and items are added at the bottom of the menu. By default the action character string is treated as R input, being echoed on the command line and parsed and executed as usual.

If the `menuname` parameter of `winMenuAddItem` does not already exist, it will be created automatically.

Normally new submenus and menu items are added to the main console menu. They may be added elsewhere using the following special names:

- `$ConsoleMain` The console menu (the default)
- `$ConsolePopup` The console popup menu
- `$Graph<n>Main` The menu for graphics window `<n>`
- `$Graph<n>Popup` The popup menu for graphics window `<n>`
Specifying an existing item in `winMenuAddItem` enables the action to be changed.

Submenus can be specified by separating the elements in `menuname` by slashes: as a consequence menu names may not contain slashes.

If the action is specified as "none" no action is taken: this can be useful to reserve items for future expansion.

The function `winMenuNames` can be used to find out what menus have been created by the user and returns a vector of the existing menu names.

The `winMenuItems` function will take the name of a menu and return the items that exist in that menu. The return value is a named vector where the names correspond to the names of the items and the values of the vector are the corresponding actions.

The `winMenuDel` function will delete a menu and all of its items and submenus. `winMenuDelItem` just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu string cannot exceed 500 bytes.

Value

NULL, invisibly. If an error occurs, an informative error message will be given.

Note

These functions are only available on Windows and only when using the Rgui, hence not in ESS nor RStudio.

See Also

`winDialog`

Examples

```r
## Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit/extras")
winMenuAddItem("Testit", ",", ",")
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit/extras", "one more", "ddd")
winMenuAddItem("Testit/extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")

## End(Not run)
```
winProgressBar

Progress Bars under MS Windows

Description
Put up a Windows progress bar widget, update and access it.

Usage

```r
winProgressBar(title = "R progress bar", label = ",
               min = 0, max = 1, initial = 0, width = 300)
```

```r
getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'winProgressBar'
close(con, ...)
```

Arguments

- `title, label` character strings, giving the window title and the label on the dialog box respectively.
- `min, max` (finite) numeric values for the extremes of the progress bar.
- `initial, value` initial or new value for the progress bar.
- `width` the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb, con` an object of class "winProgressBar".
- `...` for consistency with the generic.

Details

`winProgressBar` will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.

`setWinProgressbar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be closed when finished with, but it will be garbage-collected once no R object refers to it.

Value

For `winProgressBar` an object of class "winProgressBar".

For `getWinProgressbar` and `setWinProgressbar`, a length-one numeric vector giving the previous value (invisibly for `setWinProgressbar`).

Note

These functions are only available on Windows.
See Also

On all platforms, `txtProgressBar`, `tkProgressBar`

Examples

```r
pb <- winProgressBar("test progress bar", "Some information in %", 0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setWinProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

**write.table**

**Data Output**

**Description**

`write.table` prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

**Usage**

```r
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
  eol = "\n", na = "NA", dec = ".", row.names = TRUE,
  col.names = TRUE, qmethod = c("escape", "double"),
  fileEncoding = "")
```

write.csv(...)
write.csv2(...)

**Arguments**

- `x` the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce `x` to a data frame.
- `file` either a character string naming a file or a connection open for writing. "" indicates output to the console.
- `append` logical. Only relevant if `file` is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
- `quote` a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.
- `sep` the field separator string. Values within each row of `x` are separated by this string.
write.table

eol the character(s) to print at the end of each line (row). For example, eol = "\r\n" will produce Windows’ line endings on a Unix-alike OS, and eol = "\r" will produce files as expected by Excel:mac 2004.

na the string to use for missing values in the data.

dec the string to use for decimal points in numeric or complex columns: must be a single character.

row.names either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.

col.names either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on ‘CSV files’ for the meaning of col.names = NA.

qmethod a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for write.table), in which case the quote character is escaped in C style by a backslash, or "double" (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter.

fileEncoding character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file.

... arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered.

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via as.matrix) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use options("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see options), but with the internal equivalent of digits = 15. For finer control, use format to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename", "wb").
CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```r
read.csv(file = "<filename>", row.names = 1)
```

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "," for the decimal point and a comma for the separator.

write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use fileEncoding = "UTF-16LE") or perhaps in the current Windows codepage (e.g., "CP1252"), but the 'Text Import Wizard' (from the 'Data' tab) allows far more choice of encodings. Excel:mac 2004/8 can import only 'Macintosh' (which seems to mean Mac Roman), 'Windows' (perhaps Latin-1) and 'PC-8' files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (https://tools.ietf.org/html/rfc4180) for CSV files, which mandates comma as the separator and CRLF line endings. write.csv writes compliant files on Windows: use eol = "\r\n" on other platforms.

Note

write.table can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

read.table, write.

write.matrix in package MASS.

Examples

```r
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".
```

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)

zip

Create Zip Archives

Description
A wrapper for an external zip command to create zip archives.

Usage
zip(zipfile, files, flags = "-r9X", extras = ",
zip = Sys.getenv("R_ZIPCMD", "zip")

Arguments
zipfile The pathname of the zip file: tilde expansion (see path.expand) will be performed.
files A character vector of recorded filepaths to be included.
flags A character string of flags to be passed to the command: see ‘Details’.
extras An optional character vector: see ‘Details’.
zip A character string specifying the external command to be used.

Details
On a Unix-alike, the default for zip will use the value of R_ZIPCMD, whose default is set in 
/etc/Renviron’ to the zip command found during configuration. On Windows, the default re-
lies on a zip program (for example that from Rtools) being in the path.
The default for flags is that appropriate for zipping up a directory tree in a portable way: see the
system-specific help for the zip command for other possibilities.
Argument extras can be used to specify -x or -i followed by a list of filepaths to exclude or
include. Since extras will be treated as if passed to system, if the filepaths contain spaces they
must be quoted e.g. by shQuote.

Value
The status value returned by the external command, invisibly.

unzip, unz; further, tar and untar for (un)packing tar archives.
Part II
Chapter 15

The KernSmooth package

bkde Compute a Binned Kernel Density Estimate

Description
Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

Usage
bkde(x, kernel = "normal", canonical = FALSE, bandwidth, gridsize = 401L, range.x, truncate = TRUE)

Arguments
x numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
bandwidth the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the 'oversmoothed bandwidth selector' of Wand and Jones (1995, page 61).
kernel character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
canonical length-one logical vector: if TRUE, canonically scaled kernels are used.
gridsize the number of equally spaced points at which to estimate the density.
rangep x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each x value in the sample, the kernel is centered on that x and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding y value in the output.

Value

a list containing the following components:

- x vector of sorted x values at which the estimate was computed.
- y vector of density estimates at the corresponding x.

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

bkde2D

Compute a 2D Binned Kernel Density Estimate

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

bkde2D(x, bandwidth, gridsize = c(51L, 51L), range.x, truncate = TRUE)
Arguments

x  a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.
bandwidth  numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.
gridsize  vector containing the number of equally spaced points in each direction over which the density is to be estimated.
range.x  a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction
truncate  logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

a list containing the following components:

x1  vector of values of the grid points in the first coordinate direction at which the estimate was computed.

x2  vector of values of the grid points in the second coordinate direction at which the estimate was computed.

fhat  matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1,x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

persp(est$fhat)
**Compute a Binned Kernel Functional Estimate**

**Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```r
bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

- `x`: numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- `drv`: order of derivative in the density functional. Must be a non-negative even integer.
- `bandwidth`: the kernel bandwidth smoothing parameter. Must be supplied.
- `gridsize`: the number of equally-spaced points over which binning is performed.
- `range.x`: vector containing the minimum and maximum values of `x` at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- `binned`: logical flag: if TRUE, then `x` and `y` are taken to be grid counts rather than raw data.
- `truncate`: logical flag: if TRUE, data with `x` values outside the range specified by `range.x` are ignored.

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

Examples

```r
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

---

**dpih**

*Select a Histogram Bin Width*

**Description**

Uses direct plug-in methodology to select the bin width of a histogram.

**Usage**

```
dpih(x, scalest = "minim", level = 2L, gridsize = 401L, range.x = range(x), truncate = TRUE)
```

**Arguments**

- **x**: numeric vector containing the sample on which the histogram is to be constructed.
- **scalest**: estimate of scale.
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- **level**: number of levels of functional estimation used in the plug-in rule.
- **gridsize**: number of grid points used in the binned approximations to functional estimates.
- **range.x**: range over which functional estimates are obtained. The default is the minimum and maximum data values.
- **truncate**: if `truncate` is TRUE then observations outside of the interval specified by `range.x` are omitted. Otherwise, they are used to weight the extreme grid points.

**Details**

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

**Value**

the selected bin width.

**Background**

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

```

dpik  Select a Bandwidth for Kernel Density Estimation

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

```r
dpik(x, scalest = "minim", level = 2L, kernel = "normal", canonical = FALSE, gridsize = 401L, range.x = range(x), truncate = TRUE)
```

Arguments

- **x** numeric vector containing the sample on which the kernel density estimate is to be constructed.
- **scalest** estimate of scale.
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- **level** number of levels of functional estimation used in the plug-in rule.
- **kernel** character string which determines the smoothing kernel. kernel can be:
  - "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- **canonical** logical flag: if TRUE, canonically scaled kernels are used.
- **gridsize** the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
dpill

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05, gridsize = 401L, range.x, truncate = TRUE)
Arguments

- **x**: numeric vector of x data. Missing values are not accepted.
- **y**: numeric vector of y data. This must be same length as x, and missing values are not accepted.
- **blockmax**: the maximum number of blocks of the data for construction of an initial parametric estimate.
- **divisor**: the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
- **trim**: the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
- **proptrun**: the proportion of the range of x at each end truncated in the functional estimates.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s $C_p$ is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

**Examples**

```r
data(geyser, package = "MASS")
x <- geyser$duration
y <- geyser$waiting
plot(x, y)
h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)
```

---

**locpoly**

*Estimate Functions Using Local Polynomials*

**Description**

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

**Usage**

```r
locpoly(x, y, drv = 0L, degree, kernel = "normal",
  bandwidth, gridsize = 401L, bwdisc = 25,
  range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

- **x**: numeric vector of x data. Missing values are not accepted.
- **bandwidth**: the kernel bandwidth smoothing parameter. It may be a single number or an array having length gridsize, representing a bandwidth that varies according to the location of estimation.
- **y**: vector of y data. This must be same length as x, and missing values are not accepted.
- **drv**: order of derivative to be estimated.
- **degree**: degree of local polynomial used. Its value must be greater than or equal to the value of drv. The default value is of degree is drv + 1.
- **kernel**: "normal" - the Gaussian density function. Currently ignored.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **bwdisc**: number of logarithmically-equally-spaced bandwidths on which bandwidth is discretised, to speed up computation.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate.
- **binned**: logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Value

if y is specified, a local polynomial regression estimate of E[Y|X] (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

x vector of sorted x values at which the estimate was computed.
y vector of smoothed estimates for either the density or the regression at the corresponding x.

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length gridsize.

**addterm**

*Try All One-Term Additions to a Model*

**Description**

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```
addterm(object, ...)  
```

### Default S3 method:
```
addterm(object, scope, scale = 0, test = c("none", "Chisq"),  
        k = 2, sorted = FALSE, trace = FALSE, ...)  
```

### S3 method for class 'lm'
```
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
        k = 2, sorted = FALSE, ...)  
```

### S3 method for class 'glm'
```
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
        k = 2, sorted = FALSE, trace = FALSE, ...)  
```

**Arguments**

- `object` An object fitted by some model-fitting function.
- `scope` a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
- `scale` used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
- `test` should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known `scale`) or a likelihood-ratio test depending on the method.
- `k` the multiple of the number of degrees of freedom used for the penalty. Only `k=2` gives the genuine AIC: `k = log(n)` is sometimes referred to as BIC or SBC.
- `sorted` should the results be sorted on the value of AIC?
- `trace` if `TRUE` additional information may be given on the fits as they are tried.
- `...` arguments passed to or from other methods.
The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

**anova.negbin**

*Likelihood Ratio Tests for Negative Binomial GLMs*

**Description**

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

**Usage**

```r
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```
Arguments

- **object**: Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of `glm.nb()`.
- **...**: Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.
- **test**: Argument to match the `test` argument of `anova.glm`. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function `anova()` for class "negbin". It can be invoked by calling `anova(x)` for an object `x` of the appropriate class, or directly by calling `anova.negbin(x)` regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The `theta` parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case `theta` is assumed to have been re-estimated for each model.

Examples

```r
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

```r
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
```
**bacteria**

**Arguments**

- **f**: The integrand as an S function object. The variable of integration must be the first argument.
- **a**: Lower limit of integration.
- **b**: Upper limit of integration.
- **...**: Additional arguments needed by the integrand.
- **fa**: Function value at the lower limit.
- **fb**: Function value at the upper limit.
- **limit**: Limit on the depth to which recursion is allowed to go.
- **eps**: Error tolerance to control the process.

**Details**

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

**Value**

The integral from a to b of f(x).

**References**

**Examples**

```r
area(sin, 0, pi)  # integrate the sin function from 0 to pi.
```

**bacteria**  
*Presence of Bacteria after Drug Treatments*

**Description**

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

**Usage**

bacteria

**Format**

This data frame has 220 rows and the following columns:

- **y**: presence or absence: a factor with levels n and y.
- **ap**: active/placebo: a factor with levels a and p.
- **hilo**: hi/low compliance: a factor with levels hi and lo.
- **week**: numeric: week of test.
- **ID**: subject ID: a factor.
- **trt**: a factor with levels placebo, drug and drug+, a re-coding of ap and hilo.
Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of \textit{H. influenzae} was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

Source

Dr Amanda Leach \textit{via} Mr James McBroom.

\textbf{bandwidth.nrd} \quad \textit{Bandwidth for \texttt{density}() via Normal Reference Distribution}

\textbf{Description}

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

\textbf{Usage}

`bandwidth.nrd(x)`
bcv

Arguments

x A data vector.

Value

A bandwidth on a scale suitable for the width argument of density.

References

Examples

# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}

Description

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

bcv(x, nb = 1000, lower, upper)

Arguments

x a numeric vector

nb number of bins to use.

lower, upper Range over which to minimize. The default is almost always satisfactory.

Value

a bandwidth

beav1  Body Temperature Series of Beaver 1

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

beav1

Format

The beav1 data frame has 114 rows and 4 columns. This data frame contains the following columns:

- **day**: Day of observation (in days since the beginning of 1990), December 12–13.
- **time**: Time of observation, in the form 0330 for 3.30am.
- **temp**: Measured body temperature in degrees Celsius.
- **activ**: Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing.

Description

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

Usage

biopsy

Format

This data frame contains the following columns:

- **ID**: sample code number (not unique).
- **V1**: clump thickness.
- **V2**: uniformity of cell size.
- **V3**: uniformity of cell shape.
- **V4**: marginal adhesion.
- **V5**: single epithelial cell size.
- **V6**: bare nuclei (16 values are missing).
- **V7**: bland chromatin.
- **V8**: normal nucleoli.
- **V9**: mitoses.
- **class**: "benign" or "malignant".

birthwt

Risk Factors Associated with Low Infant Birth Weight

Description

The birthwt data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

Usage

birthwt

Format

This data frame contains the following columns:

- low  indicator of birth weight less than 2.5 kg.
- age  mother's age in years.
- lwt  mother's weight in pounds at last menstrual period.
- race  mother's race (1 = white, 2 = black, 3 = other).
- smoke  smoking status during pregnancy.
- ptl  number of previous premature labours.
- ht  history of hypertension.
- ui  presence of uterine irritability.
- ftv  number of physician visits during the first trimester.
- bwt  birth weight in grams.

Source

References

Examples

bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))
  ptd <- factor(ptl > 0)
  ftv <- factor(ftv)
  levels(ftv)[-(1:2)] <- "2+
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
              ptd, ht = (ht > 0), ui = (ui > 0), ftv)
  })
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
The Boston data frame has 506 rows and 14 columns.

This data frame contains the following columns:

- `crim`: per capita crime rate by town.
- `zn`: proportion of residential land zoned for lots over 25,000 sq.ft.
- `indus`: proportion of non-retail business acres per town.
- `chas`: Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).
- `nox`: nitrogen oxides concentration (parts per 10 million).
- `rm`: average number of rooms per dwelling.
- `age`: proportion of owner-occupied units built prior to 1940.
- `dis`: weighted mean of distances to five Boston employment centres.
- `rad`: index of accessibility to radial highways.
- `tax`: full-value property-tax rate per \$10,000.
- `ptratio`: pupil-teacher ratio by town.
- `black`: $1000(Bk - 0.63)^2$ where $Bk$ is the proportion of blacks by town.
- `lstat`: lower status of the population (percent).
- `medv`: median value of owner-occupied homes in \$1000s.

Box-Cox Transformations for Linear Models

Description

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

Usage

boxcox(object, ...)

## Default S3 method:
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
       interp, eps = 1/50, xlab = expression(lambda),
       ylab = "log-Likelihood", ...)

## S3 method for class 'formula'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
       interp, eps = 1/50, xlab = expression(lambda),
       ylab = "log-Likelihood", ...)

## S3 method for class 'lm'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
       interp, eps = 1/50, xlab = expression(lambda),
       ylab = "log-Likelihood", ...)

Arguments

object a formula or fitted model object. Currently only lm and aov objects are handled.
lambda vector of values of lambda – default (-2, 2) in steps of 0.1.
plotit logical which controls whether the result should be plotted.
interp logical which controls whether spline interpolation is used. Default to TRUE if
       plotting with lambda of length less than 100.
eps Tolerance for lambda = 0; defaults to 0.02.
xlab defaults to "lambda".
ylab defaults to "log-Likelihood".
... additional parameters to be used in the model fitting.

Value

A list of the lambda vector and the computed profile log-likelihood vector, invisibly if the result is
plotted.

Side Effects

If plotit = TRUE plots log-likelihood vs lambda and indicates a 95% confidence interval about
the maximum observed value of lambda. If interp = TRUE, spline interpolation is used to give a
smoother plot.
References

Examples

```r
boxcox(Volume ~ log(Height) + log(Girth), data = trees, 
       lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine, 
       lambda = seq(-0.05, 0.45, len = 20))
```

---

### Description

The `cabbages` data set has 60 observations and 4 variables.

#### Usage

```r
cabbages
```

#### Format

This data frame contains the following columns:

- **Cult** Factor giving the cultivar of the cabbage, two levels: c39 and c52.
- **Date** Factor specifying one of three planting dates: d16, d20 or d21.
- **HeadWt** Weight of the cabbage head, presumably in kg.
- **VitC** Ascorbic acid content, in undefined units.

#### Source

plot(corresp(caith, nf=2)); title("symmetric")
plot(corresp(caith, nf=2), type="rows"); title("rows")
plot(corresp(caith, nf=2), type="col"); title("columns")
par(mfrow=c(1,1))

Cars93  Data from 93 Cars on Sale in the USA in 1993

Description

The *Cars93* data frame has 93 rows and 27 columns.

Usage

Cars93
Format

This data frame contains the following columns:

- **Manufacturer** Manufacturer.
- **Model** Model.
- **Type** Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".
- **Min.Price** Minimum Price (in \$1,000): price for a basic version.
- **Price** Midrange Price (in \$1,000): average of Min.Price and Max.Price.
- **Max.Price** Maximum Price (in \$1,000): price for “a premium version”.
- **MPG.city** City MPG (miles per US gallon by EPA rating).
- **MPG.highway** Highway MPG.
- **AirBags** Air Bags standard. Factor: none, driver only, or driver & passenger.
- **DriveTrain** Drive train type: rear wheel, front wheel or 4WD; (factor).
- **Cylinders** Number of cylinders (missing for Mazda RX-7, which has a rotary engine).
- **EngineSize** Engine size (litres).
- **Horsepower** Horsepower (maximum).
- **RPM** RPM (revs per minute at maximum horsepower).
- **Rev.per.mile** Engine revolutions per mile (in highest gear).
- **Man.trans.avail** Is a manual transmission version available? (yes or no, Factor).
- **Fuel.tank.capacity** Fuel tank capacity (US gallons).
- **Passengers** Passenger capacity (persons)
- **Length** Length (inches).
- **Wheelbase** Wheelbase (inches).
- **Width** Width (inches).
- **Turn.circle** U-turn space (feet).
- **Rear.seat.room** Rear seat room (inches) (missing for 2-seater vehicles).
- **Luggage.room** Luggage capacity (cubic feet) (missing for vans).
- **Weight** Weight (pounds).
- **Origin** Of non-USA or USA company origins? (factor).
- **Make** Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the Consumer Reports issue and the PACE Buying Guide. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the Consumer Reports source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once. Further description can be found in Lock (1993).

con2tr Convert Lists to Data Frames for use by lattice

Description
Convert lists to data frames for use by lattice.

Usage
con2tr(obj)

Arguments
obj A list of components x, y and z as passed to contour.

Details
con2tr repeats the x and y components suitably to match the vector z.
Value

A data frame suitable for passing to lattice (formerly trellis) functions.

References

---

confint-MASS

Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage

```r
## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

Arguments

- `object`: a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `trace`: logical. Should profiling be traced?
- `...`: additional argument(s) for methods.

Details

confint is a generic function in package stats. These confint methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1 - level)/2 and 1 - (1 - level)/2 in % (by default 2.5% and 97.5%).

References

               function(b0, b1, th, x) {})

wtloss.gr <- nls(Weight ~ expn1(b0, b1, th, Days),
                 data = wtloss, start = c(b0=90, b1=95, th=120))

expn2 <- deriv(-b0 + b1*((w0 - b0)/b1)^(x/d0),
               c("b0","b1","d0"), function(b0, b1, d0, x, w0) {})

wtloss.init <- function(obj, w0) {
  p <- coef(obj)
  d0 <- - log((w0 - p["b0"]/p["b1"])/log(2) * p["th"]
           * p[c("b0", "b1")], d0 = as.vector(d0))
}

out <- NULL
w0s <- c(110, 100, 90)
for(w0 in w0s) {
  fm <- nls(Weight ~ expn2(b0, b1, d0, Days, w0),
             wtloss, start = wtloss.init(wtloss.gr, w0))
  out <- rbind(out, c(coef(fm)["d0"], confint(fm, "d0")))
}

dimnames(out) <- list(paste(w0s, "kg:"), c("d0", "low", "high"))
out
```

ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 13, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
confint(budworm.lg0)
confint(budworm.lg0, "ldose")
```

contr.sdif

Description

A coding for factors based on successive differences.

Usage

```r
contr.sdif(n, contrasts = TRUE, sparse = FALSE)
```

Arguments

- `n` The number of levels required.
- `contrasts` logical: Should there be `n - 1` columns orthogonal to the mean (the default) or `n` columns spanning the space?
sparse logical. If true and the result would be sparse (only true for contrasts = FALSE), return a sparse matrix.

Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

Value

If contrasts is TRUE, a matrix with n rows and n - 1 columns, and the n by n identity matrix if contrasts is FALSE.

References

corresp

Simple Correspondence Analysis

description

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

Usage

corresp(x, ...)

## S3 method for class 'matrix'
corresp(x, nf = 1, ...)

## S3 method for class 'factor'
corresp(x, y, ...)

## S3 method for class 'data.frame'
corresp(x, ...)

## S3 method for class 'xtabs'
corresp(x, ...)

## S3 method for class 'formula'
corresp(formula, data, ...)

Arguments

x, formula The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulae of the form ~ F1 + F2, where F1 and F2 are factors.

nf The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.

ty a second factor for a cross-classification.

data an optional data frame, list or environment against which to preferentially resolve variables in the formula.

... If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.
Details

See Venables & Ripley (2002). The plot method produces a graphical representation of the table if \( nf=1 \), with the areas of circles representing the numbers of points. If \( nf \) is two or more the biplot method is called, which plots the second and third columns of the matrices \( A = D r^{-1/2} U L \) and \( B = D c^{-1/2} V L \) where the singular value decomposition is \( U L V \). Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does not have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class "correspondence" for which print, plot and biplot methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

References

Examples

(ct <- corresp(~ Age + Eth, data = quine))
plot(ct)
corresp(caith)
biplot(corresp(caith, nf = 2))

cov.rob

Resistant Estimation of Multivariate Location and Scatter

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. cov.mve and cov.mcd are compatibility wrappers.

Usage

cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
method = c("mve", "mcd", "classical"),
nsamp = "best", seed)
cov.mve(...)
cov.mcd(...)
cov.rob

Arguments

- **x**: a matrix or data frame.
- **cor**: should the returned result include a correlation matrix?
- **quantile.used**: the minimum number of the data points regarded as good points.
- **method**: the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using `cov.mve` or `cov.mcd` forces `mve` or `mcd` respectively.
- **nsamp**: the number of samples or "best" or "exact" or "sample". The limit If "sample" the number chosen is min(5*p, 3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted.
- **seed**: the seed to be used for random sampling: see `RNGkind`. The current value of `.Random.seed` will be preserved if it is set.
- **...**: arguments to `cov.rob` other than `method`.

Details

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an *ad hoc* finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of p of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

There is a hard limit on the allowed number of samples, $2^{31} - 1$. However, practical limits are likely to be much lower and one might check the number of samples used for exhaustive enumeration, `combn(NROW(x), NCOL(x) + 1)`, before attempting it.

Value

A list with components

- **center**: the final estimate of location.
- **cov**: the final estimate of scatter.
- **cor**: (only is `cor = TRUE`) the estimate of the correlation matrix.
- **sing**: message giving number of singular samples out of total
- **crit**: the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
- **best**: the subset used. For MVE the best sample, for MCD the best set of size `quantile.used`.
- **n.obs**: total number of observations.

**cov.trob**  
*Covariance Estimation for Multivariate t Distribution*

### Description

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

### Usage

```r
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
maxit = 25, tol = 0.01)
```

### Arguments

- **x**: data matrix. Missing values (NAs) are not allowed.
- **wt**: A vector of weights for each case: these are treated as if the case i actually occurred wt[i] times.
- **cor**: Flag to choose between returning the correlation (cor = TRUE) or covariance (cor = FALSE) matrix.
- **center**: a logical value or a numeric vector providing the location about which the covariance is to be taken. If center = FALSE, no centering is done; if center = TRUE the MLE of the location vector is used.
- **nu**: ‘degrees of freedom’ for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
- **maxit**: Maximum number of iterations in fitting.
- **tol**: Convergence tolerance for fitting.
Value

A list with the following components

- **cov**: the fitted covariance matrix.
- **center**: the estimated or specified location vector.
- **wt**: the specified weights: only returned if the `wt` argument was given.
- **n.obs**: the number of cases used in the fitting.
- **cor**: the fitted correlation matrix: only returned if `cor = TRUE`.
- **call**: The matched call.
- **iter**: The number of iterations used.

**crabs**

*Morphological Measurements on Leptograpsus Crabs*

Description

The *crabs* data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

Usage

`crabs`

Format

This data frame contains the following columns:

- **sp** species: "B" or "O" for blue or orange.
- **sex** as it says.
- **index** index 1:50 within each of the four groups.
- **FL** frontal lobe size (mm).
- **RW** rear width (mm).
- **CL** carapace length (mm).
- **CW** carapace width (mm).
- **BD** body depth (mm).

Cushings

Diagnostic Tests on Patients with Cushing’s Syndrome

Description

Cushing’s syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

Usage

Cushings

Format

The Cushings data frame has 27 rows and 3 columns:

- Tetrahydrocortisone urinary excretion rate (mg/24hr) of Tetrahydrocortisone.
- Pregnanetriol urinary excretion rate (mg/24hr) of Pregnanetriol.
- Type underlying type of syndrome, coded a (adenoma), b (bilateral hyperplasia), c (carcinoma) or u for unknown.

denumerate

Transform an Allowable Formula for `loglm` into one for `terms`

Description
`loglm` allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that `terms` can process.

Usage
denumerate(x)

Arguments
x A formula conforming to the conventions of `loglm`, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

Details
The model fitting function `loglm` fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, . . . for the first, second, third, . . . margins in a similar way to variable names. As the model formula has to be parsed by `terms`, which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely n is replaced by .vn. This allows `terms` to parse the formula in the usual way.
dose.p

Value

A linear model formula like that presented, except that where dimension numbers, say \( n \), have been used to specify fixed margins these are replaced by names of the form \(.vn\) which may be processed by terms.

See Also

renumerate

Examples

denumerate(~(1+2+3)*3 + a/b)
## which gives ~ (.v1 + .v2 + .v3)*3 + a/b

dose.p

Predict Doses for Binomial Assay model

Description

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

dose.p(obj, cf = 1:2, p = 0.5)

Arguments

obj A fitted model object of class inheriting from "glm".

cf The terms in the coefficient vector giving the intercept and coefficient of (log-)
dose

p Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

References

Examples

ldose <- rep(0:5, 2)
umdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)

**References**

---

**dropterm**

*Try All One-Term Deletions from a Model*

**Description**

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```r
dropterm(object, ...)  
## Default S3 method:  
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),  
  k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'  
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
  k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'glm'  
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
  k = 2, sorted = FALSE, trace = FALSE, ...)
```
Arguments

object A object fitted by some model-fitting function.
scope a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
scale used in the definition of the AIC statistic for selecting the models, currently only for lm, aov and glm models. Specifying scale asserts that the residual standard error or dispersion is known.
test should the results include a test statistic relative to the original model? The F test is only appropriate for lm and aov models, and perhaps for some over-dispersed glm models. The Chisq test can be an exact test (lm models with known scale) or a likelihood-ratio test depending on the method.
k the multiple of the number of degrees of freedom used for the penalty. Only k = 2 gives the genuine AIC: k = log(n) is sometimes referred to as BIC or SBC.
sorted should the results be sorted on the value of AIC?
trace if TRUE additional information may be given on the fits as they are tried.
... arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

Seizure Counts for Epileptics

Description

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

Usage

epil

Format

This data frame has 236 rows and the following 9 columns:

- **y**: the count for the 2-week period.
- **trt**: treatment, “placebo” or “progabide”.
- **base**: the counts in the baseline 8-week period.
- **age**: subject’s age, in years.
- **V4**: 0/1 indicator variable of period 4.
- **subject**: subject number, 1 to 59.
- **period**: period, 1 to 4.
- **lbase**: log-counts for the baseline period, centred to have zero mean.
- **lage**: log-ages, centred to have zero mean.

Source

**eqscplot**

*Plots with Geometrically Equal Scales*

**Description**

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

**Usage**

```
eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

**Arguments**

- `x` vector of x values, or a 2-column matrix, or a list with components `x` and `y`
- `y` vector of y values
- `ratio` desired ratio of units on the axes. Units on the y axis are drawn at `ratio` times the size of units on the x axis. Ignored if `uin` is specified and of length 2.
- `tol` proportion of white space at the margins of plot
- `uin` desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
- `...` further arguments for `plot` and graphical parameters. Note that `par(xaxs="i", yaxs="i")` is enforced, and `xlim` and `ylim` will be adjusted accordingly.

**Details**

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by `1 + tol` to move points away from the axes, and the points plotted.

**Value**

invisibly, the values of `uin` used for the plot.
Side Effects

performs the plot.

Note

Arguments ratio and uin were suggested by Bill Dunlap.

```

fgl Measurements of Forensic Glass Fragments

Description

The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

Usage

`fgl`

Format

This data frame contains the following columns:

- `RI` refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

- `Na` sodium.
- `Mg` manganese.
- `Al` aluminium.
- `Si` silicon.
- `K` potassium.
- `Ca` calcium.
- `Ba` barium.
- `Fe` iron.

- `type` The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (WinF: 70), window non-float glass (WinNF: 76), vehicle window glass (Veh: 17), containers (Con: 13), tableware (Tabl: 9) and vehicle headlamps (Head: 29).

References

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

Usage

fitdistr(x, densfun, start, ...)

Arguments

x
A numeric vector of length at least one containing only finite values.
densfun
Either a character string or a function returning a density evaluated at its first argument.
Distributions "beta", "cauchy", "chi-squared", "exponential", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.
start
A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).
...
Additional parameters, either for densfun or for optim. In particular, it can be used to specify bounds via lower or upper or both. If arguments of densfun (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and start should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using optim. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named lower or upper are supplied (when L-BFGS-B is used) or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location m and scale s.

For the following named distributions, reasonable starting values will be computed if start is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by mu and size), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are print, coef, vcov and logLik methods for class "fitdistr".
Value

An object of class "fitdistr", a list with four components,

- `estimate` the parameter estimates,
- `sd` the estimated standard errors,
- `vcov` the estimated variance-covariance matrix, and
- `loglik` the log-likelihood.

Note

Numerical optimization cannot work miracles: please note the comments in `optim` on scaling data.

If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

References

Examples

```r
## avoid spurious accuracy

fractions Rational Approximation

Description
Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage
fractions(x, cycles = 10, max.denominator = 2000, ...)

Arguments
x
Any object of mode numeric. Missing values are now allowed.
cycles
The maximum number of steps to be used in the continued fraction approximation process.
max.denominator
An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
...
arguments passed to or from other methods.

Details
Each component is first expanded in a continued fraction of the form
\[ x = \text{floor}(x) + \frac{1}{(p_1 + 1/(p_2 + \ldots))} \]
where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \max.\text{denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.
The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.
Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.
Value

An object of class "fractions". A structure with .Data component the same as the input numeric x, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

References

GAGurine

Level of GAG in Urine of Children

Description

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrican to assess if a child’s GAG concentration is 'normal'.

Usage

GAGurine

Format

This data frame contains the following columns:

Age  age of child in years.
GAG  concentration of GAG (the units have been lost).

gamma.shape  Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE,...)

Arguments

object  Fitted model object from a Gamma family or quasi family with variance = "mu^2".

it.lim  Upper limit on the number of iterations.

eps.max  Maximum discrepancy between approximations for the iteration process to continue.

verbose  If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.

...

Details

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.
Value

List of two components

alpha the maximum likelihood estimate
SE the approximate standard error, the square-root of the reciprocal of the observed information.

gamma.dispersion

gamma.shape(clot1)

Examples

clotting <- data.frame(
  u = c(5,10,15,20,30,40,60,80,100),
  lot1 = c(118,58,42,35,27,25,21,19,18),
  lot2 = c(69,35,26,21,18,16,13,12,12))
clot1 <- glm(lot1 ~ log(u), data = clotting, family = Gamma)
gamma.shape(clot1)

qm <- glm(Days + 0.1 ~ Age*Eth*Sex*Lrn, 
  quasi(link=log, variance="mu^2"), quine, 
  start = c(3, rep(0,31)))
gamma.shape(qm, verbose = TRUE)
summary(qm, dispersion = gamma.dispersion(qm)) # better summary

gehan

Remission Times of Leukaemia Patients

Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug 6-mercaptopurine and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

Usage
gehan

Format

This data frame contains the following columns:

pair label for pair.
time remission time in weeks.
cens censoring, 0/1.
treat treatment, control or 6-MP.
## Source

## References

## Examples

```r
library(survival)
gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan,
                     conf.type = "log-log")
survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exponential")
survreg(Surv(time, cens) ~ treat, gehan, dist = "exponential")
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

## genotype

### Rat Genotype Data

**Description**

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

**Usage**

`genotype`

**Format**

The data frame has the following components:

- **Litter** genotype of the litter.
- **Mother** genotype of the foster mother.
- **Wt** Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

**Source**

**References**

Old Faithful Geyser Data

Description
A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

Usage
geyser

Format
A data frame with 299 observations on 2 variables.

<table>
<thead>
<tr>
<th>duration</th>
<th>numeric</th>
<th>Eruption time in mins</th>
</tr>
</thead>
<tbody>
<tr>
<td>waiting</td>
<td>numeric</td>
<td>Waiting time for this eruption</td>
</tr>
</tbody>
</table>

Note
The waiting time was incorrectly described as the time to the next eruption in the original files, and corrected for MASS version 7.3-30.

CRAN package sm.
Line Transect of Soil in Gilgai Territory

Description

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

Usage

gilgais

Format

This data frame contains the following columns:

- pH00 pH at depth 0–10 cm.
- pH30 pH at depth 30–40 cm.
- pH80 pH at depth 80–90 cm.
- e00 electrical conductivity in mS/cm (0–10 cm).
- e30 electrical conductivity in mS/cm (30–40 cm).
- e80 electrical conductivity in mS/cm (80–90 cm).
- c00 chloride content in ppm (0–10 cm).
- c30 chloride content in ppm (30–40 cm).
- c80 chloride content in ppm (80–90 cm).

ginv

Generalized Inverse of a Matrix

Description
Calculates the Moore-Penrose generalized inverse of a matrix X.

Usage
ginv(X, tol = sqrt(.Machine$double.eps))

Arguments
X Matrix for which the Moore-Penrose inverse is required.
tol A relative tolerance to detect zero singular values.

Value
A MP generalized inverse matrix for X.

References

See Also
solve, svd, eigen

glm.convert
Change a Negative Binomial fit to a GLM fit

Description
This function modifies an output object from glm.nb() to one that looks like the output from glm() with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage
glm.convert(object)

Arguments
object An object of class "negbin", typically the output from glm.nb().

Details
Convenience function needed to effect some low level changes to the structure of the fitted model object.
An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

See Also
glm.nb, negative.binomial, glm

Examples
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)

glm.nb

Fit a Negative Binomial Generalized Linear Model

Description
A modification of the system function glm() to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

Usage
glm.nb(formula, data, weights, subset, na.action, start = NULL, etastart, mustart, control = glm.control(...), method = "glm.fit", model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ..., init.theta, link = log)

Arguments
formula, data, weights, subset, na.action, start, etastart, mustart, control, method, model, x, y, contrasts, ...
arguments for the glm() function. Note that these exclude family and offset (but offset() can be used).
init.theta
Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.
link
The link function. Currently must be one of log, sqrt or identity.

Details
An alternating iteration process is used. For given theta the GLM is fitted using the same process as used by glm(). For fixed means the theta parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating theta are controlled by the maxit parameter of glm.control.)

Setting trace > 0 traces the alternating iteration process. Setting trace > 1 traces the glm fit, and setting trace > 2 traces the estimation of theta.
Value

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of theta, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

References

See Also

`glm`, `negative.binomial`, `anova.negbin`, `summary.negbin`, `theta.md`

There is a `simulate` method.

Examples

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

---

**glmmPQL**

Fit Generalized Linear Mixed Models via PQL

**Description**

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

**Usage**

```r
glmmPQL(fixed, random, family, data, correlation, weights, control, niter = 10, verbose = TRUE, ...)
```

**Arguments**

- `fixed`: a two-sided linear formula giving fixed-effects part of the model.
- `random`: a formula or list of formulae describing the random effects.
- `family`: a GLM family.
- `data`: an optional data frame, list or environment used as the first place to find variables in the formulae, weights and if present in ..., subset.
- `correlation`: an optional correlation structure.
- `weights`: optional case weights as in `glm`.
- `control`: an optional argument to be passed to `lme`.
- `niter`: maximum number of iterations.
- `verbose`: logical: print out record of iterations?
- `...`: Further arguments for `lme`.
Details

glmmPQL works by repeated calls to \texttt{lme}, so package \texttt{nlme} will be loaded at first use if necessary.

Value

A object of class "lme": see \texttt{lmeObject}.

References

See Also

\texttt{lme}

Examples

library(nlme) # will be loaded automatically if omitted
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
    family = binomial, data = bacteria))

---

hills

\textit{Record Times in Scottish Hill Races}

Description

The record times in 1984 for 35 Scottish hill races.

Usage

hills

Format

The components are:

- \texttt{dist} distance in miles (on the map).
- \texttt{climb} total height gained during the route, in feet.
- \texttt{time} record time in minutes.

Source

[A.C. Atkinson (1988) Transformations unmasked. \textit{Technometrics} 30, 311–318 “corrects” the time for Knock Hill from 78.65 to 18.65. It is unclear if this based on the original records.]
**hist.scott**

*Plot a Histogram with Automatic Bin Width Selection*

**Description**

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

**Usage**

```r
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

**Arguments**

- `x` A data vector
- `prob` Should the plot have unit area, so be a density estimate?
- `xlab, ...` Further arguments to `hist`

**Value**

For the *nclass.* functions, the suggested number of classes.

**Side Effects**

Plot a histogram.

**References**

**See Also**

`hist`
The housing data frame has 72 rows and 5 variables.

Sat  Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).
Infl  Perceived degree of influence householders have on the management of the property (High, Medium, Low).
Type  Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).
Cont  Contact residents are afforded with other residents, (Low, High).
Freq  Frequencies: the numbers of residents in each class.

*Huber M-estimator of Location with MAD Scale*

**Description**

Finds the Huber M-estimator of location with MAD scale.

**Usage**

huber(y, k = 1.5, tol = 1e-06)
Arguments

- **y**: vector of data values
- **k**: Winsorizes at k standard deviations
- **tol**: convergence tolerance

Value

- list of location and scale parameters
- **mu**: location estimate
- **s**: MAD scale estimate

References

**hubers**  
*Huber Proposal 2 Robust Estimator of Location and/or Scale*

Description

Finds the Huber M-estimator for location with scale specified, scale with location specified, or both if neither is specified.

Usage

```
hubers(y, k = 1.5, mu, s, initmu = median(y), tol = 1e-06)
```

Arguments

- **y**: vector y of data values
- **k**: Winsorizes at k standard deviations
- **mu**: specified location
- **s**: specified scale
- **initmu**: initial value of mu
- **tol**: convergence tolerance
**Value**

- list of location and scale estimates
  - `mu` location estimate
  - `s` scale estimate

```

Insurance

Numbers of Car Insurance claims

Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

Usage

`Insurance`

Format

This data frame contains the following columns:

- **District**: factor: district of residence of policyholder (1 to 4): 4 is major cities.
- **Group**: an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
- **Age**: an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.
- **Holders**: numbers of policyholders.
- **Claims**: numbers of claims.

Source

References

Examples

```r
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
   data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```
isoMDS

Kruskal’s Non-metric Multidimensional Scaling

Description

One form of non-metric multidimensional scaling

Usage

isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
     tol = 1e-3, p = 2)

Shepard(d, x, p = 2)

Arguments

d        distance structure of the form returned by dist, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.

y        An initial configuration. If none is supplied, cmdscale is used to provide the classical solution, unless there are missing or infinite dissimilarities.

k        The desired dimension for the solution, passed to cmdscale.

maxit    The maximum number of iterations.

trace    Logical for tracing optimization. Default TRUE.

tol      convergence tolerance.

p        Power for Minkowski distance in the configuration space.

x        A final configuration.

Details

This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since for the default $p = 2$ the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

Value

Two components:

- points A k-column vector of the fitted configuration.
- stress The final stress achieved (in percent).

Side Effects

If trace is true, the initial stress and the current stress are printed out every 5 iterations.

cmdscale, sammon

Examples

```r
swiss.x <- as.matrix(swiss[, -1])
swiss.dist <- dist(swiss.x)
swiss.mds <- isoMDS(swiss.dist)
plot(swiss.mds$points, type = "n")
text(swiss.mds$points, labels = as.character(1:nrow(swiss.x)))
swiss.sh <- Shepard(swiss.dist, swiss.mds$points)
plot(swiss.sh, pch = ".")
lines(swiss.sh$x, swiss.sh$yf, type = "S")
```

### kde2d

**Two-Dimensional Kernel Density Estimation**

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

#### Usage

```r
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

#### Arguments

- **x**: x coordinate of data
- **y**: y coordinate of data
- **h**: vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see `bandwidth.nrd`). A scalar value will be taken to apply to both directions.
- **n**: Number of grid points in each direction. Can be scalar or a length-2 integer vector.
- **lims**: The limits of the rectangle covered by the grid as `c(x1, xu, y1, yu)`.

#### Value

A list of three components.

- **x**, **y**: The x and y coordinates of the grid points, vectors of length n.

detach("geyser")

lda

Linear Discriminant Analysis

Description

Linear discriminant analysis.

Usage

lda(x, ...)

## S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

## Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
   method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
lda(x, ...)

## S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
Arguments

formula  A formula of the form groups ~ x1 + x2 + .... That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
data  An optional data frame, list or environment from which variables specified in formula are preferentially to be taken.
x  (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
grouping  (required if no formula principal argument is given.) a factor specifying the class for each observation.
prior  the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
tol  A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than tol^2.
subset  An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
na.action  A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
method  "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use cov.mve, or "t" for robust estimates based on a t distribution.
CV  If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
nu  degrees of freedom for method = "t".
...  arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than tol^2 it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the prior will affect the classification unless over-ridden in predict.lda. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If CV = TRUE the return value is a list with components class, the MAP classification (a factor), and posterior, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:
prior  the prior probabilities used.
means the group means.

scaling a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.

svd the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.

N The number of observations used.

call The (matched) function call.

Note This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but subset= and na.action=, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using update() in the usual way.

ldahist Histograms or Density Plots of Multiple Groups

Description

Plot histograms or density plots of data on a single Fisher linear discriminant.
Usage

\texttt{ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,}
\texttt{ xlim = range(breaks), ymax = 0, width,}
\texttt{ type = c("histogram", "density", "both"),}
\texttt{ sep = (type != "density"),}
\texttt{ col = 5, xlab = deparse(substitute(data)), bty = "n", ...)}

Arguments

data vector of data. Missing values (\texttt{NA}s) are allowed and omitted.
g factor or vector giving groups, of the same length as \texttt{data}.
nbins Suggested number of bins to cover the whole range of the data.
h The bin width (takes precedence over \texttt{nbins}).
x0 Shift for the bins - the breaks are at \texttt{x0 + h * (\ldots, -1, 0, 1, \ldots)}
breaks The set of breakpoints to be used. (Usually omitted, takes precedence over \texttt{h}
and \texttt{nbins}).
xlim The limits for the x-axis.
ymax The upper limit for the y-axis.
width Bandwidth for density estimates. If missing, the Sheather-Jones selector is used
for each group separately.
type Type of plot.
sep Whether there is a separate plot for each group, or one combined plot.
col The colour number for the bar fill.
xlab label for the plot x-axis. By default, this will be the name of \texttt{data}.
bty The box type for the plot - defaults to none.
... additional arguments to \texttt{polygon}.

Side Effects

Histogram and/or density plots are plotted on the current device.

Survival Times and White Blood Counts for Leukaemia Patients

Description
A data frame of data from 33 leukaemia patients.

Usage
leuk

Format
A data frame with columns:

- wbc white blood count.
- ag a test result, "present" or "absent".
- time survival time in weeks.

Details
Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

Source

Taken from

References

Examples

```r
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```
Description

Fit linear models by Generalized Least Squares

Usage

```r
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
       method = "qr", model = FALSE, x = FALSE, y = FALSE,
       contrasts = NULL, ...)
```

Arguments

- **formula**: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- **data**: an optional data frame, list or environment in which to interpret the variables occurring in `formula`.
- **W**: a weight matrix.
- **subset**: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- **na.action**: a function to filter missing data.
- **inverse**: logical: if true `W` specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
- **method**: method to be used by `lm.fit`.
- **model**: should the model frame be returned?
- **x**: should the design matrix be returned?
- **y**: should the response be returned?
- **contrasts**: a list of contrasts to be used for some or all of
- **...**: additional arguments to `lm.fit`.

Details

The problem is transformed to uncorrelated form and passed to `lm.fit`.

Value

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

See Also

gls, lm, lm.ridge
lm.ridge

Ridge Regression

Description

Fit a linear model by ridge regression.

Usage

```r
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
  x = FALSE, y = FALSE, contrasts = NULL, ...)
```

Arguments

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `data`: an optional data frame, list or environment in which to interpret the variables occurring in `formula`.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `lambda`: A scalar or vector of ridge constants.
- `model`: should the model frame be returned? Not implemented.
- `x`: should the design matrix be returned? Not implemented.
- `y`: should the response be returned? Not implemented.
- `contrasts`: a list of contrasts to be used for some or all of factor terms in the formula. See `contrasts.arg` of `model.matrix.default`.
- `...`: additional arguments to `lm.fit`.

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

- `coef`: matrix of coefficients, one row for each value of `lambda`. Note that these are not on the original scale and are for use by the `coef` method.
- `scales`: scalings used on the X matrix.
- `Inter`: was intercept included?
- `lambda`: vector of `lambda` values
- `ym`: mean of `y`
- `xm`: column means of `x` matrix
- `GCV`: vector of GCV values
- `kHKB`: HKB estimate of the ridge constant
- `kLW`: L-W estimate of the ridge constant.

               lambda = seq(0,0.1,0.0001)))

loglm

Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, \texttt{loglin}, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as \texttt{glm}.

Usage

\texttt{loglm(formula, data, subset, na.action, ...)}

Arguments

formula A linear model formula specifying the log-linear model. If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the \texttt{dimnames} attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for 'all other variables in the data frame' is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.

data Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to \texttt{xtabs}.

subset Specifies a subset of the rows in the data frame to be used. The default is to take all rows.

na.action Specifies a method for handling missing observations. The default is to fail if missing values are present.

... May supply other arguments to the function \texttt{loglm}. 
**Details**

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

**Value**

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

**Warning**

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

## 3 4 7 2 0
##minn38a <- array(0, c(3,4,7,2), lapply(minn38[, -5], levels))
##minn38a[data.matrix(minn38[, -5])] <- minn38$f

## or more simply
minn38a <- xtabs(f ~ ., minn38)
```
fm <- loglm(~ 1 + 2 + 3 + 4, minn38a)  # numerals as names.
deviance(fm)
## [1] 3711.9
fm1 <- update(fm, .~.^2)
fm2 <- update(fm, .~.^3, print = TRUE)
## 5 iterations: deviation 0.075
anova(fm, fm1, fm2)

# Case 1. An array generated with xtabs.
loglm(~ Type + Origin, xtabs(~ Type + Origin, Cars93))

# Case 2. Frequencies given as a vector in a data frame
names(quine)
## [1] "Eth" "Sex" "Age" "Lrn" "Days"
fm <- loglm(Days ~ .^2, quine)
gm <- glm(Days ~ .^2, poisson, quine)  # check glm.
c(deviance(fm), deviance(gm))  # deviances agree
## [1] 1368.7 1368.7
c(fm$df, gm$df)  # resid df do not!
c(fm$df, gm$df.residual)  # resid df do not!
## [1] 127 128
# The loglm residual degrees of freedom is wrong because of
# a non-detectable redundancy in the model matrix.

---

### logtrans

**Estimate log Transformation Parameter**

**Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form \( \log(y + \alpha) \sim x1 + x2 + \ldots \).

**Usage**

logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
plotit = TRUE, interp =, xlab = "alpha",
ylab = "log Likelihood")

## S3 method for class 'formula'
logtrans(object, data, ...)

## S3 method for class 'lm'
logtrans(object, ...)

**Arguments**

- **object** Fitted linear model object, or formula defining the untransformed model that is \( y \sim x1 + x2 + \ldots \). The function is generic.
- **...** If object is a formula, this argument may specify a data frame as for `lm`. 
alpha  Set of values for the transformation parameter, alpha.
plotit Should plotting be done?
interp Should the marginal log-likelihood be interpolated with a spline approximation? (Default is TRUE if plotting is to be done and the number of real points is less than 100.)
xlab as for plot.
ylab as for plot.
data optional data argument for lm fit.

Value
List with components x (for alpha) and y (for the marginal log-likelihood values).

Side Effects
A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

References

See Also
boxcox

Examples
logtrans(Days ~ Age*Sex*Eth*Lrn, data = quine,  
alpha = seq(0.75, 6.5, len=20))

---

lqs  Resistant Regression

Description
Fit a regression to the good points in the dataset, thereby achieving a regression estimator with a high breakdown point. lmsreg and ltsreg are compatibility wrappers.

Usage
lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ...,  
method = c("lts", "lqs", "lms", "S", "model.frame"),  
subset, na.action, model = TRUE,  
x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),  
...
\begin{verbatim}
quantile, control = lqs.control(...), k0 = 1.548, seed, ...)
lmsreg(...)
ltsreg(...)

Arguments

formula  a formula of the form \( y \sim x1 + x2 + \ldots \).
data     an optional data frame, list or environment from which variables specified in
          formula are preferentially to be taken.
subset  an index vector specifying the cases to be used in fitting. (NOTE: If given, this
         argument must be named exactly.)
na.action function to specify the action to be taken if NAs are found. The default action is
          for the procedure to fail. Alternatives include na.omit and na.exclude, which
          lead to omission of cases with missing values on any required variable. (NOTE:
          If given, this argument must be named exactly.)
model, x.ret, y.ret logical. If TRUE the model frame, the model matrix and the response are re-
                     turned, respectively.
contrasts an optional list. See the contrasts.arg of \texttt{model.matrix.default}.
x        a matrix or data frame containing the explanatory variables.
y        the response: a vector of length the number of rows of \( x \).
intercept should the model include an intercept?
method   the method to be used. \texttt{model.frame} returns the model frame: for the others
          see the Details section. Using \texttt{lmsreg} or \texttt{ltsreg} forces "lms" and "lts"
          respectively.
quantile the quantile to be used: see Details. This is over-ridden if method = "lms".
control additional control items: see Details.
k0       the cutoff / tuning constant used for \( \chi() \) and \( \psi() \) functions when method = "S",
          currently corresponding to Tukey's 'biweight'.
seed     the seed to be used for random sampling: see \texttt{.Random.seed}. The current value
          of \texttt{.Random.seed} will be preserved if it is set..
...      arguments to be passed to \texttt{lqs.default} or \texttt{lqs.control}, see control above
          and Details.

Details

Suppose there are \( n \) data points and \( p \) regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods
"lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile
smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are
floor((n+p+1)/2) and floor((n+1)/2) respectively. For "lts" the default is floor(n/2) +
floor((p+1)/2).

The "S" estimation method solves for the scale \( s \) such that the average of a function chi of the
residuals divided by \( s \) is equal to a given constant.

The control argument is a list with components

\texttt{psamp}: the size of each sample. Defaults to \( p \).
\end{verbatim}
**lqs**

`nsamp`: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is \text{min}(5*p, 3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

`adjust`: should the intercept be optimized for each sample? Defaults to TRUE.

**Value**

An object of class "lqs". This is a list with components

- `crit`: the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.
- `sing`: character. A message about the number of samples which resulted in singular fits.
- `coefficients`: of the fitted linear model
- `bestone`: the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
- `fitted.values`: the fitted values.
- `residuals`: the residuals.
- `scale`: estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

**Note**

There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate $n^{-1/3}$) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of $(\text{floor}((n-p)/2) + 1)/n$ attained if $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$. The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if $n$ is large and $p$ small.

Opinions differ over the choice of `psamp`. Rousseeuw and Hubert (1997) only consider $p$; Marazzi (1993) recommends $p+1$ and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

**mca**

*Multiple Correspondence Analysis*

**Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```r
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

- `df`: A data frame containing only factors
- `nf`: The number of dimensions for the MCA. Rarely 3 might be useful.
- `abbrev`: Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if `abbrev = TRUE` they are just ‘level’ which will suffice if the factors have distinct levels.

**Value**

An object of class "mca", with components

- `rs`: The coordinates of the rows, in `nf` dimensions.
- `cs`: The coordinates of the column vertices, one for each level of each factor.
- `fs`: Weights for each row, used to interpolate additional factors in `predict.mca`.
- `p`: The number of factors
- `d`: The singular values for the `nf` dimensions.
- `call`: The matched call.

             binomial(link = probit), data = menarche)
```
### michelson

**Michelson’s Speed of Light Data**

**Description**

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

**Usage**

michelson

**Format**

The data frame contains the following components:

- **Expt**: The experiment number, from 1 to 5.
- **Run**: The run number within each experiment.
- **Speed**: Speed-of-light measurement.

**Source**

**motors**

*Accelerated Life Testing of Motorettes*

**Description**

The *motors* data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

**Usage**

`motors`

**Format**

This data frame contains the following columns:

- `temp` the temperature (degrees C) of the test.
- `time` the time in hours to failure or censoring at 8064 hours (= 336 days).
- `cens` an indicator variable for death.

**Source**

**References**

**Examples**

```r
library(survival)
plot(survfit(Surv(time, cens) ~ factor(temp), motors), conf.int = FALSE)
# fit Weibull model
motor.wei <- survreg(Surv(time, cens) ~ temp, motors)
summary(motor.wei)
# and predict at 130C
unlist(predict(motor.wei, data.frame(temp=130), se.fit = TRUE))

motor.cox <- coxph(Surv(time, cens) ~ temp, motors)
summary(motor.cox)
# predict at temperature 200
```
Effect of Calcium Chloride on Muscle Contraction in Rat Hearts

Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

Usage

muscle

Format

This data frame contains the following columns:

- Strip: which heart muscle strip was used?
- Conc: concentration of calcium chloride solution, in multiples of 2.2 mM.
- Length: the change in length (shortening) of the strip, (allegedly) in mm.

Source

References

Examples

```r
## IGNORE_RDIFF_BEGIN
A <- model.matrix(~ Strip - 1, data=muscle)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),
    data = muscle, start = c(rho=0.1), algorithm="plinear")
(B <- coef(rats.nls1))
st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho^Conc,
    data = muscle, start = st))
## IGNORE_RDIFF_END

Muscle <- with(muscle, {
    Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
})
```
mvrnorm <- predict(rats.nls2, Muscle)
Muscle <- cbind(Muscle, logLength = rep(as.numeric(NA), 126))
ind <- match(paste(Strip, Conc),
            paste(Muscle$Strip, Muscle$Conc))
Muscle$logLength[ind] <- log(Length)
Muscle})

lattice::xyplot(Yhat ~ Conc | Strip, Muscle, as.table = TRUE,
    ylim = range(c(Muscle$Yhat, Muscle$logLength), na.rm = TRUE),
    subscripts = TRUE, xlab = "Calcium Chloride concentration (mM)",
    ylab = "log(Length in mm)", panel =
    function(x, y, subscripts, ...) {
        panel.xyplot(x, Muscle$logLength[subscripts], ...)
        llines(spline(x, y))
    })

mvrnorm

Simulate from a Multivariate Normal Distribution

Description

Produces one or more samples from the specified multivariate normal distribution.

Usage

mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)

Arguments

n
the number of samples required.

mu
a vector giving the means of the variables.

Sigma
a positive-definite symmetric matrix specifying the covariance matrix of the variables.

tol
tolerance (relative to largest variance) for numerical lack of positive-definiteness in Sigma.

empirical
logical. If true, mu and Sigma specify the empirical not population mean and covariance matrix.

EISPACK
logical: values other than FALSE are an error.

Details

The matrix decomposition is done via eigen; although a Choleski decomposition might be faster,
the eigendecomposition is stabler.

Value

If n = 1 a vector of the same length as mu, otherwise an n by length(mu) matrix with one sample in each row.

Side Effects

Causes creation of the dataset .Random.seed if it does not already exist, otherwise its value is updated.
negative.binomial

Family function for Negative Binomial GLMs

Description
Specifies the information required to fit a Negative Binomial generalized linear model, with known theta parameter, using glm().

Usage
negative.binomial(theta = stop("'theta' must be specified"), link = "log")

Arguments
theta
The known value of the additional parameter, theta.
link
The link function, as a character string, name or one-element character vector specifying one of log, sqrt or identity, or an object of class "link-glm".

Value
An object of class "family", a list of functions and expressions needed by glm() to fit a Negative Binomial generalized linear model.

References

See Also
glm.nb, anova.negbin, summary.negbin

Examples
# Fitting a Negative Binomial model to the quine data
# with theta = 2 assumed known.
#

newcomb

Newcomb’s Measurements of the Passage Time of Light

Description

A numeric vector giving the ‘Third Series’ of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The ‘true’ value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

```
28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
36 23 27 27 28 27 31 27 26 33 26 32 24 28 24 25 32 25
29 27 28 29 16 23
```

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

Usage

newcomb

nlschools

Eighth-Grade Pupils in the Netherlands

Description

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

Usage

nlschools
Format

This data frame contains 2287 rows and the following columns:

- lang language test score.
- IQ verbal IQ.
- class class ID.
- GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).
- SES social-economic status of pupil’s family.
- COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

Source

References

Examples

```r
nl1 <- within(nlschools, {
  IQave <- tapply(IQ, class, mean)[as.character(class)]
  IQ <- IQ - IQave
})

cen <- c("IQ", "IQave", "SES")
nl1[cen] <- scale(nl1[cen], center = TRUE, scale = FALSE)

nl.lme <- nlme::lme(lang ~ IQ*COMB + IQave + SES,
  random = ~ IQ | class, data = nl1)

npk

Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk
Format

The npk data frame has 24 rows and 5 columns:

- block: which block (label 1 to 6).
- N: indicator (0/1) for the application of nitrogen.
- P: indicator (0/1) for the application of phosphate.
- K: indicator (0/1) for the application of potassium.
- yield: Yield of peas, in pounds/plot (the plots were 1/70 acre).

Note

This dataset is also contained in R 3.0.2 and later.

Source

References

Examples

```r
options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
npk.aov

npr1

US Naval Petroleum Reserve No. 1 data

Description

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

Usage

npr1
Format

This data frame contains the following columns:

- x  x coordinates, in miles (origin unspecified).
- y  y coordinates, in miles.
- perm permeability in milli-Darcies.
- por porosity (%).

Null Spaces of Matrices

Description

Given a matrix, M, find a matrix N giving a basis for the (left) null space. That is crossprod(N, M) = t(N) %*% M is an all-zero matrix and N has the maximum number of linearly independent columns.

Usage

Null(M)

Arguments

M Input matrix. A vector is coerced to a 1-column matrix.

Details

For a basis for the (right) null space \{x : Mx = 0\}, use Null(t(M)).

Value

The matrix N with the basis for the (left) null space, or a matrix with zero columns if the matrix M is square and of maximal rank.

References

qr, qr.Q.
Examples

# The function is currently defined as
function(M)
{
  tmp <- qr(M)
  set <- if(tmp$rank == 0L) seq_len(ncol(M)) else -seq_len(tmp$rank)
  qr.Q(tmp, complete = TRUE)[, set, drop = FALSE]
}

Data from an Oats Field Trial

Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

Usage

oats

Format

This data frame contains the following columns:

- **B**: Blocks, levels I, II, III, IV, V, and VI.
- **V**: Varieties, 3 levels.
- **N**: Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt, and 0.6cwt, showing the application in cwt/acre.
- **Y**: Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

Source

plot(fitted(oats.aov[[4]]), studres(oats.aov[[4]]))
```
Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power). The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

Usage

OME

Format

The OME data frame has 1129 rows and 7 columns:

- ID  Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- OME  "low" or "high" or "N/A" (at ages other than 30 and 60 months).
- Age  Age of the subject (months).
- Loud  Loudness of stimulus, in decibels.
- Noise  Whether the signal in the stimulus was "coherent" or "incoherent".
- Correct  Number of correct responses from Trials trials.
- Trials  Number of trials performed.

Background

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term 'binaural hearing' is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of
severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

## End(Not run)
Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

Usage

painters

Format

The row names of the data frame are the painters. The components are:

Composition Composition score.
Drawing Drawing score.
Colour Colour score.
Expression Expression score.
School The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

pairs.lda  Produce Pairwise Scatterplots from an 'lda' Fit

Description

Pairwise scatterplot of the data on the linear discriminants.

Usage

## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda, dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
Arguments

\( x \)  
Object of class "lda".

\( \text{labels} \)  
vector of character strings for labelling the variables.

\( \text{panel} \)  
panel function to plot the data in each panel.

\( \text{dimen} \)  
The number of linear discriminants to be used for the plot; if this exceeds the number determined by \( x \) the smaller value is used.

\( \text{abbrev} \)  
whether the group labels are abbreviated on the plots. If \( \text{abbrev} > 0 \) this gives \text{minlength} in the call to \text{abbreviate}.

\( \ldots \)  
additional arguments for \text{pairs.default}.

\( \text{cex} \)  
graphics parameter \text{cex} for labels on plots.

\( \text{type} \)  
type of plot. The default is in the style of \text{pairs.default}; the style "trellis" uses the Trellis function \text{splom}.

Details

This function is a method for the generic function \text{pairs()} for class "lda". It can be invoked by calling \text{pairs(x)} for an object \( x \) of the appropriate class, or directly by calling \text{pairs.lda(x)} regardless of the class of the object.

References

parcoord  
Parallel Coordinates Plot

Description

Parallel coordinates plot

Usage

\text{parcoord}(x, \text{col} = 1, \text{lty} = 1, \text{var.label} = \text{FALSE}, \ldots)

Arguments

\( x \)  
a matrix or data frame who columns represent variables. Missing values are allowed.

\( \text{col} \)  
A vector of colours, recycled as necessary for each observation.

\( \text{lty} \)  
A vector of line types, recycled as necessary for each observation.

\( \text{var.label} \)  
If \text{TRUE}, each variable's axis is labelled with maximum and minimum values.

\( \ldots \)  
Further graphics parameters which are passed to \text{matplot}.
petrol

Side Effects

A parallel coordinates plot is drawn.

Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples

```r
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.
These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

Usage

```r
petrol
```

Format

The variables are as follows

- **No**: crude oil sample identification label. (Factor.)
- **SG**: specific gravity, degrees API. (Constant within sample.)
- **VP**: vapour pressure in pounds per square inch. (Constant within sample.)
- **V10**: volatility of crude; ASTM 10% point. (Constant within sample.)
- **EP**: desired volatility of gasoline. (The end point. Varies within sample.)
- **Y**: yield as a percentage of crude.

Source

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.
References

Examples

```r
library(nlme)
Petrol <- petrol
Petrol[, 2:5] <- scale(as.matrix(Petrol[, 2:5]), scale = FALSE)
pet3.lme <- lme(Y ~ SG + VP + V10 + EP,
    random = ~ 1 | No, data = Petrol)
pet3.lme <- update(pet3.lme, method = "ML")
pet4.lme <- update(pet3.lme, fixed = Y ~ V10 + EP)
anova(pet4.lme, pet3.lme)
```

Pima.tr  

**Diabetes in Pima Indian Women**

Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

Pima.tr  
Pima.tr2  
Pima.te

Format

These data frames contains the following columns:

- npreg  number of pregnancies.
- glu  plasma glucose concentration in an oral glucose tolerance test.
- bp  diastolic blood pressure (mm Hg).
- skin  triceps skin fold thickness (mm).
- bmi  body mass index (weight in kg/(height in m)^2).  
- ped  diabetes pedigree function.
- age  age in years.
- type  Yes or No, for diabetic according to WHO criteria.

Details

The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 332 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.
plot.lda

Plot Method for Class 'lda'

Description

Plots a set of data on one, two or more linear discriminants.

Usage

## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
     abbrev = FALSE, xlab = "LD1", ylab = "LD2")

Arguments

x                An object of class "lda".
panel            the panel function used to plot the data.
...             additional arguments to pairs, ldahist or eqscplot.
cex             graphics parameter cex for labels on plots.
dimen          The number of linear discriminants to be used for the plot; if this exceeds the
     number determined by x the smaller value is used.
abbrev          whether the group labels are abbreviated on the plots. If abbrev > 0 this gives
     minlength in the call to abbreviate.
xlab            label for the x axis
ylab            label for the y axis

Details

This function is a method for the generic function plot() for class "lda". It can be invoked
by calling plot(x) for an object x of the appropriate class, or directly by calling plot.lda(x)
regardless of the class of the object.

The behaviour is determined by the value of dimen. For dimen > 2, a pairs plot is used. For dimen
= 2, an equiscaled scatter plot is drawn. For dimen = 1, a set of histograms or density plots are
drawn. Use argument type to match "histogram" or "density" or "both".

plot.mca  

Plot Method for Objects of Class 'mca'

Description

Plot a multiple correspondence analysis.

Usage

## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)

Arguments

x                      An object of class "mca".
rows                   Should the coordinates for the rows be plotted, or just the vertices for the levels?
col, cex               The colours and cex to be used for the row points and level vertices respectively.
...                     Additional parameters to plot.

References

See Also

mca, predict.mca

Examples

plot(mca(farms, abbrev = TRUE))

plot.profile  

Plotting Functions for 'profile' Objects

Description

plot and pairs methods for objects of class "profile".

Usage

## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)

Arguments

x                      an object inheriting from class "profile".
colours                Colours to be used for the mean curves conditional on x and y respectively.
...                     arguments passed to or from other methods.
Details

This is the main plot method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters x and y, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of y|x and x|y, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

pr1 <- profile(fm1, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated
```

```r
## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

---

**polr**

**Ordered Logistic or Probit Regression**

**Description**

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

**Usage**

```r
polr(formula, data, weights, start, ..., subset, na.action,
    contrasts = NULL, Hess = FALSE, model = TRUE,
    method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```
Arguments

formula  a formula expression as for regression models, of the form response ~ predictors. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of formula for other details.
data  an optional data frame, list or environment in which to interpret the variables occurring in formula.
weights  optional case weights in fitting. Default to 1.
start  initial values for the parameters. This is in the format c(coefficients, zeta): see the Values section.
...  additional arguments to be passed to optim, most often a control argument.
subset  expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action  a function to filter missing data.
contrasts  a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
Hess  logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call summary or vcov on the fit.
model  logical for whether the model matrix should be returned.
method  logistic or probit or (complementary) log-log or cauchit (corresponding to a Cauchy latent variable).

Details

This model is what Agresti (2002) calls a cumulative link model. The basic interpretation is as a coarsened version of a latent variable \( Y_i \) which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin \( Y_i \) falls into with breakpoints \( \zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty \).

This leads to the model

\[
\text{logit} P(Y \leq k|x) = \zeta_k - \eta
\]

with logit replaced by probit for a normal latent variable, and \( \eta \) being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for \( \eta \) (and hence the coefficients beta).

In the logistic case, the left-hand side of the last display is the log odds of category \( k \) or less, and since these are log odds which differ only by a constant for different \( k \), the odds are proportional. Hence the term proportional odds logistic regression.

The log-log and complementary log-log links are the increasing functions \( F^{-1}(p) = -\log(-\log(p)) \) and \( F^{-1}(p) = \log(-\log(1-p)) \); some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A proportional hazards model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

predict, summary, vcov, anova, model.frame and an extractAIC method for use with stepAIC (and step). There are also profile and confint methods.
Value

A object of class "polr". This has components

- **coefficients**: the coefficients of the linear predictor, which has no intercept.
- **zeta**: the intercepts for the class boundaries.
- **deviance**: the residual deviance.
- **fitted.values**: a matrix, with a column for each level of the response.
- **lev**: the names of the response levels.
- **terms**: the terms structure describing the model.
- **df.residual**: the number of residual degrees of freedoms, calculated using the weights.
- **edf**: the (effective) number of degrees of freedom used by the model
- **n, nobs**: the (effective) number of observations, calculated using the weights. (nobs is for use by `stepAIC`.
- **call**: the matched call.
- **method**: the matched method used.
- **convergence**: the convergence code returned by `optim`.
- **niter**: the number of function and gradient evaluations used by `optim`.
- **lp**: the linear predictor (including any offset).
- **Hessian**: (if Hess is true). Note that this is a numerical approximation derived from the optimization process.
- **model**: (if model is true).

Note

The `vcov` method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, method = "cloglog" confusingly gave the log-log link, implicitly assuming the first response level was the ‘best’.

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
house.plr <- polr(Sat ~ Infl + Type + Cont, weights = Freq, data = housing)
house.plr
summary(house.plr, digits = 3)
## slightly worse fit from
summary(update(house.plr, method = "probit", Hess = TRUE), digits = 3)
## although it is not really appropriate, can fit
summary(update(house.plr, method = "loglog", Hess = TRUE), digits = 3)
```
predict.glmmPQL

Predict Method for glmmPQL Fits

Description

Obtains predictions from a fitted generalized linear model with random effects.

Usage

## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
        level, na.action = na.pass, ...)

Arguments

object
newdata
type
level
na.action
... 

a fitted object of class inheriting from "glmmPQL".
optionally, a data frame in which to look for variables with which to predict.
the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
function determining what should be done with missing values in newdata. The default is to predict NA.
further arguments passed to or from other methods.

Value

If level is a single integer, a vector otherwise a data frame.

See Also

glmmPQL, predict.lme.
Examples

```r
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
    family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

predict.lda

---

**Classify Multivariate Observations by Linear Discrimination**

**Description**

Classify multivariate observations in conjunction with lda, and also project data onto the linear discriminants.

**Usage**

```r
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
    method = c("plug-in", "predictive", "debiased"), ...)
```

**Arguments**

- `object`: object of class "lda"
- `newdata`: data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the lda object.
- `prior`: The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to lda.
- `dimen`: the dimension of the space to be used. If this is less than \( \min(p, ng-1) \), only the first \( \text{dimen} \) discriminant components are used (except for `method="predictive"`), and only those dimensions are returned in \( \mathbf{x} \).
- `method`: This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
- `...`: arguments based from or to other methods

**Details**

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.
predict.lqs

Value

a list with components

class The MAP classification (a factor)
posterior posterior probabilities for the classes
x the scores of test cases on up to dimen discriminant variables

Examples

tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- lda(train, cl)
predict(z, test)$class

predict.lqs Predict from an lqs Fit

Description

Predict from an resistant regression fitted by lqs.

Usage

## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)

Arguments

object object inheriting from class "lqs"
newdata matrix or data frame of cases to be predicted or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the lqs object.
na.action function determining what should be done with missing values in newdata. The default is to predict NA.
... arguments to be passed from or to other methods.
Details

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

Value

A vector of predictions.

lqs

Examples

```r
set.seed(123)
fm <- lqs(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)
```

Description

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

Usage

```r
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)```

Arguments

- `object`: An object of class "mca", usually the result of a call to `mca`.
- `newdata`: A data frame containing either additional rows of the factors used to fit `object` or additional factors for the cases used in the original fit.
- `type`: Are predictions required for further rows or for new factors?
- `...`: Additional arguments from `predict`: unused.

Value

If `type = "row"`, the coordinates for the additional rows.
If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.
References

mca, plot.mca

predict.qda

Classify from Quadratic Discriminant Analysis

Description
Classify multivariate observations in conjunction with qda

Usage
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
method = c("plug-in", "predictive", "debiased", "looCV"), ...)

Arguments
object object of class "qda"
newdata data frame of cases to be classified or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the qda object.
prior The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to qda.
method This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned.
...
arguments based from or to other methods

Details
This function is a method for the generic function predict() for class "qda". It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.qda(x) regardless of the class of the object.

Missing values in newdata are handled by returning NA if the quadratic discriminants cannot be evaluated. If newdata is omitted and the na.action of the fit omitted cases, these will be omitted on the prediction.
Value

- a list with components
  - class: The MAP classification (a factor)
  - posterior: posterior probabilities for the classes

References

See Also

qda, lda, predict.lda

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
qz <- qda(train, cl)
predict(qz, test)$class
```

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```r
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
        del = zmax/5, trace = FALSE, ...)
```

Arguments

- fitted: the original fitted model object.
- which: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- alpha: highest significance level allowed for the profile t-statistics.
- maxsteps: maximum number of points to be used for profiling each parameter.
- del: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- trace: logical: should the progress of profiling be reported?
- ...: further arguments passed to or from other methods.
Details

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

- `par.vals` a matrix of parameter values for each fitted model.
- `tau` the profile t-statistics.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

qda

**Quadratic Discriminant Analysis**

Description

Quadratic discriminant analysis.

Usage

```r
qda(x, ...)
```

### S3 method for class 'formula'
```
qda(formula, data, ..., subset, na.action)
```

### Default S3 method:
```
qda(x, grouping, prior = proportions, 
    method, CV = FALSE, nu, ...)
```

### S3 method for class 'data.frame'
```
qda(x, ...)
```
## S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)

**Arguments**

- **formula**: A formula of the form groups ~ x1 + x2 + ... That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- **data**: An optional data frame, list or environment from which variables specified in formula are preferentially to be taken.
- **x**: (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
- **grouping**: (required if no formula principal argument is given.) a factor specifying the class for each observation.
- **prior**: the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.
- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- **method**: "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a t distribution.
- **CV**: If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
- **nu**: degrees of freedom for method = "t".
- **...**: arguments passed to or from other methods.

**Details**

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

**Value**

an object of class "qda" containing the following components:

- **prior**: the prior probabilities used.
- **means**: the group means.
- **scaling**: for each group i, `scaling[,i]` is an array which transforms observations so that within-groups covariance matrix is spherical.
- **ldet**: a vector of half log determinants of the dispersion matrix.
- **lev**: the levels of the grouping factor.
- **terms**: (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

class The MAP classification (a factor)
posterior posterior probabilities for the classes

predict.qda, lda

Examples

tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z,test)$class

Description

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

Usage

quine

Format

This data frame contains the following columns:

Eth ethnic background: Aboriginal or Not, ("A" or "N").
Sex sex: factor with levels ("F" or "M").
Age age group: Primary ("F0"), or forms "F1," "F2" or "F3".
Lrn learner status: factor with levels Average or Slow learner, ("AL" or "SL").
Days days absent from school in the year.

**Blood Pressure in Rabbits**

**Description**

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the $5-HT_3$ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of $5-HT_3$ receptors.

**Usage**

Rabbit

**Format**

This data frame contains 60 rows and the following variables:

- **BPchange** change in blood pressure relative to the start of the experiment.
- **Dose** dose of Phenylbiguanide in micrograms.
- **Run** label of run ("C1" to "C5", then "M1" to "M5").
- **Treatment** placebo or the $5-HT_3$ antagonist MDL 72222.
- **Animal** label of animal used ("R1" to "R5").

**Source**

[The numerical data are not in the paper but were supplied by Professor Ludbrook]

**References**

rational

Rational Approximation

Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

rational(x, cycles = 10, max.denominator = 2000, ...)

Arguments

x
Any object of mode numeric. Missing values are now allowed.
cycles
The maximum number of steps to be used in the continued fraction approximation process.
max.denominator
An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
...
arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

\[ x = \text{floor}(x) + \frac{1}{p_1 + \frac{1}{p_2 + \ldots}} \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at \( \text{cycles} \) terms or when a \( p_j > \) \( \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

Value

A numeric object with the same attributes as \( x \) but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

See Also

fractions

Examples

X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
**renumerate**

*Convert a Formula Transformed by 'denumerate'*

**Description**

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

**Usage**

```r
renumerate(x)
```

**Arguments**

- `x`: A formula, normally as modified by `denumerate`.

**Details**

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

**Value**

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

**See Also**

- `denumerate`

**Examples**

```r
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

**r1m**

*Robust Fitting of Linear Models*

**Description**

Fit a linear model by robust regression using an M estimator.
Usage

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
    method = c("M", "MM", "model.frame"),
    wt.method = c("inv.var", "case"),
    model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
    init = "ls", psi = psi.huber,
    scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
    method = c("M", "MM"), wt.method = c("inv.var", "case"),
    maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

Arguments

formula a formula of the form y ~ x1 + x2 + ....
data an optional data frame, list or environment from which variables specified in
    formula are preferentially to be taken.
weights a vector of prior weights for each case.
subset An index vector specifying the cases to be used in fitting.
na.action A function to specify the action to be taken if NAs are found. The 'factory-fresh'
    default action in R is na.omit, and can be changed by options(na.action=).
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
method currently either M-estimation or MM-estimation or (for the formula method
    only) find the model frame. MM-estimation is M-estimation with Tukey's bi-
    weight initialized by a specific S-estimator. See the 'Details' section.
wt.method are the weights case weights (giving the relative importance of case, so a weight
    of 2 means there are two of these) or the inverse of the variances, so a weight
    of two means this error is half as variable?
model should the model frame be returned in the object?
x.ret should the model matrix be returned in the object?
y.ret should the response be returned in the object?
contrasts optional contrast specifications: see lm.
w (optional) initial down-weighting for each case.
init (optional) initial values for the coefficients OR a method to find initial values
    OR the result of a fit with a coef component. Known methods are "ls" (the
    default) for an initial least-squares fit using weights w*weights, and "lts" for
    an unweighted least-trimmed squares fit with 200 samples.
psi the psi function is specified by this argument. It must give (possibly by name)
    a function g(x, ..., deriv) that for deriv=0 returns psi(x)/x and for deriv=1
    returns psi'(x). Tuning constants will be passed in via ....
scale.est | method of scale estimation: re-scaled MAD of the residuals (default) or Huber’s proposal 2 (which can be selected by either "Huber" or "proposal 2").
k2 | tuning constant used for Huber proposal 2 scale estimation.
maxit | the limit on the number of IWLS iterations.
acc | the accuracy for the stopping criterion.
test.vec | the stopping criterion is based on changes in this vector.
... | additional arguments to be passed to rlm.default or to the psi function.
lqs.control | An optional list of control values for lqs.
u | numeric vector of evaluation points.
k, a, b, c | tuning constants.
deriv | 0 or 1: compute values of the psi function or of its first derivative.

Details

Fitting is done by iterated re-weighted least squares (IWLS).
Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as psi.huber, psi.hampel and psi.bisquare. Huber’s corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.
Selecting method = "MM" selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with k0 = 1.548; this gives (for n ≫ p) breakdown point 0.5. The final estimator is an M-estimator with Tukey’s biweight and fixed scale that will inherit this breakdown point provided c > k0; this is true for the default value of c that corresponds to 95% relative efficiency at the normal. Case weights are not supported for method = "MM".

Value

An object of class "rlm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.
The additional components not in an lm object are

s | the robust scale estimate used
w | the weights used in the IWLS process
psi | the psi function with parameters substituted
conv | the convergence criteria at each iteration
converged | did the IWLS converge?
wresid | a working residual, weighted for "inv.var" weights only.

Note

Prior to version 7.3–52, offset terms in formula were omitted from fitted and predicted values.
rmusrv

Examples

summary(rlm(stack.loss ~ ., stackloss))
rlm(stack.loss ~ ., stackloss, psi = psi.hampel, init = "lts")
rlm(stack.loss ~ ., stackloss, psi = psi.bisquare)

Description

Calculates the root mean square parameter effects and intrinsic relative curvatures, $c_\theta$ and $c_\iota$, for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

Usage

rms.curv(obj)

Arguments

obj Fitted model object of class "nls". The model must be fitted using the default algorithm.

Details

The method of section 7.3.1 of Bates & Watts is implemented. The function deriv3 should be used to generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, print.rms.curv, prints the pc and ic components only, suitably annotated.

If either pc or ic exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

Value

A list of class rms.curv with components pc and ic for parameter effects and intrinsic relative curvatures multiplied by $\sqrt{F}$, ct and ci for $c_\theta$ and $c_\iota$ (unmultiplied), and C the C-array as used in section 7.3.1 of Bates & Watts.
**rnegbin**

Simulate Negative Binomial Variates

**Description**

Function to generate random outcomes from a Negative Binomial distribution, with mean \( \mu \) and variance \( \mu + \mu^2/\theta \).

**Usage**

```r
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

**Arguments**

- `n` if a scalar, the number of sample values required. If a vector, `length(n)` is the number required and `n` is used as the mean vector if `mu` is not specified.
- `mu` the vector of means. Short vectors are recycled.
- `theta` vector of values of the theta parameter. Short vectors are recycled.

**Details**

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

**Value**

Vector of random Negative Binomial variate values.

**Side Effects**

Changes `.Random.seed` in the usual way.

---

`deriv3`

**Examples**

```r
# The treated sample from the Puromycin data
mmcurve <- deriv3(~ Vm * conc/(K + conc), c("Vm", "K"),
                   function(Vm, K, conc) NULL)
Treated <- Puromycin[Puromycin$state == "treated", ]
(Purfit1 <- nls(rate ~ mmcurve(Vm, K, conc), data = Treated,
                start = list(Vm=200, K=0.1)))
rms.curv(Purfit1)
##Parameter effects: c^\theta x sqrt(F) = 0.2121
## Intrinsic: c^iota x sqrt(F) = 0.092
```
Examples

# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)

road

Road Accident Deaths in US States

Description

A data frame with the annual deaths in road accidents for half the US states.

Usage

road

Format

Columns are:

state name.
deaths number of deaths.
drivers number of drivers (in 10,000s).
popden population density in people per square mile.
rural length of rural roads, in 1000s of miles.
temp average daily maximum temperature in January.
fuel fuel consumption in 10,000,000 US gallons per year.

rotifer

Numbers of Rotifers by Fluid Density

Description

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, pm Polyartha major and kc, Keratella cochlearis and for each species the number falling out and the total number are given.

Usage

rotifer
**Rubber**

**Format**

- **density** specific density of fluid.
- **pm.y** number falling out for *P. major*.
- **pm.total** total number of *P. major*.
- **kc.y** number falling out for *K. cochlearis*.
- **kc.tot** total number of *K. cochlearis*.

**Source**

<table>
<thead>
<tr>
<th>Rubber</th>
<th><em>Accelerated Testing of Tyre Rubber</em></th>
</tr>
</thead>
</table>

**Description**

Data frame from accelerated testing of tyre rubber.

**Usage**

Rubber

**Format**

- **loss** the abrasion loss in gm/hr.
- **hard** the hardness in Shore units.
- **tens** tensile strength in kg/sq m.

**Source**

**References**

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
        magic = 0.2, tol = 1e-4)
```

**Arguments**

- **d**: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.
- **y**: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution. (If there are missing values in `d`, an initial configuration must be provided.) This must not have duplicates.
- **k**: The dimension of the configuration.
- **niter**: The maximum number of iterations.
- **trace**: Logical for tracing optimization. Default `TRUE`.
- **magic**: Initial value of the step size constant in diagonal Newton method.
- **tol**: Tolerance for stopping, in units of stress.

**Details**

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (magic) to ensure that it always goes downhill.

**Value**

Two components:

- **points**: A two-column vector of the fitted configuration.
- **stress**: The final stress achieved.

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.
**ships**

**Ships Damage Data**

**Description**

Data frame giving the number of damage incidents and aggregate months of service by ship type, year of construction, and period of operation.

**Usage**

ships

**Format**

- **type**: type: "A" to "E".
- **year**: year of construction: 1960–64, 65–69, 70–74, 75–79 (coded as "60", "65", "70", "75").
- **period**: period of operation: 1960–74, 75–79.
- **service**: aggregate months of service.
- **incidents**: number of damage incidents.

### Space Shuttle Autolander Problem

**Description**

The `shuttle` data frame has 256 rows and 7 columns. The first six columns are categorical variables giving example conditions; the seventh is the decision. The first 253 rows are the training set, the last 3 the test conditions.

**Usage**

`shuttle`

**Format**

This data frame contains the following factor columns:

- `stability`: stable positioning or not (`stab` / `xstab`).
- `error`: size of error (`MM` / `SS` / `LX` / `XL`).
- `sign`: sign of error, positive or negative (`pp` / `nn`).
- `wind`: wind sign (`head` / `tail`).
- `magn`: wind strength (`Light` / `Medium` / `Strong` / `Out of Range`).
- `vis`: visibility (`yes` / `no`).
- `use`: use the autolander or not (`auto` / `noauto`).

snails  

**Snail Mortality Data**

**Description**

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

**Usage**

snails

**Format**

The data frame contains the following components:

- **Species**  snail species A (1) or B (2).
- **Exposure**  exposure in weeks.
- **Rel.Hum**  relative humidity (4 levels).
- **Temp**  temperature, in degrees Celsius (3 levels).
- **Deaths**  number of deaths.
- **N**  number of snails exposed.

stepAIC  Choose a model by AIC in a Stepwise Algorithm

Description

Performs stepwise model selection by AIC.

Usage

stepAIC(object, scope, scale = 0,
        direction = c("both", "backward", "forward"),
        trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
        k = 2, ...)

Arguments

- object  an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.
- scope  defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.
- scale  used in the definition of the AIC statistic for selecting the models, currently only for *lm* and *aov* models (see *extractAIC* for details).
direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".

trace | if positive, information is printed during the running of stepAIC. Larger values may give more information on the fitting process.

keep | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.

steps | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

use.start | if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for glm (and other fits), but it can also slow them down. Not used in R.

k | the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.

... | any additional arguments to extractAIC. (None are currently used.)

Details

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by update.formula.

There is a potential problem in using glm fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The glm method for extractAIC makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

Where a conventional deviance exists (e.g. for lm, aov and glm fits) this is quoted in the analysis of variance table: it is the unscaled deviance.

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the keep= argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding lm, aov and survreg fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an na.action other than na.fail is used (as is the default in R). We suggest you remove the missing values first.

summary.loglm

Summary Method Function for Objects of Class 'loglm'

Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using \texttt{loglm}.

Usage

```r
## S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)
```

Arguments

- `object`: a fitted \texttt{loglm} model object.
- `fitted`: if \texttt{TRUE} return observed and expected frequencies in the result. Using `fitted = TRUE` may necessitate re-fitting the object.
- `...`: arguments to be passed to or from other methods.

Details

This function is a method for the generic function \texttt{summary()} for class "\texttt{loglm}". It can be invoked by calling \texttt{summary(x)} for an object \texttt{x} of the appropriate class, or directly by calling \texttt{summary.loglm(x)} regardless of the class of the object.

Value

A list is returned for use by \texttt{print.summary.loglm}. This has components

- `formula`: the formula used to produce \texttt{object}
- `tests`: the table of test statistics (likelihood ratio, Pearson) for the fit.
- `oe`: if \texttt{fitted = TRUE}, an array of the observed and expected frequencies, otherwise \texttt{NULL}.

References

\texttt{loglm}, \texttt{summary}
Summary Method Function for Objects of Class 'negbin'

Description

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

Usage

```r
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

Arguments

- `object`: fitted model object of class `negbin` inheriting from `glm` and `lm`. Typically the output of `glm.nb`.
- `dispersion`: as for `summary.glm`, with a default of 1.
- `correlation`: as for `summary.glm`.
- `...`: arguments passed to or from other methods.

Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class `"negbin"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

References

`summary`, `glm.nb`, `negative.binomial`, `anova.negbin`

Examples

```r
summary(glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log))
```
**Summary Method for Robust Linear Models**

**Description**

summary method for objects of class "rlm"

**Usage**

```r
## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

**Arguments**

- `object` the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class `rlm`, in the sense that the components returned by the `rlm` function will be available.
- `method` Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?
- `correlation` logical. Should correlations be computed (and printed)?
- `...` arguments passed to or from other methods.

**Details**

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

**Value**

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

- `correlation` The computed correlation coefficient matrix for the coefficients in the model.
- `cov.unscaled` The unscaled covariance matrix; i.e. a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.
- `sigma` The scale estimate.
- `stddev` A scale estimate used for the standard errors.
- `df` The number of degrees of freedom for the model and for residuals.
- `coefficients` A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.
- `terms` The terms object used in fitting this model.

**Student Survey Data**

**Description**

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

**Usage**

survey

**Format**

The components of the data frame are:

- **Sex**  
  The sex of the student. (Factor with levels "Male" and "Female").

- **Wr.Hnd**  
  Span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.

- **NW.Hnd**  
  Span of non-writing hand.

- **W.Hnd**  
  Writing hand of student. (Factor, with levels "Left" and "Right").

- **Fold**  
  "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither").

- **Pulse**  
  Pulse rate of student (beats per minute).

- **Clap**  
  "Clap your hands! Which hand is on top?" (Factor, with levels "Right", "Left", "Neither").

- **Exer**  
  How often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None").

- **Smoke**  
  How much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never").

- **Height**  
  Height of the student in centimetres.

- **M.I**  
  Whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial").

- **Age**  
  Age of the student in years.

### synth.tr: Synthetic Classification Problem

**Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```r
synth.tr
synth.te
```

**Format**

These data frames contain the following columns:

- `xs` x-coordinate
- `ys` y-coordinate
- `yc` class, coded as 0 or 1.

**Source**

---

### theta.md: Estimate theta of the Negative Binomial

**Description**

Given the estimated mean vector, estimate theta of the Negative Binomial Distribution.

**Usage**

```r
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)
theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25, trace = FALSE)
theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```
Arguments

y  Vector of observed values from the Negative Binomial.
mu Estimated mean vector.
n  Number of data points (defaults to the sum of weights)
dfr Residual degrees of freedom (assuming theta known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
weights Case weights. If missing, taken as 1.
limit Limit on the number of iterations.
eps Tolerance to determine convergence.
trace logical: should iteration progress be printed?

Details

theta.md estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.
theta.ml uses maximum likelihood.
theta.mm calculates the moment estimator of theta by equating the Pearson chi-square \(\sum(y - \mu)^2/(\mu + \mu^2/\theta)\) to the residual degrees of freedom.

Value

The required estimate of theta, as a scalar. For theta.ml, the standard error is given as attribute "SE".

### Traffic 

**Effect of Swedish Speed Limits on Accidents**

**Description**

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day j in 1962 was comparable to day j in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

Traffic

**Format**

This data frame contains the following columns:

- year: 1961 or 1962.
- day: of year.
- limit: was there a speed limit?
- y: traffic accident count for that day.
truehist

Source

References

truehist

*Plot a Histogram*

Description

Creates a histogram on the current graphics device.

Usage

truehist(data, nbins = "Scott", h, x0 = -h/1000,
breaks, prob = TRUE, xlim = range(breaks),
ymax = max(est), col = "cyan",
xlab = deparse(substitute(data)), bty = "n", ...)

Arguments

data numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.

nbins The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)

h The bin width, a strictly positive number (takes precedence over nbins).

x0 Shift for the bins - the breaks are at x0 + h * (...,-1,0,1,...)

breaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).

prob If true (the default) plot a true histogram. The vertical axis has a relative frequency density scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.

xlim The limits for the x-axis.

ymax The upper limit for the y-axis.

col The colour for the bar fill: the default is colour 5 in the default R palette.

xlab label for the plot x-axis. By default, this will be the name of data.

bty The box type for the plot - defaults to none.

... additional arguments to rect or plot.
Details

This plots a true histogram, a density estimate of total area 1. If breaks is specified, those breakpoints are used. Otherwise if h is specified, a regular grid of bins is used with width h. If neither breaks nor h is specified, nbins is used to select a suitable h.

Side Effects

A histogram is plotted on the current device.

UScereal

Description

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

Usage

UScereal

Format

This data frame contains the following columns:

- **mfr** Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.
- **calories** number of calories in one portion.
- **protein** grams of protein in one portion.
- **fat** grams of fat in one portion.
- **sodium** milligrams of sodium in one portion.
- **fibre** grams of dietary fibre in one portion.
- **carbo** grams of complex carbohydrates in one portion.
- **sugars** grams of sugars in one portion.
- **shelf** display shelf (1, 2, or 3, counting from the floor).
- **potassium** grams of potassium.
- **vitamins** vitamins and minerals (none, enriched, or 100%).

Counts of Waders at 15 Sites in South Africa

Description
The wader's data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

Usage
waders
Format

This data frame contains the following columns (species)

S1  Oystercatcher
S2  White-fronted Plover
S3  Kitt Lutz’s Plover
S4  Three-banded Plover
S5  Grey Plover
S6  Ringed Plover
S7  Bar-tailed Godwit
S8  Whimbrel
S9  Marsh Sandpiper
S10 Greenshank
S11 Common Sandpiper
S12 Turnstone
S13 Knot
S14 Sanderling
S15 Little Stint
S16 Curlew Sandpiper
S17 Ruff
S18 Avocet
S19 Black-winged Stilt

The rows are the sites:
A = Namibia North coast
B = Namibia North wetland
C = Namibia South coast
D = Namibia South wetland
E = Cape North coast
F = Cape North wetland
G = Cape West coast
H = Cape West wetland
I = Cape South coast
J = Cape South wetland
K = Cape East coast
L = Cape East wetland
M = Transkei coast
N = Natal coast
O = Natal wetland

House Insulation: Whiteside’s Data

Description

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

Usage

whiteside

Format

The whiteside data frame has 56 rows and 3 columns:

- Insul: A factor, before or after insulation.
- Temp: Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)
- Gas: The weekly gas consumption in 1000s of cubic feet.

Source

References

Examples

```r
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...)
  {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  },
  xlab = "Average external temperature (deg. C)",
  ylab = "Gas consumption (1000 cubic feet)",
  aspect = "xy",
  strip = function(...)
  strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))

width.SJ

Bandwidth Selection by Pilot Estimation of Derivatives

Description

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))

Arguments

x a numeric vector

nb number of bins to use.

upper, lower range over which to search for solution if method = "ste".

method Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

a bandwidth.

Note

A faster version for large n (thousands) is available in R ≥ 3.4.0 as part of bw.SJ: quadruple its value for comparability with this version.

References

\[
\text{width.SJ(galaxies, method = "dpi")}
\]
\[
\text{width.SJ(galaxies)}
\]

write.matrix

Write a Matrix or Data Frame

Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

\[
\text{write.matrix(x, file = "", sep = " ", blocksize)}
\]

Arguments

\[
x \quad \text{matrix or data frame.}
\]
\[
\text{file} \quad \text{name of output file. The default ("\") is the console.}
\]
\[
\text{sep} \quad \text{The separator between columns.}
\]
\[
\text{blocksize} \quad \text{If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available.}
\]

Details

If \( x \) is a matrix, supplying blocksize is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If \( x \) is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects

A formatted file is produced, with column headings (if \( x \) has them) and columns of data.

Chapter 17
The Matrix package

abIndex-class  Class "abIndex" of Abstract Index Vectors

Description
The "abIndex" class, short for "Abstract Index Vector", is used for dealing with large index vectors more efficiently, than using integer (or numeric) vectors of the kind 2:1000000 or c(0:1e5, 1000:1e6).

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (packageDescription("Matrix")$Maintainer).

Objects from the Class
Objects can be created by calls of the form new("abIndex", ...), but more easily and typically either by as(x, "abIndex") where x is an integer (valued) vector, or directly by abIseq() and combination c(...) of such.

Slots
kind: a character string, one of ("int32", "double", "rleDiff"), denoting the internal structure of the abIndex object.
x: Object of class "numLike"; is used (i.e., not of length 0) only if the object is not compressed, i.e., currently exactly when kind != "rleDiff".
rleD: object of class "rleDiff", used for compression via rle.

Methods
as.numeric, as.integer, as.vector signature(x = "abIndex"): ...
[ signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...
coerce signature(from = "numeric", to = "abIndex"): ...
coerce signature(from = "abIndex", to = "numeric"): ...
coerce signature(from = "abIndex", to = "integer"): ...
length signature(x = "abIndex"): ...

2289
abIseq

Signature

**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**: see **Ops** for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"): ...

**Ops** signature(e1 = "abIndex", e2 = "numeric"): ...

**Summary** signature(x = "abIndex"): ...

**show** ("abIndex"): simple **show** method, building on **show(<rleDiff>)**.

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite**, **is.infinite** ("abIndex"): ditto.

**Note**

This is currently experimental and not yet used for our own code. Please contact us (**packageDescription("Matrix")$Maintainer**), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlægel, as implemented (around 2008, in the GPL’ed part of) package **ff**.

**See Also**

**rle** (**base**) which is used here: **numeric**

**Examples**

```r
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> **show** method

stopifnot(identical(-3:20,
    as(abIseq1(-3,20), "vector")))
```

---

**abIseq**

*Sequence Generation of "abIndex", Abstract Index Vectors*

**Description**

Generation of abstract index vectors, i.e., objects of class "abIndex".

**abIseq()** is designed to work entirely like **seq**, but producing "abIndex" vectors.

**abIseq1()** is its basic building block, where **abIseq1(n,m)** corresponds to **n:m**.

**c(x, ...)** will return an "abIndex" vector, when **x** is one.

**Usage**

```r
abIseq1(from = 1, to = 1)
abIseq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
    length.out = NULL, along.with = NULL)
```

## S3 method for class 'abIndex'

```r
c(...)
```
Arguments

- `from, to`: the starting and (maximal) end value of the sequence.
- `by`: number: increment of the sequence.
- `length.out`: desired length of the sequence. A non-negative number, which for `seq` and `seq.int` will be rounded up if fractional.
- `along.with`: take the length from the length of this argument.
- `...`: in general an arbitrary number of R objects; here, when the first is an "abIndex" vector, these arguments will be concatenated to a new "abIndex" object.

Value

An abstract index vector, i.e., object of class "abIndex".

See Also

the class `abIndex` documentation; `rep2abI()` for another constructor; `rle` (base).

Examples

```r
stopifnot(identical(-3:20, as(abIseq1(-3,20), "vector")))

try( ## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)
```

Description

The basic R functions `all` and `any` now have methods for Matrix objects and should behave as for matrix ones.

Methods

```r
all signature(x = "Matrix", ..., na.rm = FALSE): ...
any signature(x = "Matrix", ..., na.rm = FALSE): ...
all signature(x = "ldenseMatrix", ..., na.rm = FALSE): ...
all signature(x = "lsparseMatrix", ..., na.rm = FALSE): ...
```

Examples

```r
M <- Matrix(1:12 +0, 3,4)
all(M >= 1) # TRUE
any(M < 0 ) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0 ) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
```
Matrix Package Methods for Function `all.equal()`

**Description**

Methods for function `all.equal()` (from R package `base`) are defined for all `Matrix` classes.

**Methods**

- `target = "Matrix", current = "Matrix"`
- `target = "ANY", current = "Matrix"`
- `target = "Matrix", current = "ANY"` these three methods are simply using `all.equal.numeric` directly and work via `as.vector()`.

There are more methods, notably also for "sparseVector"'s, see `showMethods("all.equal")`.

**Examples**

```r
showMethods("all.equal")
```

```r
(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
                    lu.@L %*% lu.@U),
          with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
                            L %*% U)),
          with(ex, all.equal(as(A, "CsparseMatrix"),
                             t(P) %*% L %*% U %*% t(Q))))
```

**atomicVector-class**

*Virtual Class "atomicVector" of Atomic Vectors*

**Description**

The `class` "atomicVector" is a virtual class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Methods**

In the `Matrix` package, the "atomicVector" is used in signatures where typically "old-style" "matrix" objects can be used and can be substituted by simple vectors.

**Extends**

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".
Author(s)

Martin Maechler

See Also

Examples

\begin{verbatim}
showClass("atomicVector")
\end{verbatim}

\begin{verbatim}
band          
Extract bands of a matrix
\end{verbatim}

Description

Returns a new matrix formed by extracting the lower triangle (\texttt{tril}) or the upper triangle (\texttt{triu}) or a general band relative to the diagonal (\texttt{band}), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

Usage

\begin{verbatim}
band(x, k1, k2, ...)
tril(x, k = 0, ...)
triu(x, k = 0, ...)
\end{verbatim}

Arguments

- \texttt{x} a matrix-like object
- \texttt{k, k1, k2} integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is \texttt{k=0}. A negative value of \texttt{k} indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal.
- \texttt{...} Optional arguments used by specific methods. (None used at present.)

Value

An object of an appropriate matrix class. The class of the value of \texttt{tril} or \texttt{triu} inherits from \texttt{triangularMatrix} when appropriate. Note that the result is of class \texttt{sparseMatrix} only if \texttt{x} is.

Methods

\begin{verbatim}
x = "CsparseMatrix" method for compressed, sparse, column-oriented matrices.
x = "TsparseMatrix" method for sparse matrices in triplet format.
x = "RsparseMatrix" method for compressed, sparse, row-oriented matrices.
x = "ddenseMatrix" method for dense numeric matrices, including packed numeric matrices.
\end{verbatim}

See Also

\texttt{bandSparse} for the \textit{construction} of a banded sparse matrix directly from its non-zero diagonals.
Examples

```r
## A random sparse matrix:
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)     # lower triangle
tril(mm, -1) # strict lower triangle
triu(mm, 1)  # strict upper triangle
band(mm, -1, 2) # general band

(m5 <- Matrix(rnorm(25), nc = 5))

tril(m5)     # lower triangle
tril(m5, -1) # strict lower triangle
triu(m5, 1)  # strict upper triangle
band(m5, -1, 2) # general band

(m65 <- Matrix(rnorm(30), nc = 5)) # not square

triu(m65)     # result not "dtrMatrix" unless square

(sm5 <- crossprod(m65)) # result not "dtrMatrix" unless square

band(sm5, -1, 1) # symmetric bandpreserves symmetry property

as(band(sm5, -1, 1), "sparseMatrix") # often preferable

(sm <- round(crossprod(triu(mm/2)))) # sparse symmetric ("dsC")(sm5 <- crossprod(m65)) # symmetric

band(sm, -1, 1) # remains "dsC", however
band(sm, -2, 1) # -> "dgC"
```

**bandSparse**

Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals

Description

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

Usage

```r
bandSparse(n, m = n, k, diagonals, symmetric = FALSE,
repr = "C", giveCsparse = (repr == "C"))
```

Arguments

- **n,** **m**
  the matrix dimension \((n, m) = (nrow, ncol)\).
- **k**
  integer vector of "diagonal numbers", with identical meaning as in `band(*, k)`, i.e., relative to the main diagonal, which is \(k=0\).
- **diagonals**
  optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class `nMatrix`. diagonals can also be \(n' \times d\) matrix, where \(d <= length(k)\) and \(n' >= min(n, m)\). In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals.
**Examples**

diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1, "dsCMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7,9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
lLis <- lapply(list(rpois(20, 2), rpois(20,1), rpois(20,3))[c(1:3,2:3,3:2)],
as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lLis))
(s4. <- as(drop0(s4), "nsparseMatrix"))

n <- 1e4
bk <- c(0:5, 7,11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
lLis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]

## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE))
, inherits(B, "dtCMatrix") # triangular!)

---

**Value**
a sparse matrix (of class CsparseMatrix) of dimension n × m with diagonal "bands" as specified.

**See Also**

band, for extraction of matrix bands; bdiag, diag, sparseMatrix, Matrix.
Construct a Block Diagonal Matrix

Description

Build a block diagonal matrix given several building block matrices.

Usage

bdiag(...)
bdiag(lst)

Arguments

... individual matrices or a list of matrices.
lst non-empty list of matrices.

Details

For non-trivial argument list, bdiag() calls .bdiag(). The latter maybe useful to programmers.

Value

A sparse matrix obtained by combining the arguments into a block diagonal matrix.

The value of bdiag() inherits from class CsparseMatrix, whereas .bdiag() returns a TsparseMatrix.

Note

This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.

It is currently inefficient for the case of many small dense block matrices. For the case of many dense $k \times k$ matrices, the bdiag_m() function in the ‘Examples’ is an order of magnitude faster.

Author(s)

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on TsparseMatrix objects.

See Also

Diagonal for constructing matrices of class diagonalMatrix, or kronecker which also works for "Matrix" inheriting matrices.

bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of bdiag() which return traditional matrices.
Examples

```r
bdiag(matrix(1:4, 2), diag(3))
# combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3, 4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
   bdiag(lapply(mlist, as.matrix))))

m <- c(as(matrix((1:24)%% 11 == 0, 6,4),"nMatrix"),
   rep(list(Diagonal(2, x=TRUE)), 3))
ml <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
   is(bdiag(mln),"dsparseMatrix") )

## random (diagonal-)block-triangular matrices:
rblockTri <- function(nb, max.ni, lambda = 3) {
   .bdiag(replicate(nb, {
      n <- sample.int(max.ni, 1)
      tril(Matrix(rpois(n*n, lambda=lambda), n,n))
   }))
}

(T4 <- rblockTri(4, 10, lambda = 1))
image(T1 <- rblockTri(12, 20))
```

## Fast version of Matrix :: .bdiag() -- for the case of *many* (k x k) matrices:

```r
@param lmat list(<mat1>, <mat2>, ..., <mat_N>) where each mat_j is a k x k 'matrix'

@return a sparse (N*k x N*k) matrix of class \code{"dgCMatrix"}.

bdiag_m <- function(lmat) {
   ## Copyright (C) 2016 Martin Maechler, ETH Zurich
   if(!length(lmat)) return(new("dgCMatrix"))
   stopifnot(is.list(lmat), is.matrix(lmat[[1]]),
   (k <- (d <- dim(lmat[[1]])[1]) == d[2], # k x k
    all(vapply(lmat, dim, integer(2)) == k)) # all of them
   N <- length(lmat)
   if(N * k > .Machine$integer.max)
      stop("resulting matrix too large; would be M x M, with M=%d, N=%d")
   M <- as.integer(N * k)
   ## result: an M x M matrix
   new("dgCMatrix", Dim = c(M,M),
    i = as.vector(matrix(0L:(M-1L), nrow=k)),
    p = k * 0L:M,
    x = as.double(unlist(lmat, recursive=FALSE, use.names=FALSE))
   )
}
```

l12 <- replicate(12, matrix(rpois(16, lambda = 6.4), 4,4), simplify=FALSE)
dim(T12 <- bdiag_m(l12))# 48 x 48
T12[1:20, 1:20]

BunchKaufman-methods  Bunch-Kaufman Decomposition Methods
**Description**

The Bunch-Kaufman Decomposition of a square symmetric matrix \( A \) is \( A = PDLP' \) where \( P \) is a permutation matrix, \( L \) is unit-lower triangular and \( D \) is block-diagonal with blocks of dimension \( 1 \times 1 \) or \( 2 \times 2 \).

This is generalization of a pivoting \( LDL' \) Cholesky decomposition.

**Usage**

```r
## S4 method for signature 'dsyMatrix'
BunchKaufman(x, ...)
## S4 method for signature 'dspMatrix'
BunchKaufman(x, ...)
## S4 method for signature 'matrix'
BunchKaufman(x, uplo = NULL, ...)
```

**Arguments**

- `x`: a symmetric square matrix.
- `uplo`: optional string, "U" or "L" indicating which “triangle” half of \( x \) should determine the result. The default is "U" unless \( x \) has a `uplo` slot which is the case for those inheriting from class `symmetricMatrix`, where \( x@uplo \) will be used.
- `...`: potentially further arguments passed to methods.

**Details**

FIXME: We really need an `expand()` method in order to work with the result!

**Value**

an object of class `BunchKaufman`, which can also be used as a (triangular) matrix directly. Somewhat amazingly, it inherits its `uplo` slot from \( x \).

**Methods**

Currently, only methods for dense numeric symmetric matrices are implemented. To compute the Bunch-Kaufman decomposition, the methods use either one of two Lapack routines:

```r
x = "dspMatrix" routine dsptrf(); whereas
x = "dsyMatrix", and
x = "matrix" use dsytrf().
```

**References**

The original LAPACK source code, including documentation: [https://www.netlib.org/lapack/double/dsytrf.f](https://www.netlib.org/lapack/double/dsytrf.f) and [https://www.netlib.org/lapack/double/dsptrf.f](https://www.netlib.org/lapack/double/dsptrf.f)

**See Also**

The resulting class, `BunchKaufman`. Related decompositions are the LU, \( lu \), and the Cholesky, \( chol \) (and for sparse matrices, \( Cholesky \)).
Examples

```r
data(CAex)
dim(CAex)
isSymmetric(CAex)# TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
  bk. <- BunchKaufman(CAs)
  ## does apply to *dense* symmetric matrices:
  bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA

image(bkCA)# shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
  ## an upper triangular 72x72 matrix with only 144 non-zero entries
```

Description

An example of a sparse matrix for which `eigen()` seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (https://stat.ethz.ch/mailman/listinfo/r-help), by Casper J Albers, Open University, UK.

Usage

```r
data(CAex)
```

Format

This is a \(72 \times 72\) symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

Details

Historical note (2006-03-30): In earlier versions of R, `eigen(CAex)` fell into an infinite loop whereas `eigen(CAex, EISPACK=TRUE)` had been okay.

Examples

```r
data(CAex)
str(CAex) # of class "dgCMatrix"

image(CAex)# -> it's a simple band matrix with 5 bands
  ## and the eigen values are basically 1 (42 times) and 0 (30 x):
  zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
  ## i.e., the matrix is symmetric, hence
  sCA <- as(CAex, "symmetricMatrix")
  ## and
  stopifnot(class(sCA) == "dsCMatrix",
    as(sCA, "matrix") == as(CAex, "matrix"))
```
cBind

'cbind()' and 'rbind()' recursively built on cbind2/rbind2

Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument .... Now, when S4 objects are found among the arguments, base `cbind()` and `rbind()` internally “dispatch” recursively, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

`cbind2()` and `rbind2()` are from the `methods` package, i.e., standard R, and have been provided for binding together two matrices, where in `Matrix`, we have defined methods for these and the 'Matrix' matrices.

Usage

```r
## cbind(..., deparse.level = 1)
## rbind(..., deparse.level = 1)

## and e.g.,
## S4 method for signature 'denseMatrix,sparseMatrix'
cbind2(x,y, sparse = NA, ...)
## S4 method for signature 'sparseMatrix,denseMatrix'
cbind2(x,y, sparse = NA, ...)
## S4 method for signature 'denseMatrix,sparseMatrix'
rcbind2(x,y, sparse = NA, ...)
## S4 method for signature 'sparseMatrix,denseMatrix'
rcbind2(x,y, sparse = NA, ...)
```

Arguments

- `...`, `x`, `y` matrix-like R objects to be bound together, see `cbind` and `rbind`.
- `sparse` option `logical` indicating if the result should be sparse, i.e., formally inheriting from "sparseMatrix". The default, `NA`, decides from the “sparsity” of `x` and `y`, see e.g., the R code in `selectMethod(cbind2, c("sparseMatrix","denseMatrix"))`.
- `deparse.level` integer determining under which circumstances column and row names are built from the actual arguments’ `expression`, see `cbind`.

Value

typically a ‘matrix-like’ object of a similar `class` as the first argument in ....

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries is than non-zero ones (as the default `sparse` in `Matrix()`).

Historical Remark

Before R version 3.2.0 (April 2015), we have needed a substitute for S4-enabled versions of `cbind` and `rbind`, and provided cBind and rBind with identical syntax and semantic in order to bind together multiple matrices ("matrix" or "Matrix" and vectors. With R version 3.2.0 and newer,
CHMfactor-class

cBind and rBind are deprecated and produce a deprecation warning (via `.Deprecated`), and your code should start using cbind() and rbind() instead.

`cbind2`, `cbind`, Documentation in base R's methods package.

Our class definition help pages mentioning cbind2() and rbind2() methods: "denseMatrix", "diagonalMatrix", "indMatrix".

Examples

```r
(a <- matrix(c(2:1,1:2), 2,2))
(M1 <- cbind(0, rbind(a, 7))) # a traditional matrix
D <- Diagonal(2)
(M2 <- cbind(4, a, D, -1, D, 0)) # a sparse Matrix
stopifnot(validObject(M2), inherits(M2, "sparseMatrix"),
          dim(M2) == c(2,9))
```

---

**CHMfactor-class**

**CHOLMOD-based Cholesky Factorizations**

Description

The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "CHMsimpl") or supernodal (virtual class "CHMsuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMsimpl" and "dCHMsuper") or symbolic factorizations (classes "nCHMsimpl" and "nCHMsuper").

Usage

```r
isLDL(x)
```

## S4 method for signature 'CHMfactor'
update(object, parent, mult = 0, ...)
.updateCHMfactor(object, parent, mult)

## and many more methods, notably,

## solve(a, b, system = c("A","LDLt","LD","DLt","L","Lt","D","P","Pt"), ...)
## ----- see below
Arguments

- `x`, `object`, `a`
  - `a` is a "CHMfactor" object (almost always the result of `Cholesky()`).
- `parent`
  - `a` is a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated object. If `parent` is symmetric, of class "dsCMatrix", then object should be a decomposition of a matrix with the same nonzero pattern as `parent`. If `parent` is not symmetric then object should be the decomposition of a matrix with the same nonzero pattern as `tcrossprod(parent)`.
  - Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to `dsparseMatrix` and `CsparseMatrix` if needed.
- `mult`
  - A numeric scalar (default 0). `mult` times the identity matrix is (implicitly) added to `parent` or `tcrossprod(parent)` before updating the decomposition object.
- `...`
  - Potentially further arguments to the methods.

Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper", ...)`, but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

Slots

- `perm`: An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.
- `colcount`: Object of class "integer".
- `type`: Object of class "integer".

Slots of the non virtual classes "[dl]CHM(supersimpl)":

- `p`: Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".
- `i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".
- `x`: For the "d*" classes: "numeric" - the non-zero elements of the matrix.

Methods

- `isLDL(x)` returns a `logical` indicating if `x` is an `LDL'` decomposition or (when `FALSE`) an `LL'` one.
- `coerce` signature(from = "CHMfactor", to = "sparseMatrix") (or equivalently, to = "Matrix" or to = "triangularMatrix")

  - `as(*, "sparseMatrix")` returns the lower triangular factor `L` from the `LL'` form of the Cholesky factorization. Note that (currently) the factor from the `LL'` form is always returned, even if the "CHMfactor" object represents an `LDL'` decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the `expand` method for obtaining both the permutation matrix, `P`, and the lower Cholesky factor, `L`.
- `coerce` signature(from = "CHMfactor", to = "pMatrix") returns the permutation matrix `P`, representing the fill-reducing permutation used in the decomposition.
expand signature(x = "CHMfactor") returns a list with components \( P \), the matrix representing the fill-reducing permutation, and \( L \), the lower triangular Cholesky factor. The original positive-definite matrix \( A \) corresponds to the product \( A = P'LL'P \). Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying \texttt{drop0} to it. However, the extra 'non-zeros' should be very small in magnitude.

image signature(x = "CHMfactor"): Plot the image of the lower triangular factor, \( L \), from the decomposition. This method is equivalent to \texttt{image(as(x, "sparseMatrix"))} so the comments in the above description of the coerce method apply here too.

solve signature(a = "CHMfactor", b = "ddenseMatrix"), \texttt{system = *}: The solve methods for a "CHMfactor" object take an optional third argument \texttt{system} whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve \( Ax = b \) for \( x \) where \( A \) is the sparse, positive-definite matrix that was factored to produce \( a \). Analogously, \texttt{system = "L"} returns the solution \( x \), of \( Lx = b \). Similarly, for all system codes but "P" and "Pt" where, e.g., \texttt{x <- solve(a, b, system="P")} is equivalent to \texttt{x <- P %*% b}.

See also \texttt{solve-methods}.

determinant signature(x = "CHMfactor", logarithm = "logical") returns the determinant (or the logarithm of the determinant, if \texttt{logarithm = TRUE}, the default) of the factor \( L \) from the \( LL' \) decomposition (even if the decomposition represented by \( x \) is of the \( LDL' \) form (!)). This is the square root of the determinant (half the logarithm of the determinant when \texttt{logarithm = TRUE}) of the positive-definite matrix that was decomposed.

update signature(object = "CHMfactor"), \texttt{parent}. The update method requires an additional argument \texttt{parent}, which is either a "dsCMatrix" object, say \( A \), (with the same structure of nonzeros as the matrix that was decomposed to produce object) or a general "dgCMatrix", say \( M \), where \( A := MM' (= \texttt{tcrossprod(parent)}) \) is used for \( A \). Further it provides an optional argument \texttt{mult}, a numeric scalar. This method updates the numeric values in object to the decomposition of \( A + mI \) where \( A \) is the matrix above (either the \texttt{parent} or \( MM' \)) and \( m \) is the scalar \texttt{mult}. Because only the numeric values are updated this method should be faster than creating and decomposing \( A + mI \). It is not uncommon to want, say, the determinant of \( A + mI \) for many different values of \( m \). This method would be the preferred approach in such cases.

See Also

\texttt{Cholesky}, also for examples; class \texttt{dgCMatrix}.

Examples

```r
### An example for the expand() method
n <- 1000; m <- 200; nz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
  i = sample(n, nz, replace = TRUE),
  j = sample(m, nz, replace = TRUE),
  x = round(rnorm(nz),1))
XX <- crossprod(M1)  ## = M1'M1 = M'M
CX <- Cholesky(XX)
isLDL(CX)
str(CX)  ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P))  ## == L'P
PLL.P <- crossprod(L.P)  ## == (L'P)' L'P == P'LL'P = XX = M'M
```

b <- sample(m)
stopifnot(all.equal(PLLP, XX),
  all(as.vector(solve(CX, b, system="P" )) == r$P %*% b),
  all(as.vector(solve(CX, b, system="Pt")) == t(r$P) %*% b) )

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M1), mult=pi) # with the original M, where XX = M M'
stopifnot(all.equal(u1,u2, tol=1e-14))

## [ See help(Cholesky) for more examples ]
## ------------

chol

Choleski Decomposition - 'Matrix' S4 Generic and Methods

Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

Usage

chol(x, ...)

## S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)

## S4 method for signature 'dsparseMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)

Arguments

x
a (sparse or dense) square matrix, here inheriting from class Matrix; if x is not pos
positive definite, an error is signalled.
pivot
logical indicating if pivoting is to be used. Currently, this is not made use of for dense
matrices.
cache
logical indicating if the result should be cached in @factors; note that this argument
is experimental and only available for some sparse matrices.
... potentially further arguments passed to methods.

Details

Note that these Cholesky factorizations are typically cached with x currently, and these caches are
available in @factors, which may be useful for the sparse case when pivot = TRUE, where the
permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider
Cholesky() in such situations, since chol(x, pivot=TRUE) uses the same algorithm (but not the
same return value!) as Cholesky(x, LDL=FALSE) and chol(x) corresponds to Cholesky(x,
perm=FALSE, LDL=FALSE).

Value

a matrix of class Cholesky, i.e., upper triangular: R such that R'R = x (if pivot=FALSE) or
P'R'R'P = x (if pivot=TRUE and P is the corresponding permutation matrix).
Methods

Use `showMethods(chol)` to see all; some are worth mentioning here:

- **`chol` signature(x = "dgeMatrix"):** works via "dpoMatrix", see class `dpoMatrix`.
- **`chol` signature(x = "dpoMatrix"):** Returns (and stores) the Cholesky decomposition of `x`, via LAPACK routines `dlacpy` and `dpotrf`.
- **`chol` signature(x = "dppMatrix"):** Returns (and stores) the Cholesky decomposition via LAPACK routine `dpptrf`.
- **`chol` signature(x = "dsCMatrix", pivot = "logical"):** Returns (and stores) the Cholesky decomposition of `x`. If `pivot` is true, the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of `x` so as to reduce fill-in.

References

See Also

The default from `base`, `chol`; for more flexibility (but not returning a matrix!) `Cholesky`.

Examples

```r
t # show different methods
sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77))
c2 <- chol(sy2)#-> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)
## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector"))) # 5 x 5
(R <- chol(mm)) # default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot(identical(R, R2), all.equal(crossprod(R), mm))
(R. <- chol(mm, pivot=TRUE))# nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
          all.equal(prod(diag(R)), det(R)),
          all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
(M2 <- toeplitz(as(c(1, 1.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
## For the experts, check the caching of the factorizations:
ff <- M2@factors[["spdCholesky"]]```
FF <- M2@factors[["sPdCholesky"]]
L1 <- as(ff, "Matrix")# pivot=FALSE: no perm.
L2 <- as(FF, "Matrix"); P2 <- as(FF, "pMatrix")
stopifnot(identical(t(L1), c2),
  all.equal(t(L2), C2, tolerance=0),#-- why not identical()? 
  all.equal(M2, tcrossprod(L1)),
  all.equal(M2, crossprod(crossprod(L2, P2)))# M = P'L L'P
)

\section{chol2inv-methods}{ \emph{Inverse from Choleski or QR Decomposition – Matrix Methods} }

\textbf{Description}

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute $(X'X)^{-1}$ from the (R part) of the QR decomposition of $X$.

Even more generally, given an upper triangular matrix $R$, compute $(R' R)^{-1}$.

\textbf{Methods}

\begin{itemize}
  \item \texttt{x = "ANY"} the default method from \texttt{base}, see \texttt{chol2inv}, for traditional matrices.
  \item \texttt{x = "dtrMatrix"} method for the numeric triangular matrices, built on the same LAPACK \texttt{DPOTRI} function as the base method.
  \item \texttt{x = "denseMatrix"} if \texttt{x} is coercable to a \texttt{triangularMatrix}, call the "dtrMatrix" method above.
  \item \texttt{x = "sparseMatrix"} if \texttt{x} is coercable to a \texttt{triangularMatrix}, use \texttt{solve}() currently.
\end{itemize}

\textbf{See Also}

\texttt{chol} (for \texttt{Matrix} objects); further, \texttt{chol2inv} (from the \texttt{base} package), \texttt{solve}.

\textbf{Examples}

\begin{verbatim}
(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cM <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cM) %*% M # the identity
stopifnot(all(chol2inv(cM) %*% M - Diagonal(nrow(M))) < 1e-10)
\end{verbatim}

\section{Cholesky}{ \emph{Cholesky Decomposition of a Sparse Matrix} }

\textbf{Description}

Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically \texttt{chol()} should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

\textbf{Usage}

\begin{verbatim}
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)
\end{verbatim}
Arguments

- \( A \): sparse symmetric matrix. No missing values or IEEE special values are allowed.
- \( \text{perm} \): logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of \( A \). Default is TRUE.
- \( \text{LDL} \): logical scalar indicating if the decomposition should be computed as \( LDL' \) where \( L \) is a unit lower triangular matrix. The alternative is \( LL' \) where \( L \) is lower triangular with arbitrary diagonal elements. Default is TRUE. Setting it to \( \text{NA} \) leaves the choice to a CHOLMOD-internal heuristic.
- \( \text{super} \): logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is FALSE. Setting it to \( \text{NA} \) leaves the choice to a CHOLMOD-internal heuristic.
- \( \text{Imult} \): numeric scalar which defaults to zero. The matrix that is decomposed is \( A + m*I \) where \( m \) is the value of \( \text{Imult} \) and \( I \) is the identity matrix of order \( \text{ncol}(A) \).
- \( \ldots \): further arguments passed to or from other methods.

Details

This is a generic function with special methods for different types of matrices. Use \( \text{showMethods}(\text{"Cholesky"}) \) to list all the methods for the \text{Cholesky} generic.

The method for class \text{dsCMatrix} of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use \text{chol}().

Note that if \( \text{perm}=\text{TRUE} \) (default), the decomposition is

\[
A = P' \tilde{L} \tilde{D} \tilde{L}' P = P' LL' P,
\]

where \( L \) can be extracted by \( \text{as}(*, \text{"Matrix"}) \), \( P \) by \( \text{as}(*, \text{"pMatrix"}) \) and both by \( \text{expand}(*) \), see the class \text{CHMfactor} documentation.

Note that consequently, you cannot easily get the “traditional” cholesky factor \( R \), from this decomposition, as

\[
R'R = A = P' LL' P = P' \tilde{R} \tilde{R}' P = (\tilde{R} P)' (\tilde{R} P),
\]

but \( \tilde{R} P \) is not triangular even though \( \tilde{R} \) is.

Value

an object inheriting from either "\text{CHMsuper}" or "\text{CHMsimpl}" depending on the super argument; both classes extend "\text{CHMfactor}" which extends "\text{MatrixFactorization}".

In other words, the result of \text{Cholesky()} is not a matrix, and if you want one, you should probably rather use \text{chol}(), see Details.

References

See Also

Class definitions `CHMfactor` and `dsCMatrix` and function `expand`. Note the extra `solve(*, system = . )` options in `CHMfactor`.

Note that `chol()` returns matrices (inheriting from "Matrix") whereas `Cholesky()` returns a "CHMfactor" object, and hence a typical user will rather use `chol(A)`.

Examples

data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'sPDCholesky' (simpl)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'sPDCholesky' *and* 'SPdCholesky'
str(cm1 <- as(C1, "sparseMatrix"))
str(cm1 <- as(Cm, "sparseMatrix")) # hmm: super is *less* sparse here
Cn <- Cholesky(mtm, perm = FALSE)# no permutation -- much worse:
sizes <- c(simple = object.size(C1),
          super = object.size(Cm),
          noPerm = object.size(Cn))
## simple is 100, super= 137, noPerm= 812 :
oquote(cbind(format(100 * sizes / sizes[1], digits=4)))

## Visualize the sparseness:
dq <- function(ch) paste("\",ch,"\", sep="\") # dQuote(<UTF-8>) gives bad plots
image(mtm, main=paste("crossprod(mm) : Sparse", dq(class(mtm))))
image(cm1, main= paste("as(Cholesky(crossprod(mm)),"sparseMatrix")\":",
             dq(class(cm1))))

## Smaller example, with same matrix as in help(chol) :
(mm <- Matrix(toeplitz(c(10, 0, 1 , 0, 3)), sparse = TRUE)) # 5 x 5
(nn <- do.call(expand.grid, c(attr(opts, "out.attr")$dimnames,
stringsAsFactors=FALSE,KEEP.OUT.ATTRS=FALSE))
names(rr) <- apply(nn, 1, function(r)
paste(sub("(=.).*","\1", r), collapse="",})
str(rr, max=1)

str(re <- lapply(rr, expand), max=2) # each has a 'P' and a 'L' matrix
R0 <- chol(mm, pivot=FALSE)
R1 <- chol(mm, pivot=TRUE)
stopifnot(all.equal(t(R1), re[[1]]$L),
          all.equal(t(R0), re[[2]]$L),
          identical(as(1:5, "pMatrix"), re[[2]]$P), # no pivoting
          TRUE)

# Version of the underlying SuiteSparse library by Tim Davis:
.SuiteSparse_version()

---

**Cholesky-class**

**Cholesky and Bunch-Kaufman Decompositions**

**Description**

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "Bunch-Kaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their packed storage versions.

**Objects from the Class**

Objects can be created by calls of the form `new("Cholesky", ...)` or `new("BunchKaufman", ...)`, etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "dpoMatrix" or "dsyMatrix" class or as a side-effect of other functions applied to "dpoMatrix" objects (see `dpoMatrix`).

**Slots**

A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "dtrMatrix" class.

- `uplo`: inherited from the "dtrMatrix" class.
- `diag`: inherited from the "dtrMatrix" class.
- `x`: inherited from the "dtrMatrix" class.
- `Dim`: inherited from the "dtrMatrix" class.
- `Dimnames`: inherited from the "dtrMatrix" class.

A Bunch-Kaufman decomposition also extends the "dtrMatrix" class and has a `perm` slot representing a permutation matrix. The packed versions extend the "dtpMatrix" class.

**Extends**

Class "MatrixFactorization" and "dtrMatrix", directly. Class "dgeMatrix", by class "dtrMatrix". Class "Matrix", by class "dtrMatrix".

**Methods**

Both these factorizations can *directly* be treated as (triangular) matrices, as they extend "dtrMatrix", see above. There are currently no further explicit methods defined with class "Cholesky" or "BunchKaufman" in the signature.
Note

1. Objects of class "Cholesky" typically stem from chol(D), applied to a dense matrix D.
   On the other hand, the function Cholesky(S) applies to a sparse matrix S, and results in objects inheriting from class CHMfactor.

2. For traditional matrices m, chol(m) is a traditional matrix as well, triangular, but simply an n × n numeric matrix. Hence, for compatibility, the "Cholesky" and "BunchKaufman" classes (and their "p*" packed versions) also extend triangular Matrix classes (such as "dtrMatrix"). Consequently, determinant(R) for R <- chol(A) returns the determinant of R, not of A. This is in contrast to class CHMfactor objects C, where determinant(C) gives the determinant of the original matrix A, for C <- Cholesky(A), see also the determinant method documentation on the class CHMfactor page.

See Also

Classes dtrMatrix, dpoMatrix; function chol.

Function Cholesky resulting in class CHMfactor objects, not class "Cholesky" ones, see the section 'Note'.

Examples

(sm <- as(as(Matrix(diag(5) + 1), "dsyMatrix"), "dspMatrix"))
signif(csm <- chol(sm), 4)

(pm <- crossprod(Matrix(rnorm(18), nrow = 6, ncol = 3)))
(ch <- chol(pm))
if (toupper(ch@uplo) == "U") # which is TRUE
crossprod(ch)
stopifnot(all.equal(as(crossprod(ch), "matrix"),
                     as(pm, "matrix"), tolerance=1e-14))

colSums Form Row and Column Sums and Means

Description

Form row and column sums and means for objects, for sparseMatrix the result may optionally be sparse (sparseVector), too. Row or column names are kept respectively as for base matrices and colSums methods, when the result is numeric vector.

Usage

colSums(x, na.rm = FALSE, dims = 1, ...)
rowSums(x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE, dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE,
Arguments

x
na.rm
dims
...
sparseResult

Value

returns a numeric vector if sparseResult is FALSE as per default. Otherwise, returns a sparseVector.

dimnames(x) are only kept (as names(v)) when the resulting v is numeric, since sparseVectors do not have names.

See Also

colSums and the sparseVector classes.

Examples

(M <- bdiag(Diagonal(2), matrix(1:3, 3, 4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0'; drop those:
MM <- drop0(MM)
length(MM@x) # 32

cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
  identical(cm, as.numeric(scm)))
rowSums (MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero

## Since we have no 'NA' s, these two are equivalent:
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
  rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
  rowMeans(Diagonal(16)) == 1/16,
  colSums(Diagonal(7)) == 1)

## dimnames(x) --> names( <value> ) :
dimnames(M) <- list(paste0("r", 1:7), paste0("v",1:8))
M
colSums(M)
rowMeans(M)

## Assertions :
stopifnot(all.equal(colSums(M),
    setNames(c(1,1,6,6,6,6,3,2), colnames(M))),
all.equal(rowMeans(M), structure(c(1,1,4,8,12,3,2) / 8,
    .Names = paste0("r", 1:7)))))

---

### Description

Virtual class of composite matrices; i.e., matrices that can be factorized, typically as a product of simpler matrices.

### Objects from the Class

A virtual Class: No objects may be created from it.

### Slots

- **factors**: Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e., list(), initially and is updated *automagically* whenever a matrix factorization is computed.

- **Dim, Dimnames**: inherited from the Matrix class, see there.

### Extends

Class "Matrix", directly.

### Methods

- **dimnames<-**: signature(x = "compMatrix", value = "list"):
  set the dimnames to a list of length 2, see dimnames<-. The factors slot is currently reset to empty, as the factorization dimnames would have to be adapted, too.

### See Also

The matrix factorization classes "MatrixFactorization" and their generators, lu(), qr(), chol() and Cholesky(), BunchKaufman(), Schur().
condest

Compute Approximate CONDition number and 1-Norm of (Large) Matrices

Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix A. It works by apply a fast randomized approximation of the 1-norm, norm(A,"1"), through onenormest(.)

Usage

condest(A, t = min(n, 5), normA = norm(A, "1"), silent = FALSE, quiet = TRUE)
onenormest(A, t = min(n, 5), A.x, At.x, n, silent = FALSE, quiet = silent, iter.max = 10, eps = 4 * .Machine$double.eps)

Arguments

A a square matrix, optional for onenormest(), where instead of A, A.x and At.x can be specified, see there.
t number of columns to use in the iterations.
normA number; (an estimate of) the 1-norm of A, by default norm(A, "1"); may be replaced by an estimate.
silent logical indicating if warning and (by default) convergence messages should be displayed.
quiet logical indicating if convergence messages should be displayed.
A.x, At.x when A is missing, these two must be given as functions which compute A %% x, or t(A) %% x, respectively.
n == nrow(A), only needed when A is not specified.
iter.max maximal number of iterations for the 1-norm estimator.
eps the relative change that is deemed irrelevant.

Details

condest() calls lu(A), and subsequently onenormest(A.x = , At.x = ) to compute an approximate norm of the inverse of A, A^(-1), in a way which keeps using sparse matrices efficiently when A is sparse.

Note that onenormest() uses random vectors and hence both functions’ results are random, i.e., depend on the random seed, see, e.g., set.seed().

Value

Both functions return a list; condest() with components,
est a number > 0, the estimated (1-norm) condition number \( \hat{\kappa} \); when \( r := \text{rcond}(A), 1/\hat{\kappa} \approx r \).
The maximal $Ax$ column, scaled to $\|v\| = 1$. Consequently, $\|Av\| = \|A\|/\text{est}$; when $\text{est}$ is large, $v$ is an approximate null vector.

The function `onenormest()` returns a list with components,

- `est`: a number $> 0$, the estimated $\|A\|_{1}$.
- `v`: 0-1 integer vector length $n$, with an 1 at the index $j$ with maximal column $A[,j]$ in $A$.
- `w`: numeric vector, the largest $Ax$ found.
- `iter`: the number of iterations used.

**Author(s)**

This is based on octave’s `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

**References**

**See Also**

`norm, rcond`.

**Examples**

```r
data(KNex)
mtm <- with(KNex, crossprod(mm))
system.time(ce <- condest(mtm))
sum(abs(ce$v)) ## $\|v\|_1 = 1$
## Prove that $\|Av\| = \|A\|/\text{est}$ (as $\|v\| = 1$):
stopifnot(all.equal(norm(mtm %*% ce$v),
                   norm(mtm) / ce$est))

## reciprocal
1 / ce$est

one <- onenormest(mtm)
str(one) ## est = 12.3
## the maximal column:
which(one$v == 1) # mostly 4, rarely 1, depending on random seed
```
Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form

Description
The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("CsparseMatrix") for its subclasses.

Slots
i: Object of class "integer" of length nnzero (number of non-zero elements). These are the 0-based row numbers for each non-zero element in the matrix, i.e., i must be in 0:(nrow(.)-1).

p: integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. .@p is of length ncol(.) + 1, with p[1] == 0 and p[length(p)] == nnzero, such that in fact, diff(.@p) are the number of non-zero elements for each column.
In other words, m@p[1:ncol(m)] contains the indices of those elements in m@x that are the first elements in the respective column of m.

Dim, Dimnames: inherited from the superclass, see the sparseMatrix class.

Extends
Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods
matrix products %*%, crossprod() and tcrossprod(), several solve methods, and other matrix methods available:
signature(e1 = "CsparseMatrix", e2 = "numeric"): ...

ddenseMatrix-class

Virtual Class "ddenseMatrix" of Numeric Dense Matrices

Description

This is the virtual class of all dense numeric (i.e., double, hence "ddense") S4 matrices. Its most important subclass is the dgeMatrix class.

Extends

Class "dgeMatrix" directly; class "Matrix", by the above.

Slots

the same slots at its subclass dgeMatrix, see there.

Methods

Most methods are implemented via as(*, "dgeMatrix") and are mainly used as "fallbacks" when the subclass doesn’t need its own specialized method. Use showMethods(class = "ddenseMatrix", where = "package:Matrix") for an overview.
**ddiMatrix-class**

See Also

The virtual classes `Matrix`, `dMatrix`, and `dsparseMatrix`.

Examples

```r
showClass("ddenseMatrix")
showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

**ddiMatrix-class**  
Class "ddiMatrix" of Diagonal Numeric Matrices

Description

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend `sparseMatrix`, whereas they did extend dense matrices earlier.

Objects from the Class

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via `Diagonal`.

Slots

- `x`: numeric vector. For an \( n \times n \) matrix, the \( x \) slot is of length \( n \) or 0, depending on the \( \text{diag} \) slot:
  - `diag`: "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

- `Dim`, `Dimnames`: matrix dimension and `dimnames`, see the `Matrix` class description.

Extends

Class "diagonalMatrix", directly. Class "dMatrix", directly. Class "sparseMatrix", indirectly, see `showClass("ddiMatrix")`.

Methods

- `%*% signature(x = "ddiMatrix", y = "ddiMatrix")`: ...

See Also

Class `diagonalMatrix` and function `Diagonal`.
denseMatrix-class

Examples

(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> ‘fast’ multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
  all.equal(cd2@x, c(sqrt(10),1)))

denseMatrix-class Virtual Class "denseMatrix" of All Dense Matrices

Description

This is the virtual class of all dense (S4) matrices. It is the direct superclass of ddenseMatrix, ldenseMatrix

Extends
class "Matrix" directly.

Slots

exactly those of its superclass "Matrix".

Methods

Use showMethods(class = "denseMatrix", where = "package:Matrix") for an overview of methods.

Extraction ("[") methods, see [methods.

See Also
colSums, kronecker, and other such methods with own help pages.

Its superclass Matrix, and main subclasses, ddenseMatrix and sparseMatrix.

Examples

showClass("denseMatrix")
The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the "standard" class for sparse numeric matrices in the `Matrix` package.

Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE)`, or most efficiently via `sparseMatrix()`.

Slots

- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- ... all other slots are inherited from the superclass "CsparseMatrix".

Methods

Matrix products (e.g., `crossprod-methods`), and (among other)

- `coerce` signature(from = "matrix", to = "dgCMatrix")
- `coerce` signature(from = "dgCMatrix", to = "matrix")
- `coerce` signature(from = "dgCMatrix", to = "dgTMatrix")
- `diag` signature(x = "dgCMatrix"): returns the diagonal of x
- `dim` signature(x = "dgCMatrix"): returns the dimensions of x
- `image` signature(x = "dgCMatrix"): plots an image of x using the `levelplot` function
- `solve` signature(a = "dgCMatrix", b = ") see `solve-methods`, notably the extra argument sparse.
- `lu` signature(x = "dgCMatrix"): computes the LU decomposition of a square dgCMatrix object

See Also

Classes `dsCMatrix`, `dtCMatrix`, `lu`

Examples

```r
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```
Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices

Description
A general numeric dense matrix in the S4 Matrix representation. dgeMatrix is the "standard" class for dense numeric matrices in the Matrix package.

Objects from the Class
Objects can be created by calls of the form new("dgeMatrix", ...) or, more commonly, by coercion from the Matrix class (see Matrix) or by Matrix(...).

Slots
- x: Object of class "numeric" - the numeric values contained in the matrix, in column-major order.
- Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- Dimnames: a list of length two - inherited from class Matrix.
- factors: Object of class "list" - a list of factorizations of the matrix.

Methods
The are group methods (see, e.g., Arith)

Arith signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...
Arith signature(e1 = "dgeMatrix", e2 = "numeric"): ...
Arith signature(e1 = "numeric", e2 = "dgeMatrix"): ...
Math signature(x = "dgeMatrix"): ...
Math2 signature(x = "dgeMatrix", digits = "numeric"): ...

matrix products %*%, crossprod() and tcrossprod(), several solve methods, and other matrix methods available:

Schur signature(x = "dgeMatrix", vectors = "logical"): ...
Schur signature(x = "dgeMatrix", vectors = "missing"): ...
chol signature(x = "dgeMatrix"): see chol.
coerce signature(from = "dgeMatrix", to = "lgeMatrix"): ...
coerce signature(from = "dgeMatrix", to = "matrix"): ...
coerce signature(from = "matrix", to = "dgeMatrix"): ...
colMeans signature(x = "dgeMatrix"): columnwise means (averages)
colSums signature(x = "dgeMatrix"): columnwise sums
diag signature(x = "dgeMatrix"): ...
dim signature(x = "dgeMatrix"): ...
dimnames signature(x = "dgeMatrix"): ...
eigen signature(x = "dgeMatrix", only.values = "logical"): ...
The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., `dgCMatrix`, are preferred and better supported in the `Matrix` package.

### Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...)

### Slots

- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.
- **p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- **x**: Object of class "numeric" - the non-zero elements of the matrix.
- **Dim**: Object of class "integer" - the dimensions of the matrix.

### Methods

- **coerce** signature(from = "matrix", to = "dgRMatrix")
- **coerce** signature(from = "dgRMatrix", to = "matrix")
- **coerce** signature(from = "dgRMatrix", to = "dgTMatrix")
- **diag** signature(x = "dgRMatrix"): returns the diagonal of x
- **dim** signature(x = "dgRMatrix"): returns the dimensions of x
- **image** signature(x = "dgRMatrix"): plots an image of x using the `levelplot` function

### See Also

The `RsparseMatrix` class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The `dgCMatrix` class (column compressed sparse) is really preferred.
**Description**

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class `dgCMatrix`.

**Objects from the Class**

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via `as(*, "dgTMatrix")`, `spMatrix()`, or `sparseMatrix(*, repr = "T")`.

**Slots**

- **i**: integer row indices of non-zero entries in 0-base, i.e., must be in \(0:(\text{nrow}(.)-1)\).
- **j**: integer column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in \(0:(\text{ncol}(.)-1)\).
- **x**: numeric vector - the (non-zero) entry at position \((i,j)\). Must be the same length as slot i. If an index pair occurs more than once, the corresponding values of slot x are added to form the element of the matrix.
- **Dim**: Object of class "integer" of length 2 - the dimensions of the matrix.

**Methods**

- `signature(e1 = "dgTMatrix", e2 = "dgTMatrix")`
- `signature(from = "dgTMatrix", to = "dgCMatrix")`
- `signature(from = "dgTMatrix", to = "dgeMatrix")`
- `signature(from = "dgTMatrix", to = "matrix")`, and typically coercion methods for more specific signatures, we are not mentioning here.
  
  Note that these are not guaranteed to continue to exist, but rather you should use calls like `as(x, "CsparseMatrix"), as(x, "generalMatrix"), as(x, "dMatrix"), i.e. coercion to higher level virtual classes.
- `signature(from = "matrix", to = "dgTMatrix"), (direct coercion from tradition matrix).
- `image` signature(x = "dgTMatrix") : plots an image of x using the `levelplot` function
- `t` signature(x = "dgTMatrix") : returns the transpose of x

**Note**

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to `dgCMatrix` objects.

Note that both `new(.)` and `spMatrix` constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add \(x_i\)'s that belong to identical \((i_k,j_k)\) pairs.

However this means that a matrix typically can be stored in more than one possible "TsparseMatrix" representations. Use `uniqTsparse()` in order to ensure uniqueness of the internal representation of such a matrix.
Diagonal

Create Diagonal Matrix Object

Description

Create a diagonal matrix object, i.e., an object inheriting from diagonalMatrix (or a “standard” CsparseMatrix diagonal matrix in cases that is preferred).

Usage

Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1,n), uplo = "U", kind)
.trDiagonal(n, x = 1, uplo = "U", unitri=TRUE, kind)
.sparseDiagonal(n, x = 1, uplo = "U", shape = if(missing(cols)) "t" else "g", unitri, kind, cols = if(n) 0:(n - 1L) else integer(0))

Arguments

n integer specifying the dimension of the (square) matrix. If missing, length(x) is used.

x numeric or logical; if missing, a unit diagonal $n \times n$ matrix is created.

uplo for .symDiagonal (.trDiagonal), the resulting sparse symmetricMatrix (or triangularMatrix) will have slot uplo set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default.
**shape**
string of 1 character, one of c("t", "s", "g"), to choose a triangular, symmetric or general result matrix.

**unitri**
optional logical indicating if a triangular result should be “unit-triangular”, i.e., with diag = "U" slot, if possible. The default, missing, is the same as TRUE.

**kind**
string of 1 character, one of c("d", "l", "n"), to choose the storage mode of the result, from classes dsparseMatrix, lsparseMatrix, or nsparseMatrix, respectively.

**cols**
integer vector with values from 0:(n-1), denoting the columns to subselect conceptually, i.e., get the equivalent of Diagonal(n, *)[, cols + 1].

**Value**
Diagonal() returns an object of class ddiMatrix or ldiMatrix (with “superclass” diagonalMatrix).

.symDiagonal() returns an object of class dsCMatrix or lsCMatrix, i.e., a sparse symmetric matrix. Analogously, .triDiagonal gives a sparse triangularMatrix. This can be more efficient than Diagonal(n) when the result is combined with further symmetric (sparse) matrices, e.g., in kronecker, however not for matrix multiplications where Diagonal() is clearly preferred.

.sparseDiagonal(), the workhorse of .symDiagonal and .triDiagonal returns a CsparseMatrix (the resulting class depending on shape and kind) representation of Diagonal(n), or, when cols are specified, of Diagonal(n)[, cols+1].

**Author(s)**
Martin Maechler

**See Also**
the generic function diag for extraction of the diagonal from a matrix works for all “Matrices”.

**Examples**
```r
Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2) #-> "ldiMatrix"
```

```r
## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2,3)
(M <- kronecker(Diagonal(3), M1))
```

```r
(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
```

```r
(I4 <- .sparseDiagonal(4, shape="t")# now (2012-10) unitriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))
```
diagonalMatrix-class

Class "diagonalMatrix" of Diagonal Matrices

Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

diag: code"character" string, either "U" or "N", where "U" means 'unit-diagonal'.
Dim: matrix dimension, and
Dimnames: the dimnames, a list, see the Matrix class description. Typically list(NULL,NULL) for diagonal matrices.

Extends

Class "sparseMatrix", directly.

Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

coerce signature(from = "matrix", to = "diagonalMatrix"): ...
coerce signature(from = "Matrix", to = "diagonalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "generalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "triangularMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "nMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "matrix"): ...
coerce signature(from = "diagonalMatrix", to = "sparseVector"): ...
t signature(x = "diagonalMatrix"): ...
and many more methods
solve signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also solve-methods.
which signature(x = "nMatrix"): semantically equivalent to base function which(x, arr.ind).
"Math" signature(x = "diagonalMatrix"): all these group methods return a "diagonalMatrix", apart from cumsum() etc which return a vector also for base matrix.
* signature(e1 = "ddiMatrix", e2="denseMatrix"): arithmetic and other operators from the Ops group have a few dozen explicit method definitions, in order to keep the results diagonal in many cases, including the following:
signature(e1 = "ddiMatrix", e2="denseMatrix"): the result is from class \texttt{ddiMatrix} which is typically very desirable. Note that when \(e2\) contains off-diagonal zeros or NAs, we implicitly use \(0/x = 0\), hence differing from traditional R arithmetic (where \(0/0 \rightarrow \text{NaN}\)), in order to preserve sparsity.

\textbf{summary} (object = "diagonalMatrix"): Returns an object of S3 class "diagSummary" which is the summary of the vector \texttt{object@x} plus a simple heading, and an appropriate \texttt{print} method.

\textbf{See Also}

\texttt{Diagonal()} as constructor of these matrices, and \texttt{isDiagonal}. \texttt{ddiMatrix} and \texttt{lidiMatrix} are "actual" classes extending "diagonalMatrix".

\textbf{Examples}

\begin{verbatim}
I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
           identical(tcrossprod(I5), I5),
           identical(crossprod(I5, D5), D5),
           identical(tcrossprod(D5, I5), D5),
           identical(solve(D5), solve(solve(D5)), tolerance = 1e-12)
)
solve(D5)# efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
       cbind2(D5, I5))
\end{verbatim}

\textbf{diagU2N} \textit{Transform Triangular Matrices from Unit Triangular to General Triangular and Back}

\textbf{Description}

Transform a triangular matrix \(x\), i.e., of class "\texttt{triangularMatrix}"., from (internally!) unit triangular ("unitriangular") to "general" triangular (\texttt{diagU2N}(\(x\))) or back (\texttt{diagN2U}(\(x\))). Note that the latter, \texttt{diagN2U}(\(x\)), also sets the diagonal to one in cases where \texttt{diag}(\(x\)) was not all one.

\texttt{.diagU2N}(\(x\)) assumes but does not check that \(x\) is a \texttt{triangularMatrix} with \texttt{diag} slot "U", and should hence be used with care.

\textbf{Usage}

\begin{verbatim}
.diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl, checkDense = FALSE)
\end{verbatim}
Arguments

- **x**: a `triangularMatrix`, often sparse.
- **cl** (optional, for speedup only): class (definition) of `x`.
- **checkDense**: logical indicating if dense (see `denseMatrix`) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when `x` is dense.

Details

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

Value

A triangular matrix of the same `class` but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

Note

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

See Also

"triangularMatrix", "dCMatrix".

Examples

```r
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unitriangular"
(t.u <- diagN2U(10*T))# changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1, identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T, "triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dT)
dtU <- diagN2U(dT, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
  all(dT == dt.), all(dT == dtU),
  dt.@diag == "U", dtU@diag == "U")
```

```
##
dMatrix-class (Virtual) Class "dMatrix" of "double" Matrices

Description

The `dMatrix` class is a virtual class contained by all actual classes of numeric matrices in the `Matrix` package. Similarly, all the actual classes of logical matrices inherit from the `lMatrix` class.
```
Slots

Common to all matrix object in the package:

**Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding **Dim** element.

Methods

There are (relatively simple) group methods (see, e.g., **Arith**)

**Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...
**Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...
**Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Math** signature(x = "dMatrix"): ...
**Math2** signature(x = "dMatrix", digits = "numeric"): this group contains **round()** and **signif()**.

**Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...
**Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...
**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions **max()**, **min()**, **range()**, **prod()**, **sum()**, **any()**, and **all()**.

The following methods are also defined for all double matrices:

**coerce** signature(from = "dMatrix", to = "matrix"): ...
**expm** signature(x = "dMatrix"): computes the "Matrix Exponential", see **expm**.
**zapsmall** signature(x = "dMatrix"): ...

The following methods are defined for all logical matrices:

**which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the base function **which**(x, arr.ind) returns the indices of the TRUE entries in x; if arr.ind is true, as a 2-column matrix of row and column indices. Since **Matrix** version 1.2-9, if useNames is true, as by default, with **dimnames**, the same as base::which.

See Also

The nonzero-pattern matrix class **nMatrix**, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes **dgeMatrix**, **dgCMatrix**, and **Matrix**.

**drop0**(x, tol=1e-10) is sometimes preferable to (and more efficient than) **zapsmall**(x, digits=10).
Examples

showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4,7), 2)
M <- Matrix(rlnorm(56, sd=10), 4,14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))

dpoMatrix-class  Positive Semi-definite Dense (Packed \ Non-packed) Numeric Matrices

Description

• The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked
  storage.
• The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the
  lower triangle is required to be available.
• The "corMatrix" class of correlation matrices extends "dpoMatrix" with a slot sd, which
  allows to restore the original covariance matrix.

Objects from the Class

Objects can be created by calls of the form new("dpoMatrix", ...) or from crossprod applied
to an "dgeMatrix" object.

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower
  triangular.

x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-
  major order.

Dim: Object of class "integer". The dimensions of the matrix which must be a two-element vector
  of non-negative integers.

Dimnames: inherited from class "Matrix"

factors: Object of class "list". A named list of factorizations that have been computed for the
  matrix.

sd: (for "corMatrix") a numeric vector of length n containing the (original) \sqrt{\text{var}(\cdot)}
  entries which allow reconstruction of a covariance matrix from the correlation matrix.

Extends

Class "dsyMatrix", directly.
Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".
Methods

chol signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, see chol.

determinant signature(x = "dpoMatrix"): Returns the determinant of x, via chol(x), see above.

rcond signature(x = "dpoMatrix", norm = "character"): Returns (and stores) the reciprocal of the condition number of x. The norm can be "1" for the one-norm (the default) or "∞" for the infinity-norm. For symmetric matrices the result does not depend on the norm.

solve signature(a = "dpoMatrix", b = "...", and
solve signature(a = "dppMatrix", b = "...") work via the Cholesky composition, see also the Matrix solve-methods.

Arith signature(e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically not positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with positive length(.) == 1 numbers (or logicals).

See Also

Classes dsyMatrix and dgeMatrix; further, Matrix, rcond, chol, solve, crossprod.

Examples

h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is `integer`
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))

### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
  all.equal(ch6@sd^(-2), 2*(1:6)-1, tolerance= 1e-12))
chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors$Cholesky),
  all(abs(crossprod(chch) - ch6) < 1e-10))

---

drop0

Drop "Explicit Zeroes" from a Sparse Matrix

Description

Returns a sparse matrix with no "explicit zeroes", i.e., all zero or FALSE entries are dropped from the explicitly indexed matrix entries.

Usage

drop0(x, tol = 0, is.Csparse = NA)
dsCMatrix-class

Arguments

- **x**: a Matrix, typically sparse, i.e., inheriting from `sparseMatrix`.
- **tol**: non-negative number to be used as tolerance for checking if an entry $x_{i,j}$ should be considered to be zero.
- **is.Csparse**: logical indicating prior knowledge about the “Csparseness” of $x$. This exists for possible speedup reasons only.

Value

A Matrix like x but with no explicit zeros, i.e., !any(x@x == 0), always inheriting from `CsparseMatrix`.

Note

When a sparse matrix is the result of matrix multiplications, you may want to consider combining `drop0()` with `zapsmall()`, see the example.

See Also

`spMatrix`, `class sparseMatrix`; `nnzero`

Examples

```r
m <- spMatrix(10,20, i= 1:8, j=2:9, x = c(0:2,3:-1))
m
drop0(m)

## A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
  x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
  i = c(0L,2L,4L, 1L, 3L,2L,4L, 3L, 4L),
  p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5,t5), t5))
IT <- solve(TT)
I. <- TT %*% IT ; nnzero(I.) # 697 ( = 625 + 72 )
I.0 <- drop0(zapsmall(I.))
## which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)),
  nnzero(I..) == 625)
```

---

**dsCMatri-class**: Numeric Symmetric Sparse (column compressed) Matrices

Description

The `dsCMatri` class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The `dsTMatrix` class is the class of symmetric, sparse numeric matrices in triplet format.
Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix", ...)` or `new("dsTMatrix", ...).` or automatically via e.g., `as(*, "symmetricMatrix").` or (for dsCMatrix) also from `Matrix().` Creation “from scratch” most efficiently happens via `sparseMatrix(*, symmetric=TRUE).

Slots

- `uplo`: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.
- `i`: Object of class "integer" of length `nnZ` (half number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.
- `p`: (only in class "dsCMatrix"): an integer vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.
- `j`: (only in class "dsTMatrix"): Object of class "integer" of length `nnZ` (as `i`). These are the column numbers for each non-zero element in the lower triangle of the matrix.
- `x`: Object of class "numeric" of length `nnZ` – the non-zero elements of the matrix (to be duplicated for full matrix).
- `factors`: Object of class "list" - a list of factorizations of the matrix.
- `Dim`: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Extends

Both classes extend classes and `symmetricMatrix dsparseMatrix` directly; dsCMatrix further directly extends `CsparseMatrix`, where dsTMatrix does `TsparseMatrix`.

Methods

- `solve` signature(a = "dsCMatrix", b = "..."): `x <- solve(a,b)` solves $Ax = b$ for $x$; see `solve-methods`.
- `chol` signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x, see `chol`.
- `Cholesky` signature(A = "dsCMatrix",...): Computes more flexibly Cholesky decompositions, see `Cholesky`.
- `determinant` signature(x = "dsCMatrix", logarithm = "missing"): Evaluate the determinant of x on the logarithm scale. This creates and stores the Cholesky factorization.
- `determinant` signature(x = "dsCMatrix", logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.
- `t` signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the `uplo` slot is swapped, and the row and column indices are interchanged.
- `t` signature(x = "dsTMatrix"): Transpose. The `uplo` slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.
- `coerce` signature(from = "dsCMatrix", to = "dgTMatrix")
- `coerce` signature(from = "dsCMatrix", to = "dgeMatrix")
- `coerce` signature(from = "dsCMatrix", to = "matrix")
- `coerce` signature(from = "dsTMatrix", to = "dgeMatrix")
dsparseMatrix-class

Virtual Class "dsparseMatrix" of Numeric Sparse Matrices

Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

Slots

- `Dim`: the matrix dimension, see class "Matrix".
- `Dimnames`: see the "Matrix" class.
- `x`: a numeric vector containing the (non-zero) matrix entries.

Extends

Class "dMatrix" and "sparseMatrix", directly.
Class "Matrix", by the above classes.

See Also

the documentation of the (non virtual) sub classes, see showClass("dsparseMatrix"); in particular, dgTMatrix, dgCMatrix, and dgRMatrix.

Examples

showClass("dsparseMatrix")
The `dsRMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

### Objects from the Class

These "..RMatrix" classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix", ...)`.  

#### Slots

- **uplo**: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.
- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- **p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- **factors**: Object of class "list" - a list of factorizations of the matrix.
- **x**: Object of class "numeric" - the non-zero elements of the matrix.
- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- **Dimnames**: List of length two, see `Matrix`.

### Extends

Classes `RsparseMatrix`, `dsparseMatrix` and `symmetricMatrix`, directly.

Class "dMatrix", by class "dsparseMatrix", class "sparseMatrix", by class "dsparseMatrix" or "RsparseMatrix"; class "compMatrix" by class "symmetricMatrix" and of course, class "Matrix".

### Methods

- **forceSymmetric** signature(x = "dsRMatrix", uplo = "missing"): a trivial method just returning `x`
- **forceSymmetric** signature(x = "dsRMatrix", uplo = "character"): if `uplo == x@uplo`, this trivially returns `x`; otherwise `t(x)`.
- **coerce** signature(from = "dsCMatrix", to = "dsRMatrix")

### See Also

- the classes `dgCMatrix`, `dgTMatrix`, and `dgeMatrix`. 

dsyMatrix-class
Symmetric Dense (Packed \ Non-packed) Numeric Matrices

Description

- The "dsyMatrix" class is the class of symmetric, dense matrices in *non-packed* storage and
- "dspMatrix" is the class of symmetric dense matrices in *packed* storage, see \pack(). Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form \texttt{new("dsyMatrix", ...)} or \texttt{new("dspMatrix", ...)}, respectively.

Slots

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **x**: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- **Dim, Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), see \Matrix.
- **factors**: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"dsyMatrix" extends class "dgeMatrix", directly, whereas
"dspMatrix" extends class "ddenseMatrix", directly.
Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use \showClass("dsyMatrix"), e.g., for details.

Methods

- \texttt{coerce signature(from = "ddenseMatrix", to = "dgeMatrix")}
- \texttt{coerce signature(from = "dspMatrix", to = "matrix")}
- \texttt{coerce signature(from = "dsyMatrix", to = "matrix")}
- \texttt{coerce signature(from = "dsyMatrix", to = "dspMatrix")}
coerce signature(from = "dspMatrix", to = "dsyMatrix")

norm signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the matrix norm of the desired type, see, norm.

rcond signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the reciprocal condition number, rcond().

solve signature(a = "dspMatrix", b = "...."), and solve signature(a = "dsyMatrix", b = "...."): x <- solve(a,b) solves $Ax = b$ for $x$; see solve-methods.

t signature(x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

See Also

The positive (Semi-)definite dense (packed or non-packed numeric matrix classes dpoMatrix, dppMatrix and corMatrix,

Classes dgeMatrix and Matrix; solve, norm, rcond, t

Examples

```r
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).
chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite

## 4x4 example
m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
sym <- m+t(m)+diag(11:14, 4); sym
S1 <- as(sym, "dspMatrix")
(S2 <- t(S1))
stopifnot(all(S1 == S2)) # equal "seen as matrix", but differ internally :
str(S1)
S2@x
```

dtCMatrix-class

Triangular, (compressed) sparse column matrices

dtCMatrix-class

Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.
Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via `Matrix()` or coercion such as `as(x, "triangularMatrix"), or `as(x, "dtCMatrix")`.

Slots

`uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

`diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.

`p`: (only present in "dtCMatrix"): an `integer` vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

`i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

`j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the `dtTMatrix` class.)

`x`: Object of class "numeric" - the non-zero elements of the matrix.

`Dim, Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc. see the examples.

Methods

`coerce` signature(from = "dtCMatrix", to = "dgTMatrix")

`coerce` signature(from = "dtCMatrix", to = "dgeMatrix")

`coerce` signature(from = "dtTMatrix", to = "dgeMatrix")

`coerce` signature(from = "dtTMatrix", to = "dtrMatrix")

`coerce` signature(from = "dtTMatrix", to = "matrix")

`solve` signature(a = "dtCMatrix", b = "..."): sparse triangular solve (aka “backsolve” or “forwardsolve”), see `solve-methods`.

`t` signature(x = "dtCMatrix"): returns the transpose of x

`t` signature(x = "dtTMatrix"): returns the transpose of x

See Also

Classes `dgCMatrix`, `dgTMatrix`, `dgeMatrix`, and `dtrMatrix`. 
Examples

showClass("dtCMatrix")

showClass("dtTMatrix")

```r
n1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
```

```r
t1 # from @diagonal to unit-diagonal (low-level step):
tu <- t1; tu@diag <- "U"
tu
```

```r
(cu <- as(tu, "dtCMatrix"))
```

```r
str(cu)# only two entries in @i and @x
```

```r
stopifnot(cu@i == 1:0,
           all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu)))
```

```r
t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
```

```r
(it1 <- solve(t1))
t1. <- solve(it1)
```

```r
all(abs(t1 - t1.) < 10 * .Machine$double.eps)
```

```r
## 2nd example
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
x = rep(1, 5), diag = "U")
```

```r
U5
```

```r
(iu <- solve(U5)) # contains one '0'
```

```r
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions
```

```r
I5 <- iu %*% U5 # should equal the identity matrix
```

```r
i5 <- iu %*% U5
```

```r
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
```

```r
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
```

```r
stopifnot( 
           all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
           all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
           identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)) )
)
```

---

dtpMatrix-class

Packed Triangular Dense Matrices - "dtpMatrix"

Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

Objects from the Class

Objects can be created by calls of the form new("dtpMatrix", ...) or by coercion from other classes of matrices.
dtpMatrix-class

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension \(d \times d\), \(\text{length}(x)\) is of length \(d(d+1)/2\) (also when diag == "U"!).

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

Methods

\%*% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see showMethods("%*%", class = "dtpMatrix").

coerce signature(from = "dtpMatrix", to = "dtrMatrix")

coerce signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the determinant(x) trivially is \(\prod(\text{diag}(x))\), but computed on log scale to prevent over- and underflow.

diag signature(x = "dtpMatrix"): ...

norm signature(x = "dtpMatrix", type = "character"): ...

rcond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forward-solve, see solve-methods.

t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x is upper triangular, and vice versa.

See Also

Methods

No methods currently with class "dsRMatrix" in the signature.

See Also

Classes `dgCMatrix, dgTMatrix, dgeMatrix`
Examples

```r
(m0 <- new("dtRMatriX"))
(m2 <- new("dtRMatrix", Dim = c(2L,2L),
           x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatriX
```

dtrMatrix-class

Triangular, dense, numeric matrices

Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage, see `pack()`.

Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix", ...)`. 

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- `x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- `Dim`: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

Methods

Among others (such as matrix products, e.g. `?crossprod-methods`),

- `coerce` signature(from = "dgeMatrix", to = "dtrMatrix")
- `coerce` signature(from = "dtrMatrix", to = "matrix")
- `coerce` signature(from = "dtrMatrix", to = "ltrMatrix")
- `coerce` signature(from = "dtrMatrix", to = "matrix")
- `norm` signature(x = "dtrMatrix", type = "character")
- `rcond` signature(x = "dtrMatrix", norm = "character")
- `solve` signature(a = "dtrMatrix", b = "....")efficiently use a "forwardsolve" or backsolve for a lower or upper triangular matrix, respectively, see also `solve-methods`.
- `+,-,*,.....,==,>=,...` all the Ops group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.
See Also

Classes `ddenseMatrix`, `dtpMatrix`, `triangularMatrix`

Examples

```r
(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))

(T <- as(M, "dtrMatrix")) ## upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))

m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
(t1 <- Matrix(m+diag(,4)))
str(t1p <- pack(t1))
(t1pu <- diagN2U(t1p))
stopifnot(exprs = {
  inherits(t1 , "dtrMatrix"); validObject(t1)
  inherits(t1p, "dtpMatrix"); validObject(t1p)
  inherits(t1pu,"dtCMatrix"); validObject(t1pu)
  t1pu@x == 1:6
  all(t1pu == t1p)
  identical((t1pu - t1)@x, numeric())# sparse all-0
})
```

---

**expand**

Expand a (Matrix) Decomposition into Factors

Description

Expands decompositions stored in compact form into factors.

Usage

```r
expand(x, ...)
```

Arguments

- `x` a matrix decomposition.
- `...` further arguments passed to or from other methods.

Details

This is a generic function with special methods for different types of decompositions, see `showMethods(expand)` to list them all.

Value

The expanded decomposition, typically a list of matrix factors.

Note

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `expand` allows all factors to be fully expanded.
expm

See Also
The LU lu, and the Cholesky decompositions which have expand methods; facmul.

Examples
```r
(x <- Matrix(round(rnorm(9),2), 3, 3))
(ex <- expand(lux <- lu(x)))
```

expm

Matrix Exponential

Description
Compute the exponential of a matrix.

Usage
```r
expm(x)
```

Arguments
- `x` a matrix, typically inheriting from the dMatrix class.

Details
The exponential of a matrix is defined as the infinite Taylor series \( \expm(A) = I + A + A^2/2! + A^3/3! + \ldots \) (although this is definitely not the way to compute it). The method for the dgeMatrix class uses Ward’s diagonal Pade’ approximation with three step preconditioning.

Value
The matrix exponential of \( x \).

Note
The expm package contains newer (partly faster and more accurate) algorithms for expm() and includes logm and sqrtm.

Author(s)
This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

References
- [https://en.wikipedia.org/wiki/Matrix_exponential](https://en.wikipedia.org/wiki/Matrix_exponential)
See Also

Schur; additionally, expm, logm, etc in package expm.

Examples

```r
(m1 <- Matrix(c(1,0,1,1), nc = 2))
(e1 <- expm(m1)) ; e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0,rbind(6*diag(3),0))))# sparse!
(e3 <- expm(m3)) # upper triangular
```

externalFormats  Read and write external matrix formats

Description

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write sparseMatrix objects to one of these formats.

Usage

```r
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

Arguments

- `obj` a real sparse matrix
- `file` for writeMM - the name of the file to be written. For readHB and readMM the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in ".rua" or "rsa". Those storing matrices in the MatrixMarket format usually end in ".mtx". Alternatively, readHB and readMM accept connection objects.
- `...` optional additional arguments. Currently none are used in any methods.

Value

The readHB and readMM functions return an object that inherits from the "Matrix" class. Methods for the writeMM generic functions usually return NULL and, as a side effect, the matrix obj is written to file in the MatrixMarket format (writeMM).

Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function writeHB was deprecated and has now been removed. Please use writeMM instead.

Note that these formats do not know anything about dimnames, hence these are dropped by writeMM().

A very simple way to export small sparse matrices S, is to use summary(S) which returns a data.frame with columns i, j, and possibly x, see summary in sparseMatrix-class, and an example below.
References

https://math.nist.gov/MatrixMarket/
https://sparse.tamu.edu/

Examples

str(pores <- readMM(system.file("external/pores_1.mtx", package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua", package = "Matrix")))
str(lundA <- readMM(system.file("external/lund_a.mtx", package = "Matrix")))
str(lundA <- readHB(system.file("external/lund_a.rsa", package = "Matrix")))
str(jgl009 <- readMM(system.file("external/jgl009.mtx", package = "Matrix")))
## Not run:
## NOTE: The following examples take quite some time
## ---- even on a fast internet connection:
## if(FALSE) # the URL has been corrected, but we need an un-tar step!
str(sm <- readHB(gzcon(url("https://www.cise.ufl.edu/research/sparse/RB/Boeing/msc00726.tar.gz"))))
## End(Not run)
data(KNex)
## Store as MatrixMarket (".mtx") file, here inside temporary dir./folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)
file.info(MMfile)[,c("size", "ctime")]
## very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
## has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))

facmul Multiplication by Decomposition Factors

Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

Usage

facmul(x, factor, y, transpose, left, ...)
Arguments

- **x**: a matrix decomposition. No missing values or IEEE special values are allowed.
- **factor**: an indicator for selecting a particular factor for multiplication.
- **y**: a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.
- **transpose**: a logical value. When `FALSE` (the default) the factor is applied. When `TRUE` the transpose of the factor is applied.
- **left**: a logical value. When `TRUE` (the default) the factor is applied from the left. When `FALSE` the factor is applied from the right.

... the method for "qr.Matrix" has additional arguments.

Value

the product of the selected factor (or its transpose) and y

NOTE

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `facmul` allows multiplication without explicit formation of the factors, saving both storage and operations.

References

Examples

```r
library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qrx <- qr(x) # QR factorization of x
y <- rnorm(3)
facmul(qr(x), factor = "Q", y) # form Q y
## End(Not run)
```

---

**forceSymmetric**

*Force a Matrix to 'symmetricMatrix' Without Symmetry Checks*

Description

Force a square matrix `x` to a `symmetricMatrix`, **without** a symmetry check as it would be applied for `as(x, "symmetricMatrix")`.

Usage

`forceSymmetric(x, uplo)`
formatSparseM

Formatting Sparse Numeric Matrices Utilities

Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the format and print methods for sparse matrices and can be applied as well to standard R matrices. Note that all arguments but the first are optional.

formatSparseM() is the main “workhorse” of formatSpMatrix, the format method for sparse matrices.

.formatSparseSimple() is a simple helper function, also dealing with (short/empty) column names construction.

Usage

formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
               m = as(x,"matrix"), asLogical=NULL, uniDiag=NULL,
               digits=NULL, cx, iN0, dn = dimnames(m))

Arguments

x
  any square matrix (of numbers), either “traditional” (matrix) or inheriting from Matrix.

uplo
  optional string, "U" or "L" indicating which “triangle” half of x should determine the result. The default is "U" unless x already has a uplo slot (i.e., when it is symmetricMatrix, or triangularMatrix), where the default will be x@uplo.

Value

a square matrix inheriting from class symmetricMatrix.

See Also

symmpart for the symmetric part of a matrix, or the coercions as(x, <symmetricMatrix class>).

Examples

## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try( as(hh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)

formatSparseM

Arguments

- **x**: an R object inheriting from class `sparseMatrix`.
- **zero.print**: character which should be used for structural zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like `print()`ing of non-sparse matrices.
- **align**: a string specifying how the zero.print codes should be aligned, see `formatSpMatrix`.
- **m**: (optional) a (standard R) matrix version of x.
- **asLogical**: should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for `formatSparseM()`.
- **uniDiag**: logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "1" instead of "1" (to emphasize that the 1's are "structural").
- **digits**: significant digits to use for printing, see `print.default`.
- **cx**: (optional) character matrix; a formatted version of x, still with strings such as "0.00" for the zeros.
- **iN0**: (optional) integer vector, specifying the location of the non-zeroes of x.
- **col.names, note.dropping.colnames**: see `formatSpMatrix`.
- **dn**: dimnames to be used; a list (of length two) with row and column names (or NULL).

Value

A character matrix like cx, where the zeros have been replaced with (padded versions of) zero.print. As this is a dense matrix, do not use these functions for really large (really) sparse matrices!

Author(s)

Martin Maechler

See Also

`formatSpMatrix` which calls `formatSparseM()` and is the format method for sparse matrices.
`printSpMatrix` which is used by the (typically implicitly called) show and print methods for sparse matrices.

Examples

```r
m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11, 0, 0, 0, -7, 0), 4, 9))
f <- formatSparseM(m)
oquote(f)
## nice, but this is nicer (with "units" vertically aligned):
print(f, quote = FALSE, right = TRUE)
## and "the same" as :
```
Matrix(m)

## align = "right" is cheaper --> the \".\" are not aligned:
noquote(f2 <- formatSparseM(m,align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
               (f2 == ".") == (m == 0))

generalMatrix-class  Class "generalMatrix" of General Matrices

Description

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

  factors ,
  Dim ,
  Dimnames: all slots inherited from compMatrix; see its description.

Extends

Class “compMatrix”, directly. Class “Matrix”, by class “compMatrix”.

See Also

Classes compMatrix, and the non-general virtual classes: symmetricMatrix, triangularMatrix, diagonalMatrix.

graph-sparseMatrix  Conversions "graph" <--> (sparse) Matrix

Description

The Matrix package has supported conversion from and to "graph" objects from (Bioconductor) package graph since summer 2005, via the usual as(. , "<class>") coercion,

as(from, Class)

Since 2013, this functionality is further exposed as the graph2T() and T2graph() functions (with further arguments than just from), which convert graphs to and from the triplet form of sparse matrices (of class "TsparseMatrix").
Usage

graph2T(from, use.weights = )
T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)

Arguments

from for graph2T(), an R object of class "graph":
for T2graph(), a sparse matrix inheriting from "TsparseMatrix".
use.weights logical indicating if weights should be used, i.e., equivalently the result will be
numeric, i.e. of class dgTMatrix; otherwise the result will be ngTMatrix or
nsTMatrix, the latter if the graph is undirected. The default looks if there are
weights in the graph, and if any differ from 1, weights are used.
need.uniq a logical indicating if from may need to be internally “uniqified”; do not set this
and hence rather use the default, unless you know what you are doing!
edgemode one of NULL, "directed", or "undirected". The default NULL looks if the
matrix is symmetric and assumes "undirected" in that case.

Value

For graph2T(), a sparse matrix inheriting from "TsparseMatrix".
For T2graph() an R object of class "graph".

See Also

Note that the CRAN package igraph also provides conversions from and to sparse matrices (of
package Matrix) via its graph.adjacency() and get.adjacency().

Examples

if(isTRUE(try(require(graph)))) { ## super careful .. for "checking reasons"
n4 <- LETTERS[1:4]; dns <- list(n4,n4)
show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
show(g1 <- as(a1, "graph")) # directed
unlist(edgeWeights(g1)) # all '2'

show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
show(g2 <- as(a2, "graph")) # directed
# now if you want it undirected:
show(g3 <- T2graph(as(a2,"TsparseMatrix"), edgemode="undirected"))
show(m3 <- as(g3,"Matrix"))
show( graph2T(g3) ) # a "pattern Matrix" (nsTMatrix)

a. <- sparseMatrix(i= 4:1, j=1:4, dimnames=list(n4,n4), giveC=FALSE) # no 'x'
show(a.) # "ngTMatrix"
show(g. <- as(a., "graph"))
}
Generate a Hilbert matrix

Description
Generate the $n$ by $n$ symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large $n$, they are often used for testing numerical linear algebra code.

Usage
Hilbert(n)

Arguments
n a non-negative integer.

Value
the $n$ by $n$ symmetric Hilbert matrix as a "dpoMatrix" object.

See Also
the class dpoMatrix

Examples
Hilbert(6)

Methods for image() in Package 'Matrix'

Description
Methods for function image in package Matrix. An image of a matrix simply color codes all matrix entries and draws the $n \times m$ matrix using an $n \times m$ grid of (colored) rectangles. The Matrix package image methods are based on levelplot() from package lattice; hence these methods return an “object” of class "trellis", producing a graphic when (auto-) print()ed.

Usage
## S4 method for signature 'dgTMatrix'
image(x,
    xlim = c(1, di[2]),
    ylim = c(di[1], 1), aspect = "iso",
    sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
    xlab = "Column", ylab = "Row", cuts = 15,
    useRaster = FALSE,
    useAbs = NULL, colorkey = !useAbs,
    col.regions = NULL,
    lwd = NULL, border.col = NULL, ...)
Arguments

- **x**: a Matrix object, i.e., fulfilling `is(x, "Matrix").
- **xlim, ylim**: x- and y-axis limits; may be used to “zoom into” matrix. Note that x, y “feel reversed”: ylim is for the rows (= 1st index) and xlim for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, ylim is always used decreasingly.
- **aspect**: aspect ratio specified as number (y/x) or string; see `levelplot`.
- **sub, xlab, ylab**: axis annotation with sensible defaults; see `plot.default`.
- **cuts**: number of levels the range of matrix values would be divided into.
- **useRaster**: logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, `panel.levelplot.raster` (from lattice package) is used, and the colorkey is also done via rasters, see also `levelplot` and possibly `grid.raster`.
  - Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions).
- **useAbs**: logical indicating if `abs(x)` should be shown; if TRUE, the former (implicit) default, the default `col.regions` will be grey colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.
- **colorkey**: logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless useAbs is true. You can also specify a list, see `levelplot`, such as `list(raster=TRUE)` in the case of rastering.
- **col.regions**: vector of gradually varying colors; see `levelplot`.
- **lwd**: (only used when useRaster is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by `grid.rect`). The default depends on the matrix dimension and the device size.
- **border.col**: color for the border of each rectangle. NA means no border is drawn. When NULL as by default, `border.col <- if(lwd < .01) NA else NULL` is used. Consider using an opaque color instead of NULL which corresponds to `grid::get.gpar("col")`.

... further arguments passed to methods and `levelplot`, notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseding cuts above).

Value

as all lattice graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

Methods

All methods currently end up calling the method for the dgTMatrix class. Use `showMethods(image)` to list them all.

See Also

`levelplot`, and `print.trellis` from package lattice.
Examples

```r
showMethods(image)
## If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)"

cCA <- Cholesky(crossprod(CAex), Imult = .01)
## See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)"),
     split=c(x=1,y=1,nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE), split=c(x=2,y=1,nx=2,ny=1))

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
    # how the result looks, may depend heavily on
    # the device, screen resolution, antialiasing etc
    # e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
    # again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=5)
image(USCounties, c(1,300), c(1,200), lwd=.01)
## These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2, check.environment=FALSE),
          all.equal(I2, I3, check.environment=FALSE))
## using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyblue", 1/2))

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) ||
   identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))) {
## Using raster graphics: For PDF this would give a 77 MB file,
## however, for such a large matrix, this is typically considerably
## *slower* (than vector graphics rectangles) in most cases :
if(doPNG <- !dev.interactive())
  png("image-USCounties-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
if(doPNG)
  dev.off()
## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)
```

**Virtual Class "index" - Simple Class for Matrix Indices**
Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of Matrix matrices.

In fact, it is currently implemented as a simple class union (setClassUnion) of "numeric", "logical" and "character".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

[-methods, and
Subassign-methods, also for examples.

Examples

showClass("index")

---

**indMatrix-class**

*Index Matrices*

Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or "sampling rows with replacement", and is implemented that way in the Matrix package, see the ‘Details’ below.

Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting columns.) The crossproduct of an index matrix \( M \) with itself is a diagonal matrix with the number of entries in each column of \( M \) on the diagonal, i.e., \( M' M = \text{Diagonal}(x=\text{table}(M@\text{perm})) \).

Permutation matrices (of class pMatrix) are special cases of index matrices: They are square, of dimension, say, \( n \times n \), and their index vectors contain exactly all of \( 1:n \).

While "row-indexing" (of more than one row or using drop=FALSE) stays within the "indMatrix" class, all other subsetting/indexing operations ("column-indexing", including, diag) on "indMatrix" objects treats them as nonzero-pattern matrices ("ngTMatrix" specifically), such that non-matrix subsetting results in logical vectors. Sub-assignment \( M[i,j] \leftarrow v \) is not sensible and hence an error for these matrices.

Objects from the Class

Objects can be created by calls of the form new("indMatrix", ...) or by coercion from an integer index vector, see below.
indMatrix-class

Slots

perm: An integer, 1-based index vector, i.e. an integer vector of length \( \text{Dim}[1] \) whose elements are taken from \( 1:\text{Dim}[2] \).

Dim: integer vector of length two. In some applications, the matrix will be skinny, i.e., with at least as many rows as columns.

Dimnames: a list of length two where each component is either NULL or a character vector of length equal to the corresponding Dim element.

Extends

Class "sparseMatrix" and "generalMatrix", directly.

Methods

\%\%\% signature(x = "matrix", y = "indMatrix") and other signatures (use showMethods("%\%\%", class="indMatrix"): ...

coerce signature(from = "integer", to = "indMatrix"): This enables typical "indMatrix" construction, given an index vector from elements in \( 1:\text{Dim}[2] \), see the first example.

coerce signature(from = "numeric", to = "indMatrix"): a user convenience, to allow as(perm, "indMatrix") for numeric perm with integer values.

coerce signature(from = "list", to = "indMatrix"): The list must have two (integer-valued) entries: the first giving the index vector with elements in \( 1:\text{Dim}[2] \), the second giving \( \text{Dim}[2] \). This allows "indMatrix" construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values \( \text{Dim}[2], \text{Dim}[2]-1, \text{Dim}[2]-2, \ldots \)

coerce signature(from = "indMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE matrix of mode logical.

coerce signature(from = "indMatrix", to = "ngTMatrix"): coercion to sparse logical matrix of class ngTMatrix.

t signature(x = "indMatrix"): return the transpose of the index matrix (which is no longer an indMatrix, but of class ngTMatrix).

colSums, colMeans, rowSums, rowMeans signature(x = "indMatrix"): return the column or row sums or means.

rbind2 signature(x = "indMatrix", y = "indMatrix"): a fast method for rowwise catenation of two index matrices (with the same number of columns).

kronecker signature(x = "indMatrix", y = "indMatrix"): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

Author(s)

Fabian Scheipl, Uni Muenchen, building on existing "pMatrix", after a nice hike’s conversation with Martin Maechler; diverse tweaks by the latter. The crossprod(x,y) and kronecker(x,y) methods when both arguments are "indMatrix" have been made considerably faster thanks to a suggestion by Boris Vaillant.

See Also

The permutation matrices pMatrix are special index matrices. The “pattern” matrices, nMatrix and its subclasses.
Examples

```r
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
## random index matrix for 30 observations and 10 unique values:
(sm1 <- as(sample(10, 30, replace=TRUE),"indMatrix"))

## Sample rows of a numeric matrix :
(mm <- matrix(1:10, nrow=10, ncol=3))
sm1 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1,IM2))

## same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

# 3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
# 3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sm1, "ngTMatrix")
sm1[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4, ] # preserves "indMatrix"-class

I1 <- as(c(5:1,6:4,7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- rbind(I1, I2))
stopifnot(is(I12, "indMatrix"), identical(I12, rbind(I1, I2)),
colSums(I12) == c(2L,2:4,4:2))
```

invPerm

**Inverse Permutation Vector**

Description

From a permutation vector p, compute its *inverse* permutation vector.

Usage

```r
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

Arguments

- **p**: an integer vector of length, say, n.
is.na-methods

zero.p     logical indicating if p contains values 0:(n-1) or rather (by default, zero.p = FALSE) 1:n.

zero.res   logical indicating if the result should contain values 0:(n-1) or rather (by default, zero.res = FALSE) 1:n.

Value

an integer vector of the same length (n) as p. By default, (zero.p = FALSE, zero.res = FALSE),
invPerm(p) is the same as order(p) or sort.list(p) and for that case, the function is equivalent
to invPerm. <- function(p) { p[p] <- seq_along(p) ; p }.

Author(s)

Martin Maechler

See Also

the class of permutation matrices, pMatrix.

Examples

p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
## they are indeed inverse of each other:
stopifnot(
  identical(p[ip], 1:10),
  identical(ip[p], 1:10),
  identical(invPerm(ip), p)
)

is.na-methods is.na(), is.infinite() Methods for 'Matrix' Objects

Description

Methods for function is.na(), is.finite(), and is.infinite() for all Matrices (objects extending the Matrix class):
x = "denseMatrix" returns a "nMatrix" object of same dimension as x, with TRUE's whenever x is NA, finite, or infinite, respectively.
x = "sparseMatrix" ditto.

Usage

## S4 method for signature 'sparseMatrix'
is.na(x)
## S4 method for signature 'dsparseMatrix'
is.finite(x)
## S4 method for signature 'ddenseMatrix'
is.infinite(x)
## and for other classes

## S4 method for signature 'xMatrix'
anyNA(x)

## S4 method for signature 'nsparseMatrix'
anyNA(x)

## S4 method for signature 'sparseVector'
anyNA(x)

## S4 method for signature 'nsparseVector'
anyNA(x)

### Arguments

- **x**: sparse or dense matrix or sparse vector (here; any R object in general).

### See Also

- `NA`, `is.na`, `is.finite`, `is.infinite`;
- `nMatrix`, `denseMatrix`, `sparseMatrix`
- The `sparseVector` class.

### Examples

```r
M <- Matrix(1:6, nrow=4, ncol=3,
        dimnames = list(c("a", "b", "c", "d"),
                        c("A", "B", "C")))
stopifnot(all(!is.na(M)))

stopifnot(sum(inA) == 1+1+5)
```

---

### is.null.DN

**Are the Dimnames dn NULL-like?**

### Description

Are the dimnames dn NULL-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true (TRUE) when the dimnames dn are “like” NULL, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices (`matrix`) which have no formal class definition, and hence much freedom in how their dimnames look like.
Usage

is.null.DN(dn)

Arguments

dn dimnames() of a matrix-like R object.

Value

logical TRUE or FALSE.

Note

This function is really to be used on “traditional” matrices rather than those inheriting from Matrix, as the latter will always have dimnames list(NULL,NULL) exactly, in such a case.

Author(s)

Martin Maechler

See Also

is.null, dimnames, matrix.

Examples

m <- matrix(round(100 * rnorm(6)), 2,3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)

m4 ## prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
identical(capture.output(m) -> cm,
capture.output(m1)),
identical(cm, capture.output(m2)),
identical(cm, capture.output(m3)),
identical(cm, capture.output(m4)))
isTriangular

Examples

```r
isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (and of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE
```

## Look at implementations:
showMethods("isSymmetric", includeDefs=TRUE)# "ANY": base's S3 generic; 6 more

Description

`isTriangular(M)` returns a logical indicating if `M` is a triangular matrix. Analogously, `isDiagonal(M)` is true iff `M` is a diagonal matrix.

Contrary to `isSymmetric()`, these two functions are generically from package `Matrix`, and hence also define methods for traditional (class "matrix") matrices.

By our definition, triangular, diagonal and symmetric matrices are all square, i.e. have the same number of rows and columns.

Usage

```r
isDiagonal(object)
isTriangular(object, upper = NA, ...
```

Arguments

- `object` any R object, typically a matrix (traditional or Matrix package).
- `upper` logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE.
- `...` potentially further arguments for other methods.

Value

a ("scalar") logical, TRUE or FALSE, never NA. For `isTriangular()`, if the result is TRUE, it may contain an attribute (see attributes "kind", either "L" or "U" indicating if it is a lower or upper triangular matrix.

See Also

`isSymmetric`; formal class (and subclasses) "triangularMatrix" and "diagonalMatrix".
Examples

isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE

---

**Khatri-Rao Matrix Product**

**Description**

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

**Usage**

KhatriRao(X, Y = X, FUN = "+", make.dimnames = FALSE)

**Arguments**

- **X, Y** matricies of with the same number of columns.
- **FUN** the (name of the) function to be used for the column-wise Kronecker products, see kronecker, defaulting to the usual multiplication.
- **make.dimnames** logical indicating if the result should inherit dimnames from X and Y in a simple way.

**Value**

a "CsparseMatrix", say R, the Khatri-Rao product of X \((n \times k)\) and Y \((m \times k)\), is of dimension \((n \cdot m) \times k\), where the j-th column, R[, j] is the kronecker product kronecker(X[, j], Y[, j]).

**Note**

The current implementation is efficient for large sparse matrices.

**Author(s)**

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

Examples

```r
## Example with very small matrices:
m <- matrix(1:12,3,4)
d <- diag(1:4)
KhatriRao(m,d)
KhatriRao(d,m)
dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("d", 10*1:4), paste0("D", 1:4))
(Kmd <- KhatriRao(m,d, make.dimnames=TRUE))
(Kdm <- KhatriRao(d,m, make.dimnames=TRUE))

nm <- as(m,"nMatrix")
nd <- as(d,"nMatrix")
KhatriRao(nm,nd, make.dimnames=TRUE)
KhatriRao(nd,nm, make.dimnames=TRUE)

stopifnot(dim(KhatriRao(m,d)) == c(nrow(m)*nrow(d), ncol(d)))
## border cases / checks:
zm <- nm; zm[] <- 0 # all 0 matrix
stopifnot(all(K1 <- KhatriRao(nd, zm) == 0), identical(dim(K1), c(12L, 4L)),
all(K2 <- KhatriRao(zm, nd) == 0), identical(dim(K2), c(12L, 4L)))

d0 <- d; d0[] <- 0; m0 <- Matrix(d0[-1,])
stopifnot(all(K3 <- KhatriRao(d0, m) == 0), identical(dim(K3), dim(Kdm)),
all(K4 <- KhatriRao(m, d0) == 0), identical(dim(K4), dim(Kmd)),
all(KhatriRao(d0, d0) == 0), all(KhatriRao(m0, d0) == 0),
all(KhatriRao(d0, m0) == 0), all(KhatriRao(m0, m0) == 0),
identical(dimnames(KhatriRao(m, d0, make.dimnames=TRUE)), dimnames(Kmd)))
```

Ko<ref>\textregistered</ref>nker-Ng Example Sparse Model Matrix and Response Vector
**Description**

A model matrix \( mm \) and corresponding response vector \( y \) used in an example by Koenker and Ng. The matrix \( mm \) is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector \( y \) is just numeric of length 1850.

**Usage**

data(KNex)

**References**

**Examples**

data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time( # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol,3))

## Compare with QR-based solution ("more accurate, but slightly slower"):

system.time(  
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y )))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE

---

**kronecker-methods**

*Methods for Function 'kronecker()' in Package 'Matrix'*

**Description**

Computes Kronecker products for objects inheriting from "Matrix".

In order to preserver sparseness, we treat 0 * NA as 0, not as NA as usually in R (and as used for the base function kronecker).

**Methods**

kronecker signature(X = "Matrix", Y = "ANY")
kronecker signature(X = "ANY", Y = "Matrix")
kronecker signature(X = "diagonalMatrix", Y = "ANY")
kronecker signature(X = "sparseMatrix", Y = "ANY")
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix")
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix")
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix")
kronecker signature(X = "indMatrix", Y = "indMatrix")
ldenseMatrix-class

Examples

```r
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=1:4)) # 5 x 4
t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix") # (lost "triangularity"
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dtTMatrix" i.e. did keep
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
is(NN2, "sparseMatrix"), all(NN2 == NN),
is(NN, "triangularMatrix"))
```

ldenseMatrix-class Virtual Class "ldenseMatrix" of Dense Logical Matrices

Description

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

- `x`: logical vector containing the entries of the matrix.
- `Dim`, `Dimnames`: see Matrix.

Extends

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

Methods

- `coerce` signature(from = "matrix", to = "ldenseMatrix"): ...
- `coerce` signature(from = "ldenseMatrix", to = "matrix"): ...
- `as.vector` signature(x = "ldenseMatrix", mode = "missing"): ...
- `which` signature(x = "ndenseMatrix"), semantically equivalent to base function which(x, arr.ind): for details, see the lMatrix class documentation.

See Also

Class lgeMatrix and the other subclasses.

Examples

```r
showClass("ldenseMatrix")
as(diag(3) > 0, "ldenseMatrix")
```
ldiMatrix-class

Class "ldiMatrix" of Diagonal Logical Matrices

Description
The class "ldiMatrix" of logical diagonal matrices.

Objects from the Class
Objects can be created by calls of the form new("ldiMatrix", ...) but typically rather via Diagonal.

Slots
x: "logical" vector.
diag: "character" string, either "U" or "N", see ddiMatrix.
Dim, Dimnames: matrix dimension and dimnames, see the Matrix class description.

Extends
Class "diagonalMatrix" and class "lMatrix", directly.
Class "sparseMatrix", by class "diagonalMatrix".

See Also
Classes ddiMatrix and diagonalMatrix; function Diagonal.

Examples
(lM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(lM)#> gory details (slots)
crossprod(lM) # numeric
(nM <- as(lM, "nMatrix"))# -> sparse (not formally ``diagonal'')
crossprod(nM) # logical sparse

lgeMatrix-class

Class "lgeMatrix" of General Dense Logical Matrices

Description
This is the class of general dense logical matrices.

Slots
x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
factors: Object of class "list". A named list of factorizations that have been computed for the matrix.
lsparseMatrix-classes

Extends

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="lgeMatrix") for details.

See Also

Non-general logical dense matrix classes such as ltrMatrix, or lsyMatrix: sparse logical classes such as lgCMatrix.

Examples

showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgeMatrix
set.seed(1)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgCMatrix
as(lM, "lgCMatrix")

lsparseMatrix-classes  Sparse logical matrices

Description

The lsparseMatrix class is a virtual class of sparse matrices with TRUE/FALSE or NA entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (class TsparseMatrix, subclasses lgTMatrix, lsTMatrix, and ltTMatrix) or in compressed column-oriented form (class CsparseMatrix, subclasses lgCMatrix, lsCMatrix, and ltCMatrix) or--rarely--in compressed row-oriented form (class RsparseMatrix, subclasses lgRMatrix, lsRMatrix, and ltRMatrix). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

Details

Note that triplet stored (TsparseMatrix) matrices such as lgTMatrix may contain duplicated pairs of indices (i,j) as for the corresponding numeric class dgTMatrix where for such pairs, the corresponding x slot entries are added. For logical matrices, the x entries corresponding to duplicated index pairs (i,j) are “added” as well if the addition is defined as logical or, i.e., “TRUE + TRUE |-> TRUE” and “TRUE + FALSE |-> TRUE”. Note the use of uniqTsparse() for getting an internally unique representation without duplicated (i,j) entries.
Objects from the Class

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

Slots

- **x**: Object of class "logical", i.e., either TRUE, NA, or FALSE.
- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- **p**: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- **i**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.
- **Dim**: Object of class "integer" - the dimensions of the matrix.

Methods

- **coerce** signature(from = "dgCMatrix", to = "lgCMatrix")
- **t** signature(x = "lgCMatrix"): returns the transpose of `x`
- **which** signature(x = "lsparseMatrix"). semantically equivalent to base function which(x, arr.ind); for details, see the `lMatrix` class documentation.

See Also

the class `dgCMatrix` and `dgTMatrix`

Examples

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
  identical(!lm, m <= 1))

data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1)# "lgC..."

```

However with many "non-structural zeros"
## from logical to nz_pattern -- okay when there are no NA's:

```
mG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
## from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included
```

```
stopifnot(identical(nmG.1, as((KNex $ mm) != 0,"nMatrix")),
    validObject(lmG.1), all(lmG.1@x),
    # same "logical" but lmG.1 has no 'FALSE' in x slot:
    all(lmG.1 == mmG.1))
```

```
class(xnx <- crossprod(nmG.1))# "nsC.."
class(xlx <- crossprod(mmG.1))# "dsC.." : numeric
is0 <- (xlx == 0)
mean(as.vector(is0))# 99.3% zeros: quite sparse, but
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
    ## compare xnx and xlx : have the *same* non-structural 0s :
sapply(slotNames(xnx),
        function(n) identical(slot(xnx, n), slot(xlx, n))))
```

### lsyMatrix-class

Symmetric Dense Logical Matrices

Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form new("lsyMatrix", ...).

Slots

- uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
- factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Both extend classes "ldenseMatrix" and "symmetricMatrix", directly; further, class "Matrix" and others, indirectly. Use showClass("lsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.); use, e.g., showMethods(class="dsyMatrix") for details.
ltrMatrix-class

Triangular Dense Logical Matrices

Description

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltpMatrix" class is the same except in packed storage.

Slots

- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Both extend classes "ldenseMatrix" and "triangularMatrix", directly; further, class "Matrix", "lMatrix" and others, indirectly. Use `showClass("ltrMatrix")`, e.g., for details.

Methods

Currently, mainly `t()` and coercion methods (for `as()`; use, e.g., `showMethods(class="ltpMatrix")` for details.

See Also

Classes `lgeMatrix, Matrix`; function `t`
Examples

showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(,4,4), "ltrMatrix")))
str(lutp <- as(lutr, "ltpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!lutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(lutp, as(!lutp, "ltpMatrix")))

## (Generalized) Triangular Decomposition of a Matrix

Description

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

Usage

lu(x, ...)
## S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1,
   keep.dimnames = TRUE, ...)

Arguments

x a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.

warnSing (when x is a "denseMatrix") logical specifying if a warning should be signalled when x is singular.

errSing (when x is a "sparseMatrix") logical specifying if an error (see stop) should be signalled when x is singular. When x is singular, lu(x, errSing=FALSE) returns NA instead of an LU decomposition. No warning is signalled and the useR should be careful in that case.

order logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.

tol positive number indicating the pivoting tolerance used in cs_lu. Do only change with much care.

keep.dimnames logical indicating that dimnames should be propagated to the result, i.e., “kept”. This was hardcoded to FALSE in upto Matrix version 1.2-0. Setting to FALSE may gain some performance.

... further arguments passed to or from other methods.
\textbf{Details}

\texttt{lu()} is a generic function with special methods for different types of matrices. Use \texttt{showMethods("lu")} to list all the methods for the \texttt{lu} generic.

The method for class \texttt{dgeMatrix} (and all dense matrices) is based on LAPACK's "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class \texttt{dgCMatrix} (and all sparse matrices) is based on functions from the CSparse library. It signals an error (or returns \texttt{NA}, when \texttt{errSing = FALSE}, see above) when the decomposition algorithm fails, as when \texttt{x} is (too close to) singular.

\textbf{Value}

An object of class "LU", i.e., "denseLU" (see its separate help page), or "sparseLU", see \texttt{sparseLU}; this is a representation of a triangular decomposition of \texttt{x}.

\textbf{Note}

Because the underlying algorithm differ entirely, in the dense case (class \texttt{denseLU}), the decomposition is

\[ A = PLU, \]

where as in the sparse case (class \texttt{sparseLU}), it is

\[ A = P'LUQ. \]

\textbf{References}

\textbf{See Also}

Class definitions \texttt{denseLU} and \texttt{sparseLU} and function \texttt{expand}; \texttt{qr}, \texttt{chol}.

\textbf{Examples}

```r
##--- Dense -------------------------
x <- Matrix(rnorm(9), 3, 3)
lu(x)
dim(x2 <- round(10 * x[,,-3]))# non-square
expand(lu2 <- lu(x2))
##--- Sparse (see more in ?"sparseLU-class")----- % ./sparseLU-class.Rd
pm <- as(readMM(system.file("external/pores_1.mtx", package = "Matrix")),
         "CsparseMatrix")
str(pmLU <- lu(pm)) # p is a 0-based permutation of the rows
                     # q is a 0-based permutation of the columns
ppm <- pm[pmLU@p + 1L, pmLU@q + 1L]
pLU <- drop0(pmLU@L %*% pmLU@U) # L %*% U -- dropping extra zeros
## equal up to "rounding"
```
LU-class

Description

The "LU" class is the virtual class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

Details

The decomposition is of the form

\[ A = PLU \]

where typically all matrices are of size \( n \times n \), and the matrix \( P \) is a permutation matrix, \( L \) is lower triangular and \( U \) is upper triangular (both of class \texttt{dtrMatrix}).

Note that the dense decomposition is also implemented for a \( m \times n \) matrix \( A \), when \( m \neq n \).

If \( m < n \) ("wide case"), \( U \) is \( m \times n \), and hence not triangular.

If \( m > n \) ("long case"), \( L \) is \( m \times n \), and hence not triangular.

Objects from the Class

Objects can be created by calls of the form \texttt{new("denseLU", ...)}. More commonly the objects are created explicitly from calls of the form \texttt{lu(mm)} where \( mm \) is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

Extends

"LU" directly extends the virtual class "MatrixFactorization".

"denseLU" directly extends "LU".

Slots

\texttt{x}: object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can retrieved by the \texttt{expand()} method, see below.

\texttt{perm}: Object of class "integer" - a vector of length \( \min(\text{Dim}) \) that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.

\texttt{Dim}: the dimension of the original matrix; inherited from class \texttt{MatrixFactorization}.

Methods

\texttt{expand signature(x = "denseLU")}: Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

\texttt{solve signature(a = "denseLU", b = "missing")}: Compute the inverse of \( A \), \( A^{-1} \), solve\((A) \) using the LU decomposition, see also \texttt{solve-methods}. 

ppm[1:14, 1:5]
pLU[1:14, 1:5]
See Also

class `sparseLU` for LU decompositions of `sparse` matrices; further, class `dgeMatrix` and functions `lu`, `expand`.

Examples

```r
set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
mm
str(lum <- lu(mm))
elu <- expand(lum)
elu # three components: "L", "U", and "P", the permutation
eu$L %*% eu$U
(m2 <- with(elu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"),
                   as(m2, "matrix")))
```

### mat2triplet

**Map Matrix to its Triplet Representation**

**Description**

From an R object coercible to "TsparseMatrix", typically a (sparse) matrix, produce its triplet representation which may collapse to a "Duplet" in the case of binary aka pattern, such as "nMatrix" objects.

**Usage**

```r
mat2triplet(x, uniqT = FALSE)
```

**Arguments**

- `x` any R object for which `as(x, "TsparseMatrix")` works; typically a `matrix` of one of the Matrix package matrices.
- `uniqT` logical indicating if the triplet representation should be ‘unique’ in the sense of `uniqTsparse()`.

**Value**

A list, typically with three components,

- `i` vector of row indices for all non-zero entries of `x`
- `i` vector of columns indices for all non-zero entries of `x`
- `x` vector of all non-zero entries of `x`; exists only when `as(x, "TsparseMatrix")` is not a "nsparseMatrix".

Note that the order of the entries is determined by the coercion to "TsparseMatrix" and hence typically with increasing j (and increasing i within ties of j).
Note

The mat2triplet() utility was created to be a more efficient and more predictable substitute for summary(<sparseMatrix>). UseRs have wrongly expected the latter to return a data frame with columns i and j which however is wrong for a "diagonalMatrix".

See Also

mat2triplet() is conceptually the inverse function of spMatrix and (one case of) sparseMatrix.

Examples

```r
if(FALSE) ## The function is defined (don't redefine here!), simply as
mat2triplet <- function(x, uniqT = FALSE) {
  T <- as(x, "TsparseMatrix")
  if(uniqT && anyDuplicatedT(T)) T <- .uniqTsparse(T)
  if(is(T, "nsparseMatrix"))
    list(i = T@i + 1L, j = T@j + 1L)
  else list(i = T@i + 1L, j = T@j + 1L, x = T@x)
}
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(Ax <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
str(trA <- mat2triplet(Ax))
stopifnot(i == sort(trA$i), sort(j) == trA$j, x == sort(trA$x))
D <- Diagonal(x=4:2)
summary(D)
str(mat2triplet(D))
```

Matrix

Construct a Classed Matrix

Description

Construct a Matrix of a class that inherits from Matrix.

Usage

```r
Matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE, dimnames = NULL,
       sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

Arguments

data an optional numeric data vector or matrix.
nrow when data is not a matrix, the desired number of rows
ncol when data is not a matrix, the desired number of columns
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the
       matrix is filled by rows.
dimnames a dimnames attribute for the matrix: a list of two character components. They
       are set if not NULL (as per default).
sparse logical or NULL, specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0.

doDiag logical indicating if a diagonalMatrix object should be returned when the resulting matrix is diagonal (mathematically). As class diagonalMatrix extends sparseMatrix, this is a natural default for all values of sparse. Otherwise, if doDiag is false, a dense or sparse (depending on sparse) symmetric matrix will be returned.

forceCheck logical indicating if the checks for structure should even happen when data is already a "Matrix" object.

Details

If either of nrow or ncol is not given, an attempt is made to infer it from the length of data and the other parameter. Further, Matrix() makes efforts to keep logical matrices logical, i.e., inheriting from class lMatrix, and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a symmetric matrix also needs symmetric dimnames, e.g., by specifying dimnames = list(NULL,NULL), see the examples.

Most of the time, the function works via a traditional (full) matrix. However, Matrix(0, nrow,ncol) directly constructs an “empty” sparseMatrix, as does Matrix(FALSE, *).

Although it is sometime possible to mix unclassed matrices (created with matrix) with ones of class "Matrix”, it is much safer to always use carefully constructed ones of class "Matrix”.

Value

Returns matrix of a class that inherits from "Matrix". Only if data is not a matrix and does not already inherit from class Matrix are the arguments nrow, ncol and byrow made use of.

See Also

The classes Matrix, symmetricMatrix, triangularMatrix, and diagonalMatrix; further, matrix.

Special matrices can be constructed, e.g., via sparseMatrix (sparse), bdiag (block-diagonal), bandSparse (banded sparse), or Diagonal.

Examples

Matrix(0, 3, 2) # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE)# -> 'dense'

## 4 cases - 3 different results :
Matrix(0, 2, 2) # diagonal !
Matrix(0, 2, 2, sparse=FALSE)# (ditto)
Matrix(0, 2, 2, doDiag=FALSE)# -> sparse symm. "dsCMatrix"
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE)# -> dense symm. "dsyMatrix"

Matrix(1:6, 3, 2) # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # (ditto)
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')

## triangular
Matrix-class

Virtual Class "Matrix" Class of Matrices

Description

The Matrix class is a class contained by all actual classes in the Matrix package. It is a “virtual” class.

Slots

Common to all matrix objects in the package:

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

Methods

determinant signature(x = "Matrix", logarithm = "missing"): and
determinant signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that det also works for all our matrices, calling the appropriate determinant() method. The Matrix:::det is an exact copy of base:::det, but in the correct namespace, and hence calling the S4-aware version of determinant().

diff signature(x = "Matrix"): As diff() for traditional matrices, i.e., applying diff() to each column.
dim signature(x = "Matrix"): extract matrix dimensions dim.
dim<- signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to reshape Matrix objects, but only when prod(value) == prod(dim(x)).
dimnames signature(x = "Matrix"): extract dimnames.
dimnames<- signature(x = "Matrix", value = "list"): set the dimnames to a list of length 2, see dimnames<-.
**Matrix-class**

**length** signature(x = "Matrix"): simply defined as \( \text{prod(dim(x))} \) (and hence of mode "double").

**show** signature(object = "Matrix"): show method for printing. For printing sparse matrices, see `printSpMatrix`.

**image** signature(object = "Matrix"): draws an image of the matrix entries, using `levelplot()` from package lattice.

**head** signature(object = "Matrix"): return only the "head", i.e., the first few rows.

**tail** signature(object = "Matrix"): return only the "tail", i.e., the last few rows of the respective matrix.

**as.matrix, as.array** signature(x = "Matrix"): the same as `as(x, "matrix")`; see also the note below.

**as.vector** signature(x = "Matrix", mode = "missing"): `as.vector(m)` should be identical to `as.vector(as(m, "matrix"))`, implemented more efficiently for some subclasses.

**as(x, "vector"), as(x, "numeric")** etc, similarly.

**coerce** signature(from = "ANY", to = "Matrix"): This relies on a correct `as.matrix()` method for from.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., `colSums, rowMeans`. Even base functions may work automagically (if they first call `as.matrix()` on their principal argument), e.g., `apply, eigen, svd` or `kappa` all do work via coercion to a "traditional" (dense) matrix.

**Note**

Loading the Matrix namespace “overloads” `as.matrix` and `as.array` in the base namespace by the equivalent of function(x) as(x, "matrix"). Consequently, as.matrix(m) or as.array(m) will properly work when m inherits from the "Matrix" class — also for functions in package base and other packages. E.g., `apply` or `outer` can therefore be applied to "Matrix" matrices.

Douglas Bates <bates@stat.wisc.edu> and Martin Maechler

**See Also**

the classes dgeMatrix, dgCMatrix, and function `Matrix` for construction (and examples).

Methods, e.g., for `kronecker`.

**Examples**

```r
slotNames("Matrix")

c1 <- getClass("Matrix")
names(c1@subclasses) # more than 40 ..

showClass("Matrix")#> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M) diag(M) cm <- M[1:4,] + 10*Diagonal(4)
```
diff(M)    # can reshape it even :
\text{dim}(M) \leftarrow c(2, 12)
M
\text{stopifnot}(\text{identical}(M, \text{Matrix}(c(0,1,0,0), 2,12)),
  \text{all.equal}(\text{det}(\text{cm}),
    \text{determinant}(\text{as}(\text{cm},"\text{matrix}"), \text{log}=FALSE)\$\text{modulus},
    \text{check.attributes}=\text{FALSE}))

\section*{matrix-products}
\textit{Matrix (Cross) Products (of Transpose)}

\subsection*{Description}
The basic matrix product, $\%\%$ is implemented for all our \texttt{Matrix} and also for \texttt{sparseVector} classes, fully analogously to \texttt{R}'s base \texttt{matrix} and vector objects.
The functions \texttt{crossprod} and \texttt{tcrossprod} are matrix products or “cross products”, ideally implemented efficiently without computing $t(.)$'s unnecessarily. They also return \texttt{symmetricMatrix} classed matrices when easily detectable, e.g., in \texttt{crossprod(m)}, the one argument case.
\texttt{tcrossprod()} takes the cross-product of the transpose of a matrix. \texttt{tcrossprod(x)} is formally equivalent to, but faster than, the call $x \%\% t(x)$, and so is \texttt{tcrossprod(x, y)} instead of $x \%\% t(y)$.

\texttt{Boolean} matrix products are computed via either $\%\&\%$ or \texttt{boolArith} = \texttt{TRUE}.

\subsection*{Usage}
\begin{verbatim}
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
x \%\% y

## S4 method for signature 'dgeMatrix,missing'
crossprod(x, y = NULL, boolArith = NA, ...)

## S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)
  ## ..... and for many more signatures

## S4 method for signature 'CsparseMatrix,ddenseMatrix'
tcrossprod(x, y = NULL, boolArith = NA, ...)

## S4 method for signature 'TsparseMatrix,missing'
tcrossprod(x, y = NULL, boolArith = NA, ...)
  ## ..... and for many more signatures
\end{verbatim}

\subsection*{Arguments}
x a matrix-like object
y a matrix-like object, or for [t]crossprod() NULL (by default); the latter case is formally equivalent to $y = x$.
boolArith \texttt{logical}, i.e., \texttt{NA}, \texttt{TRUE}, or \texttt{FALSE}. If true the result is (coerced to) a pattern matrix, i.e., "nMatrix", unless there are NA entries and the result will be a "lMatrix". If false the result is (coerced to) numeric. When \texttt{NA}, currently the default, the result is a pattern matrix when $x$ and $y$ are "\texttt{nsparseMatrix}" and numeric otherwise.
\ldots potentially more arguments passed to and from methods.
Details

For some classes in the Matrix package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith = TRUE` for regular (“non cross”) matrix products, `%*%` cannot be specified. Instead, we provide the `%&%` operator for boolean matrix products.

Value

A `Matrix` object, in the one argument case of an appropriate symmetric matrix class, i.e., inheriting from `symmetricMatrix`.

Methods

```r
%*% signature(x = "dgeMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dgeMatrix")`.
%*% signature(x = "dtrMatrix", y = "matrix") and other signatures (use `showMethods("%*%", class="dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).
```

crossprod signature(x = "dgeMatrix", y = "dgeMatrix"): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.

crossprod signature(x = "CsparseMatrix", y = "missing") returns `t(x) %*% x` as an `dsCMatrix` object.

crossprod signature(x = "TsparseMatrix", y = "missing") returns `t(x) %*% x` as an `dsCMatrix` object.

crossprod,tcrossprod signature(x = "dtrMatrix", y = "matrix") and other signatures, see "%*%" above.

Note

`boolArith = TRUE`, `FALSE` or `NA` has been newly introduced for `Matrix 1.2.0` (March 2015). Its implementation may be incomplete and partly missing. Please report such omissions if detected!

Currently, `boolArith = TRUE` is implemented via `CsparseMatrix` coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

See Also

`tcrossprod` in R’s base, `crossprod` and `%*%`.

Examples

```r
## A random sparse "incidence" matrix:
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "dgCMatrix")
object.size(m) / object.size(mm) # smaller by a factor of > 200

## tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm)) # 0 (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
```
system.time(cm. <- tcrossprod(m)) # 0.02
stopifnot(cm == as(tCmm, "matrix"))
## show sparse sub matrix
tCmm[1:16, 1:30]

MatrixClass

The Matrix (Super-) Class of a Class

Description

Return the (maybe super-)class of class cl from package Matrix, returning character(0) if there is none.

Usage

MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE, dropVirtual = TRUE, ...)

Arguments

c1: string, class name
cld: its class definition
...Matrix: logical indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind.
dropVirtual: logical indicating if virtual classes are included or not.
...: further arguments are passed to .selectSuperClasses().

Value

a character string

Author(s)

Martin Maechler, 24 Mar 2009

Class "MatrixFactorization" of Matrix Factorizations

Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package Matrix.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from Matrix (and trivial sub class of "MatrixFactorization").

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

Dim: Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

Methods

\texttt{dim (x)} simply returns \texttt{x@Dim}, see above.

\texttt{expand} signature\(x = "\text{MatrixFactorization}\)\): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original Matrix object.

\texttt{show} signature\(\text{object} = "\text{MatrixFactorization}\)\): simple printing, see \texttt{show}.

\texttt{solve} signature\(a = "\text{MatrixFactorization}\), \texttt{b=} .\): solve \(Ax = b\) for \(x\); see \texttt{solve-methods}.

See Also

classes inheriting from "MatrixFactorization", such as \texttt{LU}, \texttt{Cholesky}, \texttt{CHMfactor}, and \texttt{sparseQR}.

Examples

ndenseMatrix-class
Virtual Class "ndenseMatrix" of Dense Logical Matrices

Description

ndenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

x: logical vector containing the entries of the matrix.
Dim, Dimnames: see Matrix.

Extends

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix". Class "Matrix", by class "denseMatrix".

Methods

%*% signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
%*% signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
coerce signature(from = "matrix", to = "ndenseMatrix"): ...
coerce signature(from = "ndenseMatrix", to = "matrix"): ...
crossprod signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
crossprod signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
as.vector signature(x = "ndenseMatrix", mode = "missing"): ...
diag signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic diag().

which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

Class ngeMatrix and the other subclasses.

Examples

showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
**nearPD**

**Nearest Positive Definite Matrix**

**Description**

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

**Usage**

```r
closePD(x, corr = FALSE, keepDiag = FALSE, base.matrix = FALSE, do2eigen = TRUE, doSym = FALSE, doDykstra = TRUE, only.values = FALSE, ensureSymmetry = !isSymmetric(x), eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08, maxit = 100, conv.norm.type = "I", trace = FALSE)
```

**Arguments**

- **x** numeric \( n \times n \) approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If \( x \) is not symmetric (and ensureSymmetry is not false), \( \text{symmpart}(x) \) is used.
- **corr** logical indicating if the matrix should be a correlation matrix.
- **keepDiag** logical, generalizing **corr**: if TRUE, the resulting matrix should have the same diagonal (\( \text{diag}(x) \)) as the input matrix.
- **base.matrix** logical indicating if the resulting mat component should be a base matrix or (by default) a Matrix of class \text{dpoMatrix}.
- **do2eigen** logical indicating if a \text{posdefify()} eigen step should be applied to the result of the Higham algorithm.
- **doSym** logical indicating if \( X \leftarrow (X + t(X))/2 \) should be done, after \( X \leftarrow \text{tcrossprod(Qd, Q)} \); some doubt if this is necessary.
- **doDykstra** logical indicating if Dykstra’s correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration \( Y_k = P_U(P_S(Y_{k-1})) \).
- **only.values** logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.
- **ensureSymmetry** logical; by default, \text{symmpart}(x) is used whenever \text{isSymmetric}(x) is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. *Beware* however that setting it FALSE for an asymmetric input \( x \), is typically nonsense!
- **eig.tol** defines relative positiveness of eigenvalues compared to largest one, \( \lambda_1 \). Eigenvalues \( \lambda_k \) are treated as if zero when \( \lambda_k/\lambda_1 \leq \text{eig.tol} \).
- **conv.tol** convergence tolerance for Higham algorithm.
- **posd.tol** tolerance for enforcing positive definiteness (in the final \text{posdefify} step when \text{do2eigen} is TRUE).
- **maxit** maximum number of iterations allowed.
- **conv.norm.type** convergence norm type (\text{norm(*, type)}) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham’s proposal.
- **trace** logical or integer specifying if convergence monitoring should be traced.
Details

This implements the algorithm of Higham (2002), and then (if do2eigen is true) forces positive definiteness using code from posdefify. The algorithm of Knol and ten Berge (1989) (not implemented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting corr = TRUE just sets diag(.) <- 1 within the algorithm.

Higham (2002) uses Dykstra’s correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and still gave reasonable results; this simplification, now only used if doDykstra = FALSE, was active in nearPD() up to Matrix version 0.999375-40.

Value

If only.values = TRUE, a numeric vector of eigenvalues of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

- mat: a matrix of class dpoMatrix, the computed positive-definite matrix.
- eigenvalues: numeric vector of eigenvalues of mat.
- corr: logical, just the argument corr.
- normF: the Frobenius norm (norm(x-X, "F")) of the difference between the original and the resulting matrix.
- iterations: number of iterations needed.
- converged: logical indicating if iterations converged.

Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.1$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr)# still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.1 $ iterations # 27 / 30 !
ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")

stopifnot(all.equal(ncr, ncF))# norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently :
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805

### 3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW)# "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV)# all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(require("sfsmisc")) {
  plot(pmax(1e-3, EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
  eaxis(1); eaxis(2)
} else plot(pmax(1e-3, EV), EV2, type="o", log="xy")
abline(0,1, col="red3", lty=2)

ngeMatrix-class

Class “ngeMatrix” of General Dense Nonzero-pattern Matrices

Description

This is the class of general dense nonzero-pattern matrices, see nMatrix.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="ngeMatrix") for details.

See Also

Non-general logical dense matrix classes such as ntrMatrix, or nsysMatrix; sparse logical classes such as ngCMatrix.

Examples

showClass("ngeMatrix")
## "lgeMatrix" is really more relevant
Class \textit{nMatrix} of Non-zero Pattern Matrices

**Description**

The \textit{nMatrix} class is the virtual “mother” class of all \textit{non-zero pattern} (or simply \textit{pattern}) matrices in the \textbf{Matrix} package.

**Slots**

Common to \textit{all} matrix object in the package:

- \textbf{Dim}: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- \textbf{Dimnames}: list of length two; each component containing NULL or a \textit{character} vector length equal the corresponding \textbf{Dim} element.

**Methods**

There is a bunch of coercion methods (for \texttt{as(..)}), e.g.,

\begin{itemize}
  \item \texttt{coerce signature(from = "matrix", to = "nMatrix")}: Note that these coercions (must) coerce NAs to non-zero, hence conceptually TRUE. This is particularly important when \texttt{sparseMatrix} objects are coerced to \texttt{"nMatrix"} and hence to \texttt{nsparseMatrix}.
  \item \texttt{coerce signature(from = "dMatrix", to = "nMatrix"), and}
  \item \texttt{coerce signature(from = "lMatrix", to = "nMatrix")}: For dense matrices with NAs, these coercions are valid since \texttt{Matrix} version 1.2.0 (still with a \texttt{warning} or a \texttt{message} if \texttt{"Matrix.warn"}, or \texttt{"Matrix.verbose"} options are set.)
  \item \texttt{coerce signature(from = "nMatrix", to = "matrix"): ...}
  \item \texttt{coerce signature(from = "nMatrix", to = "dMatrix"): ...}
  \item \texttt{coerce signature(from = "nMatrix", to = "lMatrix"): ...}
\end{itemize}

Additional methods contain group methods, such as

\begin{itemize}
  \item \texttt{Ops signature(e1 = "nMatrix", e2 = "..."):...}
  \item \texttt{Arith signature(e1 = "nMatrix", e2 = "..."):...}
  \item \texttt{Compare signature(e1 = "nMatrix", e2 = "..."):...}
  \item \texttt{Logic signature(e1 = "nMatrix", e2 = "..."):...}

as(L3, "nMatrix") # -> ntC*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix")# currently "ngTMatrix"

nnzero

The Number of Non-Zero Values of a Matrix

Description

Returns the number of non-zero values of a numeric-like R object, and in particular an object x inheriting from class Matrix.

Usage

nnzero(x, na.counted = NA)

Arguments

x
an R object, typically inheriting from class Matrix or numeric.

na.counted
a logical describing how NAs should be counted. There are three possible settings for na.counted:

TRUENAs are counted as non-zero (since “they are not zero”).

NA (default) the result will be NA if there are NA’s in x (since “NA’s are not known, i.e., may be zero”).

FALSE NAs are omitted from x before the non-zero entries are counted.

For sparse matrices, you may often want to use na.counted = TRUE.

Value

the number of non zero entries in x (typically integer).

Note that for a symmetric sparse matrix S (i.e., inheriting from class symmetricMatrix), nnzero(S) is typically twice the length(S@x).

Methods

signature(x = "ANY") the default method for non- Matrix class objects, simply counts the number 0s in x, counting NA’s depending on the na.counted argument, see above.

signature(x = "denseMatrix") conceptually the same as for traditional matrix objects, care has to be taken for "symmetricMatrix" objects.

signature(x = "diagonalMatrix"), and signature(x = "indMatrix") fast simple methods for these special "sparseMatrix" classes.

signature(x = "sparseMatrix") typically, the most interesting method, also carefully taking "symmetricMatrix" objects into account.
See Also

The `Matrix` class also has a `length` method; typically, `length(M)` is much larger than `nnzero(M)` for a sparse matrix M, and the latter is a better indication of the size of M.

drop0, zapsmall.

Examples

```r
m <- Matrix(0+1:28, nrow = 4)
m[-3, c(2, 4:5, 7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))

nnzero(mT)
(S <- crossprod(mT))

nnzero(S)
str(S) # slots are smaller than nnzero()

stopifnot(nnzero(S) == sum(as.matrix(S) != 0))
# failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)

length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length

# the above are also visible from
str(M)
```

---

### norm

#### Matrix Norms

**Description**

Computes a matrix norm of x, using Lapack for dense matrices. The norm can be the one ("O", or "1") norm, the infinity ("I" or "i") norm, the Frobenius ("F" or "f") norm, the maximum modulus ("M" or "m") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of `type`.

**Usage**

```r
norm(x, type, 
```

**Arguments**

- `x` a real or complex matrix.
- `type` A character indicating the type of norm desired. "O", "o" or "1" specifies the one norm, (maximum absolute column sum); "I" or "i" specifies the infinity norm (maximum absolute row sum); "F" or "f" specifies the Frobenius norm (the Euclidean norm of x treated as if it were a vector); "M" or "m" specifies the maximum modulus of all the elements in x; and "2" specifies the “spectral norm” or 2-norm, which is the largest singular value (svd) of x.

The default is "O". Only the first character of `type[1]` is used.

... further arguments passed to or from other methods.
Details

For dense matrices, the methods eventually call the Lapack functions \texttt{dlange}, \texttt{dlansy}, \texttt{dlantr}, \texttt{zlange}, \texttt{zlansy}, and \texttt{zlantr}.

Value

A numeric value of class "norm", representing the quantity chosen according to type.

Examples

```r
x <- Hilbert(9)
norm(x)# = "O" = "1"
stopifnot(identical(norm(x), norm(x, "1")))
norm(x, "1")# the same, because 'x' is symmetric

allnorms <- function(d) vapply(c("1","1","F","M","2"),
                             norm, x = d, double(1))

allnorms(x)
allnorms(Hilbert(10))
```

```r
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
A <- sparseMatrix(i, j, x = x) ## 8 x 10 "dgCMatrix"
(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular = TRUE)) ## 10 x 10 "dtCMatrix"

(allnorms(A) -> nA)
allnorms(sA)
allnorms(tA)

stopifnot(all.equal(nA, allnorms(as(A, "matrix")))),
          all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)

A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error
```

nsparseMatrix-classes \hspace{1cm} \textit{Sparse "pattern" Matrices}

\textbf{Description}

The \texttt{nsparseMatrix} class is a virtual class of sparse "pattern" matrices, i.e., binary matrices conceptually with \texttt{TRUE}/\texttt{FALSE} entries. Only the positions of the elements that are \texttt{TRUE} are stored. These can be stored in the "triplet" form (\texttt{TsparseMatrix}, subclasses \texttt{ngTMatrix}, \texttt{nsTMatrix}, and \texttt{ntTMatrix} which really contain pairs, not triplets) or in compressed column-oriented form (class \texttt{CsparseMatrix}, subclasses \texttt{ngCMatrix}, \texttt{nsCMatrix}, and \texttt{ntCMatrix}) or--rarely--in compressed
row-oriented form (class RsparseMatrix, subclasses ngRMatrix, nsRMatrix, and ntRMatrix).
The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

**Objects from the Class**

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

**Slots**

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- `p`: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- `i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- `j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- `Dim`: Object of class "integer" - the dimensions of the matrix.

**Methods**

- `coerce` signature(from = "dgCMatrix", to = "ngCMatrix"), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.
- `t` signature(x = "ngCMatrix"): returns the transpose of x
- `which` signature(x = "lsparseMatrix"), semantically equivalent to base function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

**See Also**

the class `dgCMatrix`

**Examples**

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
## `extract the nonzero-pattern of (m) into an nMatrix'
mm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(mm) # no 'x' slot
```
nsyMatrix-class
Symmetric Dense Nonzero-Pattern Matrices

Description
The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class
Objects can be created by calls of the form new("nsyMatrix", ...).

Slots
uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends
"nsyMatrix" extends class "ngeMatrix", directly, whereas "nspMatrix" extends class "ndenseMatrix", directly.
Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use showClass("nsyMatrix"), e.g., for details.

Methods
Currently, mainly t() and coercion methods (for as(.,)); use, e.g., showMethods(class="dsyMatrix") for details.
See Also

ngeMatrix, Matrix, t

Examples

(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2,2)) # logical dense (ltr)
(sM <- M2 & t(M2))         # "lge"
class(sM <- as(sM, "nMatrix")) # -> "nge"
(sM <- as(sM, "nsyMatrix"))  # -> "nsy"
str ( sM <- as(sM, "nspMatrix")) # -> "nsp": packed symmetric

---

ntrMatrix-class Triangular Dense Logical Matrices

Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas "ntpMatrix" extends class "ndenseMatrix", directly.
Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, indirectly, use showClass("nsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.); use, e.g., showMethods(class="nsyMatrix") for details.

See Also

Classes ngeMatrix, Matrix; function t
Examples

showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(,4,4)), "ntrMatrix"))
str(nutp <- as(nutr, "ntpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!nutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(nutp, as(!nutp, "ntpMatrix")))

number-class

Class "number" of Possibly Complex Numbers

Description

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union (setClassUnion) of "numeric" and "complex".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

Examples

showClass("number")
stopifnot( is(1i, "number"), is(pi, "number"), is(1:3, "number") )

pMatrix-class

Permutation matrices

Description

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.

Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the Matrix package, see the ‘Details’ below.

Details

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix \( M \) and a permutation matrix \( P \) (where we assume matching dimensions):

\[
MP = M \%\% P = M[i(p)] \\
PM = P \%\% M = M[p,] \\
P'M = \text{crossprod}(P,M) (= t(P) \%\% M) = M[i(p),] \\
MP' = \text{tcrossprod}(M,P) (= M \%\% t(P)) = M[, p] 
\]
where \( p \) is the “permutation vector” corresponding to the permutation matrix \( P \) (see first note), and \( i(p) \) is short for \( \text{invPerm}(p) \).

Also one could argue that these are really only two cases if you take into account that inversion (\text{solve}) and transposition (\text{t}) are the same for permutation matrices \( P \).

**Objects from the Class**

Objects can be created by calls of the form \texttt{new("pMatrix", \ldots)} or by coercion from an integer permutation vector, see below.

**Slots**

- \texttt{perm}: An integer, 1-based permutation vector, i.e. an integer vector of length \texttt{Dim[1]} whose elements form a permutation of \texttt{1:Dim[1]}.
- \texttt{Dim}: Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.
- \texttt{Dimnames}: list of length two; each component containing NULL or a character vector length equal the corresponding \texttt{Dim} element.

**Extends**

Class "\texttt{indMatrix}", directly.

**Methods**

\[
\begin{align*}
\%*\% & \quad \text{signature}(x = "\text{matrix}", y = "\text{pMatrix}") \quad \text{and other signatures (use showMethods("\%*\%, class="pMatrix"):\ldots)} \\
\text{coerce} & \quad \text{signature(from = "integer", to = "pMatrix")}: \text{This is enables typical "pMatrix" construction, given a permutation vector of 1:n, see the first example.} \\
\text{coerce} & \quad \text{signature(from = "numeric", to = "pMatrix")}: \text{a user convenience, to allow as(perm, "pMatrix") for numeric perm with integer values.} \\
\text{coerce} & \quad \text{signature(from = "pMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE matrix of mode logical. (in earlier version of Matrix, it resulted in a 0/1-integer matrix; logical makes slightly more sense, corresponding better to the “natural” sparseMatrix counterpart, "ngTMatrix".)} \\
\text{coerce} & \quad \text{signature(from = "pMatrix", to = "ngTMatrix")}: \text{coercion to sparse logical matrix of class ngTMatrix.} \\
\text{determinant} & \quad \text{signature(x = "pMatrix", logarithm="logical")}: \text{Since permutation matrices are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the sign of the permutation.} \\
\text{solve} & \quad \text{signature(a = "pMatrix", b = "missing")}: \text{return the inverse permutation matrix; note that solve(P) is identical to t(P) for permutation matrices. See solve-methods for other methods.} \\
\text{t} & \quad \text{signature(x = "pMatrix")}: \text{return the transpose of the permutation matrix (which is also the inverse of the permutation matrix).}
\end{align*}
\]
Note

For every permutation matrix \( P \), there is a corresponding permutation vector \( p \) (of indices, 1:n), and these are related by

\[
P \leftarrow \text{as}(p, \text{"pMatrix"})
p \leftarrow P@perm
\]

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an "indMatrix". See "indMatrix" for all other subsetting/indexing and subassignment (\( A[.\] \leftarrow v \)) operations.

See Also

\( \text{invPerm}(p) \) computes the inverse permutation of an integer (index) vector \( p \).

Examples

\[
(pm1 \leftarrow \text{as}(\text{as.integer(c(2,3,1)), \"pMatrix\"}))
\]
\[
t(pm1) \quad \# \text{is the same as}
\]
\[
solve(pm1)
\]
\[
\text{pm1} \ %*% \ t(pm1) \quad \# \text{check that the transpose is the inverse}
\]
\[
\text{stopifnot}(\text{all(diag(3) == as(pm1 \ %*% \ t(pm1), \"matrix\")),}
\]
\[
\quad \quad \text{is.logical(as(pm1, \"matrix\")))}
\]

set.seed(11)

## random permutation matrix :

\[
(p10 \leftarrow \text{as}(\text{sample(10),\"pMatrix\"}))
\]

## Permute rows / columns of a numeric matrix :

\[
(mm \leftarrow \text{round}(\text{array(rnorm(3 * 3), c(3, 3)), 2}))
\]
\[
\text{mm} \ %*% \ pm1
\]
\[
\text{try(as(\text{as.integer(c(3,3,1)), \"pMatrix\")))\# Error: not a permutation}
\]
\[
\text{as(pm1, \"ngTMatrix\")}
\]
\[
p10[1:7, 1:4] \quad \# \text{gives an \"ngTMatrix\" (most economic!)}
\]

## row-indexing of a \(<pMatrix>\) keeps it as an \<indMatrix>:

\[
p10[1:3,]
\]

printSpMatrix

Format and Print Sparse Matrices Flexibly

Description

Format and print sparse matrices flexibly. These are the “workhorses” used by the \text{format}, \text{show} and \text{print} methods for sparse matrices. If \( x \) is large, \text{printSpMatrix2}(x) calls \text{printSpMatrix()} twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when \( x \) is too wide.

\text{printSpMatrix()} basically prints the result of \text{formatSpMatrix()}. 

printSpMatrix
printSpMatrix

Usage

formatSpMatrix(x, digits = NULL, maxp = 1e9,
cld = getClassDef(class(x)), zero.print = ".",
col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
align = c("fancy", "right"))

printSpMatrix(x, digits = NULL, maxp = max(100L,getOption("max.print")),
cld = getClassDef(class(x)),
zero.print = ".", col.names, note.dropping.colnames = TRUE,
uniDiag = TRUE, col.trailer = "",
align = c("fancy", "right"))

printSpMatrix2(x, digits = NULL, maxp = max(100L,getOption("max.print")),
zero.print = ".", col.names, note.dropping.colnames = TRUE,
uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
col.trailer = if(suppCols) "......" else "",
align = c("fancy", "right"),
width =getOption("width"), fitWidth = TRUE)

Arguments

x an R object inheriting from class sparseMatrix.
digits significant digits to use for printing, see print.default, the default, NULL, corresponds to using getOption("digits").
maxp integer, default from options(max.print), influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently "rounded up" to 100.
cld the class definition of x; must be equivalent to getClassDef(class(x)) and exists mainly for possible speedup.
zero.print character which should be printed for structural zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like print()ing of non-sparse matrices.
col.names logical or string specifying if and how column names of x should be printed, possibly abbreviated. The default is taken from options("sparse.colnames") if that is set, otherwise FALSE unless there are less than ten columns. When TRUE the full column names are printed. When col.names is a string beginning with "abb" or "sub" and ending with an integer n (i.e., of the form "abb...<n>"), the column names are abbreviate()ed or substring()ed to (target) length n, see the examples.
note.dropping.colnames logical specifying, when col.names is FALSE if the dropping of the column names should be noted, TRUE by default.
uniDiag logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1’s are "structural").
col.trailer a string to be appended to the right of each column; this is typically made use of by show(<sparseMatrix>) only, when suppressing columns.
suppRows, suppCols logicals or NULL, for printSpMatrix2() specifying if rows or columns should be suppressed in printing. If NULL, sensible defaults are determined from dim(x)
and `options(c("width", "max.print"))`. Setting both to FALSE may be a very bad idea.

align

a string specifying how the zero.print codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical zero.print = ",," with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas align = "right" just makes use of `print(*, right = TRUE)`.

width

number, a positive integer, indicating the approximately desired (line) width of the output, see also `fitWidth`.

fitWidth

logical indicating if some effort should be made to match the desired width or temporarily enlarge that if deemed necessary.

Details

`formatSpMatrix`: If x is large, only the first rows making up the approximately first maxp entries is used, otherwise all of x. `.formatSparseSimple()` is applied to (a dense version of) the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without x slot.

Value

`formatSpMatrix()`

returns a character matrix with possibly empty column names, depending on col.names etc, see above.

`printSpMatrix*()`

return x invisibly, see `invisible`.

Author(s)

Martin Maechler

See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

Examples

```r
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X # shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12],"c",sep=".")),
    "sparseMatrix")
X2

# less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

# Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = ",", col.names="abbr. 1")
```
Description

The Matrix package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses qr as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

Usage

```r
qr(x, ...) 
qrR(qr, complete=FALSE, backPermute=TRUE, row.names = TRUE)
```

Arguments

- `x` a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
- `qr` a QR decomposition of the type computed by qr.
- `complete` logical indicating whether the \( R \) matrix is to be completed by binding zero-value rows beneath the square upper triangle.
- `backPermute` logical indicating if the rows of the \( R \) matrix should be back permuted such that `qrR()`’s result can be used directly to reconstruct the original matrix \( X \).
- `row.names` logical indicating if `rownames` should propagated to the result.
- `...` further arguments passed to or from other methods

Methods

- `x = "dgCMatrix"` QR decomposition of a general sparse double-precision matrix with `nrow(x) >= ncol(x)`. Returns an object of class "sparseQR".
- `x = "sparseMatrix"` works via "dgCMatrix".

See Also

`qr`; then, the class documentations, mainly `sparseQR`, and also `dgCMatrix`.

Examples

```r
#------------- example of pivoting -- from base' qraux.Rd --------------
X <- cbind(int = 1, 
  b1=rep(1:0, each=3), b2=rep(0:1, each=3), 
  c1=rep(c(1,0,0), 2), c2=rep(c(0,1,0), 2), c3=rep(c(0,0,1),2))
rownames(X) <- paste0(" r", seq_len(nrow(X)))
dnX <- dimnames(X)
bX <- X # [b]ase version of X 
X <- as(bX, "sparseMatrix")
```
X # is singular, columns "b2" and "c3" are "extra"

## FIXME: do these make *any* sense? --- should give warnings !
qr.coef(qX, y)
qr.coef(qX, Y)
rm(m)
Description

Compute ‘the’ matrix rank, a well-defined functional in theory(*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(*) The rank of a \( n \times m \) matrix \( A, \text{rk}(A) \), is the maximal number of linearly independent columns (or rows); hence \( \text{rk}(A) \leq \min(n,m) \).

Usage

```r
rankMatrix(x, tol = NULL, 
method = c("tolNorm2", "qr.R", "qrLINPACK", "qr", 
"useGrad", "maybeGrad"), 
sval = svd(x, 0, 0)$d, warn.t = TRUE, warn.qr = TRUE)
qr2rankMatrix(qr, tol = NULL, isBqr = is.qr(qr), do.warn = TRUE)
```

Arguments

- **x**: numeric matrix, of dimension \( n \times m \), say.
- **tol**: nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, \( \max(\text{dim}(x)) \times \text{Machine}\$\text{double. eps} \) is according to Matlab’s default (for its only method which is our method="tolNorm2").
- **method**: a character string specifying the computational method for the rank, can be abbreviated:
  - "tolNorm2": the number of singular values \( \geq \text{tol} \times \max(\text{sval}) \);
  - "qrLINPACK": for a dense matrix, this is the rank of \( \text{qr}(x, \text{tol}, \text{LAPACK}=\text{FALSE}) \) (which is \( \text{qr}(\ldots)\text{rank} \));
    This ("qr ordinates") version used to be the recommended way to compute a matrix rank for a while in the past.
    For sparse \( x \), this is equivalent to "qr . R".
  - "qr . R": this is the rank of triangular matrix \( R \), where \( \text{qr()} \) uses LAPACK or a "sparseQR" method (see \text{qr-methods} to compute the decomposition \( QR \)).
    The rank of \( R \) is then defined as the number of “non-zero” diagonal entries \( d_i \) of \( R \), and “non-zero”’s fulfill \( |d_i| \geq \text{tol} \cdot \max(|d_i|) \).
  - "qr": is for back compatibility; for dense \( x \), it corresponds to "qrLINPACK", whereas for sparse \( x \), it uses "qr . R".
    For all the "qr ordinates" methods, singular values \text{sval} are not used, which may be crucially important for a large sparse matrix \( x \), as in that case, when \text{sval} is not specified, the default, computing \text{svd()} currently coerces \( x \) to a dense matrix.
  - "useGrad": considering the “gradient” of the (decreasing) singular values, the index of the smallest gap.
  - "maybeGrad": choosing method "useGrad" only when that seems reasonable; otherwise using "tolNorm2".
sval
numeric vector of non-increasing singular values of x; typically unspecified and computed from x when needed, i.e., unless method = "qr".

warn.t
logical indicating if rankMatrix() should warn when it needs t(x) instead of x. Currently, for method = "qr" only, gives a warning by default because the caller often could have passed t(x) directly, more efficiently.

warn.qr
in the QR cases (i.e., if method starts with "qr"), rankMatrix() calls qr2rankMatrix(..., do.warn = warn.qr), see below.

qr
an R object resulting from qr(x,...), i.e., typically inheriting from class "qr" or "sparseQR".

isBqr
logical indicating if qr is resulting from base qr(). (Otherwise, it is typically from Matrix package sparse qr.)

do.warn
logical; if true, warn about non-finite (or in the sparseQR case negative) diagonal entries in the R matrix of the QR decomposition. Do not change lightly!

Details
qr2rankMatrix() is typically called from rankMatrix() for the "qr"* methods, but can be used directly - much more efficiently in case the qr-decomposition is available anyway.

Value
If x is a matrix of all 0 (or of zero dimension), the rank is zero; otherwise, typically a positive integer in 1:min(dim(x)) with attributes detailing the method used.

There are rare cases where the sparse QR decomposition “fails” in so far as the diagonal entries of R, the d_i (see above), end with non-finite, typically NaN entries. Then, a warning is signalled (unless warn.qr / do.warn is not true) and NA (specifically, NA_integer_) is returned.

Note
For large sparse matrices x, unless you can specify sval yourself, currently method = "qr" may be the only feasible one, as the others need sval and call svd() which currently coerces x to a denseMatrix which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse x, method = "qr", all non-strictly zero diagonal entries d_i where counted, up to including Matrix version 1.1-0, i.e., that method implicitly used tol = 0, see also the set.seed(42) example below.

rankMatrix(cbind(1, 0, 1:3)) # 2

(meths <- eval(formals(rankMatrix)$method))

## a "border" case:
H12 <- Hilbert(12)
rcond

Estimate the Reciprocal Condition Number

Description

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by `showMethods(rcond)`.
Usage

rcond(x, norm, ...)

## S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)

Arguments

x an R object that inherits from the Matrix class.
norm character string indicating the type of norm to be used in the estimate. The default is "O" for the 1-norm ("O" is equivalent to "1"). For sparse matrices, when useInv=TRUE, norm can be any of the kinds allowed for norm; otherwise, the other possible value is "I" for the infinity norm, see also norm.
useInv logical (or "Matrix" containing solve(x)). If not false, compute the reciprocal condition number as 1/(∥x∥·∥x⁻¹∥), where x⁻¹ is the inverse of x, solve(x). This may be an efficient alternative (only) in situations where solve(x) is fast (or known), e.g., for (very) sparse or triangular matrices. Note that the result may differ depending on useInv, as per default, when it is false, an approximation is computed.

... further arguments passed to or from other methods.

Value

An estimate of the reciprocal condition number of x.

BACKGROUND

The condition number of a regular (square) matrix is the product of the norm of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices A) as

\[ \kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|} \]

Whenever x is not a square matrix, in our method definitions, this is typically computed via rcond(qr.R(qr(X)), ...) where X is x or t(x).

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

rcond() computes the reciprocal condition number 1/κ with values in [0, 1] and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka "singular").

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

References

See Also

norm, kappa() from package base computes an approximate condition number of a “traditional” matrix, even non-square ones, with respect to the \( p = 2 \) (Euclidean) norm. solve.

condest, a newer approximate estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

Examples

```r
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9))  # should be about 9.1e-13

## For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))## practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1, 0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
alld.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example ----------
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M))  # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,m)))
dim(M3 <- kronecker(bdiag(M,M),MM))  # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
  system.time(r <- rcond(M3))

## whereas this is *fast* even though it computes solve(M3)
if(interactive()) ## the values are not the same
  system.time(r. <- rcond(M3, useInv=TRUE))
  c(r, r.) # 0.05555 0.013888

## for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
  function(N) rcond(M3, norm=N, useInv=TRUE)))
```

rep2abI

Replicate Vectors into `abIndex` Result

Description

rep2abI(x, times) conceptually computes rep.int(x, times) but with an abIndex class result.

Usage

rep2abI(x, times)
replValue-class

Arguments

x numeric vector
times integer (valued) scalar: the number of repetitions

Value

a vector of class abIndex

See Also

rep.int(), the base function; abIseq, abIndex.

Examples

(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
rep(2:7, 4)))

replValue-class Virtual Class "replValue" - Simple Class for subassignment Values

Description

The class "replValue" is a virtual class used for values in signatures for sub-assignment of Matrix matrices.

In fact, it is a simple class union (setClassUnion) of "numeric" and "logical" (and maybe "complex" in the future).

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

Subassign-methods, also for examples.

Examples

showClass("replValue")
rleDiff-class

Class "rleDiff" of rle(diff(.)) Stored Vectors

Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of linear stretches. For such a vector \( x \), \( \text{diff}(x) \) consists of constant stretches and is hence well compressible via \( \text{rle}() \).

Objects from the Class

Objects can be created by calls of the form \texttt{new("rleDiff", ...)}.
Currently experimental, see below.

Slots

- \texttt{first}: A single number (of class "numLike", a class union of "numeric" and "logical").
- \texttt{rle}: Object of class "rle", basically a \texttt{list} with components "lengths" and "values", see \texttt{rle()}. As this is used to encode potentially huge index vectors, \texttt{lengths} may be of type \texttt{double} here.

Methods

There is a simple \texttt{show} method only.

Note

This is currently an experimental auxiliary class for the class \texttt{abIndex}, see there.

See Also

\texttt{rle}, \texttt{abIndex}.

Examples

\begin{verbatim}
showClass("rleDiff")

ab <- c(abIseq(2, 100), abIseq(20, -2))
ab@rleD  # is "rleDiff"
\end{verbatim}

rsparsematrix

Random Sparse Matrix

Description

Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and \texttt{rand.x = NULL} generates random pattern matrices, i.e. inheriting from \texttt{nsparseMatrix}.
Usage

rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
             symmetric = FALSE,
             rand.x = function(n) signif(rnorm(n), 2), ...)

Arguments

nrow, ncol  number of rows and columns, i.e., the matrix dimension (dim).
density  optional number in [0, 1], the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for nnz, otherwise nnz needs to be specified.

nnz  number of non-zero entries, for a sparse matrix typically considerably smaller than nrow*ncol. Must be specified if density is not.
symmetric  logical indicating if result should be a matrix of class symmetricMatrix. Note that in the symmetric case, nnz denotes the number of non-zero entries of the upper (or lower) part of the matrix, including the diagonal.

rand.x  NULL or the random number generator for the x slot, a function such that rand.x(n) generates a numeric vector of length n. Typical examples are rand.x = rnorm, or rand.x = runif; the default is nice for didactical purposes.

...  optionally further arguments passed to sparseMatrix(), notably repr.

Details

The algorithm first samples "encoded" \((i, j)\)s without replacement, via one dimensional indices, if not symmetric sample.int(nrow*ncol, nnz), then—if rand.x is not NULL—gets \(x \leftarrow \text{rand.x}(\text{nnz})\) and calls \text{sparseMatrix}(i=j, j=j, x=x, ...). When rand.x=\text{NULL}, \text{sparseMatrix}(i=i, j=j, ...) will return a pattern matrix (i.e., inheriting from \text{nsparseMatrix}).

Value

a \text{sparseMatrix}, say \(M\) of dimension (nrow, ncol), i.e., with \text{dim}(M) == c(nrow, ncol), if symmetric is not true, with \(\text{nzM} \leftarrow \text{nnzero}(M)\) fulfilling \(\text{nzM} \leq \text{nnz}\) and typically, \(\text{nzM} = \text{nnz}\).

Author(s)

Martin Maechler

Examples

set.seed(17)# to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

## a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9)# ~ 20: as 'nnz' only counts one "triangle"

## a random pattern*n* aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

## a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, repr = "T")
head(T2)

RsparseMatrix-class  
Class "RsparseMatrix" of Sparse Matrices in Row-compressed Form

Description

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("RsparseMatrix") for its subclasses.

Slots

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
P: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
Dim, Dimnames: inherited from the superclass, see sparseMatrix.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Originally, few methods were defined on purpose, as we rather use the CsparseMatrix in Matrix. Then, more methods were added but beware that these typically do not return "RsparseMatrix" results, but rather Csparse* or Tsparse* ones; e.g., R[i, j] <- v for an "RsparseMatrix" R works, but after the assignment, R is a (triplet) "TsparseMatrix".

t signature(x = "RsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"): ...

See Also

its superclass, sparseMatrix, and, e.g., class dgRMatrix for the links to other classes.

Examples

showClass("RsparseMatrix")
Schur Decomposition of a Matrix

Description

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

Usage

Schur(x, vectors, ...)

Arguments

x numeric square Matrix ( inheriting from class "Matrix") or traditional matrix. Missing values (NAs) are not allowed.

vectors logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper MatrixFactorization of class Schur.

... further arguments passed to or from other methods.

Details

Based on the Lapack subroutine dgees.

Value

If vectors are TRUE, as per default: If x is a Matrix an object of class Schur, otherwise, for a traditional matrix x, a list with components T, Q, and EValues.

If vectors are FALSE, a list with components

T the upper quasi-triangular (square) matrix of the Schur decomposition.

EValues the vector of numeric or complex eigen values of T or A.

BACKGROUND

If A is a square matrix, then A = Q T t(Q), where Q is orthogonal, and T is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of A are the same as those of T, which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

References

Schur-class

Examples

```r
Schur(Hilbert(9)) # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE)) # no 'T' => simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
          all.equal(eTA$values,
                     local({z <- Sch.A@EValues
                             z[order(Mod(z), decreasing=TRUE)]}), tolerance = 1e-13),
          identical(SchA$T, Sch.A@T),
          identical(SchA$EValues, Sch.A@EValues))
```

## For the faint of heart, we provide Schur() also for traditional matrices:

```r
a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
                               T = a.m(Sch.A @ T),
                               EValues = Sch.A@EValues)),
          all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))
```

---

Schur-class

Class "Schur" of Schur Matrix Factorizations

Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or "spectral") decompositions for general (possibly asymmetric) square matrices, see the `Schur()` function.

Objects from the Class

Objects of class "Schur" are typically created by `Schur()`.

Slots

"Schur" has slots

T: Upper Block-triangular `Matrix` object.
Q: Square `orthogonal"Matrix"`.
EValues: numeric or complex vector of eigenvalues of T.
Dim: the matrix dimension: equal to c(n,n) of class "integer".

Extends

Class "MatrixFactorization", directly.
solve-methods

See Also

Schur() for object creation; MatrixFactorization.

Examples

showClass("Schur")
Schur(M <- Matrix(c(1:7, 10:2), 4,4))
## Trivial, of course:
str(Schur(Diagonal(5)))
## for more examples, see Schur()

Solve-methods

Methods in Package Matrix for Function solve()

Description

Methods for function solve to solve a linear system of equations, or equivalently, solve for \( X \) in

\[
AX = B
\]

where \( A \) is a square matrix, and \( X, B \) are matrices or vectors (which are treated as 1-column matrices), and the R syntax is

\[
X <- \text{solve}(A,B)
\]

In \text{solve}(a,b) in the Matrix package, \( a \) may also be a MatrixFactorization instead of directly a matrix.

Usage

## S4 method for signature 'CHMfactor,ddenseMatrix'
solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

## S4 method for signature 'dgCMatrix,missing'
solve(a, b, sparse = NA , tol = .Machine$double.eps, ...)

## S4 method for signature 'dgCMatrix,matrix'
solve(a, b, sparse = FALSE, tol = .Machine$double.eps, ...)

solve(a, b, ...) ## *the* two-argument version, almost always preferred to
# solve(a)  ## *the* rarely* needed one-argument version

Arguments

a

a square numeric matrix, \( A \), typically of one of the classes in Matrix. Logical matrices are coerced to corresponding numeric ones.

b

numeric vector or matrix (dense or sparse) as RHS of the linear system \( Ax = b \).
solving methods

system only if \( a \) is a \texttt{CHMfactor}: character string indicating the kind of linear system to be solved, see below. Note that the default, \( "A" \), does \textit{not} solve the triangular system (but \( "L" \) does).

sparse only when \( a \) is a \texttt{sparseMatrix}, i.e., typically a \texttt{dgCMatrix}: logical specifying if the result should be a (formally) sparse matrix.

tol only used when \( a \) is sparse, in the \texttt{isSymmetric}(a, tol=*) test, where that applies.

... potentially further arguments to the methods.

Methods

signature(a = "ANY", b = "ANY") is simply the \texttt{base} package’s S3 generic \texttt{solve}.

signature(a = "CHMfactor", b = "....."), \texttt{system=} * The solve methods for a \texttt{CHMfactor} object take an optional third argument \texttt{system} whose value can be one of the character strings \( "A" \), \( "LDLt" \), \( "LD" \), \( "Lt" \), \( "D" \), \( "P" \) or \( "Pt" \). This argument describes the system to be solved. The default, \( "A" \), is to solve \( Ax = b \) for \( x \) where \( A \) is sparse, positive-definite matrix that was factored to produce \( a \). Analogously, \texttt{system = "L"} returns the solution \( x \), of \( Lx = b \); similarly, for all system codes \texttt{but} \( "P" \) and \( "Pt" \) where, e.g., \( x <- \text{solve}(a, b, \text{system}="P") \) is equivalent to \( x <- P \%*% b \).

If \( b \) is a \texttt{sparseMatrix}, system is used as above the corresponding sparse CHOLMOD algorithm is called.

signature(a = "ddenseMatrix", b = ".....") (for all \( b \)) work via \texttt{as(a, "dgeMatrix")}, using the its methods, see below.

signature(a = "denseLU", b = "missing") basically computes uses triangular forward- and back-solve.

signature(a = "dgCMatrix", b = "matrix") , and

signature(a = "dgCMatrix", b = "ddenseMatrix") with extra argument list (\texttt{sparse = FALSE}, \texttt{tol = .Machine$double.eps}): Uses the sparse \texttt{lu(a)} decomposition (which is cached in \( a \)’s factor slot). By default, \texttt{sparse=FALSE}, returns a \texttt{denseMatrix}, since \( U^{-1}L^{-1}B \) may not be sparse at all, even when \( L \) and \( U \) are.

If \texttt{sparse=TRUE}, returns a \texttt{sparseMatrix} (which may not be very sparse at all, even if \( a \) was sparse).

signature(a = "dgCMatrix", b = "dsparseMatrix") , and

signature(a = "dgCMatrix", b = "missing") with extra argument list (\texttt{sparse=FALSE}, \texttt{tol = .Machine$double.eps}): Checks if \( a \) is symmetric, and in that case, coerces it to \texttt{"symmetricMatrix"}, and then computes a \texttt{sparse} solution via sparse Cholesky factorization, independently of the \texttt{sparse} argument. If \( a \) is not symmetric, the sparse \texttt{lu} decomposition is used and the result will be sparse or dense, depending on the \texttt{sparse} argument, exactly as for the above (\texttt{b = "ddenseMatrix"}) case.

signature(a = "dgeMatrix", b = ".....") solve the system via internal LU, calling LAPACK routines \texttt{dgetri} or \texttt{dgetrs}.

signature(a = "diagonalMatrix", b = "matrix") and other bs: Of course this is trivially implemented, as \( D^{-1} \) is diagonal with entries \( 1/D[i, i] \).

signature(a = "dpoMatrix", b = ".....Matrix") , and

signature(a = "dppMatrix", b = ".....Matrix") The Cholesky decomposition of \( a \) is calculated (if needed) while solving the system.

signature(a = "dsCMatrix", b = ".....") All these methods first try Cholmod’s Cholesky factorization; if that works, i.e., typically if \( a \) is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the “general” matrices of class \texttt{"dgCMatrix"}. 

...
signature(a = "dspMatrix", b = "...") and
signature(a = "dysMatrix", b = "...") all end up calling LAPACK routines dsptri, dsptrs, dsytrs and dsytri.
signature(a = "dtCMatrix", b = "CsparseMatrix")
signature(a = "dtCMatrix", b = "dgeMatrix") etc sparse triangular solve, in traditional S/R
also known as backsolve, or forwardsolve. solve(a,b) is a sparseMatrix if b is, and
hence a denseMatrix otherwise.
signature(a = "dtrMatrix", b = "ddenseMatrix") and
signature(a = "dtpMatrix", b = "matrix") and similar b, including "missing", and
"diagonalMatrix":
all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.
signature(a = "Matrix", b = "diagonalMatrix") works via as(b, "CsparseMatrix").
signature(a = "sparseQR", b = "ANY") simply uses qr.coef(a, b).
signature(a = "pMatrix", b = "...") these methods typically use crossprod(a,b), as the
inverse of a permutation matrix is the same as its transpose.
signature(a = "TsparseMatrix", b = "ANY") all work via as(a, "CsparseMatrix").

Examples

## A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %x% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(i0 <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [ TODO: assertError ]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$arch == "x86_64")
  ## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
  stopifnot(all.equal(as.matrix(i0), as.matrix(i0)))
a <- a + Diagonal(n)
iaad <- solve(a)
iaas <- solve(a, sparse=TRUE)
stopifnot(all.equal(as(ias, "denseMatrix"), iad, tolerance=1e-14))
I. <- iad %x% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %x% iad
.I0 <- drop0(zapsmall(.I))
stopifnot( all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)) )
Construct Sparse Design / Model Matrices

Description

Construct a sparse model or "design" matrix, from a formula and data frame (\texttt{sparse.model.matrix}) or a single factor (\texttt{fac2sparse}).

The \texttt{fac2[Ss]parse()} functions are utilities, also used internally in the principal user level function \texttt{sparse.model.matrix()}. 

Usage

\texttt{sparse.model.matrix(object, data = environment(object),}
  \texttt{contrasts.arg = NULL, xlev = NULL, transpose = FALSE,}
  drop.unused.levels = FALSE, row.names = TRUE,}
  \texttt{sep = "", verbose = FALSE, ...) 

\texttt{fac2sparse(from, to = c("d", "i", "l", "n", "z"),}
  \texttt{drop.unused.levels = TRUE, repr = c("C","T","R"),}
  \texttt{giveCsparse})

\texttt{fac2Sparse(from, to = c("d", "i", "l", "n", "z"),}
  \texttt{drop.unused.levels = TRUE, repr = c("C","T","R"),}
  \texttt{giveCsparse, factorPatt12, contrasts.arg = NULL)}

Arguments

\texttt{object} an object of an appropriate class. For the default method, a model formula or terms object.

\texttt{data} a data frame created with \texttt{model.frame}. If another sort of object, \texttt{model.frame} is called first.

\texttt{contrasts.arg} for \texttt{sparse.model.matrix():} A list, whose entries are contrasts suitable for input to the \texttt{contrasts} replacement function and whose names are the names of columns of data containing factors.

for \texttt{fac2Sparse():} character string or \texttt{NULL} or (coercable to) "\texttt{sparseMatrix}" specifying the contrasts to be applied to the factor levels.

\texttt{xlev} to be used as argument of \texttt{model.frame} if data has no "terms" attribute.

\texttt{transpose} logical indicating if the \texttt{transpose} should be returned; if the transposed is used anyway, setting \texttt{transpose = TRUE} is more efficient.

\texttt{drop.unused.levels} should factors have unused levels dropped? The default for \texttt{sparse.model.matrix} has been changed to \texttt{FALSE}, 2010-07, for compatibility with R's standard (dense) \texttt{model.matrix}.

\texttt{row.names} logical indicating if row names should be used.

\texttt{sep} character string passed to \texttt{paste()} when constructing column names from the variable name and its levels.

\texttt{verbose} logical or integer indicating if (and how much) progress output should be printed.

... further arguments passed to or from other methods.
sparse.model.matrix

from (for fac2sparse():) a factor.

to a character indicating the “kind” of sparse matrix to be returned. The default, "d" is for double.

giveCSparse deprecated, replaced with repr; logical indicating if the result must be a CsparseMatrix.

repr character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes CsparseMatrix, TsparseMatrix, or RsparseMatrix.

factorPatt12 logical vector, say fp, of length two; when fp[1] is true, return “contrasted” t(X); when fp[2] is true, the original (“dummy”) t(X), i.e, the result of fac2sparse().

Value

a sparse matrix, extending CsparseMatrix (for fac2sparse() if repr = "C" as per default; a TsparseMatrix or RsparseMatrix, otherwise).

For fac2Sparse(), a list of length two, both components with the corresponding transposed model matrix, where the corresponding factorPatt12 is true.

Note that model.Matrix(*, sparse=TRUE) from package MatrixModels may be often be preferable to sparse.model.matrix() nowadays, as model.Matrix() returns modelMatrix objects with additional slots assign and contrasts which relate back to the variables used.

fac2sparse(), the basic workhorse of sparse.model.matrix(), returns the transpose (t) of the model matrix.

Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

See Also

model.matrix in standard R’s package stats.

model.Matrix which calls sparse.model.matrix or model.matrix depending on its sparse argument may be preferred to sparse.model.matrix.

as(f, "sparseMatrix") (see coerce(from = "factor”, ..) in the class doc sparseMatrix) produces the transposed sparse model matrix for a single factor f (and no contrasts).

Examples

dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
    Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
    all(sparse.model.matrix(~ 0+ a + b, dd) ==
    Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))
sparseLU-class

Sparse LU decomposition of a square sparse matrix

Description

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

Objects from the Class

Objects can be created by calls of the form new("sparseLU", ...) but are more commonly created by function lu() applied to a sparse matrix, such as a matrix of class dgCMatrix.

Slots

L: Object of class "dtCMatrix", the lower triangular factor from the left.
U: Object of class "dtCMatrix", the upper triangular factor from the right.
p: Object of class "integer", permutation applied from the left.
q: Object of class "integer", permutation applied from the right.
Dim: the dimension of the original matrix; inherited from class MatrixFactorization.

Extends

Class "LU", directly. Class "MatrixFactorization", by class "LU".

Methods

expand signature(x = "sparseLU") Returns a list with components P, L, U, and Q, where P and Q represent fill-reducing permutations, and L, and U the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product $P'LUQ$. 
Note

The decomposition is of the form

\[ A = P'LUQ, \]

or equivalently \( PAQ' = LU \), where all matrices are sparse and of size \( n \times n \). The matrices \( P \) and \( Q \), and their transposes \( P' \) and \( Q' \) are permutation matrices, \( L \) is lower triangular and \( U \) is upper triangular.

lu, solve, dgCMatrix

Examples

```r
## Extending the one in examples(lu), calling the matrix A, 
## and confirming the factorization identities :
A <- as(readMM(system.file("external/pores_1.mtx", 
                          package = "Matrix")),
        "CsparseMatrix")
## with dimnames(.) - to see that they propagate to L, U :
dimnames(A) <- dnA <- list(paste0("r", seq_len(nrow(A))),
                           paste0("C", seq_len(ncol(A))))
str(luA <- lu(A)) # p is a 0-based permutation of the rows
# q is a 0-based permutation of the columns
xA <- expand(luA)
## which is simply doing
stopifnot(identical(xA$L, luA$L),
          identical(xA$U, luA$U),
          identical(xA$P, as(luA$p +1L, "pMatrix")),
          identical(xA$Q, as(luA$q +1L, "pMatrix")))

P.LUQ <- with(xA, t(P) %*% L %*% U %*% Q)
stopifnot(all.equal(A, P.LUQ, tolerance = 1e-12),
          identical(dimnames(P.LUQ), dnA))
## permute rows and columns of original matrix
pA <- A[luA$p + 1L, luA$q + 1L]
stopifnot(identical(pA, with(xA, P %*% A %*% t(Q))))

pLU <- drop0(luA$L %*% luA$U) # L %*% U -- dropping extra zeros
stopifnot(all.equal(pA, pLU, tolerance = 1e-12))
```

describe sparseMatrix

General Sparse Matrix Construction from Nonzero Entries

description
User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from class CsparseMatrix (or TsparseMatrix if giveCsparses is false), from locations (and values) of its non-zero entries.

This is the recommended user interface rather than direct new("***Matrix", ....) calls.

Usage
sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
  symmetric = FALSE, triangular = FALSE, index1 = TRUE,
  repr = "C", giveCsparses = (repr == "C"),
  check = TRUE, use.last.ij = FALSE)

Arguments
i, j integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix. Note that for repeated pairs (i_k, j_k), when x is not missing, the corresponding x_k are added, in consistency with the definition of the "TsparseMatrix" class, unless use.last.ij is true, in which case only the last of the corresponding (i_k, j_k, x_k) triplet is used.

p numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of i, j or p must be missing.
_sparseMatrix_ consists of optional values of the matrix entries. If specified, must be of the same length as `i` or `j`, or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class `nsparseMatrix`.

- **dims**: optional, non-negative, integer, dimensions vector of length 2. Defaults to `c(max(i), max(j))`.
- **dimnames**: optional list of `dimnames`; if not specified, none, i.e., `NULL` ones, are used.
- **symmetric**: logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via `(i/j/p)`.
- **triangular**: logical indicating if the resulting matrix should be triangular. In that case, the lower or upper triangle needs to be specified via `(i/j/p)`.
- **index1**: logical scalar. If TRUE, the default, the index vectors `i` and/or `j` are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If FALSE, the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.
- **repr**: character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes `CsparseMatrix`, `TsparseMatrix`, or `RsparseMatrix`.
- **giveCsparse**: (deprecated, replaced with `repr`): logical indicating if the result should be a `CsparseMatrix` or a `TsparseMatrix`, where the default was TRUE, and now is determined from `repr`; very often C sparse matrices are more efficient subsequently, but not always.
- **check**: logical indicating if a validity check is performed; do not set to FALSE unless you know what you’re doing!
- **use.last.ij**: logical indicating if in the case of repeated, i.e., duplicated pairs `(i_k,j_k)` only the last one should be used. The default, FALSE, corresponds to the "TsparseMatrix" definition.

**Details**

Exactly one of the arguments `i`, `j` and `p` must be missing.

In typical usage, `p` is missing, `i` and `j` are vectors of positive integers and `x` is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If `i` or `j` is missing then `p` must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of `p`, `rep(seq_along(dp), dp)` where `dp <- diff(p)`, is used as the (1-based) row or column indices.

You cannot set both `singular` and `triangular` to true; rather use `Diagonal()` (or its alternatives, see there).

The values of `i`, `j`, `p` and `index1` are used to create 1-based index vectors `i` and `j` from which a `TsparseMatrix` is constructed, with numerical values given by `x`, if non-missing. Note that in that case, when some pairs `(i_k,j_k)` are repeated (aka “duplicated”), the corresponding `x_k` are added, in consistency with the definition of the "TsparseMatrix" class, unless `use.last.ij` is set to true.

By default, when `repr = "C"`, the `CsparseMatrix` derived from this triplet form is returned, where `repr = "R"` now allows to directly get an `RsparseMatrix` and `repr = "T"` leaves the result as `TsparseMatrix`.

The reason for returning a `CsparseMatrix` object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in `x` then a `CsparseMatrix` is a unique representation of the sparse matrix.
sparseMatrix

Value

A sparse matrix, by default (from repr = "C") in compressed, column-oriented form, as an \texttt{R} object inheriting from both \texttt{CsparseMatrix} and \texttt{generalMatrix}.

Note

You \textit{do} need to use \texttt{index1 = FALSE} (or add +1 to \texttt{i} and \texttt{j}) if you want use the 0-based \texttt{i} (and \texttt{j}) slots from existing sparse matrices.

See Also

\texttt{Matrix}(\texttt{*, sparse=TRUE}) for the constructor of such matrices from a \textit{dense} matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like \texttt{sparseMatrix()} is needed. Further \texttt{bdiag} and \texttt{Diagonal} for (block-)diagonal and \texttt{bandSparse} for banded sparse matrix constructors.

Random sparse matrices via \texttt{rsparsematrix()}. The standard \texttt{R} \texttt{xtabs}(\texttt{*, sparse=TRUE}), for sparse tables and \texttt{sparse.model.matrix()} for building sparse model matrices.

Consider \texttt{CsparseMatrix} and similar class definition help files.

Examples

## simple example
\texttt{i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)}
\texttt{(A <- sparseMatrix(i, j, x = x))} \texttt{## 8 x 10 "dgCMatrix"}
\texttt{summary(A)}
\texttt{str(A) \# note that *internally* 0-based row indices are used}

\texttt{(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE))} \texttt{## 10 x 10 "dsCMatrix"}
\texttt{(tA <- sparseMatrix(i, j, x = x, triangular = TRUE))} \texttt{## 10 x 10 "dtCMatrix"}
\texttt{stopifnot( all(sA == tA + t(tA)),}
\texttt{ identical(sA, as(tA + t(tA), "symmetricMatrix")))}

## dims can be larger than the maximum row or column indices
\texttt{(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))}
\texttt{summary(AA)}

## i, j and x can be in an arbitrary order, as long as they are consistent
\texttt{set.seed(1); (perm <- sample(1:7))}
\texttt{(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))}
\texttt{stopifnot(identical(A, A1))}

## The slots are 0-index based, so
\texttt{try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )}
\texttt{\# fails and you should say so: 1-indexing is FALSE:}
\texttt{ sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)}

## the (i,j) pairs can be repeated, in which case the x's are summed
\texttt{(args <- data.frame(i = c(1, 1), j = c(j, 2), x = c(x, 2)))}
\texttt{(Aa <- do.call(sparseMatrix, args))}
\texttt{\# explicitly ask for elimination of such duplicates, so}
\texttt{\# that the last one is used:}
\texttt{(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))}
\texttt{stopifnot(Aa[1,2] == 9, \# 2+7 == 9}
A.[1,2] == 2) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":

```r
dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
m
```

## no 'x' --> pattern matrix:

```r
(n <- sparseMatrix(i=1:6, j=rev(2:7)))
```

## an empty sparse matrix:

```r
(e <- sparseMatrix(dims = c(4,6), i={}, j={}))
```

## a symmetric one:

```r
(sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5,
                    dims = c(7,7), symmetric=TRUE))
```

```r
stopifnot(isSymmetric(sy),
          identical(sy, ## switch i <-> j {and transpose }
                    t( sparseMatrix(j= c(2,4,3:5), i= c(4,7:5,5), x = 1:5,
                      dims = c(7,7), symmetric=TRUE))))
```

## rsparsematrix() calls sparseMatrix() :

```r
M1 <- rsparsematrix(1000, 20, nnz = 200)
summary(M1)
```

## pointers example in converting from other sparse matrix representations.

```r
if(require(SparseM) && packageVersion("SparseM") >= 0.87 &&
   nzchar(dfil <- system.file("extdata", "rua_32_ax.rua", package = "SparseM")){

  X <- model.matrix(read.matrix.hb(dfil))
  XX <- sparseMatrix(j = X@ja, p = X@ia - 1L, x = X@ra, dims = X@dimension)
  validObject(XX)

  ## Alternatively, and even more user friendly :
  X. <- as(X, "Matrix") # or also
  X2 <- as(X, "sparseMatrix")
  stopifnot(identical(XX, X.), identical(X., X2))
}
```

---

**sparseMatrix-class**

Virtual Class "sparseMatrix" — Mother of Sparse Matrices

**Description**

Virtual Mother Class of All Sparse Matrices
sparseMatrix-class

Slots

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: a list of length two - inherited from class Matrix, see Matrix.

Extends

Class "Matrix", directly.

Methods

show (object = "sparseMatrix"): The show method for sparse matrices prints "structural" zeros as "." using printSpMatrix() which allows further customization.

print signature(x = "sparseMatrix").

The print method for sparse matrices by default is the same as show() but can be called with extra optional arguments, see printSpMatrix().

format signature(x = "sparseMatrix").

The format method for sparse matrices, see formatSpMatrix() for details such as the extra optional arguments.

summary (object = "sparseMatrix", uniqT=FALSE): Returns an object of S3 class "sparseSummary" which is basically a data.frame with columns (i,j,x) (or just (i,j) for n sparseMatrix class objects) with the stored (typically non-zero) entries. The print method resembles Matlab’s way of printing sparse matrices, and also the MatrixMarket format, see writeMM.

cbind2 (x = *, y = *): several methods for binding matrices together, column-wise, see the basic cbind and rbind functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

rbind2 (x = *, y = *): binding matrices together row-wise, see cbind2 above.

determinant (x = "sparseMatrix", logarithm=TRUE): determinant() methods for sparse matrices typically work via Cholesky or lu decompositions.

diag (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

dim<- signature(x = "sparseMatrix", value = "ANY"): allows to reshape a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill prod(value) == prod(dim(x)).

coerce signature(from = "factor", to = "sparseMatrix"): Coercion of a factor to sparseMatrix produces the matrix of indicator rows stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also colSums, norm, ... for methods with separate help pages.

Note

In method selection for multiplication operations (i.e. %% and the two-argument form of crossprod) the sparseMatrix class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a dgeMatrix and the appropriate sparse matrix method is used.
See Also

sparseMatrix, and its references, such as xtabs(*, sparse=TRUE), or sparse.model.matrix(), for constructing sparse matrices.

T2graph for conversion of "graph" objects (package graph) to and from sparse matrices.

Examples

showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows

data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor -> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
(f.mis <- fact)
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[-i.mis] == X.[,-i.mis]))

---

sparseQR-class

Sparse QR decomposition of a sparse matrix

Description

Objects class "sparseQR" represent a QR decomposition of a sparse \( m \times n \) ("long": \( m \geq n \)) rectangular matrix \( A \), typically resulting from qr(), see ‘Details’ notably about row and column permutations for pivoting.

Details

For a sparse \( m \times n \) ("long": \( m \geq n \)) rectangular matrix \( A \), the sparse QR decomposition is either of the form \( PA = QR \) with a (row) permutation matrix \( P \), (encoded in the p slot of the result) if the q slot is of length 0, or of the form \( PAP^* = QR \) with an extra (column) permutation matrix \( P^* \) (encoded in the q slot). Note that the row permutation \( PA \) in \( R \) is simply \( A[p+1, \] where \( p \) is the p-slot, a 0-based permutation of \( 1:n \) applied to the rows of the original matrix.

If the q slot has length \( n \) it is a 0-based permutation of \( 1:n \) applied to the columns of the original matrix to reduce the amount of "fill-in" in the matrix \( R \), and \( AP^* \) in \( R \) is simply \( A[\ , q+1] \].

\( R \) is an \( m \times n \) matrix that is zero below the main diagonal, i.e., upper triangular \( (m \times m) \) with \( m - n \) extra zero rows.

The matrix \( Q \) is a "virtual matrix". It is the product of \( n \) Householder transformations. The information to generate these Householder transformations is stored in the V and beta slots. Note however that qr.Q() returns the row permuted matrix \( Q^* := P^{-1}Q = P^*Q \) as permutation
matrices are orthogonal; and \( Q^* \) is orthogonal itself because \( Q \) and \( P \) are. This is useful because then, as in the dense matrix and base \( \mathbf{R} \) matrix \( \text{qr} \) case, we have the mathematical identity

\[
P A = Q^* R,
\]

in \( \mathbf{R} \) as

\[
\]

The "\text{sparseQR}" methods for the \( \text{qr.}\ast \) functions return objects of class "\text{dgeMatrix}" (see \text{dgeMatrix}). Results from \( \text{qr.coef}, \text{qr.resid} \) and \( \text{qr.fitted} \) (when \( k = \text{ncol}(R) \)) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix \( Q \) is not uniquely defined, the results of \( \text{qr.qy} \) and \( \text{qr.qty} \) do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of \( \text{qr.qy} \) and \( \text{qr.qty} \) apply to the permuted column order when the \( q \) slot has length \( n \).

**Objects from the Class**

Objects can be created by calls of the form \( \text{new("sparseQR", ...)} \) but are more commonly created by function \( \text{qr} \) applied to a sparse matrix such as a matrix of class \text{dgCMatrix}.

**Slots**

\( \mathbf{V} \): Object of class "\text{dgCMatrix}". The columns of \( \mathbf{V} \) are the vectors that generate the Householder transformations of which the matrix \( Q \) is composed.

\( \mathbf{beta} \): Object of class "\text{numeric}"; the normalizing factors for the Householder transformations.

\( p \): Object of class "\text{integer}": Permutation (of \( 0:(n-1) \)) applied to the rows of the original matrix.

\( \mathbf{R} \): Object of class "\text{dgCMatrix}”: An upper triangular matrix of the same dimension as \( X \).

\( q \): Object of class "\text{integer}”: Permutation applied from the right, i.e., to the columns of the original matrix. Can be of length 0 which implies no permutation.

**Methods**

\( \text{qr.R} \) signature(qr = "\text{sparseQR}"): compute the upper triangular \( R \) matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical \( \text{qr.R}() \) result, and you can suppress these warnings by setting \( \text{options()} \) either "\text{Matrix.quiet.qr.R}" or (the more general) either "\text{Matrix.quiet}" to \text{TRUE}.

\( \text{qr.Q} \) signature(qr = "\text{sparseQR}"): compute the orthogonal \( Q \) matrix of the QR decomposition.

\( \text{qr.coef} \) signature(qr = "\text{sparseQR}", y = "\text{ddenseMatrix}"): ...

\( \text{qr.coef} \) signature(qr = "\text{sparseQR}", y = "\text{matrix}"): ...

\( \text{qr.fitted} \) signature(qr = "\text{sparseQR}", y = "\text{numeric}"): ...

\( \text{qr.fitted} \) signature(qr = "\text{sparseQR}", y = "\text{ddenseMatrix}"): ...

\( \text{qr.fitted} \) signature(qr = "\text{sparseQR}", y = "\text{numeric}"): ...

\( \text{qr.fitted} \) signature(qr = "\text{sparseQR}", y = "\text{ddenseMatrix}"): ...

\( \text{qr.qty} \) signature(qr = "\text{sparseQR}", y = "\text{numeric}"): ...

\( \text{qr.qty} \) signature(qr = "\text{sparseQR}", y = "\text{ddenseMatrix}"): ...

\( \text{qr.qy} \) signature(qr = "\text{sparseQR}", y = "\text{numeric}"): ...

\( \text{qr.qy} \) signature(qr = "\text{sparseQR}", y = "\text{ddenseMatrix}"): ...
\textsf{qr.qy} \ signature(qr = "sparseQR", y = "matrix"): ...
\textsf{qr.qy} \ signature(qr = "sparseQR", y = "numeric"): ...
\textsf{qr.resid} \ signature(qr = "sparseQR", y = "ddenseMatrix"): ...
\textsf{qr.resid} \ signature(qr = "sparseQR", y = "matrix"): ...
\textsf{qr.resid} \ signature(qr = "sparseQR", y = "numeric"): ...

\textbf{Sparse Vector Construction from Nonzero Entries}

\section*{Description}

User friendly construction of sparse vectors, i.e., objects inheriting from \texttt{class sparseVector}, from indices and values of its non-zero entries.

\section*{Usage}

\texttt{sparsity}\texttt{ctor}(\texttt{x}, \texttt{i}, \texttt{length})

\section*{Arguments}

\texttt{x} vector of the non zero entries; may be missing in which case a 
"nsparseVector" will be returned.
\texttt{i} integer vector (of the same length as \texttt{x}) specifying the indices of the non-zero
(or non-TRUE) entries of the sparse vector.
\texttt{length} length of the sparse vector.

\section*{Details}

zero entries in \texttt{x} are dropped automatically, analogously as \texttt{drop0()} acts on sparse matrices.
Value

a sparse vector, i.e., inheriting from class `sparseVector`.

Author(s)

Martin Maechler

See Also

`sparseMatrix()` constructor for sparse matrices; the class `sparseVector`.

Examples

```r
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
  sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
          i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns,
  new("nsparseVector", length = 10, i = c(2, 3, 7))))
```

---

Sparse Vector Classes: The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we’ve mainly implemented methods for the d*", l* and n* ones.

Slots

- `length`: class "numeric" - the length of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `Machine$integer.max`, on purpose.
- `i`: class "numeric" - the (1-based) indices of the non-zero entries. Must not be NA and strictly sorted increasingly.
  Note that "integer" is “part of” "numeric", and can (and often will) be used for non-huge sparseVectors.
- `x`: (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.
  Note that "nsparseVector"s have no x slot. Further, mainly for ease of method definitions, we’ve defined the class union (see `setClassUnion`) of all sparse vector classes which have an x slot, as class "xsparseVector".
Methods

length signature(x = "sparseVector"): simply extracts the length slot.

show signature(object = "sparseVector"): The show method for sparse vectors prints "structural" zeroes as "." using the non-exported prSpVector function which allows further customization such as replacing "." by " " (blank).
Note that options(max.print) will influence how many entries of large sparse vectors are printed at all.

as.vector signature(x = "sparseVector", mode = "character") coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as as(x, "vector").
as ...: see coerce below

coerce signature(from = "sparseVector", to = "sparseMatrix"), and

coerce signature(from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices (sparseMatrix) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.

dim< signature(x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from sparseMatrix, of the appropriate dimension.

head signature(x = "sparseVector"): as with R's (package util) head, head(x,n) (for n >= 1) is equivalent to x[1:n], but here can be much more efficient, see the example.

tail signature(x = "sparseVector"): analogous to head, see above.
toepilz signature(x = "sparseVector"): as toeplitz(x), produce the n x n Toeplitz matrix from x, where n = length(x).

rep signature(x = "sparseVector") repeat x, with the same argument list (x, times, length.out, each,...) as the default method for rep().

which signature(x = "nsparseVector") and

which signature(x = "lsparseVector") return the indices of the non-zero entries (which is trivial for sparse vectors).

Ops signature(e1 = "sparseVector", e2 = "+"): define arithmetic, compare and logic operations, (see Ops).

Summary signature(x = "sparseVector"): define all the Summary methods.

[ signature(x = "atomicVector", i = ...): not only can you subset (aka "index into") sparseVectors x[i] using sparseVectors i, but we also support efficient subsetting of traditional vectors x by logical sparse vectors (i.e., i of class "nsparseVector" or "lsparseVector").

is.na, is.finite, is.infinite (x = "sparseVector"), and

is.na, is.finite, is.infinite (x = "nsparseVector"): return logical or "nsparseVector" of the same length as x, indicating if/where x is NA (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

c.sparseVector() is an S3 method for all "sparseVector"s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

See Also

c.sparseVector() for friendly construction of sparse vectors (apart from as(\*, "sparseVector")),
sparseVector-class

Examples

class <- getClass("sparseVector")
class <- getClass("dsparseVector")
class <- getClass("xsparseVector")
# those with an 'x' slot

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(ss))
(is <- as(ix, "sparseVector"))
# an "isparseVector" (!)
(ns <- sparseVector(i= c(7, 3, 2), length = 10))
# "nsparseVector"

# rep() works too:
(ri <- rep(is, length.out= 25))

## Using "dim<-" as in base R:

r <- ss
(dim(r) <- c(4,5) # becomes a sparse Matrix:
  r
# or coercion (as as.matrix() in base R):
  as(r, "Matrix")
  stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

## currently has "non-structural" FALSE -- printing as ":;"
(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE

## NA-case

sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
        "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)

system.time(for(i in 1:4) hv <- head(v, 1e6))

## user system elapsed
## 0.033 0.000 0.032

system.time(for(i in 1:4) h2 <- v[1:1e6])

## user system elapsed
## 1.317 0.000 1.319

stopifnot(identical(hv, h2),
  identical(is | FALSE, is != 0),
  validObject(svN), validObject(lis), as.logical(is.na(svN[4])),
  identical(is^2 > 0, is & TRUE),
  all(!lis), !any(lis), length(nn@i) == 0, !any(nn), all(!nn),
  sum(lis) == 0, !prod(lis), range(lis) == c(0,0))

## create and use the t(.) method:

T20 <- toeplitz(x20)
(t(x20) <- sparseVector(c(9,3:1), i=c(1:2,4,7), length=20))
(T20 <- toeplitz(x20))
```r
stopifnot(is(T20, "symmetricMatrix"),
          is(T20, "sparseMatrix"),
          identical(unname(as.matrix(T20)),
                     toeplitz(as.vector(x20))))

## c() method for "sparseVector" - also available as regular function
(c1 <- c(x20, 0,0,0, -10*x20))
(c2 <- c(ns, is, FALSE))
(c3 <- c(ns, !ns, TRUE, NA, FALSE))
(c4 <- c(ns, rev(ns)))

## here, c() would produce a list {not dispatching to c.sparseVector()}
(c5 <- c.sparseVector(0,0, x20))

## checking (consistency)
.v <- as.vector
.s <- function(v) as(v, "sparseVector")
stopifnot(
  all.equal(c1, .s(c(.v(x20), 0,0,0, -10*.v(x20))), tol=0),
  all.equal(c2, .s(c(.v(ns), .v(is), FALSE)), tol=0),
  all.equal(c3, .s(c(.v(ns), !.v(ns), TRUE, NA, FALSE)), tol=0),
  all.equal(c4, .s(c(.v(ns), rev(.v(ns)))), tol=0),
  all.equal(c5, .s(c(0,0, .v(x20))), tol=0)
)
```

---

**spMatrix**

**Sparse Matrix Constructor From Triplet**

**Description**

User friendly construction of a sparse matrix (inheriting from class `TsparseMatrix`) from the triplet representation.

This is much less flexible than `sparseMatrix()` and hence somewhat deprecated.

**Usage**

```r
spMatrix(nrow, ncol, i = integer(), j = integer(), x = numeric())
```

**Arguments**

- `nrow, ncol` integers specifying the desired number of rows and columns.
- `i, j` integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.
- `x` atomic vector of the same length as `i` and `j`, specifying the values of the non-zero entries.

**Value**

A sparse matrix in triplet form, as an R object inheriting from both `TsparseMatrix` and `generalMatrix`.

The matrix `M` will have `M[i[k], j[k]] == x[k]` for `k = 1, 2, \ldots, n`, where `n = length(i)` and `M[i', j'] == 0` for all other pairs `(i', j')`. 
See Also

*Matrix*(*, sparse=TRUE) for the more usual constructor of such matrices. Then, *sparseMatrix* is more general and flexible than *spMatrix()* and by default returns a *CsparseMatrix* which is often slightly more desirable. Further, *bdiag* and *Diagonal* for (block-)diagonal matrix constructors.

Consider *TsparseMatrix* and similar class definition help files.

Examples

```r
## simple example
A <- spMatrix(10, 20, i = c(1, 3:8),
              j = c(2, 9:6:10),
              x = 7 * (1:7))
A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
             (1:27) %% 4 != 1)
L # an "lgTMatrix"

## A simplified predecessor of *Matrix*' rsparsematrix() function:

rSpMatrix <- function(nrow, ncol, nnz,
                      rand.x = function(n) round(rnorm(nnz), 2)) {  
  ## Purpose: random sparse matrix
  ## --------------------------------------------------------------
  ## Arguments: (nrow,ncol): dimension
  ## nnz : number of non-zero entries
  ## rand.x: random number generator for 'x' slot
  ## --------------------------------------------------------------
  ## Author: Martin Maechler, Date: 14.-16. May 2007
  stopifnot((nnz <- as.integer(nnz)) >= 0,
            nrow >= 0, ncol >= 0, nnz <= nrow * ncol)
  spMatrix(nrow, ncol,
            i = sample(nrow, nnz, replace = TRUE),
            j = sample(ncol, nnz, replace = TRUE),
            x = rand.x(nnz))
}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)
```

**symmetricMatrix-class**

*Virtual Class of Symmetric Matrices in Package Matrix*

**Description**

The virtual class of symmetric matrices, "symmetricMatrix", from the package *Matrix* contains numeric and logical, dense and sparse matrices, e.g., see the examples with the “actual” subclasses. The main use is in methods (and C functions) that can deal with all symmetric matrices, and in *as(*, "symmetricMatrix")*. 

---

**symmetricMatrix-class**

*Virtual Class of Symmetric Matrices in Package Matrix*

**Description**

The virtual class of symmetric matrices, "symmetricMatrix", from the package *Matrix* contains numeric and logical, dense and sparse matrices, e.g., see the examples with the “actual” subclasses. The main use is in methods (and C functions) that can deal with all symmetric matrices, and in *as(*, "symmetricMatrix")*. 

---

**symmetricMatrix-class**

*Virtual Class of Symmetric Matrices in Package Matrix*

**Description**

The virtual class of symmetric matrices, "symmetricMatrix", from the package *Matrix* contains numeric and logical, dense and sparse matrices, e.g., see the examples with the “actual” subclasses. The main use is in methods (and C functions) that can deal with all symmetric matrices, and in *as(*, "symmetricMatrix")*.
Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there. See below, about storing only one of the two Dimnames components.

factors: a list of matrix factorizations, also from the Matrix class.

Extends

Class "Matrix", directly.

Methods

coerce signature(from = "ddiMatrix", to = "symmetricMatrix") and many other coercion methods, some of which are particularly optimized.

dimnames signature(object = "symmetricMatrix") returns symmetric dimnames, even when the Dimnames slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

isSymmetric signature(object = "symmetricMatrix") returns TRUE trivially.

There’s a C function symmetricMatrix_validate() called by the internal validity checking functions, and also from getValidity(getClass("symmetricMatrix")).

Validity and dimnames

The validity checks do not require a symmetric Dimnames slot, so it can be list(NULL, <character>), e.g., for efficiency. However, dimnames() and other functions and methods should behave as if the dimnames were symmetric, i.e., with both list components identical.

See Also

isSymmetric which has efficient methods (isSymmetric-methods) for the Matrix classes. Classes triangularMatrix, and, e.g., dsyMatrix for numeric dense matrices, or lsCMatrix for a logical sparse matrix class.

Examples

## An example about the symmetric Dimnames:
sy <- sparseMatrix(i = c(2,4,3:5), j = c(4,7:5,5), x = 1:5, dims = c(7,7), symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical
showClass("symmetricMatrix")

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

## Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
symmpart

Description

symmpart(x) computes the symmetric part \((x + t(x))/2\) and skewpart(x) the skew symmetric part \((x - t(x))/2\) of a square matrix \(x\), more efficiently for specific Matrix classes.

Note that \(x = \text{symmpart}(x) + \text{skewpart}(x)\) for all square matrices – apart from extraneous NA values in the RHS.

Usage

symmpart(x)
skewpart(x)

Arguments

x  
a square matrix; either “traditional” of class "matrix", or typically, inheriting from the Matrix class.

Details

These are generic functions with several methods for different matrix classes, use e.g., showMethods(symmpart) to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

Value

symmpart() returns a symmetric matrix, inheriting from symmetricMatrix iff \(x\) inherited from Matrix.

skewpart() returns a skew-symmetric matrix, typically of the same class as \(x\) (or the closest “general” one, see generalMatrix).

See Also

isSymmetric.

Examples

m <- Matrix(1:4, 2,2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == symmpart(m) + skewpart(m)))
colnames(m) <- NULL
stopifnot(all(m == symmpart(m) + skewpart(m)))
dimnames(m) <- unname(dn)
stopifnot(all(m == symmpart(m) + skewpart(m)))
## investigate the current methods:
showMethods(skewpart, include = TRUE)

---

### triangularMatrix-class

**Virtual Class of Triangular Matrices in Package Matrix**

#### Description

The virtual class of triangular matrices, "triangularMatrix", the package *Matrix* contains square (`nrow == ncol`) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

#### Slots

- **uplo**: String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when `diag` is "U". For *denseMatrix* classes, they need to be allocated though, i.e., the length of the `x` slot does not depend on `diag`.
- **Dim, Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the *Matrix*, see there.

#### Extends

Class "Matrix", directly.

#### Methods

There’s a C function `triangularMatrix_validity()` called by the internal validity checking functions.

Currently, *Schur, isSymmetric* and `as()` (i.e. `coerce`) have methods with `triangularMatrix` in their signature.

#### See Also

- `isTriangular()` for testing any matrix for triangularity; classes *symmetricMatrix*, and, e.g., `dtrMatrix` for numeric *dense* matrices, or `ltCMatrix` for a logical *sparse* matrix subclass of "triangularMatrix".

#### Examples

```r
showClass("triangularMatrix")

## The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]
```
(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")

TsparseMatrix-class

Class "TsparseMatrix" of Sparse Matrices in Triplet Form

Description

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See showClass("TsparseMatrix") for its subclasses.

Slots

Dim, Dimnames: from the "Matrix" class,

i: Object of class "integer" - the row indices of non-zero entries in 0-base, i.e., must be in 0:(nrow(.)-1).

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in 0:(ncol(.)-1). For numeric Tsparse matrices, (i,j) pairs can occur more than once, see dgTMatrix.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Extraction ("[" methods, see [-methods.

Note

Most operations with sparse matrices are performed using the compressed, column-oriented or CsparseMatrix representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a CsparseMatrix for further operations.

Note that all new(.), spMatrix and sparseMatrix(*, repr="T") constructors for "TsparseMatrix" classes implicitly add (i.e., “sum up”) x_k’s that belong to identical (i_k,j_k) pairs, see, the example below, or also "dgTMatrix".

For convenience, methods for some operations such as %*% and crossprod are defined for TsparseMatrix objects. These methods simply coerce the TsparseMatrix object to a CsparseMatrix object then perform the operation.

See Also

its superclass, sparseMatrix, and the dgTMatrix class, for the links to other classes.
Examples

```r
class(TSparseMatrix)
## or just the subclasses' names
names(getClass("TSparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
```

uniqTsparse

Unique (Sorted) TsparseMatrix Representations

**Description**

Detect or “unify” (or “standardize”) non-unique *TsparseMatrix* matrices, producing unique \((i, j, x)\) triplets which are sorted, first in \(j\), then in \(i\) (in the sense of `order(j,i)`).

Note that `new(.)`, `spMatrix` or `sparseMatrix` constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add \(x_k\)’s that belong to identical \((i_k,j_k)\) pairs.

`anyDuplicatedT()` reports the index of the first duplicated pair, or 0 if there is none.

`uniqTsparse(x)` replaces duplicated index pairs \((i, j)\) and their corresponding \(x\) slot entries by the triple \((i, j, sx)\) where \(sx = \text{sum}(x [\text{<all pairs matching } (i,j)>])\), and for logical \(x\), addition is replaced by logical `or`.

**Usage**

```r
uniqTsparse(x, class.x = c(class(x)))
anyDuplicatedT(x, di = dim(x))
```

**Arguments**

- `x` a sparse matrix stored in triplet form, i.e., inheriting from class *TsparseMatrix*.
- `class.x` optional character string specifying `class(x)`.
- `di` the matrix dimension of `x`, `dim(x)`.

**Value**

`uniqTsparse(x)` returns a *TsparseMatrix* “like x”, of the same class and with the same elements, just internally possibly changed to “unique” \((i, j, x)\) triplets in sorted order.

`anyDuplicatedT(x)` returns an integer as `anyDuplicated`, the index of the first duplicated entry (from the \((i,j)\) pairs) if there is one, and 0 otherwise.

**See Also**

*TsparseMatrix*, for uniqueness, notably *dgTMatrix*. 
Examples

```r
example("dgTMatrix-class", echo=FALSE)
## -> 'T2' with (i,j,x) slots of length 5 each
T2u <- uniqTsparse(T2)
stopifnot(# They "are" the same (and print the same):
  all.equal(T2, T2u, tol=0),
  # but not internally:
  anyDuplicated(T2) == 2,
  anyDuplicated(T2u) == 0,
  length(T2 @x) == 5,
  length(T2u@x) == 3)

## is 'x' a "uniq Tsparse" Matrix ? [requires x to be TsparseMatrix!]
non_uniqT <- function(x, di = dim(x))
  is.unsorted(x@i) || anyDuplicated(x, di)
non_uniqT(T2 ) # TRUE
non_uniqT(T2u) # FALSE

T3 <- T2u
T3[1, c(1,3)] <- 10; T3[2, c(1,5)] <- 20
T3u <- uniqTsparse(T3)
str(T3u) # sorted in 'j', and within j, sorted in i
stopifnot(!non_uniqT(T3u))

## Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- uniqTsparse(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- uniqTsparse(N2))
stopifnot(N2u@i == L2u@i, N2u@i == T2u@i, N2@i == L2@i, N2@i == T2@i,
  N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)
# now with a nasty NA [partly failed in Matrix 1.1-5]:
validObject(L2.N)
(m2N <- as.matrix(L2.N)) # looks "ok"
il <- as.integer(m2N)
stopifnot(identical(10L, which(is.na(match(il, 0:1)))))
symnum(m2N)
```

## unpack

**Representation of Packed and Unpacked (Dense) Matrices**

**Description**

“Packed” matrix storage here applies to dense matrices (denseMatrix) only, and there is available only for symmetric (symmetricMatrix) or triangular (triangularMatrix) matrices, where only one triangle of the matrix needs to be stored.

unpack() unpacks “packed” matrices, where pack() produces “packed” matrices.

**Usage**

pack(x, ...)

## S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)

### Arguments

- **x**: for `unpack()`: a matrix stored in packed form, e.g., of class "d?pMatrix" where "t" is "t" for triangular or "s" for symmetric.
  - for `pack()`: a (symmetric or triangular) matrix stored in full storage.
- **symmetric**: logical (including NA) for optionally specifying if x is symmetric (or rather triangular).
- **upperTri** (for the triangular case only) logical (incl. NA) indicating if x is upper (or lower) triangular.
- **...**: further arguments passed to or from other methods.

### Details

These are generic functions with special methods for different types of packed (or non-packed) symmetric or triangular dense matrices. Use `showMethods("unpack")` to list the methods for `unpack()`, and similarly for `pack()`.

### Value

- for `unpack()`: A Matrix object containing the full-storage representation of x.
- for `pack()`: A packed Matrix (i.e. of class "..pMatrix") representation of x.

### Examples

```r
showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- as(cp4,"dtpMatrix") # [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s ) == dim(sp), all(s == sp),
  dim(mt) == dim(pt), all(mt == pt), all(mt == tt))
showMethods("pack")
```
Unused-classes

Virtual Classes Not Yet Really Implemented and Used

Description

iMatrix is the virtual class of all integer (S4) matrices. It extends the Matrix class directly.

zMatrix is the virtual class of all complex (S4) matrices. It extends the Matrix class directly.

Examples

showClass("iMatrix")
showClass("zMatrix")

updown

Up- and Down-Dating a Cholesky Decomposition

Description

Compute the up- or down-dated Cholesky decomposition

Usage

updown(update, C, L)

Arguments

update logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.

C any R object, coercable to a sparse matrix (i.e., of subclass of sparseMatrix).

L a Cholesky factor, specifically, of class "CHMfactor".

Value

an updated Cholesky factor, of the same dimension as L. Typically of class "dCHMsimp1" (a subclass of "CHMfactor").

Methods

signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..

USCounties

USCounties Contiguity Matrix

Description

This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

Usage

data(USCounties)

Format

A $3111^2$ symmetric sparse matrix of class dsCMatrix with 9101 non-zero entries.

Details

The data were read into R using read.gal, and row-standardised and transformed to symmetry using nb2listw and similar.listw. This spatial weights object was converted to class dsCMatrix using as_dsTMatrix_listw and coercion.

Source

The data were retrieved from http://sal.uiuc.edu/weights/zips/usc.zip, files “usc.txt” and “usc\_q.GAL”, with permission for use and distribution from Luc Anselin (in early 2008).

Examples

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA, "Matrix") ^ 2
uc1 <- updown("+", Diagonal(5), cA)
## Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA, "Matrix")))
image(show(c2 <- as(uc2,"Matrix")))## severely negative entries
##--> Warning
Examples

```r
data(USCounties)
(n <- ncol(USCounties))
IM <- .symDiagonal(n)
nn <- 50
set.seed(1)
 rho <- runif(nn, 0, 1)
system.time(MJ <- sapply(rho, function(x)
determinant(IM - x * USCounties, logarithm = TRUE)$modulus))

## can be done faster, by update()ing the Cholesky factor:
 nWC <- -USCounties
C1 <- Cholesky(nWC, Imult = 2)
system.time(MJ1 <- n * log(rho) +
sapply(rho, function(x)
  2 * c(determinant(update(C1, nWC, 1/x))$modulus)))
all.equal(MJ, MJ1)

C2 <- Cholesky(nWC, super = TRUE, Imult = 2)
 system.time(MJ2 <- n * log(rho) +
sapply(rho, function(x)
  2 * c(determinant(update(C2, nWC, 1/x))$modulus)))
all.equal(MJ, MJ2)

system.time(MJ3 <- n * log(rho) + Matrix:::ldetL2up(C1, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ3))

system.time(MJ4 <- n * log(rho) + Matrix:::ldetL2up(C2, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ4))
```

wrld_1deg

World 1-degree grid contiguity matrix

Description

This matrix represents the distance-based contiguities of 15260 one-degree grid cells of land areas. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

Usage

```r
data(wrld_1deg)
```

Format

A 15260^2 symmetric sparse matrix of class dsCMatrix with 55973 non-zero entries.

Details

The data were created into R using the coordinates of a 'SpatialPixels' object containing approximately one-degree grid cells for land areas only (world excluding Antarctica), using package spdep's dnearneigh with a cutoff distance of sqrt(2), and row-standardised and transformed to symmetry using nb2listw and similar.listw. This spatial weights object was converted to a dsTMatrix using as_dsTMatrix_listw and then coerced (column-compressed).
Source

The shoreline data was read into R using Rgshhs from the GSHHS coarse shoreline database distributed with the maptools package, omitting Antarctica. A matching approximately one-degree grid was generated using Sobj_SpatialGrid, and the grids on land were found using the appropriate over method for the 'SpatialPolygons' and 'SpatialGrid' objects, yielding a 'SpatialPixels' one containing only the grid cells with centres on land.

[<-methods for subassignment to "Matrix" objects. Extract about the standard extraction.

Examples

```r
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
```

```
m[2, 3]  # simple number
m[2, 3:4] # simple numeric of length 2
m[2, 3:4, drop=FALSE] # sub matrix of class 'dgeMatrix'
## rows or columns only:
m[1,]   # first row, as simple numeric vector
m[,1:2] # sub matrix of first two columns
```

```
showMethods("[", inherited = FALSE)
```

Description

Methods for ":[<-", i.e., extraction or subsetting mostly of matrices, in package Matrix.

Note: Contrary to standard matrix assignment in base R, in m[ . . ] <- val it is typically an error (see stop) when the type or class of val would require the class of m to be changed, e.g., when x is logical, say "lsparseMatrix", and val is numeric. In other cases, e.g., when x is a "nsparseMatrix" and val is not TRUE or FALSE, a warning is signalled, and val is “interpreted” as logical, and (logical) NA is interpreted as TRUE.

Methods

There are many many more than these:

\[
\begin{align*}
&\text{x} = \text{"Matrix"}, i = \text{"missing"}, j = \text{"missing"}, \text{value= "ANY"} \\
&\text{x} = \text{"Matrix"}, i = \text{"ANY"}, j = \text{"ANY"}, \text{value= "ANY"} \\
&\text{x} = \text{"denseMatrix"}, i = \text{"index"}, j = \text{"missing"}, \text{value= "numeric"} \\
&\text{x} = \text{"denseMatrix"}, i = \text{"index"}, j = \text{"index"}, \text{value= "numeric"} \\
&\text{x} = \text{"denseMatrix"}, i = \text{"missing"}, j = \text{"index"}, \text{value= "numeric"}
\end{align*}
\]

[-methods for subsetting "Matrix" objects; the index class; Extract about the standard subset assignment (and extraction).

Examples

```r
set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))
a[] <- 2.2 # <<- replaces **every** entry
a
## as do these:
a[,] <- 3 ; a[TRUE,] <- 4
m[2, 3] <- 3.14 # simple number
m[3, 3:4]<- 3:4 # simple numeric of length 2
## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m
## rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6), ] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")
```

Boolean Arithmetic Matrix Products: %&% and Methods

Description

For boolean or “pattern” matrices, i.e., R objects of class nMatrix, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package Matrix, we use the binary operator %&% (aka “infix”) function for this and provide methods for all our matrices and the traditional R matrices (see matrix).

Value

a pattern matrix, i.e., inheriting from "nMatrix”, or an "ldiMatrix” in case of a diagonal matrix.

Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and sparseVectors in package Matrix.

signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "mMatrix", y = "mMatrix")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "mMatrix")
signature(x = "mMatrix", y = "sparseVector")
signature(x = "sparseVector", y = "sparseVector")

Note

The current implementation ends up coercing both x and y to (virtual) class nsparseMatrix which may be quite inefficient. A future implementation may well return a matrix with different class, but the “same” content, i.e., the same matrix entries $m_{ij}$.

Examples

```r
set.seed(7)
L <- Matrix(rnorm(20) > 1, 4,5)
(N <- as(L, "nMatrix"))
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %&% D
stopifnot(identical(L %&% D, N %&% D),
  all(L %&% D == as((L %*% abs(D)) > 0, "sparseMatrix")))
## cross products , possibly with boolArith = TRUE :
crossprod(N) # -> sparse patter'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N +0) # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %&% N),
  identical(crossprod(N), crossprod(N +0, boolArith=TRUE)),
  identical(crossprod(L), crossprod(N , boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMSrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMSrix"
```

abc.ci  
Nonparametric ABC Confidence Intervals

Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

Usage

abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95, 
eps=0.001/n, ...)

Arguments

data  A data set expressed as a vector, matrix or data frame.
statistic  A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the ...() argument.
index  If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.
strata  A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.
conf  A scalar or vector containing the confidence level(s) of the required interval(s).
eps  The value of epsilon to be used for the numerical differentiation.
...  Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.
Details

This function is based on the function abcnon written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is $2*n+2+2*\text{length}(\text{conf})$ where $n$ is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A $\text{length}(\text{conf})$ by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

# coefficient between the columns of the bigcity data
abc.ci(bigcity, corr, conf=c(0.90,0.95))

# A 95% confidence interval for the difference between the means of
# the last two samples in gravity
mean.diff <- function(y, w)
{ gp1 <- 1:table(as.numeric(y$series))[1]
    sum(y[gp1, 1] * w[gp1]) - sum(y[-gp1, 1] * w[-gp1])
}
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
## IGNORE_RDIFF_BEGIN
abc.ci(grav1, mean.diff, strata = grav1$series)
## IGNORE_RDIFF_END
```
**acme**

**Monthly Excess Returns**

**Description**

The acme data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

**Usage**

acme

**Format**

This data frame contains the following columns:

- **month** A character string representing the month of the observation.
- **market** The excess return of the market as a whole.
- **acme** The excess return for the Acme Cleveland Corporation.

**Source**

The data were obtained from

**aids**

**Delay in AIDS Reporting in England and Wales**

**Description**

The aids data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

**Usage**

aids
Format
This data frame contains the following columns:

- **year**: The year of the diagnosis.
- **quarter**: The quarter of the year in which diagnosis was made.
- **delay**: The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).
- **dud**: An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.
- **time**: The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.
- **y**: The number of AIDS cases reported.

Source
The data were obtained from

**aircondit**

_Fails of Air-conditioning Equipment_

Description

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The **aircondit** data frame contains the intervals for the ninth aircraft while **aircondit7** contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

Usage

**aircondit**

Format

The data frames contain the following column:

- **hours**: The time interval in hours between successive failures of the air-conditioning equipment

Source

The data were taken from

The amis data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

Usage

amis

Format

This data frame contains the following columns:

- **speed**: Speeds of cars (in miles per hour).
- **period**: A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.
- **warning**: A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.
- **pair**: A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

References

Description

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

Usage

`aml`

Format

This data frame contains the following columns:

- `time` The length of the complete remission (in weeks).
- `cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.
- `group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

Note

Package `survival` also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

beaver

**Beaver Body Temperature Data**

**Description**

The beaver data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

**Usage**

beaver

**Format**

This data frame contains the following columns:

- **day** The day number. The data includes only data from day 307 and early 308.
- **time** The time of day formatted as hour-minute.
- **temp** The body temperature in degrees Celsius.
- **activ** The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

bigcity  Population of U.S. Cities

Description

The bigcity data frame has 49 rows and 2 columns. The city data frame has 10 rows and 2 columns. The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The city data frame consists of the first 10 observations in bigcity.

Usage

bigcity

Format

This data frame contains the following columns:

u  The 1920 population.

x  The 1930 population.

Source

The data were obtained from

References

boot  Bootstrap Resampling

Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to boot. Importance resampling weights may be specified.

Usage

boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"), strata = rep(1,n), L = NULL, m = 0, weights = NULL, ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ..., parallel = c("no", "multicore", "snow"), ncpus = getOption("boot.ncpus", 1L), cl = NULL)
Arguments

**data**  The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.

**statistic**  A function which when applied to data returns a vector containing the statistic(s) of interest. When sim = "parametric", the first argument to statistic must be the data. For each replicate a simulated dataset returned by ran.gen will be passed. In all other cases statistic must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to statistic through the ... argument.

**R**  The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case R would be a vector of integers where each component gives the number of resamples from each of the rows of weights.

**sim**  A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.

**stype**  A character string indicating what the second argument of statistic represents. Possible values of stype are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for sim = "parametric".

**strata**  An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when sim = "parametric". When strata is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.

**L**  Vector of influence values evaluated at the observations. This is used only when sim is "antithetic". If not supplied, they are calculated through a call to empinf. This will use the infinitesimal jackknife provided that stype is "w", otherwise the usual jackknife is used.

**m**  The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when sim is "ordinary". m will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of statistic, which should also take an argument giving the vector of indices of the errors to be used for the predictions.

**weights**  Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in data. When simulation from more than one set of weights is required, weights should be a matrix where each row of the matrix is one set of importance weights. If weights is a matrix then R must be a vector of length nrow(weights). This parameter is ignored if sim is not "ordinary" or "balanced".

**ran.gen**  This function is used only when sim = "parametric" when it describes how random values are to be generated. It should be a function of two arguments.
The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to \texttt{ran.gen}. The returned value should be a simulated data set of the same form as the observed data which will be passed to \texttt{statistic} to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If \texttt{ran.gen} is not specified, the default is a function which returns the original data in which case all simulation should be included as part of \texttt{statistic}. Use of \texttt{sim = "parametric"} with a suitable \texttt{ran.gen} allows the user to implement any types of nonparametric resampling which are not supported directly.

\texttt{mle} \texttt{} The second argument to be passed to \texttt{ran.gen}. Typically these will be maximum likelihood estimates of the parameters. For efficiency \texttt{mle} is often a list containing all of the objects needed by \texttt{ran.gen} which can be calculated using the original data set only.

\texttt{simple} \texttt{} logical, only allowed to be \texttt{TRUE} for \texttt{sim = "ordinary"}, \texttt{stype = "i"}, \texttt{n = 0} (otherwise ignored with a warning). By default a \texttt{n} by \texttt{R} index array is created: this can be large and if \texttt{simple = TRUE} this is avoided by sampling separately for each replication, which is slower but uses less memory.

\texttt{} Other named arguments for \texttt{statistic} which are passed unchanged each time it is called. Any such arguments to \texttt{statistic} should follow the arguments which \texttt{statistic} is required to have for the simulation. Beware of partial matching to arguments of \texttt{boot} listed above, and that arguments named \texttt{X} and \texttt{FUN} cause conflicts in some versions of \texttt{boot} (but not this one).

\texttt{parallel} \texttt{} The type of parallel operation to be used (if any). If missing, the default is taken from the option \texttt{"boot.parallel"} (and if that is not set, \texttt{"no"}).

\texttt{ncpus} \texttt{} integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

\texttt{cl} \texttt{} An optional \texttt{parallel} or \texttt{snow} cluster for use if \texttt{parallel = "snow"}. If not supplied, a cluster on the local machine is created for the duration of the \texttt{boot} call.

\textbf{Details}

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. \texttt{statistic} is treated as a black box by the \texttt{boot} function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechterman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function \texttt{ran.gen} which will return a simulated data set from the observed data set and a set of parameter estimates specified in \texttt{mle}.

\textbf{Value}

The returned value is an object of class \"boot\", containing the following components:

\texttt{t0} \texttt{} The observed value of \texttt{statistic} applied to data.
t  A matrix with \( \text{sum}(R) \) rows each of which is a bootstrap replicate of the result of calling \texttt{statistic}.

\( R \)  The value of \( R \) as passed to \texttt{boot}.

data  The data as passed to \texttt{boot}.

seed  The value of \texttt{.Random.seed} when \texttt{boot} started work.

\texttt{statistic}  The function \texttt{statistic} as passed to \texttt{boot}.

\texttt{sim}  Simulation type used.

\texttt{stype}  Statistic type as passed to \texttt{boot}.

call  The original call to \texttt{boot}.

\texttt{strata}  The strata used. This is the vector passed to \texttt{boot}, if it was supplied or a vector of ones if there were no strata. It is not returned if \texttt{sim} is "parametric".

\texttt{weights}  The importance sampling weights as passed to \texttt{boot} or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if \texttt{sim} is not one of "ordinary" or "balanced".

\texttt{pred.i}  If predictions are required \((m > 0)\) this is the matrix of indices at which predictions were calculated as they were passed to \texttt{statistic}. Omitted if \( m = 0 \) or \texttt{sim} is not "ordinary".

\( L \)  The influence values used when \texttt{sim} is "antithetic". If no such values were specified and \texttt{stype} is not "w" then \( L \) is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when \texttt{sim} is not "antithetic".

\texttt{ran.gen}  The random generator function used if \texttt{sim} is "parametric". This component is omitted for any other value of \texttt{sim}.

\texttt{mle}  The parameter estimates passed to \texttt{boot} when \texttt{sim} is "parametric". It is omitted for all other values of \texttt{sim}.

There are \texttt{c}, \texttt{plot} and \texttt{print} methods for this class.

\textbf{Parallel operation}

When \texttt{parallel = "multicore"} is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when \texttt{parallel = "snow"} is used: the worker processes are newly created \( \mathbb{R} \) processes, and \texttt{statistic} needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when \texttt{statistic} is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for \texttt{jack.after.boot} where ancillary functions are nested inside the \texttt{statistic} function.) \texttt{parallel = "snow"} is primarily intended to be used on multi-core Windows machine where \texttt{parallel = " multicore"} is not available.

For most of the \texttt{boot} methods the resampling is done in the master process, but not if \texttt{simple = TRUE} nor \texttt{sim = "parametric"}. In those cases (or where \texttt{statistic} itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by \texttt{censboot(sim = "wierd")] and by most of the schemes in \texttt{tsboot} (the exceptions being \texttt{sim = "fixed"} and \texttt{sim = "geom"} with the default \texttt{ran.gen}).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with \texttt{parallel = "multicore"} or \texttt{parallel = "snow"} using the default cluster, a second approach is used if
RNGkind("L'Ecuyer-CMRG") has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if ncpus is unchanged, and for parallel = "multicore" if parallel::mc.reset.stream() is called: see the examples for mclapply.

Note that loading the parallel namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

Examples

# Usual bootstrap of the ratio of means using the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

# Stratified resampling for the difference of means. In this
# example we will look at the difference of means between the final
# two series in the gravity data.
diff.means <- function(d, f)
{ n <- nrow(d)
gp1 <- 1:table(as.numeric(d$series))[1]
m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}

# In this example we show the use of boot in a prediction from # regression based on the nuclear data. This example is taken # from Example 6.8 of Davison and Hinkley (1997). Notice also # that two extra arguments to 'statistic' are passed through boot.

```r
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date*log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)
```

# We set up a new data frame with the data, the standardized # residuals and the fitted values for use in the bootstrap.

```r
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))
```

# Now we want a prediction of plant number 32 but at date 73.00

```r
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
                       ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)
```

```r
nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
              data = dat)
  pred.b <- predict(lm.b, x.pred)
  c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}
```

```r
nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
                   fit.pred = new.fit, x.pred = new.data)
```

# The bootstrap prediction squared error would then be found by

```r
mean(nuke.boot$t[, 8]^2)
```

# Basic bootstrap prediction limits would be

```r
new.fit - sort(nuke.boot$t[, 8])[-c(975, 25)]
```

# Finally a parametric bootstrap. For this example we shall look # at the air-conditioning data. In this example our aim is to test # the hypothesis that the true value of the index is 1 (i.e. that # the data come from an exponential distribution) against the # alternative that the data come from a gamma distribution with # index not equal to 1.

```r
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1+para[1]+para[2])
  }
  khat <- nlm(ll, ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}
```

```r
air.rg <- function(data, mle) {
  # Function to generate random exponential variates.
  # mle will contain the mean of the original data
```
out <- data
out$hours <- rexp(nrow(out), 1/mle)
out
}

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
ran.gen = air.rg, mle = mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

### boot.array

**Bootstrap Resampling Arrays**

**Description**

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

**Usage**

`boot.array(boot.out, indices)`

**Arguments**

- `boot.out`: An object of class "boot" returned by one of the generation functions for such an object.
- `indices`: A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

**Details**

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.
Side Effects

This function temporarily resets .Random.seed to the value in boot.out$seed and then returns it to its original value at the end of the function.

boot.censboot.freq.array.tilt.boot.tsboot

Examples

# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)

Nonparametric Bootstrap Confidence Intervals

Description

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

Usage

boot.ci(boot.out, conf = 0.95, type = "all",
index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
var.t = NULL, t0 = NULL, t = NULL, L = NULL,
h = function(t) t, hdot = function(t) rep(1,length(t)),
hinv = function(t) t, ...)

Arguments

boot.out An object of class "boot" containing the output of a bootstrap calculation.
conf A scalar or vector containing the confidence level(s) of the required interval(s).
type A vector of character strings representing the type of intervals required. The value should be any subset of the values c("norm","basic","stud","perc","bca") or simply "all" which will compute all five types of intervals.
index This should be a vector of length 1 or 2. The first element of index indicates the position of the variable of interest in boot.out$t0 and the relevant column in boot.out$t. The second element indicates the position of the variance of the variable of interest. If both var.t0 and var.t are supplied then the second element of index (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in boot.out$t0).
If supplied, a value to be used as an estimate of the variance of the statistic for
the normal approximation and studentized intervals. If it is not supplied and
length(index) is 2 then var.t0 defaults to boot.out$t0[index[2]] otherwise var.t0 is undefined. For studentized intervals var.t0 must be defined.
For the normal approximation, if var.t0 is undefined it defaults to var(t). If a
transformation is supplied through the argument h then var.t0 should be the
variance of the untransformed statistic.

This is a vector (of length boot.out$R) of variances of the bootstrap replicates
of the variable of interest. It is used only for studentized intervals. If it is not sup-
plied and length(index) is 2 then var.t defaults to boot.out$t[,index[2]],
otherwise its value is undefined which will cause an error for studentized inter-
vals. If a transformation is supplied through the argument h then var.t should
be the variance of the untransformed bootstrap statistics.

The observed value of the statistic of interest. The default value is
boot.out$t0[index[1]]. Specification of t0 and t allows the user to get inter-
vals for a transformed statistic which may not be in the bootstrap output object.
See the second example below. An alternative way of achieving this would be
to supply the functions h, hdot, and hinv below.

The bootstrap replicates of the statistic of interest. It must be a vector of length
boot.out$R. It is an error to supply one of t0 or t but not the other. Also if
studentized intervals are required and t0 and t are supplied then so should be
var.t0 and var.t. The default value is boot.out$t[,index].

The empirical influence values of the statistic of interest for the observed data.
These are used only for BCa intervals. If a transformation is supplied through
the parameter h then L should be the influence values for t; the values for h(t)
are derived from these and hdot within the function. If L is not supplied then
the values are calculated using empinf if they are needed.

A function defining a transformation. The intervals are calculated on the scale of
h(t) and the inverse function hinv applied to the resulting intervals. It must be a
function of one variable only and for a vector argument, it must return a vector of
the same length, i.e. h(c(t1,t2,t3)) should return c(h(t1),h(t2),h(t3)).
The default is the identity function.

A function of one argument returning the derivative of h. It is a required argu-
ment if h is supplied and normal, studentized or BCa intervals are required. The
function is used for approximating the variances of h(t0) and h(t) using the
delta method, and also for finding the empirical influence values for BCa inter-
vals. Like h it should be able to take a vector argument and return a vector of
the same length. The default is the constant function 1.

A function, like h, which returns the inverse of h. It is used to transform the
intervals calculated on the scale of h(t) back to the original scale. The default is
the identity function. If h is supplied but hinv is not, then the intervals returned
will be on the transformed scale.

Any extra arguments that boot.out$statistic is expecting. These arguments
are needed only if BCa intervals are required and L is not supplied since in that
case L is calculated through a call to empinf which calls boot.out$statistic.

Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley
(1997). Function boot must be run prior to running this function to create the object to be passed
as boot.out.
Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the R values in boot.out a warning is generated and such intervals should not be considered reliable.

**Value**

An object of type "bootci" which contains the intervals. It has components

- R: The number of bootstrap replicates on which the intervals were based.
- t0: The observed value of the statistic on the same scale as the intervals.
- call: The call to boot.ci which generated the object. It will also contain one or more of the following components depending on the value of type used in the call to boot.ci.
- normal: A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
- basic: The intervals calculated using the basic bootstrap method.
- student: The intervals calculated using the studentized bootstrap method.
- percent: The intervals calculated using the bootstrap percentile method.
- bca: The intervals calculated using the adjusted bootstrap percentile (BCa) method. These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

        var.t0 = vt0, var.t = vt)

brambles

Spatial Location of Bramble Canes

Description
The brambles data frame has 823 rows and 3 columns.
The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of
distance so that the plot can be thought of as a unit square. The bramble canes were also classified
by their age.

Usage
brambles
**Format**

This data frame contains the following columns:

- **x** The x coordinate of the position of the cane in the plot.
- **y** The y coordinate of the position of the cane in the plot.
- **age** The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

`breslow`

**Format**

This data frame contains the following columns:

- **age** The mid-point of the 10 year age-group for the doctors.
- **smoke** An indicator of whether the doctors smoked (1) or not (0).
- **n** The number of person-years in the category.
- **y** The number of deaths attributed to coronary artery disease.
- **ns** The number of smoker years in the category (`smoke*n`).

calcium  
*Calcium Uptake Data*

Description

The calcium data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

Usage

calcium

Format

This data frame contains the following columns:

- **time**: The time (in minutes) that the cells were suspended in the solution.
- **cal**: The amount of calcium uptake (nmoles/mg).

Source

The data were obtained from

**Description**

The cane data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

**Usage**

cane

**Format**

This data frame contains the following columns:

- **n**: The total number of shoots in each plot.
- **r**: The number of diseased shoots.
- **x**: The number of pieces of the stems, out of 50, planted in each plot.
- **var**: A factor indicating the variety of sugar-cane in each plot.
- **block**: A factor for the blocks.

**Details**

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

cav  Position of Muscle Caveolae

Description

The cav data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65mm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset caveolae.dat in the spatial package by B.D. Ripley (1994).

Usage

cav

Format

This data frame contains the following columns:

x  The x coordinate of the caveola’s position in the region.
y  The y coordinate of the caveola’s position in the region.

References

Description

The cd4 data frame has 20 rows and 2 columns.
CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

Usage

cd4

Format

This data frame contains the following columns:

- baseline  The CD4 counts (in 100’s) on admission to the trial.
- oneway  The CD4 counts (in 100’s) after one year of treatment with the new drug.

censboot

Bootstrap for Censored Data

Description

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
   sim = "ordinary", cox = NULL, index = c(1, 2), . . . ,
   parallel = c("no", "multicore", "snow"),
   ncpus = getOption("boot.ncpus", 1L), cl = NULL)

Arguments

data

The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for \texttt{sim = "weird"} when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of \texttt{index} are taken to be the times and censoring indicators.

statistic

A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the \texttt{...} argument. In the case of \texttt{sim = "weird"}, the data passed to \texttt{statistic} only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to \texttt{statistic} will be of the same form as the original data. When \texttt{sim = "weird"}, the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if \texttt{sim = "weird"} and \texttt{strata} is supplied, \texttt{statistic} should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.

R

The number of bootstrap replicates.

F.surv

An object returned from a call to \texttt{survfit} giving the survivor function for the data. This is a required argument unless \texttt{sim = "ordinary"} or \texttt{sim = "model"} and \texttt{cox} is missing.

G.surv

Another object returned from a call to \texttt{survfit} but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to \texttt{survfit}. This is a required argument whenever \texttt{sim = "cond"} or when \texttt{sim = "model"} and \texttt{cox} is supplied.

strata

The strata used in the calls to \texttt{survfit}. It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When \texttt{sim = "weird"} only the strata for the survival distribution are used since the
censoring times are considered fixed. When \texttt{sim = "ordinary"}, only one set of strata is used to stratify the observations, this is taken to be the first column of \texttt{strata} when it is a matrix.

\textbf{sim}

The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if \texttt{cox} is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if \texttt{cox} is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

\textbf{cox}

An object returned from \texttt{coxph}. If it is supplied, then \texttt{F.surv} should have been generated by a call of the form \texttt{survfit(cox)}.

\textbf{index}

A vector of length two giving the positions of the columns in \texttt{data} which correspond to the times and censoring indicators respectively.

\textbf{...}

Other named arguments which are passed unchanged to \texttt{statistic} each time it is called. Any such arguments to \texttt{statistic} must follow the arguments which \texttt{statistic} is required to have for the simulation. Beware of partial matching to arguments of \texttt{censboot} listed above, and that arguments named \texttt{X} and \texttt{FUN} cause conflicts in some versions of \texttt{boot} (but not this one).

\textbf{parallel, ncpus, cl}

See the help for \texttt{boot}.

\section*{Details}

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of \texttt{Inf} and conversely if it is uncensored it is given a nominal censoring time of \texttt{Inf}. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (\texttt{sim = "model"}) or from the conditional censoring distribution as in the previous paragraph (\texttt{sim = "cond"}).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is at least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and \texttt{sim} is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of \texttt{Inf}, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of \texttt{Inf} and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.
When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

**Value**

An object of class "boot" containing the following components:

- **t0**: The value of `statistic` when applied to the original data.
- **t**: A matrix of bootstrap replicates of the values of `statistic`.
- **R**: The number of bootstrap replicates performed.
- **sim**: The simulation type used. This will usually be the input value of `sim` unless that was "model" but `cox` was not supplied, in which case it will be "ordinary".
- **data**: The data used for the bootstrap. This will generally be the input value of `data` unless `sim = "weird"`, in which case it will just be the columns containing the times and the censoring indicators.
- **seed**: The value of `.Random.seed` when `censboot` started work.
- **statistic**: The input value of `statistic`.
- **strata**: The strata used in the resampling. When `sim = "ordinary"` this will be a vector which stratifies the observations, when `sim = "weird"` it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
- **call**: The original call to `censboot`.

describe(channing)

Description

The channing data frame has 462 rows and 5 columns.
Channing House is a retirement centre in Palo Alto, California. These data were collected between
the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed
through the centre. For each of these, their age on entry and also on leaving or death was recorded.
A large number of the observations were censored mainly due to the resident being alive on July
1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at
Channing House. Differences between the survival of the sexes, taking age into account, was one
of the primary concerns of this study.

Usage

channing

Format

This data frame contains the following columns:

sex A factor for the sex of each resident ("Male" or "Female").
entry The residents age (in months) on entry to the centre
exit The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever
event occurred first.
time The length of time (in months) that the resident spent at Channing House.
(time=exit-entry)
cens The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

claridge  Genetic Links to Left-handedness

Description
The claridge data frame has 37 rows and 2 columns.
The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

Usage
claridge

Format
This data frame contains the following columns:
dnan The genetic measurement on each woman’s DNA.
hand The measure of left-handedness on an integer scale from 1 to 8.

Source
The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

**References**

Description

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

Usage

control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,  
t = NULL, bias.adj = FALSE, alpha = NULL, ...)

Arguments

boot.out  A bootstrap output object returned from boot. The bootstrap replicates must have been generated using the usual nonparametric bootstrap.
L  The empirical influence values for the statistic of interest. If L is not supplied then empinf is called to calculate them from boot.out.
distn  If present this must be the output from smooth.spline giving the distribution function of the linear approximation. This is used only if bias.adj is FALSE. Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by saddle.distn.
index  The index of the variable of interest in the output of boot.out$statistic.
t0  The observed value of the statistic of interest on the original data set boot.out$data. This argument is used only if bias.adj is FALSE. The input value is ignored if t is not also supplied. The default value is is boot.out$t0[index].
t  The bootstrap replicate values of the statistic of interest. This argument is used only if bias.adj is FALSE. The input is ignored if t0 is not supplied also. The default value is boot.out$t[,index].
bias.adj  A logical variable which if TRUE specifies that the adjusted bias estimate using post-simulation balance is all that is required. If bias.adj is FALSE (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.
alpha  The alpha levels for the required quantiles if bias.adj is FALSE.
...  Any additional arguments that boot.out$statistic requires. These are passed unchanged every time boot.out$statistic is called. boot.out$statistic is called once if bias.adj is TRUE, otherwise it may be called by empinf for empirical influence calculations if L is not supplied.

Details

If bias.adj is FALSE then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation $T^* = Tl^*+(T^*-Tl^*)$, moment estimates can be found. For quantile estimation the distribution of the linear approximation to t is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of t and hence to estimate the bootstrap quantiles of t.
Value

If `bias.adj` is TRUE then the returned value is the adjusted bias estimate.
If `bias.adj` is FALSE then the returned value is a list with the following components

- **L**: The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by `empinf`.
- **tL**: The linear approximations to the bootstrap replicates \( t \) of the statistic of interest.
- **bias**: The control estimate of bias using the linear approximation to \( t \) as a control variate.
- **var**: The control estimate of variance using the linear approximation to \( t \) as a control variate.
- **k3**: The control estimate of the third cumulant using the linear approximation to \( t \) as a control variate.
- **quantiles**: A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to \( t \) as a control variate.
- **distn**: An output object from `smooth.spline` describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to \( t \). If `distn` was supplied on input then this is the same as the input otherwise it is calculated by a call to `saddle.distn`.

Examples

```r
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
  { m <- mean(d$hours[i])
    n <- nrow(d)
    v <- (n-1)*var(d$hours[i])/n^2
    c(m, v)
  }
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
  t = log(air.boot$t[, 2]))
```
**Correlation Coefficient**

**Description**

Calculates the weighted correlation given a data set and a set of weights.

**Usage**

\[ \text{corr}(d, w = \text{rep}(1, \text{nrow}(d))/\text{nrow}(d)) \]

**Arguments**

- **d**: A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
- **w**: A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so \( \sum(w) \) need not equal 1.

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between \( d[,1] \) and \( d[,2] \).

**See Also**

- cor

---

**Calculate Third Order Cumulants**

**Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

\[ \text{cum3}(a, b = a, c = a, \text{unbiased} = \text{TRUE}) \]
Arguments

- **a**: A vector of observations.
- **b**: Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.
- **c**: Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.
- **unbiased**: A logical value indicating whether the unbiased estimator should be used.

Details

The unbiased estimator uses a multiplier of \( \frac{n}{(n-1)(n-2)} \) where \( n \) is the sample size, if unbiased is FALSE then a multiplier of \( \frac{1}{n} \) is used. This is multiplied by \( \text{sum}((a-\text{mean}(a))*(b-\text{mean}(b))*(c-\text{mean}(c))) \) to give the required estimate.

Value

The required estimate.

---

**cv.glm**  
*Cross-validation for Generalized Linear Models*

---

Description

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

Usage

`cv.glm(data, glmfit, cost, K)`

Arguments

- **data**: A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.
- **glmfit**: An object of class "glm" containing the results of a generalized linear model fitted to data.
- **cost**: A function of two vector arguments specifying the cost function for the cross-validation. The first argument to cost should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. cost must return a non-negative scalar value. The default is the average squared error function.
- **K**: The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of K must be such that all groups are of approximately equal size. If the supplied value of K does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of K used. The default is to set K equal to the number of observations in data which gives the usual leave-one-out cross-validation.
Details

The data is divided randomly into \( K \) groups. For each group the generalized linear model is fit to data omitting that group, then the function \( \text{cost} \) is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When \( K \) is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When \( K \) is less than the number of observations the \( K \) splits to be used are found by randomly partitioning the data into \( K \) groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in \( \text{delta} \) is the estimate adjusted by this method.

Value

The returned value is a list with the following components.

- call: The original call to \( \text{cv.glm} \).
- \( K \): The value of \( K \) used for the \( K \)-fold cross validation.
- \( \text{delta} \): A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.
- seed: The value of \( \text{.Random.seed} \) when \( \text{cv.glm} \) was called.

Side Effects

The value of \( \text{.Random.seed} \) is updated.

darwin  

**Darwin’s Plant Height Differences**

**Description**

The darwin data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over
self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant
and one self-fertilized plant which germinated at the same time and grew in the same pot. The
plants were measured at a fixed time after planting and the difference in heights between the cross-
and self-fertilized plants are recorded in eighths of an inch.

**Usage**

darwin

**downs.bc**

**Incidence of Down’s Syndrome in British Columbia**

**Description**

The downs.bc data frame has 30 rows and 3 columns.

Down’s syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down’s syndrome is highly dependent on the mother’s age and rises sharply after age 30. In the 1960’s a large scale study of the effect of maternal age on the incidence of Down’s syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

**Usage**

downs.bc

**Format**

This data frame contains the following columns:

- **age** The average age of all mothers in the age category.
- **m** The total number of live births to mothers in the age category.
- **r** The number of cases of Down’s syndrome.
Source

**ducks**

**Behavioral and Plumage Characteristics of Hybrid Ducks**

Description

The ducks data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

Usage

ducks

Format

This data frame contains the following columns:

- plumage  The index of physical appearance based on the plumage of individual ducks.
- behaviour  The index of behavioural characteristics of the ducks.

Source

The data were obtained from

References

Description

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

Usage

```r
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
            u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
          u = function(y, t) y - t)
```

Arguments

- `y` A vector or matrix of data
- `tmin` The minimum value of the range over which the likelihood should be computed. This must be larger than `min(y)`.
- `tmax` The maximum value of the range over which the likelihood should be computed. This must be smaller than `max(y)`.
- `n.t` The number of points between `tmin` and `tmax` at which the value of the log-likelihood should be computed.
- `u` A function of the data and the parameter.

Details

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package boot for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the boot package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL `https://statweb.stanford.edu/~owen/empirical/`.

Value

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

Empirical Influence Values

Description
This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

Usage
empinf(boot.out = NULL, data = NULL, statistic = NULL,
        type = NULL, stype = NULL ,index = 1, t = NULL,
        strata = rep(1, n), eps = 0.001, ...)

Arguments
boot.out  A bootstrap object created by the function boot. If type is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of data, statistic, stype, and strata are taken from the components of boot.out and any values passed to empinf directly are ignored.
data     A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if boot.out is not supplied. If boot.out is supplied then data is set to boot.out$data and any value supplied here is ignored.
statistic The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of stype. Any other arguments that it takes must be supplied to empinf and will be passed to statistic unchanged. This is a required argument if boot.out is not supplied, otherwise its value is taken from boot.out and any value supplied here will be ignored.
type     The calculation type to be used for the empirical influence values. Possible values of type are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If t is supplied then the default value of type is "reg" and boot.out should be present so that its frequency array can be found. If t is not supplied then if stype is "w", the default value of type is "inf"; otherwise, if boot.out is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for type to be "reg" if boot.out is missing or to be "inf" if stype is not "w".
stype     A character variable giving the nature of the second argument to statistic. It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If boot.out is supplied the value of stype is set to boot.out$stype and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If type is "inf" then stype MUST be "w".
empinf

index: An integer giving the position of the variable of interest in the output of statistic.

t: A vector of length boot.out$R which gives the bootstrap replicates of the statistic of interest. t is used only when type is reg and it defaults to boot.out$t[,index].

strata: An integer vector or a factor specifying the strata for multi-sample problems. If boot.out is supplied the value of strata is set to boot.out$strata. Otherwise it is an optional argument which has default corresponding to the single sample situation.

eps: This argument is used only if type is "inf". In that case the value of epsilon to be used for numerical differentiation will be eps divided by the number of observations in data.

...: Any other arguments that statistic takes. They will be passed unchanged to statistic every time that it is called.

Details

If type is "inf" then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. stype is "w"). If type is "jack" then the usual leave-one-out jackknife estimates of the empirical influence are returned. If type is "pos" then the positive (include-one-twice) jackknife values are used. If type is "reg" then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of statistic on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to boot.array. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call empinf when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

Value

A vector of the empirical influence values of statistic applied to data. The values will be in the same order as the observations in data.

Warning

All arguments to empinf must be passed using the name = value convention. If this is not followed then unpredictable errors can occur.

**Examples**

```r
# The empirical influence values for the ratio of means in
# the city data.
ratio <- function(d, w) sum(d$x *w)/sum(d$u*w)
empinf(data = city, statistic = ratio)

city.boot <- boot(city, ratio, 499, stype="w")
empinf(boot.out = city.boot, type = "reg")

# A statistic that may be of interest in the difference of means
# problem is the t-statistic for testing equality of means. In
# the bootstrap we get replicates of the difference of means and
# the variance of that statistic and then want to use this output
# to get the empirical influence values of the t-statistic.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2])

gv.z <- (grav.boot$t[,1]-grav.boot$t0[1])/sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)
```

---

**envelope**  

**Confidence Envelopes for Curves**

**Description**

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

**Usage**

```r
evelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))
```

**Arguments**

- **boot.out**: An object of class "boot" for which boot.out$t contains the replicates of the curve at a number of fixed points.

- **mat**: A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if boot.out is not supplied and is set to boot.out$t otherwise.
level  The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.

index  The numbers of the columns of mat which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of mat.

Value

A list with the following components:

point  A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.

overall  A matrix similar to point but containing the envelope which controls the overall error.

k.pt  The quantiles used for the pointwise envelope.

err.pt  A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.

k.ov  The quantiles used for the overall envelope.

err.ov  A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.

err.nom  A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

exp.tilt

**Exponential Tilting**

**Description**

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

**Usage**

```r
exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL,
         strata = rep(1, length(L)))
```

**Arguments**

- `L`: The empirical influence values for the statistic of interest based on the observed data. The length of `L` should be the same as the size of the original data set. Typically `L` will be calculated by a call to `empinf`.
- `theta`: The value at which the tilted distribution is to be centred. This is not required if `lambda` is supplied but is needed otherwise.
- `t0`: The current value of the statistic. The default is that the statistic equals 0.
- `lambda`: The Lagrange multiplier(s). For each value of `lambda` a multinomial distribution is found with probabilities proportional to `exp(lambda * L/n)`, where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.
- `strata`: A vector or factor of the same length as `L` giving the strata for the observed data and the empirical influence values `L`.

**Details**

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic has mean `theta`. The weights chosen to achieve this are given by `p[j]` proportional to `exp(lambda[j] * L[j]/n)`, where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.
Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions imp.prob or imp.quantile to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of smooth.f. The function tilt.boot uses exp.tilt or smooth.f to find the weights for a tilted bootstrap.

Value
A list with the following components:

- \( p \) The tilted probabilities. There will be \( m \) distributions where \( m \) is the length of \( \theta \) (or \( \lambda \) if supplied). If \( m \) is 1 then \( p \) is a vector of length(L) probabilities. If \( m \) is greater than 1 then \( p \) is a matrix with \( m \) rows, each of which contain length(L) probabilities. In this case the vector \( p[i,] \) is the distribution tilted to \( \theta[i] \). \( p \) is in the form required by the argument weights of the function boot for importance resampling.

- \( \lambda \) The Lagrange multiplier used in the equation to determine the tilted probabilities. \( \lambda \) is a vector of the same length as \( \theta \).

- \( \theta \) The values of \( \theta \) to which the distributions have been tilted. In general this will be the input value of \( \theta \) but if \( \lambda \) was supplied then this is the vector of the corresponding \( \theta \) values.

Examples

```r
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling distribution of the studentized statistic to be centred at the observed value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2]) >=7 , ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
                 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
```
The `fir` data frame has 50 rows and 3 columns. The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

The `freq.array` function takes a matrix of indices for nonparametric bootstrap resamples and returns the frequencies of the original observations in each resample.

```r
freq.array(i.array)
```

**Arguments**

- `i.array`: This will be a matrix of integers between 1 and n, where n is the number of observations in a data set. The matrix will have n columns and R rows where R is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.?
Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

frets  

Head Dimensions in Brothers

Description

The frets data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

Usage

frets

Format

This data frame contains the following columns:

- l1  The head length of the eldest son.
- b1  The head breadth of the eldest son.
- l2  The head length of the second son.
- b2  The head breadth of the second son.

glm.diag

Generalized Linear Model Diagnostics

Description

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

Usage

glm.diag(glmfit)

Arguments

glmfit

is a glm.object - the result of a call to glm()

Value

Returns a list with the following components

res

The vector of jackknife deviance residuals.

rd

The vector of standardized deviance residuals.

rp

The vector of standardized Pearson residuals.

cook

The vector of approximate Cook statistics.

h

The vector of leverages of the observations.

sd

The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1.

Note

See the help for glm.diag.plots for an example of the use of glm.diag.

References

glm.diag.plots

Diagnostics plots for generalized linear models

Description

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

Usage

```r
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL, iden = FALSE, labels = NULL, ret = FALSE)
```

Arguments

- `glmfit`: `glm.object`: the result of a call to `glm()`
- `glmdiag`: Diagnostics of `glmfit` obtained from a call to `glm.diag`. If it is not supplied then it is calculated.
- `subset`: Subset of data for which glm fitting performed: should be the same as the subset option used in the call to `glm()` which generated `glmfit`. Needed only if the `subset` option was used in the call to `glm`.
- `iden`: A logical argument. If TRUE then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke `identify()` on that plot. After exiting `identify()`, the user is again prompted, this loop continuing until the user responds to the prompt with 0. If `iden` is FALSE (default) the user cannot interact with the plots.
- `labels`: A vector of labels for use with `identify()` if `iden` is TRUE. If it is not supplied then the labels are derived from `glmfit`.
- `ret`: A logical argument indicating if `glmdiag` should be returned. The default is FALSE.

Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at $8/(n-2p)$ where n is the number of observations and p is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at $2p/(n-2p)$ and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.
Use of iden=T is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

**Value**

If ret is TRUE then the value of glm.diag is returned otherwise there is no returned value.

**Side Effects**

The current device is cleared and four plots are plotted by use of split.screen(c(2,2)). If iden is TRUE, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

**Description**

The `gravity` data frame has 81 rows and 2 columns. The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity, \( g \), at Washington. Each experiment produced a number of replicate estimates of \( g \) using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.
Usage

gravity

Format

This data frame contains the following columns:

- **g**: The deviation of the estimate from 980.000 centimetres per second squared.
- **series**: A factor describing from which experiment the estimate was derived.

Source

The data were obtained from

Importance Sampling Estimates

Description

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

Usage

```r
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
            w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
         t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
             t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
```

Arguments

- `boot.out`: A object of class "boot" generated by a call to `boot` or `tilt.boot`. Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights `w` are not supplied then `boot.out` is a required argument. It is also required if `t` is not supplied.
- `alpha`: The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.
- `index`: The index of the variable of interest in the output of `boot.out$statistic`. This is not used if the argument `t` is supplied.
- `t0`: The values at which tail probability estimates are required. For each value `t0[i]` the function will estimate the bootstrap cdf evaluated at `t0[i]`. If `imp.prob` is called without the argument `t0` then the bootstrap cdf evaluated at the observed value of the statistic is found.
- `t`: The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object `boot.out` but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in `boot.out`). Either `boot.out` or `t` must be supplied.
- `w`: The importance resampling weights for the bootstrap replicates. If they are not supplied then `boot.out` must be supplied, in which case the importance weights are calculated by a call to `imp.weights`.
- `def`: A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if `w` is missing and it is passed unchanged to `imp.weights` to calculate `w`.
- `q`: A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights `w` so this argument is ignored if `w` is supplied. If `w` is missing then `q` is passed as an argument to `imp.weights` and used to find `w`. 
Value

A list with the following components:

alpha The alpha levels used for the quantiles, if `imp.quantile` is used.
t0 The values at which the tail probabilities are estimated, if `imp.prob` is used.
raw The raw importance resampling estimates. For `imp.moments` this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For `imp.prob`, `raw` is of the same length as `t0`, and for `imp.quantile` it is of the same length as `alpha`.
rat The ratio importance resampling estimates. In this method the weights are rescaled to have average value one before they are used. The format of this vector is the same as `raw`.
reg The regression importance resampling estimates. In this method the weights which are used are derived from a regression of `t*w` on `w`. This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as `raw`.

as.data.frame(grav.q)

imp.weights

Importance Sampling Weights

Description

This function calculates the importance sampling weight required to correct for simulation from a
distribution with probabilities \( p \) when estimates are required assuming that simulation was from an
alternative distribution with probabilities \( q \).

Usage

imp.weights(boot.out, def = TRUE, q = NULL)

Arguments

boot.out  A object of class "boot" generated by boot or tilt.boot. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.
def  A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in boot.out were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.
q  A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. \( q \) must have length equal to the number of observations in the boot.out$data and all elements of \( q \) must be positive.

Details

The importance sampling weight for a bootstrap replicate with frequency vector \( f \) is given by
\[ \prod (q/p)^f. \] This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities \( q \) even though, in fact, they came from the distribution \( p \).
**inv.logit**

**Inverse Logit Function**

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```
inv.logit(x)
```

**Arguments**

- `x` A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by \( \exp(x)/(1+\exp(x)) \). Values in \( x \) of \(-\infty\) or \( \infty \) return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as \( x \) containing the inverse logits of the input values.

**See Also**

logit, plogis for which this is a wrapper.

---

**Value**

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities \( q \).

**Note**

See the example in the help for `imp.moments` for an example of using `imp.weights`.

**Description**

The *islay* data frame has 18 rows and 1 column.
Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

**Usage**

*islay*

**Format**

This data frame contains the following column:

*theta*  The angle of the azimuth in degrees East of North.

**Source**

The data were obtained from

**References**

---

**Description**

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

**Usage**

```r
jack.after.boot(boot.out, index = 1, t = NULL, L = NULL, useJ = TRUE, stinf = TRUE, alpha = NULL, main = "", ylab = NULL, ...)
```
Arguments

boot.out  An object of class "boot" which would normally be created by a call to boot. It should represent a nonparametric bootstrap. For reliable results boot.out$R should be reasonably large.

index  The index of the statistic of interest in the output of boot.out$statistic.

t  A vector of length boot.out$R giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is boot.out$t[,index].

L  The empirical influence values for the statistic of interest. These are used only if useJ is FALSE. If they are not supplied and are needed, they are calculated by a call to empinf. If L is supplied then it is assumed that they are the infinitesimal jackknife values.

useJ  A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If FALSE the empirical influence values are used. The default is TRUE.

stinf  A logical variable indicating whether to standardize the jackknife values before plotting them. If TRUE then the jackknife values used are divided by their standard error.

alpha  The quantiles at which the plots are required. The default is c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95).

main  A character string giving the main title for the plot.

ylab  The label for the Y axis. If the default values of alpha are used and ylab is not supplied then a label indicating which percentiles are plotted is used. If alpha is supplied then the default label will not say which percentiles were used.

...  Any extra arguments required by boot.out$statistic. These are required only if useJ is FALSE and L is not supplied, in which case they are passed to empinf for use in calculation of the empirical influence values.

Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If useJ is TRUE then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If useJ is FALSE then empirical influence values are calculated by calling empinf.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

Value

There is no returned value but a plot is generated on the current graphics display.
Side Effects

A plot is created on the current graphics device.

# To draw the jackknife-after-bootstrap plot for the head size data as in
# Example 3.24 of Davison and Hinkley (1997)
frets.fun <- function(data, i) {
pcorr <- function(x) {
    # Function to find the correlations and partial correlations between
    # the four measurements.
    v <- cor(x)
    v.d <- diag(var(x))
    iv <- solve(v)
    iv.d <- sqrt(diag(iv))
    iv <- diag(1/iv.d) %*% iv %*% diag(1/iv.d)
    q <- NULL
    n <- nrow(v)
    for (i in 1:(n-1))
        q <- rbind(q, c(v[i, 1:i], iv[i,(i+1):n]) )
    q <- rbind( q, v[n, ] )
    diag(q) <- round(diag(q))
    q
}
    d <- data[i, ]
    v <- pcorr(d)
    c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)
```

---

**k3.linear**

*Linear Skewness Estimate*

Description

Estimates the skewness of a statistic from its empirical influence values.
Usage

k3.linear(L, strata = NULL)

Arguments

L Vector of the empirical influence values of a statistic. These will usually be calculated by a call to empinf.

strata A numeric vector or factor specifying which observations (and hence which components of L) come from which strata.

Value

The skewness estimate calculated from L.

References

See Also

empinf, linear.approx, var.linear

Examples

# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))

linear.approx Linear Approximation of Bootstrap Replicates

Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

Usage

linear.approx(boot.out, L = NULL, index = 1, type = NULL, t0 = NULL, t = NULL, ...)

Arguments

boot.out An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function boot.

L A vector containing the empirical influence values for the statistic of interest. If it is not supplied then L is calculated through a call to empinf.

index The index of the variable of interest within the output of boot.out$statistic.
type

This gives the type of empirical influence values to be calculated. It is not used if \( L \) is supplied. The possible types of empirical influence values are described in the help for \texttt{empinf}.

t0

The observed value of the statistic of interest. The input value is used only if one of \( t \) or \( L \) is also supplied. The default value is \texttt{boot.out$t0[index]} if \( t0 \) is supplied but neither \( t \) nor \( L \) are supplied then \( t0 \) is set to \texttt{boot.out$t0[index]} and a warning is generated.

t

A vector of bootstrap replicates of the statistic of interest. If \( t0 \) is missing then \( t \) is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in \( L \)).

... Any extra arguments required by \texttt{boot.out$statistic}. These are needed if \( L \) is not supplied as they are used by \texttt{empinf} to calculate empirical influence values.

Details

The linear approximation to a bootstrap replicate with frequency vector \( f \) is given by \( t0 + \text{sum}(L \ast f)/n \) in the one sample with an easy extension to the stratified case. The frequencies are found by calling \texttt{boot.array}.

Value

A vector of length \texttt{boot.out$R} with the linear approximations to the statistic of interest for each of the bootstrap samples.

Examples

# Using the city data let us look at the linear approximation to the # ratio statistic and its logarithm. We compare these with the # corresponding plots for the bigcity data

```r
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 499, stype = "w")
bigcity.boot <- boot(bigcity, ratio, R = 499, stype = "w")
op <- par(pty = "s", mfrow = c(2, 2))

# The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t,city.lin1))
plot(city.boot$t, city.lin1, xlim = lim, ylim = lim,
     main = "Ratio; n=10", xlab = "t\ast", ylab = "tL\ast")
abline(0, 1)

# Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot,t0 = log(city.boot$t0),
```

```
lines.saddle.distn

Add a Saddlepoint Approximation to a Plot

Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

Usage

## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
   npts = 50, lty = 1, ...)

Arguments

x 
An object of class "saddle.distn" (see saddle.distn.object representing a saddlepoint approximation to a distribution.

dens 
A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.

h 
Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.

J 
When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list.

npts 
The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.
Lines.saddle.distn

1ty The line type to be used.

... Any additional arguments to h and J.

Details

The function uses smooth.spline to produce the saddlepoint curve. When dens=TRUE the spline is on the log scale and when dens=FALSE it is on the probit scale.

Value

sad.d is returned invisibly.

Side Effects

A line is added to the current plot.

References

saddle.distn

Examples

# In this example we show how a plot such as that in Figure 9.9 of
# Davison and Hinkley (1997) may be produced. Note the large number of
# bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
  n <- length(d)
  (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata,vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t))
exp.sp <- saddle.distn(A = exp.L/12,wdist = "m", t0 = exp.t0)

# The saddlepoint approximation in this case is to the density of
# t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1,
     t0 = exp.boot$t0)
Description
This function calculates the logit of proportions.

Usage
logit(p)

Arguments
p A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

Details
If any elements of p are outside the unit interval then an error message is generated. Values of p equal to 0 or 1 (to within machine precision) will return -Inf or Inf respectively. Any NAs in the input will also be NAs in the output.

Value
A numeric object of the same type as p containing the logits of the input values.

See Also
inv.logit, qlogis for which this is a wrapper.

Description
The manaus time series is of class "ts" and has 1080 observations on one variable.
The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.
The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.
Source
The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

References

Description
The melanoma data frame has 205 rows and 7 columns.
The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

Usage
melanoma

Format
This data frame contains the following columns:

time Survival time in days since the operation, possibly censored.
status The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.
sex The patients sex; 1=male, 0=female.
age Age in years at the time of the operation.
year Year of operation.
thickness Tumour thickness in mm.
ulcer Indication of ulceration; 1=present, 0=absent.

Note
This dataset is not related to the dataset in the lattice package with the same name.
motor

**neuro**

*Neurophysiological Point Process Data*

**Description**

neuro is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

**Note**

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

**Source**

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

**References**

**nitrofen**

*Toxicity of Nitrofen in Aquatic Systems*

**Description**

The nitrofen data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

**Usage**

Nitrofen
**nodal**

**Format**

This data frame contains the following columns:

- **conc**: The nitrofen concentration in the solution (mug/litre).
- **brood1**: The number of live offspring in the first brood.
- **brood2**: The number of live offspring in the second brood.
- **brood3**: The number of live offspring in the third brood.
- **total**: The total number of live offspring in the first three broods.

**Source**

The data were obtained from

**nodal**  

**Nodal Involvement in Prostate Cancer**

**Description**

The nodal data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Usage**

nodal

**Format**

This data frame contains the following columns:

- **m**: A column of ones.
- **r**: An indicator of nodal involvement.
- **aged**: The patients age dichotomized into less than 60 (0) and 60 or over (1).
- **stage**: A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.
grade  Another indicator of the seriousness of the cancer, this one is determined by a pathology
reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case
of the cancer.

xray  A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1
indicates a more serious case of the cancer.

acid The level of acid phosphatase in the blood serum.

Source

The data were obtained from

References

University Press.

**norm.ci**  
*Normal Approximation Confidence Intervals*

**Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

**Usage**

```r
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
t0 = NULL, t = NULL, L = NULL, h = function(t) t,
hdot = function(t) 1, hinv = function(t) t)
```

**Arguments**

- `boot.out`  
  A bootstrap output object returned from a call to `boot`. If `t0` is missing then `boot.out` is a required argument. It is also required if both `var.t0` and `t` are missing.

- `conf`  
  A scalar or vector containing the confidence level(s) of the required interval(s).

- `index`  
  The index of the statistic of interest within the output of a call to `boot.out$statistic`. It is not used if `boot.out` is missing, in which case `t0` must be supplied.

- `var.t0`  
  The variance of the statistic of interest. If it is not supplied then `var(t)` is used.

- `t0`  
  The observed value of the statistic of interest. If it is missing then it is taken from `boot.out` which is required in that case.

- `t`  
  Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if `var.t0` is not supplied. The default value is `boot.out$t[, index]`.

- `L`  
  The empirical influence values for the statistic of interest. These are used to calculate `var.t0` if neither `var.t0` nor `boot.out` are supplied. If a transformation is supplied through `h` then the influence values must be for the untransformed statistic `t0`. 

norm.ci

h: A function defining a monotonic transformation, the intervals are calculated on the scale of \( h(t) \) and the inverse function \( hinv \) is applied to the resulting intervals. \( h \) must be a function of one variable only and must be vectorized. The default is the identity function.

hdot: A function of one argument returning the derivative of \( h \). It is a required argument if \( h \) is supplied and is used for approximating the variance of \( h(t_0) \). The default is the constant function 1.

hinv: A function, like \( h \), which returns the inverse of \( h \). It is used to transform the intervals calculated on the scale of \( h(t) \) back to the original scale. The default is the identity function. If \( h \) is supplied but \( hinv \) is not, then the intervals returned will be on the transformed scale.

Details

It is assumed that the statistic of interest has an approximately normal distribution with variance \( \text{var}.t_0 \) and so a confidence interval of length \( 2 \times \text{qnorm}((1 + \text{conf})/2) \times \text{sqrt}(\text{var}.t_0) \) is found. If \( \text{boot}.\text{out} \) or \( t \) are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at \( 2 \times t_0 - \text{mean}(t) \). Otherwise the interval is centred at \( t_0 \).

Value

If \( \text{length(\text{conf})} \) is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

Note

This function is primarily designed to be called by \( \text{boot}.\text{ci} \) to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as \( t_0 \) and \( \text{var}.t_0 \) can be supplied. See the examples below.

nuclear

Nuclear Power Station Construction Data

Description

The nuclear data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960’s and early 1970’s. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers’ subsidies may be hidden in the quoted capital costs.

Usage

nuclear

Format

This data frame contains the following columns:

cost  The capital cost of construction in millions of dollars adjusted to 1976 base.
date  The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.
t1   The time between application for and issue of the construction permit.
t2   The time between issue of operating license and construction permit.
cap  The net capacity of the power plant (MWe).
pr   A binary variable where 1 indicates the prior existence of a LWR plant at the same site.
ne   A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.
ct   A binary variable where 1 indicates the use of a cooling tower in the plant.
bw   A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.
cum.n The cumulative number of power plants constructed by each architect-engineer.
pt   A binary variable where 1 indicates those plants with partial turnkey guarantees.

Neurotransmission in Guinea Pig Brains

Description

The `paulsen` data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

Usage

`paulsen`

Format

This data frame contains the following column:

- `y` The current flowing into individual brain cells. The currents are measured in pico-amperes.

Source

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Plots of the Output of a Bootstrap Simulation

Description

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

Usage

```r
## S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```
Arguments

- **x**: An object of class "boot" returned from one of the bootstrap generation functions.
- **index**: The index of the variable of interest within the output of boot.out. This is ignored if t and t0 are supplied.
- **t0**: The original value of the statistic. This defaults to boot.out$t0[index] unless t is supplied when it defaults to NULL. In that case no vertical line is drawn on the histogram.
- **t**: The bootstrap replicates of the statistic. Usually this will take on its default value of boot.out$t[,index], however it may be useful sometimes to supply a different set of values which are a function of boot.out$t.
- **jack**: A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.
- **qdist**: The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.
- **nclass**: An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to ceiling(length(t)/25).
- **df**: If qdist is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.
- **...**: When jack is TRUE additional parameters to jack.after.boot can be supplied. See the help file for jack.after.boot for details of the possible parameters.

Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that t0 is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of t0. This cannot be done if t is supplied but t0 is not and so, in that case, the breakpoints are computed by hist using the nclass argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept mean(t) and slope sqrt(var(t)) while for the chi-squared it has intercept 0 and slope 1.

If jack is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See jack.after.boot for further details of this plot.

Value

boot.out is returned invisibly.

Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

poisons  \hspace{1cm} Animal Survival Times

Description

The \texttt{poisons} data frame has 48 rows and 3 columns. The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

Usage

\texttt{poisons}

Format

This data frame contains the following columns:

- \texttt{time}  The survival time of the animal in units of 10 hours.
- \texttt{poison}  A factor with levels 1, 2 and 3 giving the type of poison used.
- \texttt{treat}  A factor with levels A, B, C and D giving the treatment.

print.boot  

Print a Summary of a Bootstrap Object

Description

This is a method for the function print() for objects of the class "boot" created by a call to boot, censboot, tilt.boot or tsboot.

Usage

## S3 method for class 'boot'
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)

Arguments

x  A bootstrap output object of class "boot" generated by one of the bootstrap functions.
digits  The number of digits to be printed in the summary statistics.
index  Indices indicating for which elements of the bootstrap output summary statistics are required.
...  further arguments passed to or from other methods.

Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If boot.out$t0 is missing (such as when it was created by a call to tsboot with orig.t = FALSE) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.
print.bootci

Value
The bootstrap object is returned invisibly.

See Also
boot, censboot, imp.moments, plot.boot, tilt.boot, tsboot

print.bootci

Print Bootstrap Confidence Intervals

Description
This is a method for the function print() to print objects of the class “bootci”.

Usage
## S3 method for class 'bootci'
print(x, hinv = NULL, ...)

Arguments
x The output from a call to boot.ci.
hinv A transformation to be made to the interval end-points before they are printed.
... further arguments passed to or from other methods.

Details
This function prints out the results from boot.ci in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to boot.ci or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message
Warning: Intervals used Extreme Quantiles
Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message
Some intervals may be unstable

Value
The object ci.out is returned invisibly.

See Also
boot.ci
Description

This is a method for the function `print()` to print objects of class "saddle.distn".

Usage

```r
## S3 method for class 'saddle.distn'
print(x, ...)
```

Arguments

- `x` An object of class "saddle.distn" created by a call to `saddle.distn`.
- `...` further arguments passed to or from other methods.

Details

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

Value

The input is returned invisibly.

See Also

`lines.saddle.distn`, `saddle.distn`
Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

Value

x is returned silently.

remission

Cancer Remission and Cell Activity

Description

The remission data frame has 27 rows and 3 columns.

Usage

remission

Format

This data frame contains the following columns:

LI A measure of cell activity.

m The number of patients in each group (all values are actually 1 here).

r The number of patients (out of m) who went into remission.

Source

The data were obtained from

References

Description
This function calculates a saddlepoint approximation to the distribution of a linear combination of \( W \) at a particular point \( u \), where \( W \) is a vector of random variables. The distribution of \( W \) may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of \( W \) can be calculated for \( W \) having binary or Poisson distributions.

Usage
```
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,  
d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,  
strata = NULL, K.adj = NULL, K2 = NULL)
```

Arguments

- **A**
  A vector or matrix of known coefficients of the linear combinations of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.

- **u**
  The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.

- **wdist**
  The distribution of \( W \). This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If \( K.\text{adj} \) and \( K2 \) are given \( wdist \) is set to "o".

- **type**
  The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When \( wdist \) is "o" or "m", type is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.

- **d**
  This specifies the dimension of the whole statistic. This argument is required only when \( wdist = "o" \) and defaults to 1 if not supplied in that case. For other distributions it is set to \( \text{ncol}(A) \).

- **d1**
  When type is "cond" this is the dimension of the statistic of interest which must be less than \( \text{length}(u) \). Then the saddlepoint approximation to the conditional distribution of the first \( d1 \) linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of \( d1 \) is 1.

- **init**
  Used if \( wdist \) is either "m" or "o", this gives initial values to \( \text{nls} \) which is used to solve the saddlepoint equation.

- **mu**
  The values of the parameters of the distribution of \( W \) when \( wdist \) is "m", "p" or "b". \( \mu \) must be of the same length as \( W \) (i.e. \( \text{nrow}(A) \)). The default is that all values of \( \mu \) are equal and so the elements of \( W \) are identically distributed.

- **LR**
  If TRUE then the Lugannani-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's \( r^* \).

- **strata**
  The strata for stratified data.
K.adj
The adjusted cumulant generating function used when wdist is "o". This is a function of a single parameter, zeta, which calculates K(zeta)-u%*%zeta, where K(zeta) is the cumulant generating function of W.

K2
This is a function of a single parameter zeta which returns the matrix of second derivatives of K(zeta) for use when wdist is "o". If K.adj is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if K.adj is not supplied.

Details
If wdist is "o" or "m", the saddlepoint equations are solved using nlmin to minimize K.adj with respect to its parameter zeta. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the glm must satisfy the equation t(A)%*%y = u (t() being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to simplex. The covariate matrix for the glm is given by A.

Value
A list consisting of the following components

spa
The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.

zeta.hat
The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.

zeta2.hat
If type is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of type.

saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
saddle.distn

Saddlepoint Distribution Approximations for Bootstrap Statistics

Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of $W$ where $W$ is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of $W$ must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function control to approximate the distribution of the linear approximation to a statistic.

Usage

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m", type = "simp", npts = 20, t = NULL, t0 = NULL, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE, strata = NULL, ...)

Arguments

A

This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point $t$ at which a saddlepoint is required. The most common reason for $A$ being a function would be if the statistic is not itself a linear combination of the $W$ but is the solution to a linear estimating equation.
If \(A\) is a function then \(u\) must also be a function returning a vector with length equal to the number of columns of the matrix returned by \(A\). Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If \(A\) is a matrix with more than one column (such as when \(\text{wdist} = "\text{cond}"\)) then \(u\) should be a vector with length one less than \(n\text{col}(A)\). In this case \(u\) specifies the values of the conditioning variables. If \(A\) is a matrix with one column or a vector then \(u\) is not used.

**alpha**

The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.

**wdist**

The distribution of \(W\). Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).

**type**

The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If \(\text{wdist}\) is "m", type is set to "simp".

**npts**

The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.

**t**

A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in \(t\) as the distribution function approximation breaks down at that point. The points should, however, cover the entire effective range of the distribution including close to the centre. If \(t\) is supplied then \(\text{npts}\) is set to \(\text{length}(t)\). When \(t\) is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range.

**t0**

If \(t\) is not supplied then a vector of length 2 should be passed as \(t0\). The first component of \(t0\) should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in \(t0[1]\).

**init**

When \(\text{wdist}\) is "m", this vector should contain the initial values to be passed to \(\text{nlmin}\) when it is called to solve the saddlepoint equations.

**mu**

The vector of parameter values for the distribution. The default is that the components of \(W\) are identically distributed.

**LR**

A logical flag. When \(\text{LR}\) is \(\text{TRUE}\) the Lugannanni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's \(r^*\).

**strata**

A vector giving the strata when the rows of \(A\) relate to stratified data. This is used only when \(\text{wdist}\) is "m".

... When \(A\) and \(u\) are functions any additional arguments are passed unchanged each time one of them is called.

**Details**

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of alpha. The lower endpoint is found by evaluating the saddlepoint at the points \(t0[1]-2*t0[2]\), \(t0[1]-4*t0[2]\), \(t0[1]-8*t0[2]\) etc. until a point is found with a cdf approximation less than \(\min(\text{alpha})/10\). Then a bisection method is used to find the endpoint which has cdf approximation in the range \((\min(\text{alpha})/1000, \min(\text{alpha})/10)\). Then a number of, equally spaced, points are chosen between the lower endpoint and \(t0[1]\) until...
a total of npts/2 approximations have been made. The remaining npts/2 points are chosen to the right of t0[1] in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline. Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of t0[2] is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of t0[2] will usually solve the problem.

Value

The returned value is an object of class "saddle.distn". See the help file for saddle.distn.object for a description of such an object.

Examples

```r
# The bootstrap distribution of the mean of the air-conditioning
# data: fails to find value on R (and probably on S too)
air.t0 <- c(mean(aircondit$hours), sqrt(var(aircondit$hours)/12))
## Not run: saddle.distn(A = aircondit$hours/12, t0 = air.t0)

# alternatively using the conditional poisson
saddle.distn(A = cbind(aircondit$hours/12, 1), u = 12, wdist = "p",
            type = "cond", t0 = air.t0)

# Distribution of the ratio of a sample of size 10 from the bigcity
# data, taken from Example 9.16 of Davison and Hinkley (1997).
ratio <- function(d, w) sum(d$x *w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
bigcity.t0 <- c(mean(bigcity$x)/mean(bigcity$u), sqrt(city.v))
Afn <- function(t, data) cbind(data$x - t*data$u, 1)
ufn <- function(t, data) c(0,10)
saddle.distn(A = Afn, u = ufn, wdist = "b", type = "cond",
            t0 = bigcity.t0, data = bigcity)
```
From Example 9.16 of Davison and Hinkley (1997) again, we find the conditional distribution of the ratio given the sum of city$u. 
Afn <- function(t, data) cbind(data$x-t*data$u, data$u, 1) 
ufn <- function(t, data) c(0, sum(data$u), 10) 
city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.$v)) 
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0, data = city)
The Salinity data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

salinity

**Format**

This data frame contains the following columns:

- sal: The average salinity of the water over two weeks.
- lag: The average salinity of the water lagged two weeks. Since only spring is used, the value of lag is not always equal to the previous value of sal.
- trend: A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.
- dis: The amount of river discharge during the two weeks for which sal is the average salinity.

**Source**

The data were obtained from

The Simplex Method for Linear Programming Problems

This function will optimize the linear function \( a^\%\%x \) subject to the constraints \( A1^\%\%x \leq b1 \), \( A2^\%\%x \geq b2 \), \( A3^\%\%x = b3 \) and \( x \geq 0 \). Either maximization or minimization is possible but the default is minimization.
Usage

```r
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
        b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

Arguments

- **a**: A vector of length \( n \) which gives the coefficients of the objective function.
- **A1**: An \( m_1 \) by \( n \) matrix of coefficients for the \( \leq \) type of constraints.
- **b1**: A vector of length \( m_1 \) giving the right hand side of the \( \leq \) constraints. This argument is required if \( A1 \) is given and ignored otherwise. All values in \( b1 \) must be non-negative.
- **A2**: An \( m_2 \) by \( n \) matrix of coefficients for the \( \geq \) type of constraints.
- **b2**: A vector of length \( m_2 \) giving the right hand side of the \( \geq \) constraints. This argument is required if \( A2 \) is given and ignored otherwise. All values in \( b2 \) must be non-negative. Note that the constraints \( x \geq 0 \) are included automatically and so should not be repeated here.
- **A3**: An \( m_3 \) by \( n \) matrix of coefficients for the equality constraints.
- **b3**: A vector of length \( m_3 \) giving the right hand side of equality constraints. This argument is required if \( A3 \) is given and ignored otherwise. All values in \( b3 \) must be non-negative.
- **maxi**: A logical flag which specifies minimization if \( \text{FALSE} \) (default) and maximization otherwise. If \( \text{maxi} \) is \( \text{TRUE} \) then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
- **n.iter**: The maximum number of iterations to be conducted in each phase of the simplex method. The default is \( n + 2 \times (m_1 + m_2 + m_3) \).
- **eps**: The floating point tolerance to be used in tests of equality.

Details

The method employed by this function is the two phase tableau simplex method. If there are \( \geq \) or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each \( \geq \) or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the \( \leq \) form, the origin is a feasible solution and so the first stage can be omitted.

Value

An object of class "simplex": see \code{simplex.object}.

Note

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form \( x[i] \geq b2[i] \) they should be omitted by setting \( x[i] = x[i] - b2[i] \), changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.
References

Examples

# This example is taken from Exercise 7.5 of Gill, Murray and Wright (1991).
enj <- c(200, 6000, 3000, -200)

vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
b2 = c(600, 300, 550), maxi = TRUE)

simplex.object

Linear Programming Solution Objects

Description

Class of objects that result from solving a linear programming problem using `simplex`.

Generation

This class of objects is returned from calls to the function `simplex`.

Methods

The class "saddle.distn" has a method for the function `print`.

Structure

Objects of class "simplex" are implemented as a list with the following components.

- **soln** The values of x which optimize the objective function under the specified constraints provided those constraints are jointly feasible.
- **solved** This indicates whether the problem was solved. A value of -1 indicates that no feasible solution could be found. A value of 0 that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of 1 indicates that an optimal solution has been found.
- **value** The value of the objective function at soln.
- **val.aux** This is NULL if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.
- **obj** The original coefficients of the objective function.
- **a** The objective function coefficients re-expressed such that the basic variables have coefficient zero.
- **a.aux** This is NULL if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.
The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions \(m_1+m_2+m_3 \times n+m_1+m_2\), where the final \(m_1+m_2\) columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional \(m_1+m_2+m_3\) columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between \(n+1\) and \(n+m_1\) correspond to slack variables, those between \(n+m_1+1\) and \(n+m_2\) correspond to surplus variables and those greater than \(n+m_2\) are artificial variables. Indices greater than \(n+m_2\) should occur only if \(solved\) is \(-1\) as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the \(m_1\) slack variables which arise when the "\(\leq\)" constraints are re-expressed as the equalities \(A_1\%*\%x + \text{slack} = b_1\).

**surplus** The final values of the \(m_2\) surplus variables which arise when the "\(\leq\)" constraints are re-expressed as the equalities \(A_2\%*\%x - \text{surplus} = b_2\).

**artificial** This is NULL if a feasible solution can be found. If no solution can be found then this contains the values of the \(m_1+m_2+m_3\) artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

---

**smooth.f**

Smooth Distributions on Data Points

**Description**

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, \(\theta\), of the statistic of interest. The method results in distributions which vary smoothly with \(\theta\).

**Usage**

```r
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index], width = 0.5)
```

**Arguments**

- **theta**: The required value for the statistic of interest. If \(\theta\) is a vector, a separate distribution will be found for each element of \(\theta\).
- **boot.out**: A bootstrap output object returned by a call to `boot`.
- **index**: The index of the variable of interest in the output of `boot.out$statistic`. This argument is ignored if \(t\) is supplied. `index` must be a scalar.
- **t**: The bootstrap values of the statistic of interest. This must be a vector of length `boot.out$R` and the values must be in the same order as the bootstrap replicates in `boot.out`.
- **width**: The standardized width for the kernel smoothing. The smoothing uses a value of \(width*s\) for epsilon, where \(s\) is the bootstrap estimate of the standard error of the statistic of interest. \(width\) should take a value in the range \((0.2, 1)\) to produce a reasonable smoothed distribution. If \(width\) is too large then the distribution becomes closer to uniform.
The new distributional weights are found by applying a normal kernel smoother to the observed values of \( t \) weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value \( \theta \) but it will typically have a value which is close to \( \theta \). The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

If \( \text{length}(\theta) \) is 1 then a vector with the same length as the data set \( \text{boot.out$data} \) is returned. The value in position 1 is the probability to be given to the data point in position 1 so that the distribution has parameter value approximately equal to \( \theta \). If \( \text{length}(\theta) \) is bigger than 1 then the returned value is a matrix with \( \text{length}(\theta) \) rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of \( \theta \).

References

Examples

```r
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
data of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. In the book exponential tilting was used
# but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
d <- dat[, 1]
ns <- tabulate(strata)
w <- w/tapply(w, strata, sum)[strata]
mns <- as.vector(tapply(d * w, strata, sum)) # drop names
mn2 <- tapply(d * d * w, strata, sum)
s2hat <- sum((mn2 - mns^2)/ns)
c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1],
  weights = grav.sm)

# Estimated p-values can be found from these as follows
mean(grav.boot$t[, 3] >= grav.z0[3])
```
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

### sunspot

**Annual Mean Sunspot Numbers**

**Description**

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by \( k(f+10g) \) where \( g \) is the number of sunspot groups observed, \( f \) is the total number of spots within the groups and \( k \) is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

### survival

**Survival of Rats after Radiation Doses**

**Description**

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

**Usage**

survival
**tau**

**Format**

This data frame contains the following columns:

- **dose**: The dose of radiation administered (rads).
- **surv**: The survival rate of the batches expressed as a percentage.

**Source**

**References**

---

**tau**

*Tau Particle Decay Modes*

**Description**

The *tau* data frame has 60 rows and 2 columns.

The *tau* particle is a heavy electron-like particle discovered in the 1970’s by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the *tau* particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

- *tau*

**Format**

This data frame contains the following columns:

- **rate**: The decay rate expressed as a percentage.
- **decay**: The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

**Source**

References

---

**tilt.boot**

*Non-parametric Tilted Bootstrap*

**Description**

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

**Usage**

```r
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i", strata = rep(1, n), L = NULL, theta = NULL, alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5, index = 1, ...)
```

**Arguments**

- `data` The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.
- `statistic` A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be `data` and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to `tilt.boot` and will be passed unchanged to statistic each time it is called.
- `R` The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of `R` are the number of simulations to be performed resampling from each reweighted distribution. The first value of `R` must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus `length(R)` should always equal 1+length(theta).
- `sim` This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run `boot`, calculate the weights appropriately, and run `boot` again using the calculated weights.
- `stype` A character string indicating the type of second argument expected by `statistic`. The possible values that stype can take are "i" (indices), "w" (weights) and "f" (frequencies).
- `strata` An integer vector or factor representing the strata for multi-sample problems.
L

The empirical influence values for the statistic of interest. They are used only for exponential tilting when tilt is TRUE. If tilt is TRUE and they are not supplied then tilt.boot uses empinf to calculate them.

theta

The required parameter value(s) for the tilted distribution(s). There should be one value of theta for each of the non-uniform distributions. If R[1] is 0 theta is a required argument. Otherwise theta values can be estimated from the initial uniform bootstrap and the values in alpha.

alpha

The alpha level to which tilting is required. This parameter is ignored if R[1] is 0 or if theta is supplied, otherwise it is used to find the values of theta as quantiles of the initial uniform bootstrap. In this case R[1] should be large enough that min(c(alpha, 1-alpha)) * R[1] > 5, if this is not the case then a warning is generated to the effect that the theta are extreme values and so the tilted output may be unreliable.

tilt

A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing (smooth.f) is used. If tilt is FALSE then R[1] must be positive. In fact in this case the value of R[1] should be fairly large (in the region of 500 or more).

width

This argument is used only if tilt is FALSE, in which case it is passed unchanged to smooth.f as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See smooth.f for more details.

index

The index of the statistic of interest in the output from statistic. By default the first element of the output of statistic is used.

... Any additional arguments required by statistic. These are passed unchanged to statistic each time it is called.

Value

An object of class "boot" with the following components

t0

The observed value of the statistic on the original data.

t

The values of the bootstrap replicates of the statistic. There will be sum(R) of these, the first R[1] corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).

R

The input vector of the number of bootstrap replicates.

data

The original data as supplied.

statistic

The statistic function as supplied.

sim

The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".

stype

The type of statistic supplied, it is the same as the input value stype.

call

A copy of the original call to tilt.boot.

strata

The strata as supplied.

weights

The matrix of weights used. If R[1] is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If R[1] equals 0 then the uniform weights are omitted and only the tilted weights are output.

theta

The values of theta used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and alpha.

tsboot

**Bootstrapping of Time Series**

**Description**
Generate \( R \) bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```r
tsboot(tseries, statistic, R, l = NULL, sim = "model", endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE, ran.gen, ran.args = NULL, parallel = c("no", "multicore", "snow"), ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

- `tseries`: A univariate or multivariate time series.
- `statistic`: A function which when applied to `tseries` returns a vector containing the statistic(s) of interest. Each time `statistic` is called it is passed a time series of length `n.sim` which is of the same class as the original `tseries`. Any other arguments which `statistic` takes must remain constant for each bootstrap replicate and should be supplied through the `...` argument to `tsboot`.
- `R`: A positive integer giving the number of bootstrap replicates required.
- `sim`: The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of \( l \)), "geom" (block resampling with block lengths having a geometric distribution with mean \( l \)) or "scramble" (phase scrambling).
- `l`: If `sim` is "fixed" then \( l \) is the fixed block length used in generating the replicate time series. If `sim` is "geom" then \( l \) is the mean of the geometric distribution used to generate the block lengths. \( l \) should be a positive integer less than the length of `tseries`. This argument is not required when `sim` is "model" but it is required for all other simulation types.
- `endcorr`: A logical variable indicating whether end corrections are to be applied when `sim` is "fixed". When `sim` is "geom", `endcorr` is automatically set to TRUE; `endcorr` is not used when `sim` is "model" or "scramble".
- `n.sim`: The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which `n.sim` is larger than the original length is if `tseries` is a residual time series from fitting some model to the original time series. In this case, `n.sim` would usually be the length of the original time series.
- `orig.t`: A logical variable which indicates whether statistic should be applied to `tseries` itself as well as the bootstrap replicate series. If statistic is expecting a longer time series than `tseries` or if applying statistic to `tseries` will not yield any useful information then `orig.t` should be set to FALSE.
This is a function of three arguments. The first argument is a time series. If sim is "model" then it will always be tseries that is passed. For other simulation types it is the result of selecting n.sim observations from tseries by some scheme and converting the result back into a time series of the same form as tseries (although of length n.sim). The second argument to ran.gen is always the value n.sim, and the third argument is ran.args, which is used to supply any other objects needed by ran.gen. If sim is "model" then the generation of the replicate time series will be done in ran.gen (for example through use of arima.sim). For the other simulation types ran.gen is used for 'post-blackening'. The default is that the function simply returns the time series passed to it.

This will be supplied to ran.gen each time it is called. If ran.gen needs any extra arguments then they should be supplied as components of ran.args. Multiple arguments may be passed by making ran.args a list. If ran.args is NULL then it should not be used within ran.gen but note that ran.gen must still have its third argument.

A logical argument indicating whether normal margins should be used for phase scrambling. If norm is FALSE then margins corresponding to the exact empirical margins are used.

Extra named arguments to statistic may be supplied here. Beware of partial matching to the arguments of tsboot listed above.

See the help for boot.

Details

If sim is "fixed" then each replicate time series is found by taking blocks of length l, from the original time series and putting them end-to-end until a new series of length n.sim is created. When sim is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean l. Post-blackening can be carried out on these replicate time series by including the function ran.gen in the call to tsboot and having tseries as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function boot with the argument sim = "parametric".

Value

An object of class "boot" with the following components.

t0 If orig.t is TRUE then t0 is the result of statistic(tseries,...{}) otherwise it is NULL.

t The results of applying statistic to the replicate time series.

R The value of R as supplied to tsboot.

tseries The original time series.

statistic The function statistic as supplied.
tsboot

Sim

The simulation type used in generating the replicates.

endcorr

The value of endcorr used. The value is meaningful only when sim is "fixed": it is ignored for model based simulation or phase scrambling and is always set to TRUE if sim is "geom".

n.sim

The value of n.sim used.

l

The value of l used for block based resampling. This will be NULL if block based resampling was not used.

ran.gen

The ran.gen function used for generating the series or for 'post-blackening'.

ran.args

The extra arguments passed to ran.gen.

call

The original call to tsboot.

### tuna

**Tuna Sighting Data**

#### Description

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

#### Usage

`tuna`

#### Format

This data frame contains the following column:

- **y**: The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.
Source

The data were obtained from

**urine**  
*Urine Analysis Data*

Description

The urine data frame has 79 rows and 7 columns.  
79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

Usage

urine

Format

This data frame contains the following columns:

- r  Indicator of the presence of calcium oxalate crystals.
- gravity The specific gravity of the urine.
- ph The pH reading of the urine.
- osmo The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.
- cond The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.
- urea The urea concentration in millimoles per litre.
- calc The calcium concentration in millimoles per litre.

References

Description

Estimates the variance of a statistic from its empirical influence values.

Usage

var.linear(L, strata = NULL)

Arguments

L Vector of the empirical influence values of a statistic. These will usually be calculated by a call to empinf.

strata A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

Value

The variance estimate calculated from L.

References

tempinf.linear.approx.k3.linear

Examples

# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))

wool

Australian Relative Wool Prices

Description

wool is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

Chapter 19

The class package

batchSOM  
Self-Organizing Maps: Batch Algorithm

Description

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

batchSOM(data, grid = somgrid(), radii, init)

Arguments

data    a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
grid    A grid for the representatives: see somgrid.
radii   the radii of the neighbourhood to be used for each pass: one pass is run for each element of radii.
init    the initial representatives. If missing, chosen (without replacement) randomly from data.

Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

Value

An object of class "SOM" with components

grid    the grid, an object of class "somgrid".
codes   a matrix of representatives.

References

condense

Examples

```r
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[[rep(1:4, rep(50,4))]])
gr <- somgrid(topo = "hexagonal")
crabs.som <- batchSOM(lcrabs, gr, c(4, 4, 2, 2, 1, 1, 1, 0, 0))
plot(crabs.som)

bins <- as.numeric(knn1(crabs.som$code, lcrabs, 0:47))
plot(crabs.som$grid, type = "n")
symbols(crabs.som$grid$pts[, 1], crabs.som$grid$pts[, 2],
circles = rep(0.4, 48), inches = FALSE, add = TRUE)
text(crabs.som$grid$pts[bins, ] + rnorm(400, 0, 0.1),
as.character(crabs.grp))
```

condense

**Condense training set for k-NN classifier**

Description

Condense training set for k-NN classifier

Usage

```r
condense(train, class, store, trace = TRUE)
```

Arguments

- `train`: matrix for training set
- `class`: vector of classifications for test set
- `store`: initial store set. Default one randomly chosen element of the set.
- `trace`: logical. Trace iterations?

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

Index vector of cases to be retained (the final store set).

reduce.nn, multiedit

Examples

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep, , drop=FALSE], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2, , drop=FALSE], test, cl[keep2])

knnc

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

Usage

knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)

Arguments

train matrix or data frame of training set cases.
test matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
cl factor of true classifications of training set
k number of neighbours considered.
l minimum vote for definite decision, otherwise doubt. (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)
prob If this is true, the proportion of the votes for the winning class are returned as attribute prob.
use.all controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.
Value

Factor of classifications of test set. doubt will be returned as NA.

knn1, knn.cv

Examples

```r
train <- rbind(iris3[1:25,1], iris3[1:25,2], iris3[1:25,3])
test <- rbind(iris3[26:50,1], iris3[26:50,2], iris3[26:50,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)
```

Description

k-nearest neighbour cross-validatory classification from training set.

Usage

```r
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

Arguments

- `train`: matrix or data frame of training set cases.
- `cl`: factor of true classifications of training set.
- `k`: number of neighbours considered.
- `l`: minimum vote for definite decision, otherwise doubt. (More precisely, less than k-l dissenting votes are allowed, even if k is increased by ties.)
- `prob`: If this is true, the proportion of the votes for the winning class are returned as attribute prob.
- `use.all`: controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

Details

This uses leave-one-out cross validation. For each row of the training set train, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.
**knn1**

Value

Factor of classifications of training set. doubt will be returned as NA.

Examples

```r
train <- rbind(iris3[,1], iris3[,2], iris3[,3])
cl <- factor(c(rep("s",50), rep("c",50), rep("v",50)))
 knn.cv(train, cl, k = 3, prob = TRUE)
 attributes(.Last.value)
```

---

**knn1**

*1-Nearest Neighbour Classification*

Description

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

Usage

```r
knn1(train, test, cl)
```

Arguments

- `train` matrix or data frame of training set cases.
- `test` matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
- `cl` factor of true classification of training set.

Value

Factor of classifications of test set.

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
c1 <- factor(c(rep("s",25), rep("c",25), rep("v",25)))

knn1(train, test, c1)
```

lvq1 Learning Vector Quantization 1

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

cd1 <- lvq1(train, cl, cd0)
lvqtest(cd1, train)
```

1vq2

Learning Vector Quantization 2.1

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03,
     win = 0.3)
```

Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training
- `win`: a tolerance for the closeness of the two nearest vectors.

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

### lvq3

**Learning Vector Quantization 3**

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
    win = 0.3, epsilon = 0.1)
```

**Arguments**

- `x` a matrix or data frame of examples
- `cl` a vector or factor of classifications for the examples
- `codebk` a codebook
- `niter` number of iterations
- `alpha` constant for training
- `win` a tolerance for the closeness of the two nearest vectors.
- `epsilon` proportion of move for correct vectors

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvqtest(cd3, train)
```

**lvqinit**  
*Initialize a LVQ Codebook*

**Description**

Construct an initial codebook for LVQ methods.

**Usage**

```r
lvqinit(x, cl, size, prior, k = 5)
```

**Arguments**

- `x`: a matrix or data frame of training examples, `n` by `p`.
- `cl`: the classifications for the training examples. A vector or factor of length `n`.
- `size`: the size of the codebook. Defaults to `min(round(0.4*ng*(ng-1 + p/2),0), n)` where `ng` is the number of classes.
- `prior`: Probabilities to represent classes in the codebook. Default proportions in the training set.
- `k`: `k` used for `k`-NN test of correct classification. Default is 5.

**Details**

Selects `size` examples from the training set without replacement with proportions proportional to the prior or the original proportions.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

`lvqtest`  
*Classify Test Set from LVQ Codebook*

**Description**

Classify a test set by 1-NN from a specified LVQ codebook.

**Usage**

`lvqtest(codebk, test)`

**Arguments**

- `codebk`: codebook object returned by other LVQ software
- `test`: matrix of test examples

**Details**

Uses 1-NN to classify each test example against the codebook.

**Value**

Factor of classification for each row of `x`

**References**

multiedit  Multiedit for k-NN Classifier

Description

Multiedit for k-NN classifier

Usage

multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)

Arguments

x    matrix of training set.
class vector of classification of training set.
k    number of neighbours used in k-NN.
V    divide training set into V parts.
I    number of null passes before quitting.
trace logical for statistics at each pass.

Value

Index vector of cases to be retained.

### olvq1

**Optimized Learning Vector Quantization 1**

#### Description

Moves examples in a codebook to better represent the training set.

#### Usage

```r
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

#### Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

#### Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

#### Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

#### References

reduce.nn

Reduce Training Set for a k-NN Classifier

Description

Reduce training set for a k-NN classifier. Used after condense.

Usage

reduce.nn(train, ind, class)

Arguments

train matrix for training set
ind Initial list of members of the training set (from condense).
class vector of classifications for test set

Details

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

Value

Index vector of cases to be retained.

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
c1 <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, c1)
knn(train[,keep], test, cl[,keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[,keep2], test, cl[,keep2])
```

**SOM**

*Self-Organizing Maps: Online Algorithm*

**Description**

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```r
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

- `data`: a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
- `grid`: A grid for the representatives: see `somgrid`.
- `rlen`: the number of updates: used only in the defaults for `alpha` and `radii`.
- `alpha`: the amount of change: one update is done for each element of `alpha`. Default is to decline linearly from 0.05 to 0 over `rlen` updates.
- `radii`: the radii of the neighbourhood to be used for each update: must be the same length as `alpha`. Default is to decline linearly from 4 to 1 over `rlen` updates.
- `init`: the initial representatives. If missing, chosen (without replacement) randomly from `data`.

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

- `grid`: the grid, an object of class "somgrid".
- `codes`: a matrix of representatives.
References

See Also

`somgrid`, `batchSOM`

Examples

```r
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o") [rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training
crabs.som2 <- SOM(lcrabs, gr,
  alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
  radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)
```

### somgrid

**Plot SOM Fits**

Description

Plotting functions for SOM results.

Usage

```r
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))
```

## S3 method for class 'somgrid'

```r
plot(x, type = "p", ...)
```

## S3 method for class 'SOM'

```r
plot(x, ...)
```

Arguments

- `xdim, ydim`: dimensions of the grid
- `topo`: the topology of the grid.
- `x`: an object inheriting from class "somgrid" or "SOM".
- `type, ...`: graphical parameters.
Details

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a stars plot of the representative at each grid point.

Value

For somgrid, an object of class "somgrid", a list with components

- **pts**: a two-column matrix giving locations for the grid points.
- **xdim**, **ydim**, **topo**: as in the arguments to somgrid.

Chapter 20

The cluster package

agnes

Description

Computes agglomerative hierarchical clustering of the dataset.

Usage

agnes(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE, method = "average", par.method, keep.diss = n < 100, keep.data = !diss, trace.lev = 0)

Arguments

x data matrix or data frame, or dissimilarity matrix, depending on the value of the diss argument.

In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.

In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also a vector with length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

diss logical flag: if TRUE (default for dist or dissimilarity objects), then x is assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix of observations by variables.

metric character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.

stand logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable
(column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

**method** character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-group arithmetic average method, aka 'UPGMA'], "single" (single linkage), "complete" (complete linkage), "ward" (Ward’s method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the par.method argument, and "gaverage" a generalized "average" aka “flexible UPGMA” method also using the Lance-Williams formula and par.method.

The default is "average".

**par.method** If method is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for “gaverage”), see in the details section.

**keep.diss, keep.data** logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

**trace.lev** integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

**Details**

The agnes-algorithm constructs a hierarchy of clusterings. At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two nearest clusters are combined to form one larger cluster.

For method="average", the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In method="single", we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When method="complete", we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The method = "flexible" allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters \( C_1 \) and \( C_2 \) are agglomerated into a new cluster, the dissimilarity between their union and another cluster \( Q \) is given by

\[
D(C_1 \cup C_2, Q) = \alpha_1 \ast D(C_1, Q) + \alpha_2 \ast D(C_2, Q) + \beta \ast D(C_1, C_2) + \gamma \ast |D(C_1, Q) - D(C_2, Q)|,
\]

where the four coefficients \((\alpha_1, \alpha_2, \beta, \gamma)\) are specified by the vector par.method, either directly as vector of length 4, or (more conveniently) if par.method is of length 1, say = \( \alpha \), par.method is extended to give the “Flexible Strategy” (K&R(1990), p.236 f) with Lance-Williams coefficients \((\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)\).

Also, if length(par.method) == 3, \( \gamma = 0 \) is set.
Care and expertise is probably needed when using method = "flexible" particularly for the case when par.method is specified of longer length than one. Since cluster version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The weighted average (method="weighted") is the same as method="flexible", par.method = 0.5. Further, method="single" is equivalent to method="flexible", par.method = c(.5,.5,.5,.5), and method="complete" is equivalent to method="flexible", par.method = c(.5,.5,.5,.5).

The method = "gaverage" is a generalization of "average", aka “flexible UPGMA” method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with α₁ and α₂ not constant, but proportional to the sizes n₁ and n₂ of the clusters C₁ and C₂ respectively, i.e,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where α'_₁, α'_₂ are determined from par.method, either directly as (α₁, α₂, β, γ) or (α₁, α₂, β) with γ = 0, or (less flexibly, but more conveniently) as follows:

Belbin et al proposed “flexible beta”, i.e. the user would only specify β (as par.method), sensibly in

$$-1 \leq \beta < 1,$$

and β determines α'_₁ and α'_₂ as

$$\alpha'_j = 1 - \beta,$$

and γ = 0.

This β may be specified by par.method (as length 1 vector), and if par.method is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a β value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that method = "gaverage", par.method = 0 (or par.method = c(1,1,.0,.0)) is equivalent to the agnes() default method "average".

Value

an object of class "agnes" (which extends "twins") representing the clustering. See agnes.object for details, and methods applicable.

BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

Hierarchical methods like agnes, diana, and mona construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

Partitioning methods like pam, clara, and fanny require that the number of clusters be given by the user.

Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
plot(agn1)

op <- par(mfrow=c(2,2))
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
plot(agn2)
## alpha = 0.625 ==> beta = -1/4 is "recommended" by some
agn5 <- agnes(votes.repub, method = "flexible", par.meth = 0.625)
plot(agn5)
par(op)

## "show" equivalence of three "flexible" special cases
d.vr <- daisy(votes.repub)
 a.wgt <- agnes(d.vr, method = "weighted")
 a.sing <- agnes(d.vr, method = "single")
 a.comp <- agnes(d.vr, method = "complete")
 iC <- -(6:7) # not using 'call' and 'method' for comparisons
stopifnot(
  all.equal(a.wgt[iC], agnes(d.vr, method="flexible", par.method = 0.5)[iC]) ,
  all.equal(a.sing[iC], agnes(d.vr, method="flex", par.method= c(-.5,.5,0,-.5))[iC]),
  all.equal(a.comp[iC], agnes(d.vr, method="flex", par.method= c(-.5,.5,0,.5))[iC])
)

## Exploring the dendrogram structure
(d2 <- as.dendrogram(agn2)) # two main branches
d2[[1]] # the first branch
d2[[2]][[1]] # the 2nd one { 8 + 42 = 50 }
d2[[1]][[1]][[1]][[1]] # first sub-branch of branch 1 .. and shorter form
identical(d2[[c(1,1,1,1)]],
d2[[1]][[1]][[1]][[1]])

## a "textual picture" of the dendrogram:
str(d2)

data(agriculture)

## Plot similar to Figure 7 in ref
## Not run: plot(agnes(agriculture), ask = TRUE)

data(animals)
aa.a <- agnes(animals) # default method = "average"
aa.ga <- agnes(animals, method = "gaverage")
agnes.object

```r
op <- par(mfcol=1:2, mgp=c(1.5, 0.6, 0), mar=c(.1+ c(4,3,2,1)), cex.main=0.8)
plot(aa.a, which.plot = 2)
plot(aa.ga, which.plot = 2)
par(op)

## Show how "gaaverage" is a "generalized average":
aa.ga.0 <- agnes(animals, method = "gaaverage", par.method = 0)
stopifnot(all.equal(aa.ga.0[iC], aa.a[iC]))
```

---

**agnes.object**  
*Agglomerative Nesting (AGNES) Object*

**Description**

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

**Value**

A legitimate agnes object is a list with the following components:

- **order**: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.

- **order.lab**: a vector similar to `order`, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.

- **height**: a vector with the distances between merging clusters at the successive stages.

- **ac**: the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation i, denote by m(i) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The ac is the average of all 1 - m(i). It can also be seen as the average width (or the percentage filled) of the banner plot. Because ac grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

- **merge**: an (n-1) by 2 matrix, where n is the number of observations. Row i of `merge` describes the merging of clusters at step i of the clustering. If a number j in the row is negative, then the single observation |j| is merged at this stage. If j is positive, then the merger is with the cluster formed at stage j of the algorithm.

- **diss**: an object of class "dissimilarity" (see `dissimilarity.object`), representing the total dissimilarity matrix of the dataset.

- **data**: a matrix containing the original or standardized measurements, depending on the `stand` option of the function `agnes`. If a dissimilarity matrix was given as input structure, then this component is not available.

**GENERATION**

This class of objects is returned from `agnes`. 
METHODS

The "agnes" class has methods for the following generic functions: print, summary, plot, and as.dendrogram.

In addition, cutree(x, *) can be used to "cut" the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions pltree and as.hclust are available for agnes objects. After applying as.hclust(), all its methods are available, of course.

See Also

agnes, diana, as.hclust, hclust, plot.agnes, twins.object, cutree.

Examples

data(agriculture)
tag.ag <- agnes(agriculture)
class(tag.ag)
pltree(tag.ag) # the dendrogram

## cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(tag.ag, k = 3))
(ch6 <- cutree(as.hclust(tag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))

agriculture

European Union Agricultural Workforces

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

data(agriculture)

Format

A data frame with 12 observations on 2 variables:

[ . 1 ] x  numeric  per capita GNP
[ . 2 ] y  numeric  percentage in agriculture

The row names of the data frame indicate the countries.
Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

Examples

data(animals)

## Compute the dissimilarities using Euclidean metric and without ## standardization
daisy(animals, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(animals, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(animals), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(animals), ask = TRUE)

animals                 Attributes of Animals

Description

This data set considers 6 binary attributes for 20 animals.

Usage

data(animals)
Format

A data frame with 20 observations on 6 variables:

- [ , 1] war warm-blooded
- [ , 2] fly can fly
- [ , 3] ver vertebrate
- [ , 4] end endangered
- [ , 5] gro live in groups
- [ , 6] hai have hair

All variables are encoded as 1 = 'no', 2 = 'yes'.

Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

Source

References

see Struyf, Hubert & Rousseeuw (1996), in agnes.

Examples

data(animals)
apply(animals,2, table) # simple overview

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

Description

Draws a “banner”, i.e. basically a horizontal barplot visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

Usage

bannerplot(x, w = rev(x$height), fromLeft = TRUE,
main=NULL, sub=NULL, xlab = "Height", adj = 0,
col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
rev.xax = !fromLeft, xax.pretty = TRUE,
labels = NULL, nmax.lab = 35, max.strlen = 5,
yax.do = axes && length(x$order) <= nmax.lab,
yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
**Arguments**

- **x**: a list with components `order`, `order.lab` and `height` when `w`, the next argument is not specified.
- **w**: non-negative numeric vector of bar widths.
- **fromLeft**: logical, indicating if the banner is from the left or not.
- **main,sub**: main and sub titles, see `title`.
- **xlab**: x axis label (with ‘correct’ default e.g. for `plot.agnes`).
- **adj**: passed to `title(main, sub)` for string adjustment.
- **col**: vector of length 2, for two horizontal segments.
- **border**: color for bar border; now defaults to background (no border).
- **axes**: logical indicating if axes (and labels) should be drawn at all.
- **frame.plot**: logical indicating the banner should be framed; mainly used when `border = 0` (as per default).
- **rev.xax**: logical indicating if the x axis should be reversed (as in `plot.diana`).
- **xax.pretty**: logical or integer indicating if `pretty()` should be used for the x axis. `xax.pretty = FALSE` is mainly for back compatibility.
- **labels**: labels to use on y-axis; the default is constructed from `x`.
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- **max.strlen**: positive integer giving the length to which strings are truncated in banner plot labeling.
- **yax.do**: logical indicating if a y axis and banner labels should be drawn.
- **yaxRight**: logical indicating if the y axis is on the right or left.
- **y.mar**: positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.
- **...**: graphical parameters (see `par`) may also be supplied as arguments to this function.

**Note**

This is mainly a utility called from `plot.agnes`, `plot.diana` and `plot.mona`.

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
Description

This is a small rounded subset of the C-horizon data `chorizon` from package `mvoutlier`.

Usage

data(chorSub)

Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

Details

This data set was produced from `chorizon` via these statements:

```r
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110])[190:250,])
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub(".*", ", colnames(chorSub))
```

Source

Examples

data(chorSub)
summary(chorSub)
pairs(chorSub, gap = .1)# some outliers
**clara**

**Clustering Large Applications**

**Description**

Computes a "clara" object, a list representing a clustering of the data into k clusters.

**Usage**

```r
clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
    stand = FALSE, cluster.only = FALSE, samples = 5,
    sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
    keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)
```

**Arguments**

- **x**: data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
- **k**: integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = nrow(x)$).
- **metric**: character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", and "jaccard". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
- **stand**: logical, indicating if the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation.
- **cluster.only**: logical; if true, only the clustering will be computed and returned, see details.
- **samples**: integer, say $N$, the number of samples to be drawn from the dataset. The default, $N = 5$, is rather small for historical (and now back compatibility) reasons and we recommend to set samples an order of magnitude larger.
- **sampsize**: integer, say $j$, the number of observations in each sample. sampsize should be higher than the number of clusters ($k$) and at most the number of observations ($n = nrow(x)$). While computational effort is proportional to $j^2$, see note below, it may still be advisable to set $j = sampsize$ to a larger value than the (historical) default.
- **trace**: integer indicating a trace level for diagnostic output during the algorithm.
- **medoids.x**: logical indicating if the medoids should be returned, identically to some rows of the input data x. If FALSE, keep. data must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (i.e. med component), and the algorithm saves space by needing one copy less of x.
- **keep.data**: logical indicating if the (scaled if stand is true) data should be kept in the result. Setting this to FALSE saves memory (and hence time), but disables clusplot()ing of the result. Use medoids.x = FALSE to save even more memory.
**rngR** logical indicating if R’s random number generator should be used instead of the primitive clara()-builtin one. If true, this also means that each call to clara() returns a different result – though only slightly different in good situations.

**pamLike** logical indicating if the “swap” phase (see pam, in C code) should use the same algorithm as pam(). Note that from Kaufman and Rousseeuw’s description this should have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, pamLike = FALSE has been chosen to remain back compatible rather than “PAM compatible”.

**correct.d** logical or integer indicating that—only in the case of NAs present in x—the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016. Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies correct.d.

**Details**

clara is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as pam, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (sampsize) such that the time and storage requirements become linear in n rather than quadratic.

Each sub-dataset is partitioned into k clusters using the same algorithm as in pam. Once k representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until sampsize has been reached.

When cluster.only is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e., clara(x,k, cluster.only=TRUE) is the same as clara(x,k)$clustering but computed more efficiently.

**Value**

If cluster.only is false (as by default), an object of class "clara" representing the clustering. See clara.object for details.

If cluster.only is true, the result is the "clustering", an integer vector of length n with entries from 1:k.

**Note**

By default, the random sampling is implemented with a very simple scheme (with period $2^{16} = 65536$) inside the Fortran code, independently of R’s random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting rngR = TRUE which uses R’s random number generators. Then, clara() results are made reproducible typically by using set.seed() before calling clara.

The storage requirement of clara computation (for small k) is about $O(n \times p) + O(j^2)$ where $j = sampsize$, and $(n, p) = \text{dim}(x)$. The CPU computing time (again assuming small k) is about $O(n \times p \times j^2 \times N)$, where $N = \text{samples}$. 
For “small” datasets, the function `pam` can be used directly. What can be considered small, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “small (say with fewer than 200 observations)”; as of 2006, you can use `pam` with several thousand observations.

**Author(s)**

Kaufman and Rousseeuw (see `agnes`), originally. Metric "jaccard": Kamil Kozłowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from trace on, and most R documentation and all tests by Martin Maechler.

**See Also**

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

**Examples**

```r
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
           cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8], clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)
## cluster.only = TRUE -- save some memory/time:
clclus <- clara(x, 2, samples=50, cluster.only = TRUE)
stopifnot(identical(clclus, clarax$clustering))

## 'xclara' is an artificial data set with 3 clusters of 1000 bivariate ## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)
## Try 100 times *different* random samples -- for reliability:
set.seed(421)
(cl <- matrix(NA, nrow(xclara), nSim))
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tcl <- apply(cl,1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim)))))
if(length(iDoubt)) { # (not for all seeds)
```

clara.object

Clustering Large Applications (CLARA) Object

Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from clara.

Value

A legitimate clara object is a list with the following components:

- **sample**: labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.
- **medoids**: the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from clara(*, medoids.x=FALSE). Use the following i.med in that case.
- **i.med**: the indices of the medoids above: medoids <- x[i.med,] where x is the original data matrix in clara(x,*).
- **clustering**: the clustering vector, see partition.object.
- **objective**: the objective function for the final clustering of the entire dataset.
- **clusinfo**: matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster’s medoid, divided by the minimal dissimilarity between the cluster’s medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
- **diss**: dissimilarity (maybe NULL), see partition.object.
- **silinfo**: list with silhouette width information for the best sample, see partition.object.
- **call**: generating call, see partition.object.
- **data**: matrix, possibly standardized, or NULL, see partition.object.

Methods, Inheritance

The "clara" class has methods for the following generic functions: print, summary.

The class "clara" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a clara object.

See Also

clara, dissimilarity.object, partition.object, plot.partition.
clusGap() calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters $k$, it compares $\log(W(k))$ with $E^{*}[\log(W(k))]$ where the latter is defined via bootstrapping, i.e., simulating from a reference ($H_0$) distribution, a uniform distribution on the hypercube determined by the ranges of $x$, after first centering, and then svd (aka ‘PCA’)-rotating them when (as by default) $spaceH0 = \text{"scaledPCA"}$.

maxSE(f, SE.f) determines the location of the maximum of $f$, taking a “1-SE rule” into account for the *SE* methods. The default method “firstSEmax” looks for the smallest $k$ such that its value $f(k)$ is not more than 1 standard error away from the first local maximum. This is similar but not the same as "Tibs2001SEmax", Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

### Usage

clusGap(x, FUNcluster, K.max, B = 100, d.power = 1,
   spaceH0 = c("scaledPCA", "original"),
   verbose = interactive(), ...)

maxSE(f, SE.f,
   method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax",
   "firstmax", "globalmax"),
   SE.factor = 1)

## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

## S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]),
   main = NULL, do.arrows = TRUE,
   arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)

### Arguments

- **x**: numeric matrix or data.frame.
- **FUNcluster**: a function which accepts as first argument a (data) matrix like $x$, second argument, say $k, k \geq 2$, the number of clusters desired, and returns a list with a component named (or shortened to) cluster which is a vector of length $n = \text{nrow}(x)$ of integers in 1:$k$ determining the clustering or grouping of the $n$ observations.
- **K.max**: the maximum number of clusters to consider, must be at least two.
- **B**: integer, number of Monte Carlo (“bootstrap”) samples.
- **d.power**: a positive integer specifying the power $p$ which is applied to the euclidean distances (dist) before they are summed up to give $W(k)$. The default, d.power = 1, corresponds to the “historical” R implementation, whereas d.power = 2 corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.
spaceH0 a character string specifying the space of the $H_0$ distribution (of no cluster). Both “scaledPCA” and “original” use a uniform distribution in a hyper cube and had been mentioned in the reference; “original” been added after a proposal (including code) by Juan Gonzalez.

verbose integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.

... (for clusGap()): optionally further arguments for FUNcluster(), see kmeans example below.

f numeric vector of ‘function values’, of length $K$, whose (“1 SE respected”) maximum we want.

SE.f numeric vector of length $K$ of standard errors of $f$.

method character string indicating how the “optimal” number of clusters, $\hat{k}$, is computed from the gap statistics (and their standard deviations), or more generally how the location $\hat{k}$ of the maximum of $f_k$ should be determined.

"globalmax": simply corresponds to the global maximum, i.e., is which.max(f)

"firstmax": gives the location of the first local maximum.

"Tibs2001SEmax": uses the criterion, Tibshirani et al (2001) proposed: “the smallest $k$ such that $f(k) \geq f(k+1) - s_{k+1}$”. Note that this chooses $k = 1$ when all standard deviations are larger than the differences $f(k+1) - f(k)$.

"firstSEmax": location of the first $f()$ value which is not smaller than the first local maximum minus SE.factor * SE.f[], i.e, within an “f S.E.” range of that maximum (see also SE.factor).

This, the default, has been proposed by Martin Maechler in 2012, when adding clusGap() to the cluster package, after having seen the “globalSEmax” proposal (in code) and read the "Tibs2001SEmax" proposal.

"globalSEmax": (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first $f()$ value which is not smaller than the global maximum minus SE.factor * SE.f[], i.e, within an “f S.E.” range of that maximum (see also SE.factor).

See the examples for a comparison in a simple case.

SE.factor [When method contains “SE”] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an SE.factor $f$, the “fS.E.”-rule is used, more generally.

type, xlab, ylab, main arguments with the same meaning as in plot.default(), with different default.

do.arrows logical indicating if (1 SE -)"error bars" should be drawn, via arrows().

arrowArgs a list of arguments passed to arrows(); the default, notably angle and code, provide a style matching usual error bars.

**Details**

The main result <res>$Tab[, "gap"] of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see set.seed()). On the other hand, in our experience, using $B = 500$ gives quite precise results such that the gap plot is basically unchanged after another run.
Value

clusGap(...) returns an object of S3 class "clusGap", basically a list with components

Tab a matrix with K. max rows and 4 columns, named "logW", "E.logW", "gap", and "SE.sim", where gap = E. logW - logW, and SE. sim corresponds to the standard error of gap, SE. sim[k]=s_k, where s_k := \sqrt{1/Bsd^* (gap_j)}, and sd^*() is the standard deviation of the simulated ("bootstrapped") gap values.

call the clusGap(...) call.

spaceH0 the spaceH0 argument (match.arg()ed).
n number of observations, i.e., nrow(x).

B input B

FUNcluster input function FUNcluster

Author(s)

This function is originally based on the functions gap of (Bioconductor) package SAGx by Per Broberg, gapStat() from former package SLmisc by Matthias Kohl and ideas from gap() and its methods of package lga by Justin Harrington.

The current implementation is by Martin Maechler.

The implementation of spaceH0 = "original" is based on code proposed by Juan Gonzalez.

gsP.Z
clusplot

Bivariate Cluster Plot (of a Partitioning Object)

Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

Usage

clusplot(x, ...)

## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)

Arguments

- **x**: an R object, here, specifically an object of class “partition”, e.g. created by one of the functions pam, clara, or fanny.
- **main**: title for the plot; when NULL (by default), a title is constructed, using x$call.
- **dist**: when x does not have a diss nor a data component, e.g., for pam(dist(*), keep.diss=FALSE), dist must specify the dissimilarity for the clusplot.
- **...**: optional arguments passed to methods, notably the clusplot.default method (except for the diss one) may also be supplied to this function. Many graphical parameters (see par) may also be supplied as arguments here.

Details

The clusplot.partition() method relies on clusplot.default.

If the clustering algorithms pam, fanny and clara are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with pam or fanny, the dissimilarity matrix will be given as input to clusplot. When the clustering algorithm clara was applied to a data matrix with NAs then clusplot will replace the missing values as described in clusplot.default because a dissimilarity matrix is not available.

Value

For the partition (and default) method: An invisible list with components Distances and Shading, as for clusplot.default, see there.

Side Effects

A 2-dimensional clusplot is created on the current graphics device.

See Also

clusplot.default for references; partition.object, pam, pam.object, clara, clara.object, fanny, fanny.object, par.
Examples

```r
## For more, see ?clusplot.default

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
          cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

Usage

```r
## Default S3 method:
clusplot(x, clus, diss = FALSE,
s.x.2d = mkCheckX(x, diss), stand = FALSE,
lines = 2, shade = FALSE, color = FALSE,
labels = 0, plotchar = TRUE,
col.p = "dark green", col.txt = col.p,
col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
span = TRUE,
add = FALSE,
xlim = NULL, ylim = NULL,
main = paste("CLUSPLOT("),
deparse(substitute(x)), ")"),
sub = paste("These two components explain",
round(100 * var.dec, digits = 2), ",% of the point variability.")",
xlab = "Component 1", ylab = "Component 2",
verbose = getOption("verbose"),
...)```

Arguments

- **x**: matrix or data frame, or dissimilarity matrix, depending on the value of the diss argument.

  In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.

  In case of a dissimilarity matrix, x is the output of daisy or dist or a symmetric matrix. Also, a vector of length \(n \times (n - 1)/2\) is allowed (where \(n\) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
clus

a vector of length n representing a clustering of x. For each observation the
vector lists the number or name of the cluster to which it has been assigned.
clus is often the clustering component of the output of pam, fanny or clara.

diss

logical indicating if x will be considered as a dissimilarity matrix or a matrix of
observations by variables (see x argument above).

s.x.2d

a list with components named x (a n x 2 matrix; typically something like
principal components of original data), labs and var.dec.

stand

logical flag: if true, then the representations of the n observations in the 2-
dimensional plot are standardized.

lines

integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses.
The distance between two ellipses E1 and E2 is measured along the line con-
necting the centers m1 and m2 of the two ellipses.
In case E1 and E2 overlap on the line through m1 and m2, no line is drawn.
Otherwise, the result depends on the value of lines: If
lines = 0, no distance lines will appear on the plot;
lines = 1, the line segment between m1 and m2 is drawn;
lines = 2, a line segment between the boundaries of E1 and E2 is drawn (along
the line connecting m1 and m2).

shade

logical flag: if TRUE, then the ellipses are shaded in relation to their density.
The density is the number of points in the cluster divided by the area of the
ellipse.

color

logical flag: if TRUE, then the ellipses are colored with respect to their density.
With increasing density, the colors are light blue, light green, red and purple.
To see these colors on the graphics device, an appropriate color scheme should be
selected (we recommend a white background).

labels

integer code, currently one of 0,1,2,3,4 and 5. If
labels= 0, no labels are placed in the plot;
labels= 1, points and ellipses can be identified in the plot (see identify);
labels= 2, all points and ellipses are labelled in the plot;
labels= 3, only the points are labelled in the plot;
labels= 4, only the ellipses are labelled in the plot.
labels= 5, the ellipses are labelled in the plot, and points can be identified.

The levels of the vector clus are taken as labels for the clusters. The labels
of the points are the rownames of x if x is matrix like. Otherwise (diss =
TRUE), x is a vector, point labels can be attached to x as a "Labels" attribute
(attr(x,"Labels")), as is done for the output of daisy.
A possible names attribute of clus will not be taken into account.

plotchar

logical flag: if TRUE, then the plotting symbols differ for points belonging to
different clusters.

span

logical flag: if TRUE, then each cluster is represented by the ellipse with small-
est area containing all its points. (This is a special case of the minimum volume
ellipsoid.)
If FALSE, the ellipse is based on the mean and covariance matrix of the same
points. While this is faster to compute, it often yields a much larger ellipse.
There are also some special cases: When a cluster consists of only one point, a
tiny circle is drawn around it. When the points of a cluster fall on a straight line,
span=FALSE draws a narrow ellipse around it and span=TRUE gives the exact
line segment.
clusplot.default

add
logical indicating if ellipses (and labels if labels is true) should be added to an already existing plot. If false, neither a title or sub title, see sub, is written.

col.p
color code(s) used for the observation points.

col.txt
color code(s) used for the labels (if labels >= 2).

col.clus
color code for the ellipses (and their labels); only one if color is false (as per default).

cex, cex.txt
character expansion (size), for the point symbols and point labels, respectively.

xlim, ylim
numeric vectors of length 2, giving the x- and y- ranges as in plot.default.

main
main title for the plot; by default, one is constructed.

sub
sub title for the plot; by default, one is constructed.

xlab, ylab
x- and y- axis labels for the plot, with defaults.

verbose
a logical indicating, if there should be extra diagnostic output; mainly for 'de-bugging'.

...
Further graphical parameters may also be supplied, see par.

Details
clusplot uses function calls princomp(*, cor = (ncol(x) > 2)) or cmdscale(*, add=TRUE), respectively, depending on diss being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.

Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

Value
An invisible list with components:

Distances
When lines is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in [i,j] is the distance between ellipse i and ellipse j. If lines = 0, then the value of this component is NA.

Shading
A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, y[i] and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put shading = y/z *37 + 3.

Side Effects
a visual display of the clustering is plotted on the current graphics device.

Note
When we have 4 or fewer clusters, then the color=TRUE gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function pam to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. col.clus specifies the colors used.

The col.p and col.txt arguments, added for R, are recycled to have length the number of observations. If col.p has more than one value, using color = TRUE can be confusing because of a mix of point and ellipse colors.

Examples

## plotting votes.diss(dissimilarity) in a bivariate plot and
## partitioning into 2 clusters
data(votes.repub)
votes.diss <- daisy(votes.repub)
pamv <- pam(votes.diss, 2, diss = TRUE)
clusplot(pamv, shade = TRUE)
## is the same as
votes.clus <- pamv$clustering
clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE)
## Now look at components 3 and 2 instead of 1 and 2:
str(cMDS <- cmdscale(votes.diss, k=3, add=TRUE))
clusplot(pamv, s.x.2d = list(x=cMDS$points[, c(3,2)],
   labs=rownames(votes.repub), var.dec=NA),
   shade = TRUE, col.p = votes.clus,
   sub="", xlab = "Component 3", ylab = "Component 2")
clusplot(pamv, col.p = votes.clus, labels = 4)# color points and label ellipses
# "simple" cheap ellipses: larger than minimum volume:
# here they are *added* to the previous plot:
clusplot(pamv, span = FALSE, add = TRUE, col.clus = "midnightblue")
## Setting a small *label* size:
clusplot(votes.diss, votes.clus, diss = TRUE, labels = 3, cex.txt = 0.6)
if(dev.interactive()) { # uses identify() *interactively* :
   clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE, labels = 1)
   clusplot(votes.diss, votes.clus, diss = TRUE, labels = 5)# ident. only points
}
## plotting iris (data frame) in a 2-dimensional plot and partitioning
## into 3 clusters.
data(iris)
iris.x <- iris[, 1:4]
c13 <- pam(iris.x, 3)$clustering
op <- par(mfrow= c(2,2))
clusplot(iris.x, c13, color = TRUE)
U <- par("usr")
## zoom in :
rect(0,-1, 2,1, border = "orange", lwd=2)
clusplot(iris.x, c13, color = TRUE, xlim = c(0,2), ylim = c(-1,1))
coef.hclust

## Agglomerative / Divisive Coefficient for 'hclust' Objects

### Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for diana), measuring the clustering structure of the dataset.

For each observation \( i \), denote by \( m(i) \) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all \( 1 - m(i) \). It can also be seen as the average width (or the percentage filled) of the banner plot.

coeffHier() directly interfaces to the underlying C code, and “proves” that only object$heights is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

### Usage

```r
coeffHier(object)
coeff.hclust(object, ...)
```

#### S3 method for class 'hclust'

```r
coeff(object, ...)
```

#### S3 method for class 'twins'

```r
coeff(object, ...)
```

### Arguments

- **object**: an object of class "hclust" or "twins", i.e., typically the result of hclust(.), agnes(.), or diana(.).

  Since coeff.hclust only uses object$heights, and object$merge, object can be any list-like object with appropriate merge and heights components.

  For coeffHier, even only object$heights is needed.

  ... currently unused potential further arguments

### Value

A number specifying the agglomerative (or divisive for diana objects) coefficient as defined by Kaufman and Rousseeuw, see agnes.object$ac or diana.object$dc.
Examples

```r
data( agriculture )
aa <- agnes( agriculture )
coef( aa ) # really just extracts aa$ac
coef( as.hclust( aa ) ) # recomputes
coefHier( aa )  # ditto
```

---

**daisy**

*Dissimilarity Matrix Calculation*

**Description**

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever metric = "gower" is set, a generalization of Gower's formula is used, see 'Details' below.

**Usage**

```r
daisy( x, metric = c("euclidean", "manhattan", "gower"),
       stand = FALSE, type = list(), weights = rep.int(1, p),
       warnBin = warnType, warnAsym = warnType, warnConst = warnType,
       warnType = TRUE )
```

**Arguments**

- `x` numeric matrix or data frame, of dimension `n × p`, say. Dissimilarities will be computed between the rows of `x`. Columns of mode `numeric` (i.e. all columns when `x` is a matrix) will be recognized as interval scaled variables, columns of class `factor` will be recognized as nominal variables, and columns of class `ordered` will be recognized as ordinal variables. Other variable types should be specified with the `type` argument. Missing values (`NAs`) are allowed.

- `metric` character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. "Gower's distance" is chosen by metric "gower" or automatically if some columns of `x` are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section.

- `stand` logical flag: if TRUE, then the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If not all columns of `x` are numeric, `stand` will be ignored and Gower's standardization (based on the `range`) will be applied in any case, see argument `metric`, above, and the details section.
type

list for specifying some (or all) of the types of the variables (columns) in \( x \). The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and "symm" (symmetric binary variables). Each component’s value is a vector, containing the names or the numbers of the corresponding columns of \( x \). Variables not mentioned in the type list are interpreted as usual (see argument \( x \)).

weights

an optional numeric vector of length \( p = \text{ncol}(x) \); to be used in “case 2” (mixed variables, or \( \text{metric} = "gower" \)), specifying a weight for each variable (\( x[,k] \)) instead of 1 in Gower’s original formula.

warnBin, warnAsym, warnConst

logicals indicating if the corresponding type checking warnings should be signalled (when found).

warnType

logical indicating if all the type checking warnings should be active or not.

Details

The original version of \( \text{daisy} \) is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to \( \text{dist} \) whose input must be numeric variables, the main feature of \( \text{daisy} \) is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If \( x \) contains any columns of these data-types, both arguments \( \text{metric} \) and \( \text{stand} \) will be ignored and Gower’s coefficient will be used as the metric. This can also be activated for purely numeric data by \( \text{metric} = "gower" \). With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range \([0, 1]\), exactly.

Note that setting the type to \( \text{symm} \) (symmetric binary) gives the same dissimilarities as using \( \text{nominal} \) (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that \( \text{daisy} \) signals a warning when 2-valued numerical variables do not have an explicit type specified, because the reference authors recommend to consider using "asymm"; the warning may be silenced by \( \text{warnBin} = \text{FALSE} \).

In the \( \text{daisy} \) algorithm, missing values in a row of \( x \) are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and \( \text{metric} \) is not "gower"), the metric is "euclidean", and \( n_g \) is the number of columns in which neither row \( i \) and \( j \) have NAs, then the dissimilarity \( d(i,j) \) returned is \( \sqrt{p/n_g} \; (p = \text{ncol}(x)) \) times the Euclidean distance between the two vectors of length \( n_g \) shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is \( p/n_g \). If \( n_g = 0 \), the dissimilarity is NA.

2. When some variables have a type other than interval scaled, or if \( \text{metric} = "gower" \) is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

\[
d_{ij} = d(i, j) = \frac{\sum_{k=1}^{p} w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^{p} w_k \delta_{ij}^{(k)}}.
\]

In other words, \( d_{ij} \) is a weighted mean of \( d_{ij}^{(k)} \) with weights \( w_k \delta_{ij}^{(k)} \), where \( w_k = \text{weights}[k] \), \( \delta_{ij}^{(k)} \) is 0 or 1, and \( d_{ij}^{(k)} \) the \( k \)-th variable contribution to the total distance, is a distance between \( x[i,k] \) and \( x[j,k] \); see below.
The 0-1 weight $\delta_{ij}^{(k)}$ becomes zero when the variable $x_{i,k}$ is missing in either or both rows (i and j), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution $d_{ij}^{(k)}$ of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that “standard scoring” is applied to ordinal variables, i.e., they are replaced by their integer codes $1:K$. Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions $d_{ij}^{(k)}$ are in $[0, 1]$, the dissimilarity $d_{ij}$ will remain in this range. If all weights $w_k \delta_{ij}^{(k)}$ are zero, the dissimilarity is set to NA.

Value

an object of class "dissimilarity" containing the dissimilarities among the rows of x. This is typically the input for the functions pam, fanny, agnes or diana. For more details, see dissimilarity.object.

Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version. Martin Maechler improved the NA handling and type specification checking, and extended functionality to metric = "gower" and the optional weights argument.

Din

Computes a divisive hierarchical clustering of the dataset returning an object of class diana.

Usage
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE, stop.at.k = FALSE, keep.diss = n < 100, keep.data = !diss, trace.lev = 0)

Arguments

x
data matrix or data frame, or dissimilarity matrix or object, depending on the value of the diss argument.
In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.

In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

disslogical flag: if TRUE (default for dist or dissimilarity objects), then x will be considered as a dissimilarity matrix. If FALSE, then x will be considered as a matrix of observations by variables.

metriccharacter string specifying the metric to be used for calculating dissimilarities between observations.
The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.

standlogical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

stop.at.klogical or integer, FALSE by default. Otherwise must be integer, say k, in \{1, 2, ..., n\}, specifying that the diana algorithm should stop early. Non-default NOT YET IMPLEMENTED.
keep.diss, keep.data
logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

trace.lev
integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

Details
diana is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, diana provides (a) the divisive coefficient (see diana.object) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see plot.diana).
The diana-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all n observations. Clusters are divided until each cluster contains only a single observation. At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.) To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

Value
an object of class "diana" representing the clustering; this class has methods for the following generic functions: print, summary, plot.
Further, the class "diana" inherits from "twins". Therefore, the generic function pltree can be used on a diana object, and as.hclust and as.dendrogram methods are available.
A legitimate diana object is a list with the following components:

order
a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.

order.lab
a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.

height
a vector with the diameters of the clusters prior to splitting.

dc
the divisive coefficient, measuring the clustering structure of the dataset. For each observation i, denote by \( d(i) \) the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The dc is the average of all \( 1 - d(i) \). It can also be seen as the average width (or the percentage filled) of the banner plot. Because dc grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

merge
an (n-1) by 2 matrix, where n is the number of observations. Row i of merge describes the split at step n-i of the clustering. If a number j in row r is negative, then the single observation \(|j|\) is split off at stage n-r. If j is positive, then the cluster that will be splitted at stage n-j (described by row j), is split off at stage n-r.
dissimilarity.object

**Description**

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

**Value**

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called do, and n the number of observations, i.e., n <- attr(do, "Size"), then for i < j <= n, the dissimilarity between (row) i and j is do[n*(i-1) - i*(i-1)/2 + j-i]. The length of the vector is n * (n - 1)/2, i.e., of order n^2.

"dissimilarity" objects also inherit from class dist and can use dist methods, in particular, as.matrix, such that d[i,j] from above is just as.matrix(do)[i,j].

The object has the following attributes:

`Size`  
the number of observations in the dataset.

diss an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.

data a matrix containing the original or standardized measurements, depending on the stand option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.

See Also

agnes also for background and references; cutree (and as.hclust) for grouping extraction; daisy, dist, plot.diana, twins.object.

Examples

data(votes.repub)  
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)  
print(dv)  
plot(dv)

## Cut into 2 groups:

dv2 <- cutree(as.hclust(dv), k = 2)

table(dv2) # 8 and 42 group members

rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?

dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean

dv.2 <- cutree(as.hclust(dv0), k = 2)

table(dv2 == dv.2)## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}

data(agriculture)

## Plot similar to Figure 8 in ref

## Not run: plot(diana(agriculture), ask = TRUE)
ellipsoidhull

Metric the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".

Labels optionally, contains the labels, if any, of the observations of the dataset.

NA.message optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.

Types when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54):

A Asymmetric binary
S Symmetric binary
N Nominal (factor)
O Ordinal (ordered factor)
I Interval scaled (numeric)
T raTio to be log transformed (positive numeric)

GENERATION
daisy returns this class of objects. Also the functions pam, clara, fanny, agnes, and diana return a dissimilarity object, as one component of their return objects.

METHODS

The "dissimilarity" class has methods for the following generic functions: print, summary.

See Also
daisy, dist, pam, clara, fanny, agnes, diana.

ellipsoidhull

Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set

Description

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

Usage

ellipsoidhull(x, tol=0.01, maxit=5000,
ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)

## S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)
ellipsoidhull

Arguments

\( x \)
the \( n \times p \)-dimensional points as numeric \( n \times p \) matrix.

\( \text{tol} \)
convergence tolerance for Titterington’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase \( \text{maxit} \) as well.

\( \text{maxit} \)
integer giving the maximal number of iteration steps for the algorithm.

\( \text{ret.wt} \), \( \text{ret.sqdist} \), \( \text{ret.pr} \)
logicals indicating if additional information should be returned, \( \text{ret.wt} \) specifying the weights, \( \text{ret.sqdist} \) the squared distances and \( \text{ret.pr} \) the final probabilities in the algorithms.

\( \text{digits,...} \)
the usual arguments to \texttt{print} methods.

Details

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al (1999) who use it for \texttt{clusplot.default}.

The problem can be seen as a special case of the “Min.V ol.” ellipsoid of which a more more flexible and general implementation is \texttt{cov.mve} in the \texttt{MASS} package.

Value

an object of class "ellipsoid", basically \texttt{a list} with several components, comprising at least

\( \text{cov} \)
\( p \times p \) covariance matrix description the ellipsoid.

\( \text{loc} \)
\( p \)-dimensional location of the ellipsoid center.

\( \text{d2} \)
average squared radius. Further, \( d2 = t^2 \), where \( t \) is “the value of a t-statistic on the ellipse boundary” (from \texttt{ellipse} in the \texttt{ellipse} package), and hence, more usefully, \( d2 = \text{qchisq(alpha, df = p)} \), where \( \alpha \) is the confidence level for \( p \)-variate normally distributed data with location and covariance \( \text{loc} \) and \( \text{cov} \) to lie inside the ellipsoid.

\( \text{wt} \)
the vector of weights iff \( \text{ret.wt} \) was true.

\( \text{sqdist} \)
the vector of squared distances iff \( \text{ret.sqdist} \) was true.

\( \text{prob} \)
the vector of algorithm probabilities iff \( \text{ret.pr} \) was true.

\( \text{it} \)
number of iterations used.

\( \text{tol, maxit} \)
just the input argument, see above.

\( \text{eps} \)
the achieved tolerance which is the maximal squared radius minus \( p \).

\( \text{ ierr} \)
error code as from the algorithm; \( 0 \) means \texttt{ok}.

\( \text{conv} \)
logical indicating if the converged. This is defined as \( \text{it} < \text{maxit} && \text{ierr} == 0 \).

Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original code.

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
## --> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii],3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2, col="blue", bg = adjustcolor("blue",0.25))

fanny

Fuzzy Analysis Clustering

Description

Computes a fuzzy clustering of the data into k clusters.

Usage

fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
metric = c("euclidean", "manhattan", "SqEuclidean"),
stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
keep.diss = !diss && !cluster.only && n < 100,
keep.data = !diss && !cluster.only,
maxit = 500, tol = 1e-15, trace.lev = 0)

Arguments

x         data matrix or data frame, or dissimilarity matrix, depending on the value of the
diss argument.

In case of a matrix or data frame, each row corresponds to an observation, and
each column corresponds to a variable. All variables must be numeric. Missing
values (NA)s are allowed.

In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also
a vector of length n*(n-1)/2 is allowed (where n is the number of observations),
and will be interpreted in the same way as the output of the above-mentioned
functions. Missing values (NA)s are not allowed.
k integer giving the desired number of clusters. It is required that \(0 < k < n/2\) where \(n\) is the number of observations.

diss logical flag: if TRUE (default for dist or dissimilarity objects), then \(x\) is assumed to be a dissimilarity matrix. If FALSE, then \(x\) is treated as a matrix of observations by variables.

memb.exp number \(r\) strictly larger than 1 specifying the membership exponent used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.

metric character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root-sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the squared euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.

stand logical; if true, the measurements in \(x\) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \(x\) is already a dissimilarity matrix, then this argument will be ignored.

iniMem.p numeric \(n \times k\) matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.

cluster.only logical; if true, no silhouette information will be computed and returned, see details.

keep.diss, keep.data logicals indicating if the dissimilarities and/or input data \(x\) should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation time.

maxit, tol maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults maxit = 500 and tol = 1e-15 used to be hardwired inside the algorithm.

trace.lev integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by \(u_{iv}\) the membership of observation \(i\) to cluster \(v\).

The memberships are nonnegative, and for a fixed observation \(i\) they sum to 1. The particular method fanny stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in daisy) and has been extended by Martin Maechler to allow user specified memb.exp, iniMem.p, maxit, tol, etc.

Fanny aims to minimize the objective function

\[
\frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} u_{iv}^r u_{jv}^r d(i,j) - \sum_{v=1}^{k} \sum_{i=1}^{n} u_{iv}^r \]
where \( n \) is the number of observations, \( k \) is the number of clusters, \( r \) is the membership exponent \( \text{memb.exp} \) and \( d(i, j) \) is the dissimilarity between observations \( i \) and \( j \).

Note that \( r \to 1 \) gives increasingly crisper clusterings whereas \( r \to \infty \) leads to complete fuzzyness. \( \text{K&R}(1990) \), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default, \( r = 2 \) can lead to complete fuzzyness, i.e., memberships \( u_{iv} \equiv 1/k \). In that case a warning is signalled and the user is advised to chose a smaller \( \text{memb.exp} \) (= \( r \)).

Compared to other fuzzy clustering methods, \text{fanny} has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see \text{plot.partition}).

### Value

an object of class "fanny" representing the clustering. See \text{fanny.object} for details.

### See Also

\text{agnes} for background and references; \text{fanny.object, partition.object, plot.partition, daisy, dist}.

### Examples

```r
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
           cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
           cbind(rnorm(3, 3.2, 0.5), rnorm(3, 3.2, 0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crisper' for obs. 26:28
(fanny(x, 2, memb.exp = 3)) # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```
A legitimate fanny object is a list with the following components:

- **membership**: matrix containing the memberships for each pair consisting of an observation and a cluster.
- **memb.exp**: the membership exponent used in the fitting criterion.
- **coeff**: Dunn’s partition coefficient \( F(k) \) of the clustering, where \( k \) is the number of clusters. \( F(k) \) is the sum of all squared membership coefficients, divided by the number of observations. Its value is between \( 1/k \) and 1.

The normalized form of the coefficient is also given. It is defined as \( (F(k) - 1/k)/(1 - 1/k) \), and ranges between 0 and 1. A low value of Dunn’s coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.

- **clustering**: the clustering vector of the nearest crisp clustering, see `partition.object`.
- **k.crisp**: integer (\( \leq k \)) giving the number of crisp clusters; can be less than \( k \), where it’s recommended to decrease `memb.exp`.
- **objective**: named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance `tol` used.
- **convergence**: named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in `maxit` iterations within convergence tolerance `tol`).
- **diss**: an object of class "dissimilarity", see `partition.object`.
- **call**: generating call, see `partition.object`.
- **silinfo**: list with silhouette information of the nearest crisp clustering, see `partition.object`.
- **data**: matrix, possibly standardized, or NULL, see `partition.object`.

**GENERATION**

These objects are returned from `fanny`.

**METHODS**

The "fanny" class has methods for the following generic functions: `print`, `summary`.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a `fanny` object.

**See Also**

`fanny`, `print.fanny`, `dissimilarity.object`, `partition.object`, `plot.partition`. 
Description

8 characteristics for 18 popular flowers.

Usage

data(flower)

Format

A data frame with 18 observations on 8 variables:

\[
\begin{align*}
&[, "V1"] \text{ factor } \text{ winters} \\
&[, "V2"] \text{ factor } \text{ shadow} \\
&[, "V3"] \text{ factor } \text{ tubers} \\
&[, "V4"] \text{ factor } \text{ color} \\
&[, "V5"] \text{ ordered } \text{ soil} \\
&[, "V6"] \text{ ordered } \text{ preference} \\
&[, "V7"] \text{ numeric } \text{ height} \\
&[, "V8"] \text{ numeric } \text{ distance}
\end{align*}
\]

\textbf{V1} winters, is binary and indicates whether the plant may be left in the garden when it freezes.

\textbf{V2} shadow, is binary and shows whether the plant needs to stand in the shadow.

\textbf{V3} tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.

\textbf{V4} color, is nominal and specifies the flower’s color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).

\textbf{V5} soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.

\textbf{V6} preference, is ordinal and gives someone’s preference ranking going from 1 to 18.

\textbf{V7} height, is interval scaled, the plant’s height in centimeters.

\textbf{V8} distance, is interval scaled, the distance in centimeters that should be left between the plants.

lower.to.upper.tri.inds

*Permute Indices for Triangular Matrices*

**Description**

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

**Usage**

```r
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

**Arguments**

- `n` integer larger than 1.

**Value**

integer vector containing a permutation of 1:N where $N = n(n - 1)/2$.

**See Also**

`upper.tri`, `lower.tri` with a related purpose.

**Examples**

```r
m5 <- matrix(NA,5,5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
          lower.to.upper.tri.inds(3) == 1:3,
          upper.to.lower.tri.inds(3) == 1:3,
          sort(upper.to.lower.tri.inds(5)) == 1:10,
          sort(lower.to.upper.tri.inds(6)) == 1:15)
```

---

**mona**

*MONothetic Analysis Clustering of Binary Variables*

**Description**

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

**Usage**

```r
mona(x, trace.lev = 0)
```
Arguments

x  
data matrix or data frame in which each row corresponds to an observation, and 
each column corresponds to a variable. All variables must be binary. A limited 
number of missing values (NAs) is allowed. Every observation must have at least 
one value different from NA. No variable should have half of its values missing. 
There must be at least one variable which has no missing values. A variable 
with all its non-missing values identical is not allowed.

trace.lev  
logical or integer indicating if (and how much) the algorithm should produce 
progress output.

Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the 
sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical 
methods (including `agnes` and `diana`) are “polythetic”, i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters 
are divided until all observations in the same cluster have identical values for all variables. 
At each stage, all clusters are divided according to the values of one variable. A cluster is divided 
into one cluster with all observations having value 1 for that variable, and another cluster with all 
observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the 
other variables, according to the observations in the cluster to be splitted. The association between 
variables f and g is given by a(f,g) \* d(f,g) - b(f,g) \* c(f,g), where a(f,g), b(f,g), c(f,g), and d(f,g) are 
the numbers in the contingency table of f and g. [That is, a(f,g) \ (resp. d(f,g)) is the number of 
observations for which f and g both have value 0 \ (resp. value 1); b(f,g) \ (resp. c(f,g)) is the number 
of observations for which f has value 0 \ (resp. 1) and g has value 1 \ (resp. 0).] The total association 
of a variable f is the sum of its associations to all variables.

Value

an object of class "mona" representing the clustering. See `mona.object` for details.

Missing Values (NAs)

The `mona`-algorithm requires “pure” 0-1 values. However, `mona(x)` allows x to contain (not too 
many) NAs. In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do 
this, the same measure of association between variables is used as in the algorithm. When variable 
f has missing values, the variable g with the largest absolute association to f is looked up. When 
the association between f and g is positive, any missing value of f is replaced by the value of g for 
the same observation. If the association between f and g is negative, then any missing value of f is 
replaced by the value of 1-g for the same observation.

Note

In `cluster` versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one 
variable, i.e., ncol(x) == 1, which currently signals an error (because the algorithm now in C, haes 
not correctly taken account of this special case).

See Also

`agnes` for background and references; `mona.object, plot.mona`. 
Examples

```r
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

```r
## One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3 )
ani.idNA <- within(animals, end[!is.na(end)] <- 1 )
try( mona(ani.NA) ) ## error: .. object with all values missing
try( mona(aniNA) ) ## error: .. more than half missing values
try( mona(aniN2) ) ## error: all have at least one missing
try( mona(ani.non2) ) ## error: all must be binary
try( mona(ani.idNA) ) ## error: ditto
```

mona.object

**Monothetic Analysis (MONA) Object**

**Description**

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from `mona`.

**Value**

A legitimate `mona` object is a list with the following components:

- `data` matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
- `order` a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- `order.lab` a vector similar to `order`, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- `variable` vector of length n-1 where n is the number of observations, specifying the variables used to separate the observations of `order`.
- `step` vector of length n-1 where n is the number of observations, specifying the separation steps at which the observations of `order` are separated.

**METHODS**

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

**See Also**

`mona` for examples etc, `plot.mona`. 
Partitioning (clustering) of the data into \( k \) clusters “around medoids”, a more robust version of K-means.

**Usage**

\[
\text{pam}(x, k, \text{diss} = \text{inherits}(x, \text{"dist"}), \\
\text{metric} = \text{c("euclidean", "manhattan")}, \\
\text{medoids} = \text{if(is.numeric(nstart)) "random"}, \\
n\text{start} = \text{if(\text{variant} == "faster") 1 else NA}, \\
\text{stand} = \text{FALSE}, \text{cluster.only} = \text{FALSE}, \\
\text{do.swap} = \text{TRUE}, \\
\text{keep.diss} = \!\text{!diss && !cluster.only && n < 100}, \\
\text{keep.data} = \!\text{!diss && !cluster.only}, \\
\text{variant} = \text{c("original", "o_1", "o_2", "f_3", "f_4", "f_5", "faster"),} \\
\text{pamonce} = \text{FALSE, trace.lev = 0})
\]

**Arguments**

- **x**: data matrix or data frame, or dissimilarity matrix or object, depending on the value of the diss argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.
  - In case of a dissimilarity matrix, \( x \) is typically the output of daisy or dist. Also a vector of length \( n(n-1)/2 \) is allowed (where \( n \) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **k**: positive integer specifying the number of clusters, less than the number of observations.

- **diss**: logical flag: if TRUE (default for dist or dissimilarity objects), then \( x \) will be considered as a dissimilarity matrix. If FALSE, then \( x \) will be considered as a matrix of observations by variables.

- **metric**: character string specifying the metric to be used for calculating dissimilarities between observations.
  - The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

- **medoids**: NULL (default) or length-\( k \) vector of integer indices (in \( 1:n \)) specifying initial medoids instead of using the ‘build’ algorithm.

- **nstart**: used only when medoids = "random": specifies the number of random “starts”; this argument corresponds to the one of \text{kmeans}() (from R’s package \text{stats}).
stand logical; if true, the measurements in \( x \) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

cluster.only logical; if true, only the clustering will be computed and returned, see details.

do.swap logical indicating if the \texttt{swap} phase should happen. The default, \texttt{TRUE}, correspond to the original algorithm. On the other hand, the \texttt{swap} phase is much more computer intensive than the \texttt{build} one for large \( n \), so can be skipped by \texttt{do.swap = FALSE}.

keep.diss, keep.data logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to \texttt{FALSE} can give much smaller results and hence even save memory allocation time.

pamonce logical or integer in \( 0:6 \) specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019, 2021) see below.

variant a character string denoting the variant of PAM algorithm to use; a more self-documenting version of \texttt{pamonce} which should be used preferably; note that “faster” not only uses \texttt{pamonce = 6} but also \texttt{nstart = 1} and hence \texttt{medoids = “random”} by default.

trace.lev integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

The basic \texttt{pam} algorithm is fully described in chapter 2 of Kaufman and Rousseeu (1990). Compared to the \texttt{k-means} approach in \texttt{kmeans}, the function \texttt{pam} has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see \texttt{plot.partition}) (d) it allows to select the number of clusters using \texttt{mean(silhouette(pr)[, “sil_width”])} on the result \( pr <- \texttt{pam}(..) \), or directly its component \( pr$clustering \), see also \texttt{pam.object}.

When \texttt{cluster.only} is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e., \texttt{pam(x,k, cluster.only=TRUE)} is the same as \texttt{pam(x,k)$clustering} but computed more efficiently.

The \texttt{pam}-algorithm is based on the search for \( k \) representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of \( k \) medoids, \( k \) clusters are constructed by assigning each observation to the nearest medoid. The goal is to find \( k \) representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when \texttt{medoids} are not specified, the algorithm first looks for a good initial set of medoids (this is called the \texttt{build} phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid (i.e. a ‘swap’) that will decrease the objective (this is called the \texttt{swap} phase).

When the \texttt{medoids} are specified (or randomly generated), their order does \textit{not} matter; in general, the algorithms have been designed to not depend on the order of the observations.

The \texttt{pamonce} option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.
The default FALSE (or integer 0) corresponds to the original “swap” algorithm, whereas pamonce = 1 (or TRUE), corresponds to the first proposal .... and pamonce = 2 additionally implements the second proposal as well.

The key ideas of ‘FastPAM’ (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

pamonce = 3: reduces the runtime by a factor of O(k) by exploiting that points cannot be closest to all current medoids at the same time.

pamonce = 4: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.

pamonce = 5: adds minor optimizations copied from the pamonce = 2 approach, and is expected to be the fastest of the ‘FastPam’ variants included.

‘FasterPAM’ (Schubert and Rousseeuw, 2021) is implemented via

pamonce = 6: execute each swap which improves results immediately, and hence typically multiple swaps per iteration; this swapping algorithm runs in O(n^2) rather than O(n(n – k)k) time which is much faster for all but small k.

In addition, ‘FasterPAM’ uses random initialization of the medoids (instead of the ‘build’ phase) to avoid the O(n^2k) initialization cost of the build algorithm. In particular for large k, this yields a much faster algorithm, while preserving a similar result quality.

One may decide to use repeated random initialization by setting nstart > 1.

**Value**

an object of class “pam” representing the clustering. See ?pam.object for details.

**Note**

For large datasets, pam may need too much memory or too much computation time since both are O(n^2). Then, clara() is preferable, see its documentation.

There is hard limit currently, n ≤ 65536, at 2^{16} because for larger n, n(n – 1)/2 is larger than the maximal integer (.Machine$integer.max = 2^{31} – 1).

**Author(s)**

Kaufman and Rousseeuw’s orginal Fortran code was translated to C and augmented in several ways, e.g. to allow cluster.only=TRUE or do.swap=FALSE, by Martin Maechler.

Matthias Studer, Univ.Geneva provided the pamonce (1 and 2) implementation.

Erich Schubert, TU Dortmund contributed the pamonce (3 to 6) implementation.

**References**

pam.object

## Partitioning Around Medoids (PAM) Object

### Description

The objects of class "pam" represent a partitioning of a dataset into clusters.

### Value

A legitimate pam object is a list with the following components:

- **medoids**: the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a matrix with in each row the coordinates of one medoid.
- **id.med**: an integer vector of indices giving the medoid observation numbers.
- **clustering**: integer vector of indices giving the medoid observation numbers.
- **objective**: the objective function after the first and second step of the pam algorithm.
- **isolation**: vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated.

A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and...
any other observation of the cluster is smaller than the minimal dissimilarity between \( i \) and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.

- **clusinfo**: matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).

- **silinfo**: list with silhouette width information, see `partition.object`.
- **diss**: dissimilarity (maybe NULL), see `partition.object`.
- **call**: generating call, see `partition.object`.
- **data**: (possibly standardized) see `partition.object`.

**GENERATION**

These objects are returned from `pam`.

**METHODS**

The "pam" class has methods for the following generic functions: `print`, `summary`.

**INHERITANCE**

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a `pam` object.

**See Also**

`pam`, `dissimilarity.object`, `partition.object`, `plot.partition`.

**Examples**

```r
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
for (k in 2:20)
asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type= "h", main = "pam() clustering assessment",
     xlab= "k ( # clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```
The objects of class "partition" represent a partitioning of a dataset into clusters.

Value

a "partition" object is a list with the following (and typically more) components:

- **clustering**: the clustering vector. An integer vector of length \( n \), the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.
- **call**: the matched `call` generating the object.
- **silinfo**: a list with all silhouette information, only available when the number of clusters is non-trivial, i.e., \( 1 < k < n \) and then has the following components, see `silhouette`
  - **widths**: an \((n \times 3)\) matrix, as returned by `silhouette()`, with for each observation \( i \) the cluster to which \( i \) belongs, as well as the neighbor cluster of \( i \) (the cluster, not containing \( i \), for which the average dissimilarity between its observations and \( i \) is minimal), and the silhouette width \( s(i) \) of the observation.
  - **clus.avg.widths**: the average silhouette width per cluster.
  - **avg.width**: the average silhouette width for the dataset, i.e., simply the average of \( s(i) \) over all observations \( i \).

This information is also needed to construct a silhouette plot of the clustering, see `plot.partition`.

Note that `avg.width` can be maximized over different clusterings (e.g. with varying number of clusters) to choose an optimal clustering.

- **objective**: value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
- **diss**: an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for `clara`).
- **data**: a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

**GENERATION**

These objects are returned from `pam`, `clara` or `fanny`.

**METHODS**

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

**INHERITANCE**

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See `pam.object`, `clara.object` and `fanny.object` for details.
**plantTraits**

### See Also

pam, clara, fanny.

---

**plantTraits**  
*Plant Species Traits Data*

### Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive).

### Usage

```r
data(plantTraits)
```

### Format

A data frame with 136 observations on the following 31 variables.

- **pdias**  Diaspore mass (mg)
- **longindex**  Seed bank longevity
- **durflow**  Flowering duration
- **height**  Plant height, an ordered factor with levels $1 < 2 < \ldots < 8$.
- **begflow**  Time of first flowering, an ordered factor with levels $1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9$
- **mycor**  Mycorrhizas, an ordered factor with levels $0$never $< 1$ sometimes $< 2$always
- **vegaer**  Aerial vegetative propagation, an ordered factor with levels $0$never $< 1$ present but limited $< 2$important.
- **vegsout**  Underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.
- **autopoll**  Selfing pollination, an ordered factor with levels $0$never $< 1$ rare $< 2$ often $< 3$.
- **insects**  Insect pollination, an ordered factor with 5 levels $0$ never $< 1$ rare $< 2$ moderate $< 3$ common $< 4$.
- **wind**  Wind pollination, an ordered factor with 5 levels $0$ never $< 1$ rare $< 2$ moderate $< 3$ common $< 4$.
- **lign**  A binary factor with levels $0:1$, indicating if plant is woody.
- **piq**  A binary factor indicating if plant is thorny.
- **ros**  A binary factor indicating if plant is rosette.
- **semiros**  Semi-rosette plant, a binary factor ($0$: no; $1$: yes).
- **leafy**  Leafy plant, a binary factor.
- **suman**  Summer annual, a binary factor.
- **winan**  Winter annual, a binary factor.
- **monocarp**  Monocarpic perennial, a binary factor.
- **polycarp**  Polycarpic perennial, a binary factor.
- **seasaes**  Seasonal aestival leaves, a binary factor.
- **seashiv**  Seasonal hibernal leaves, a binary factor.
- **seasver**  Seasonal vernal leaves, a binary factor.
everal leaves always evergreen, a binary factor.

everparti leaves partially evergreen, a binary factor.

elaio fruits with an elaiosome (dispersed by ants), a binary factor.

endozoo endozoocorous fruits, a binary factor.

epizoo epizoochorous fruits, a binary factor.

aquat aquatic dispersal fruits, a binary factor.

windgl wind dispersed fruits, a binary factor.

unsp unspecialized mechanism of seed dispersal, a binary factor.

Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

Source

Examples

data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
               type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
cmds.dai.b <- cmdscale(dai.b, k=6)
plot(cmds.dai.b[, 1:2], asp = 1, col = cutree6)

plot.agnes

Plots of an Agglomerative Hierarchical Clustering

Description

Creates plots for visualizing an agnes object.

Usage

## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ",round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)

plot.agnes
Arguments

- **x**: an object of class "agnes", typically created by `agnes(.)`.  
- **ask**: logical; if true and which.plots is NULL, plot.agnes operates in interactive mode, via menu.  
- **which.plots**: integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".  
- **main, sub**: main and sub title for the plot, with convenient defaults. See documentation for these arguments in `plot.default`.  
- **adj**: for label adjustment in `bannerplot()`.  
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labelling the banner plot.  
- **max.strlen**: positive integer giving the length to which strings are truncated in banner plot labeling.  
- **xax.pretty**: logical or integer indicating if `pretty(*, n = xax.pretty)` should be used for the x axis. xax.pretty = FALSE is for back compatibility.  
- **...**: graphical parameters (see `par`) may also be supplied and are passed to `bannerplot()` or `pltree()` (see `pltree.twins`), respectively.

Details

When `ask = TRUE`, rather than producing each plot sequentially, plot.agnes displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the agnes algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot()` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:  
Banner  
Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.  

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.  

...
References

See Also

`agnes` and `agnes.object`; `bannerplot`, `pltree.twins`, and `par`.

Examples

## Can also pass 'labels' to pltree() and bannerplot():
```r
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "g"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150)# bannerplot labels are mess
```

---

**plot.diana**

*Plots of a Divisive Hierarchical Clustering*

Description

Creates plots for visualizing a diana object.

Usage

```r
## S3 method for class 'diana'
plot(x, ask = FALSE, which.plots = NULL, main = NULL, sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

Arguments

- `x` an object of class "diana", typically created by `diana(.)`.
- `ask` logical; if true and which.plots is NULL, plot.diana operates in interactive mode, via menu.
- `which.plots` integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".
- `main, sub` main and sub title for the plot, each with a convenient default. See documentation for these arguments in `plot.default`.
- `adj` for label adjustment in `bannerplot()`.
nmax.lab  integer indicating the number of labels which is considered too large for single-name labelling the banner plot.

max.strlen  positive integer giving the length to which strings are truncated in banner plot labeling.

xax.pretty  logical or integer indicating if pretty(*, n = xax.pretty) should be used for the x axis. xax.pretty = FALSE is for back compatibility.

...  graphical parameters (see par) may also be supplied and are passed to bannerplot() or pltree(), respectively.

Details

When ask = TRUE, rather than producing each plot sequentially, plot.diana displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask = TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the diana algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

- Banner
- Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

References

see those in plot.agnes.

See Also
diana, diana.object, twins.object, par.

Examples

e.g. -> dv <- diana(...)  
plot(dv, which = 1, nmax.lab = 100)

## wider labels:
op <- par(mar = par("mar") + c(0, 2, 0,0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
plot.mona

Banner of Monothetic Divisive Hierarchical Clusterings

Description

Creates the banner of a mona object.

Usage

```r
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse(x$call)),
    sub = NULL, xlab = "Separation step",
    col = c(2,0), axes = TRUE, adj = 0,
    nmax.lab = 35, max.strlen = 5, ...)
```

Arguments

- `x`: an object of class "mona", typically created by `mona(.)`.
- `main, sub`: main and sub titles for the plot, with convenient defaults. See documentation in `plot.default`.
- `xlab`: x axis label, see `title`.
- `col, adj`: graphical parameters passed to `bannerplot()`.
- `axes`: logical, indicating if (labeled) axes should be drawn.
- `nmax.lab`: integer indicating the number of labels which is considered too large for labeling.
- `max.strlen`: positive integer giving the length to which strings are truncated in labeling.
- `...`: further graphical arguments are passed to `bannerplot()` and `text`.

Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the mona algorithm, the numbers in the step vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

Side Effects

A banner is plotted on the current graphics device.

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

References

see those in `plot.agnes`. 
plot.partition

Plot of a Partition of the Data Set

Description

Creates plots for visualizing a partition object.

Usage

```r
## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
     nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
     stand = FALSE, lines = 2,
     shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
     span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

Arguments

- `x` an object of class "partition", typically created by the functions `pam`, `clara`, or `fanny`.
- `ask` logical; if true and which.plots is NULL, plot.partition operates in interactive mode, via menu.
- `which.plots` integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a clusplot or 2 for silhouette.
- `nmax.lab` integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
- `max.strlen` positive integer giving the length to which strings are truncated in silhouette plot labeling.
- `data` numeric matrix with the scaled data; per default taken from the partition object `x`, but can be specified explicitly.
- `dist` when `x` does not have a diss component as for `pam(*, keep.diss=FALSE)`, dist must be the dissimilarity if a clusplot is desired.
- `stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...` All optional arguments available for the `clusplot.default` function (except for the diss one) and graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

When `ask= TRUE`, rather than producing each plot sequentially, plot.partition displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask= TRUE)` before invoking the plot command.

The `clusplot` of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see `clusplot.partition` for more details).
The silhouette plot of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation i, a bar is drawn, representing its silhouette width s(i), see silhouette for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large s(i) (almost 1) are very well clustered, a small s(i) (around 0) means that the observation lies between two clusters, and observations with a negative s(i) are probably placed in the wrong cluster.

A clustering can be performed for several values of k (the number of clusters). Finally, choose the value of k with the largest overall average silhouette width.

Side Effects
An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:
Clusplot
Silhouette plot

Note
In the silhouette plot, observation labels are only printed when the number of observations is less than nmax.lab (40, by default), for readability. Moreover, observation labels are truncated to maximally maxlen.str len (5) characters.
For more flexibility, use plot(silhouette(x), ...), see plot.silhouette.

References
Further, the references in plot.agnes.

See Also
partition.object, clusplot.partition, clusplot.default, pam, pam.object, clara, clara.object, fanny, fanny.object, par.

Examples
```r
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))
## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```
pltree

Plot Clustering Tree of a Hierarchical Clustering

Description

pltree() Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the twins method draws the tree of a twins object, i.e., hierarchical clustering, typically resulting from agnes() or diana().

Usage

pltree(x, ...)  
## S3 method for class 'twins'  
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),  
       labels = NULL, ylab = "Height", ...)

Arguments

x in general, an R object for which a pltree method is defined; specifically, an object of class "twins", typically created by either agnes() or diana().
main main title with a sensible default.
labels labels to use; the default is constructed from x.
ylab label for y-axis.
... graphical parameters (see par) may also be supplied as arguments to this function.

Details

Creates a plot of a clustering tree given a twins object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls plot(as.hclust(x), ...), which dispatches to plot.hclust(...). If more flexible plots are needed, consider xx <- as.dendrogram(as.hclust(x)) and plotting xx, see plot.dendrogram.

Value

a NULL value is returned.

See Also

agnes, agnes.object, diana, diana.object, hclust, par, plot.agnes, plot.diana.
Examples

```r
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2))  # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
     nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
     main = deparse(agn$call))
par(op)
```

### pluton

**Isotopic Composition Plutonium Batches**

**Description**

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

**Usage**

```r
data(pluton)
```

**Format**

This data frame contains the following columns:

- **Pu238** the percentages of $^{238}Pu$, always less than 2 percent.
- **Pu239** the percentages of $^{239}Pu$, typically between 60 and 80 percent (from neutron capture of Uranium, $^{238}U$).
- **Pu240** percentage of the plutonium 240 isotope.
- **Pu241** percentage of the plutonium 241 isotope.

**Details**

Note that the percentage of plutonium−242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

**Source**

Available as 'pluton.dat' from the archive of the University of Antwerpen, `../datasets/clusplot-examples.tar.gz`, no longer available.

**References**

Examples

data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)

predict.ellipsoid

Predict Method for Ellipsoid Objects

Description

Compute points on the ellipsoid boundary, mostly for drawing.

Usage

predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)

Arguments

object an object of class ellipsoid, typically from ellipsoidhull(); alternatively
any list-like object with proper components, see details below.
n.out, n.half half the number of points to create.
A, d2, loc arguments of the auxiliary ellipsoidPoints, see below.
... passed to and from methods.

Details

Note ellipsoidPoints is the workhorse function of predict.ellipsoid a standalone function
and method for ellipsoid objects, see ellipsoidhull. The class of object is not checked; it
must solely have valid components loc (length p), the p × p matrix cov (corresponding to A) and
d2 for the center, the shape ("covariance") matrix and the squared average radius (or distance) or
qchisq(*, p) quantile.

Unfortunately, this is only implemented for p = 2, currently; contributions for p ≥ 3 are
very welcome.

Value

a numeric matrix of dimension 2*n.out times p.

See Also

ellipsoidhull, volume.ellipsoid.
Examples

```r
## see also  example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)"
   mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x,y)
C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
  lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
} # MASS
```

print.agnes

Print Method for AGNES Objects

Description

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters (`Height`) of an agnes object.

This is a method for the generic `print()` function for objects inheriting from class agnes, see `agnes.object`.

Usage

```r
## S3 method for class 'agnes'
print(x, ...)
```

Arguments

- `x`  
an agnes object.
- `...`  
potential further arguments (required by generic).

See Also

- `summary.agnes` producing more output; `agnes.agnes.object, print.print.default`
Print Method for CLARA Objects

Description
Prints the best sample, medoids, clustering vector and objective function of clara object.
This is a method for the function print() for objects inheriting from class clara.

Usage
## S3 method for class 'clara'
print(x, ...)

Arguments
x a clara object.
... potential further arguments (require by generic).

See Also
summary.clara producing more output; clara, clara.object, print, print.default.

Print Method for DIANA Objects

Description
Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.
This is a method for the function print() for objects inheriting from class diana.

Usage
## S3 method for class 'diana'
print(x, ...)

Arguments
x a diana object.
... potential further arguments (require by generic).

See Also
diana, diana.object, print, print.default.
Description

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions print() and summary() for dissimilarity objects. See print, print.default, or summary for the general behavior of these.

Usage

```r
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
         digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)
```

Arguments

- `x, object` a dissimilarity object or a summary.dissimilarity one for print.summary.dissimilarity().
- `digits` the number of digits to use, see print.default.
- `diag, upper, justify, right` optional arguments specifying how the triangular dissimilarity matrix is printed; see print.dist.
- `...` potential further arguments (require by generic).

See Also
daisy, dissimilarity.object, print, print.default, print.dist.

Examples

```r
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
         digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)
```

See Also
daisy, dissimilarity.object, print, print.default, print.dist.
**print.fanny**  
*Print and Summary Methods for FANNY Objects*

**Description**
Prints the objective function, membership coefficients and clustering vector of fanny object. This is a method for the function `print()` for objects inheriting from class `fanny`.

**Usage**
```r
## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**
- `x, object`  
  a `fanny` object.
- `digits`  
  number of significant digits for printing, see `print.default`. 
- `...`  
  potential further arguments (required by generic).

**See Also**
- `fanny, fanny.object, print, print.default`. 

---

**print.mona**  
*Print Method for MONA Objects*

**Description**
Prints the ordering of objects, separation steps, and used variables of a mona object. This is a method for the function `print()` for objects inheriting from class `mona`.

**Usage**
```r
## S3 method for class 'mona'
print(x, ...)  
```

**Arguments**
- `x`  
  a mona object.
- `...`  
  potential further arguments (require by generic).

**See Also**
- `mona, mona.object, print, print.default`. 

print.pam  
*Print Method for PAM Objects*

**Description**

Prints the medoids, clustering vector and objective function of pam object.

This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```r
## S3 method for class 'pam'
print(x, ...)
```

**Arguments**

- `x` a pam object.
- `...` potential further arguments (require by generic).

**See Also**

`pam`, `pam.object`, `print`, `print.default`.

---

ruspini  
*Ruspini Data*

**Description**

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

**Usage**

```r
data(ruspini)
```

**Format**

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

**Source**

**References**

see those in `agnes`. 
Examples

```r
data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

### silhouette

**Compute or Extract Silhouette Information from Clustering**

Description

Compute silhouette information according to a given clustering in \( k \) clusters.

Usage

```r
silhouette(x, ...)
```

## Default S3 method:

```r
silhouette(x, dist, dmatrix, ...)
```

## S3 method for class 'partition'

```r
silhouette(x, ...)
```

## S3 method for class 'clara'

```r
silhouette(x, full = FALSE, subset = NULL, ...)
```

sortSilhouette(object, ...)

## S3 method for class 'silhouette'

```r
summary(object, FUN = mean, ...)
```

## S3 method for class 'silhouette'

```r
plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width " * s[i]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)
```

Arguments

- **x**
  an object of appropriate class; for the default method an integer vector with \( k \) different integer cluster codes or a list with such an x$clustering component. Note that silhouette statistics are only defined if \( 2 \leq k \leq n - 1 \).

- **dist**
  a dissimilarity object inheriting from class `dist` or coercible to one. If not specified, `dmatrix` must be.

- **dmatrix**
  a symmetric dissimilarity matrix \( (n \times n) \), specified instead of `dist`, which can be more efficient.

- **full**
  logical or number in \([0,1]\) specifying if a full silhouette should be computed for `clara` object. When a number, say \( f \), for a random `sample.int(n, size = f*n)` of the data the silhouette values are computed. This requires \( O((f \times n)^2) \) memory, since the full dissimilarity of the (sub)sample (see `daisy`) is needed internally.
subset a subset from 1:n, specified instead of full to specify the indices of the observations to be used for the silhouette computations.

object an object of class silhouette.

... further arguments passed to and from methods.

FUN function used to summarize silhouette widths.

nmax.lab integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.

max.strlen positive integer giving the length to which strings are truncated in silhouette plot labeling.

main, sub, xlab arguments to title; have a sensible non-NULL default here.

col, border, cex.names arguments passed barplot(): note that the default used to be col = heat.colors(n), border = par("fg") instead.
col can also be a color vector of length k for clusterwise coloring, see also do.col.sort:

do.col.sort logical indicating if the colors col should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.

do.n.k logical indicating if n and k “title text” should be written.

do.clus.stat logical indicating if cluster size and averages should be written right to the silhouettes.

**Details**

For each observation i, the *silhouette width* \( s(i) \) is defined as follows:

Put \( a(i) = \) average dissimilarity between i and all other points of the cluster to which i belongs (if i is the only observation in its cluster, \( s(i) := 0 \) without further calculations). For all other clusters \( C, \) put \( d(i, C) = \) average dissimilarity of i to all observations of C. The smallest of these \( d(i, C) \) is \( b(i) := \min_{C} d(i, C), \) and can be seen as the dissimilarity between i and its “neighbor” cluster, i.e., the nearest one to which it does not belong. Finally,

\[
s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}
\]

silhouette.default() is now based on C code donated by Romain Francois (the R version being still available as cluster::silhouette.default.R).

Observations with a large \( s(i) \) (almost 1) are very well clustered, a small \( s(i) \) (around 0) means that the observation lies between two clusters, and observations with a negative \( s(i) \) are probably placed in the wrong cluster.

**Value**

silhouette() returns an object, sil, of class silhouette which is an \( n \times 3 \) matrix with attributes. For each observation i, sil[i,] contains the cluster to which i belongs as well as the neighbor cluster of (the cluster, not containing i, for which the average dissimilarity between its observations and i is minimal), and the silhouette width \( s(i) \) of the observation. The colnames correspondingly are c("cluster", "neighbor", "sil_width").

summary(sil) returns an object of class summary.silhouette, a list with components

si.summary: numerical summary of the individual silhouette widths \( s(i) \).
clus.avg.widths: numeric (rank 1) array of clusterwise means of silhouette widths where \text{mean} = \text{FUN} is used.

avg.width: the total mean \text{FUN}(s) where \text{s} are the individual silhouette widths.

clus.sizes: table of the \(k\) cluster sizes.

call: if available, the \text{call} creating \text{sil}.

Ordered: logical identical to \text{attr(sil, "Ordered")}, see below.

\text{sortSilhouette(sil)} orders the rows of \text{sil} as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width \(s(i)\).
\text{attr(sil, "Ordered")} is a logical indicating if \text{sil} is ordered as by \text{sortSilhouette()}. In that case, \text{rownames(sil)} will contain case labels or numbers, and \text{attr(sil, "iOrd")} the ordering index vector.

Note

While \text{silhouette()} is \textit{intrinsic} to the \text{partition} clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from \text{silhouette.default()} with \text{cutree()} and distance as input.

By default, for \text{clara()} partitions, the silhouette is just for the best random \text{subset} used. Use \text{full} = \text{TRUE} to compute (and later possibly plot) the full silhouette.

References

chapter 2 of Kaufman and Rousseeuw (1990), see the references in \text{plot.agnes}.

See Also

\text{partition.object}, \text{plot.partition}.

Examples

data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))

\text{plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)}
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

## the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
for(k in 2:6)
plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE, col = c6[1:k])
par(op)
## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xc1k <- xclara[sample(nrow(xclara), size = 1000),]) # rownames == indices
c13 <- clara(xc1k, 3)
plot(silhouette(c13))# only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(c13, full = TRUE) ## this is the same as
s.full <- silhouette(c13$clustering, daisy(xc1k))
stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
## color dependent on original "3 groups of each 1000": % __FIXME ??__
plot(sf, col = 2+ as.integer(names(c13$clustering)) %% 1000,
     main ="plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

sizeDiss

Sample Size of Dissimilarity Like Object

Description

Returns the number of observations (sample size) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of \( f(n) = \frac{n(n - 1)}{2} \).

Usage

sizeDiss(d)

Arguments

d any \( R \) object with length (typically) \( n(n - 1)/2 \).

Value

a number; \( n \) if length(d) == \( n(n-1)/2 \), NA otherwise.

See Also
dissimilarity.object and also as.dist for class dissimilarity and dist objects which have a Size attribute.
Examples

```r
sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply(n*(n-1)/2, function(n) sizeDiss(logical(n))))
```

Description

Returns (and prints) a summary list for an agnes object. Printing gives more output than the corresponding `print.agnes` method.

Usage

```r
## S3 method for class 'agnes'
summary(object, ...)
## S3 method for class 'summary.agnes'
print(x, ...)
```

Arguments

- `x, object` a `agnes` object.
- `...` potential further arguments (require by generic).

See Also

`agnes, agnes.object`.

Examples

```r
data(agriculture)
summary(agnes(agriculture))
```

Description

Returns (and prints) a summary list for a clara object. Printing gives more output than the corresponding `print.clara` method.

Usage

```r
## S3 method for class 'clara'
summary(object, ...)
## S3 method for class 'summary.clara'
print(x, ...)
```
Arguments

`x, object`  
a *clara* object.

`...`  
potential further arguments (require by generic).

See Also

*clara.object*

Examples

```r
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0,4), rnorm(400, 0,4)),
           cbind(rnorm(400,10,8), rnorm(400,40,6)),
           cbind(rnorm(400,30,4), rnorm(400, 0,4)),
           cbind(rnorm(400,40,4), rnorm(400,20,2)),
           cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
## Mis'classification' table:

table(rep(1:5, rep(400,5)), clx5$clust)  # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))
plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)
```

summary.diana

*Summary Method for 'diana' Objects*

Description

Returns (and prints) a summary list for a *diana* object.

Usage

```r
## S3 method for class 'diana'
summary(object, ...)
## S3 method for class 'summary.diana'
print(x, ...)
```

Arguments

`x, object`  
a *diana* object.

`...`  
potential further arguments (require by generic).

See Also

*diana, diana.object*
**summary.mona**

*Summary Method for 'mona' Objects*

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```r
## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)
```

**Arguments**

- `x, object` a mona object.
- `...` potential further arguments (require by generic).

**See Also**

`mona, mona.object`.

---

**summary.pam**

*Summary Method for PAM Objects*

**Description**

Summarize a pam object and return an object of class summary.pam. There's a print method for the latter.

**Usage**

```r
## S3 method for class 'pam'
summary(object, ...)
## S3 method for class 'summary.pam'
print(x, ...)
```

**Arguments**

- `x, object` a pam object.
- `...` potential further arguments (require by generic).

**See Also**

`pam, pam.object`.
twins.object  

Hierarchical Clustering Object

Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

Value

See agnes.object and diana.object for details.

GENERATION

This class of objects is returned from agnes or diana.

METHODS

The "twins" class has a method for the following generic function: pltree.

INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

See Also

agnes, diana.

volume.ellipsoid  

Compute the Volume (of an Ellipsoid)

Description

Compute the volume of geometric R object. This is a generic function and has a method for ellipsoid objects (typically resulting from ellipsoidhull()).

Usage

volume(object, ...)  
## S3 method for class 'ellipsoid'
volume(object, log = FALSE, ...)

Arguments

object  
an R object the volume of which is wanted; for the ellipsoid method, an object of that class (see ellipsoidhull or the example below).

log  
logical indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.

...  
potential further arguments of methods, e.g. log.
Value

a number, the volume $V$ (or $\log(V)$ if $\log = \text{TRUE}$) of the given object.

Author(s)

Martin Maechler (2002, extracting from former clusplot code); Keefe Murphy (2019) provided code for dimensions $d > 2$.

See Also

ellipsoidhull for spanning ellipsoid computation.

Examples

```r
## example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10), class = "ellipsoid")
volume(myEl)# i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100,5)
e5 <- ellipsoidhull(d5)
```

Description

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

Usage

data(votes.repub)

Source

Data from 1964 to 1976 is from R. M. Scammon, American Votes 12, Congressional Quarterly.
Description

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

Usage

data(xclara)

Format

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the x and y coordinates of the points, respectively.

Note

Our version of the xclara is slightly more rounded than the one from read.table("xclara.dat") and the relative difference measured by all.equal is 1.15e-7 for V1 and 1.17e-7 for V2 which suggests that our version has been the result of a options(digits = 7) formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. pam(*, 3) gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices \{1 : 900\}, \{901 : 2050\}, and \{2051 : 3000\}, see the example.

Source

Sample data set accompanying the reference below (file ‘xclara.dat’ in side ‘clus_examples.tar.gz’).

References

Examples

## Visualization: Assuming groups are defined as \{1:1000\}, \{1001:2000\}, \{2001:3000\)
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535)  ## PAM's medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3)  ## takes ~2 seconds
cxcl <- px$clustering ; iCl <- split(seq_along(cxcl), cxcl)
boxplot(iCl, range = 0.7, horizontal=TRUE,
main = "Indices of the 3 clusters of pam(xclara, 3)")

## Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
## We see 3 + 2 + 2 = 7 clear "outlier"s or "wrong group" observations:
with(bxCl, rbind(out, group))
## out 1038 1451 1610 30 327 562 770
## group 1 1 1 2 2 3 3

## Apart from these, what are the robust ranges of indices? -- Robust range:
```r
t(iR <- bxCl$stats[c(1,5),])
```
## 1 900
## 901 2050
## 2051 3000
```r
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
```
Chapter 21

The codetools package

---

checkUsage  
*Check R Code for Possible Problems*

### Description

Check R code for possible problems.

### Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
suppressLocal = FALSE, suppressParamAssigns = !all,
suppressParamUnused = !all, suppressFundefMismatch = FALSE,
suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,
suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

### Arguments

- **fun** closure.
- **name** character; name of closure.
- **env** environment containing closures to check.
- **pack** character naming package to check.
- **...** options to be passed to checkUsage.
- **report** function to use to report possible problems.
- **all** logical; report all possible problems if TRUE.
- **suppressLocal** suppress all local variable warnings.
- **suppressParamAssigns** suppress warnings about assignments to formal parameters.
- **suppressParamUnused** suppress warnings about unused formal parameters.

2641
supressFundefMismatch
  suppress warnings about multiple local function definitions with different formal
  argument lists
supressLocalUnused
  suppress warnings about unused local variables
supressNoLocalFun
  suppress warnings about using local variables as functions with no apparent
  local function definition
skipWith
  logical; if true, do no examine code portion of with expressions.
supressUndefined
  suppress warnings about undefined global functions and variables.
supressPartialMatchArgs
  suppress warnings about partial argument matching

Details
  checkUsage checks a single R closure. Options control which possible problems to report. The
  default settings are moderately verbose. A first pass might use suppressLocal=TRUE to suppress
  all information related to local variable usage. The supressXYZ values can either be scalar logicals
  or character vectors; then they are character vectors they only suppress problem reports for the
  variables with names in the vector.
  checkUsageEnv and checkUsagePackage are convenience functions that apply checkUsage to all
  closures in an environment or a package. checkUsagePackage requires that the package be loaded.
  If the package has a name space then the internal name space frame is checked.

Author(s)
  Luke Tierney

Examples
  checkUsage(checkUsage)
  checkUsagePackage("codetools",all=TRUE)
  ## Not run: checkUsagePackage("base",suppressLocal=TRUE)

Description
  These functions provide some tools for analysing R code. Mainly intended to support the other
  tools in this package and byte code compilation.

Usage
  collectLocals(e, collect)
  collectUsage(fun, name = "<anonymous>", ...)
  constantFold(e, env = NULL, fail = NULL)
  findFuncLocals(formals, body)
  findLocals(e, envir = .BaseEnv)
  findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
startCollectLocals, finishCollectLocals, warn, signal)
walkCode(e, w = makeCodeWalker())

Arguments

e R expression.
elist list of R expressions.
v R object.
fun closure.
formals formal arguments of a closure.
body body of a closure.
name character.
env character.
envir environment.
w code walker.
... extra elements for code walker.
collect function.
fail function.
handler function.
call function.
leaf function.
isLocal function.
exit function.
enterLocal function.
enterGlobal function.
enterInternal function.
startCollectLocals function.
finishCollectLocals function.
warn function.
signal function.

Author(s)

Luke Tierney
findGlobals  

Find Global Functions and Variables Used by a Closure

Description

Finds global functions and variables used by a closure.

Usage

findGlobals(fun, merge = TRUE)

Arguments

fun  
function object; usually a closure.

merge  
logical

Details

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of assign and rm).

Value

Character vector if merge is true; otherwise, a list with functions and variables character vector components. Character vectors are of length zero For non-closures.

Author(s)

Luke Tierney

Examples

findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)

showTree  

Print Lisp-Style Representation of R Expression

Description

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

Usage

showTree(e, write = cat)

Arguments

e  
R expression.

write  
function of one argument to write the result.
Author(s)

Luke Tierney

Examples

showTree(quote(-3))
showTree(quote("x"<1))
showTree(quote("f"(x))))
Chapter 22

The foreign package

| lookup.xport | Lookup Information on a SAS XPORT Format Library |

**Description**

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

**Usage**

`lookup.xport(file)`

**Arguments**

- `file` character variable with the name of the file to read. The file must be in SAS XPORT format.

**Value**

A list with one component for each dataset in the XPORT format library.

**Author(s)**

Saikat DebRoy

**References**

**See Also**

`read.xport`
Examples

```r
## Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

## End(Not run)
```

---

**read.arff**  
*Read Data from ARFF Files*

**Description**  
Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**  
`read.arff(file)`

**Arguments**

- `file`  
a character string with the name of the ARFF file to read from, or a `connection` which will be opened if necessary, and if so closed at the end of the function call.

**Value**  
A data frame containing the data from the ARFF file.

**References**  
Attribute-Relation File Format  

**See Also**  
`write.arff`; functions `write.arff` and `read.arff` in package `RWeka` which provide some support for logicals via conversion to or from factors.

---

**read.dbf**  
*Read a DBF File*

**Description**  
The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

**Usage**  
`read.dbf(file, as.is = FALSE)`
Arguments

file  name of input file
as.is should character vectors not be converted to factors?

Details

DBF is the extension used for files written for the ‘XBASE’ family of database languages, ‘covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products’ (https://www.clicketyclick.dk/databases/xbase/format/). Most of these follow the file structure used by Ashton-Tate’s dBase II, III or 4 (later owned by Borland).

read.dbf is based on C code from http://shapelib.maptools.org/ which implements the ‘XBASE’ specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates); all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that it is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using make.names(unique=TRUE).

There is an attribute "data_type" giving the single-character dBase types for each field.

Note

Not to be able to read a particular ‘DBF’ file is not a bug: this is a convenience function especially for shapefiles.

Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

References

http://shapelib.maptools.org/.

write.dbf

Examples

x <- read.dbf(system.file("files/sids.dbf", package="foreign")[1])
str(x)
summary(x)
**read.dta**  
*Read Stata Binary Files*

**Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```r
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,  
missing.type = FALSE, convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

- `file`  
a filename or URL as a character string.
- `convert.dates`  
Convert Stata dates to Date class, and date-times to POSIXct class?
- `convert.factors`  
Use Stata value labels to create factors? (Version 6.0 or later).
- `missing.type`  
For version 8 or later, store information about different types of missing data?
- `convert.underscore`  
Convert "_" in Stata variable names to "." in R names?
- `warn.missing.labels`  
Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes ‘http:’, ‘ftp:’ or ‘https:’) the URL is first downloaded to a temporary file and then read. (‘https:’ is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R’s Date class, and variables with Stata value labels are converted to factors. Ordinarily, read.dta will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata’s date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If `missing.type` is `TRUE` a separate list is created with the same variable names as the loaded data. For string variables the list value is `NULL`. For other variables the value is `NA` where the observation is not missing and 0–26 when the observation is missing. This is attached as the “missing” attribute of the returned value.

The default file format for Stata 13, `format-115`, is substantially different from those for Stata 5–12.
Value

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, ‘format-111’), 8 (Stata 8 and 9, ‘format-113’), 10 (Stata 10 and 11, ‘format-114’). and 12 (Stata 12, ‘format-115’).

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

Author(s)

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

References

Stata Users Manual (versions 5 & 6), Programming manual (version 7), or online help (version 8 and later) describe the format of the files. Or directly at https://www.stata.com/help.cgi?dta_114 and https://www.stata.com/help.cgi?dta_113, but note that these have been changed since first published.

See Also

Different approaches are available in package memisc (see its help for Stata.file), function read_dta in package haven and package readstata13.

write.dta, attributes, Date, factor

Examples

write.dta(swiss,swissfile <- tempfile())
read.dta(swissfile)
Arguments

- **file**: A filename, URL, or connection.
- **read.deleted**: Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.
- **guess.broken.dates**: Attempt to convert dates with 0 or 2 digit year information (see ‘Details’).
- **thisyear**: A 4-digit year to use for dates with no year. Defaults to the current year.
- **lower.case.names**: Convert variable names to lowercase?

Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to Date class. With the guess.broken.dates option the function will attempt to convert two-digit years using the operating system’s default method (see Date) and will use the current year or the thisyear argument for dates with no year information.

If read.deleted is TRUE the "deleted" attribute of the data frame indicates the deleted records.

Value

A data frame.

Note

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be readable with the RODBC package.

DateTimeClasses

Examples

```r
## Not run: ## That file is not available
read.epiinfo("oswego.rec", guess.broken.dates = TRUE, thisyear = "1972")
## End(Not run)
```

Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

Usage

`read.mtp(file)`
Arguments

file character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

Note

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

Author(s)

Douglas M. Bates

References

https://www.minitab.com/

Examples

```r
## Not run:
read.mtp("ex1-10.mtp")
## End(Not run)
```

Description

Read a file in Octave text data format into a list.

Usage

`read.octave(file)`

Arguments

file a character string with the name of the file to read.

Details

This function is used to read in files in Octave text data format, as created by `save -text` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and N-dimensional arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and `NULL` is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave’s `load` and `save (as text)` facilities as an intermediary step.
Value

A list with one named component for each variable in the file.

Author(s)

Stephen Eglen <stephen@gnu.org> and Kurt Hornik

References

https://www.gnu.org/software/octave/

---

read.spss  Read an SPSS Data File

Description

read.spss reads a file stored by the SPSS save or export commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

Usage

read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE, max.value.labels = Inf, trim.factor.names = FALSE, trim.values = TRUE, reencode = NA, use.missings = to.data.frame, sub = ".", add.undeclared.levels = c("sort", "append", "no"), duplicated.value.labels = c("append", "condense"), duplicated.value.labels.infix = ".duplicated_", ...)  

Arguments

file  character string: the name of the file or URL to read.

use.value.labels  logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching labeling are returned as NA).

to.data.frame  logical: return a data frame?

max.value.labels  logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.

trim.factor.names  logical: trim trailing spaces from factor levels?

trim.values  logical: should values and value labels have trailing spaces ignored when matching for use.value.labels = TRUE?

reencode  logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in UTF-8 or latin-1 locales, only. Alternatively a character string specifying an encoding to assume for the file.

use.missings  logical: should information on user-defined missing values be used to set the corresponding values to NA?
sub character string: If not NA it is used by iconv to replace any non-convertible
bytes in character/factor input. Default is ".". For back compatibility with
foreign versions <= 0.8-68 use sub=NA.

add.undeclared.levels
character: specify how to handle variables with at least one value label and
further non-missing values that have no value label (like a factor levels in R).
For "sort" (the default) it adds undeclared factor levels to the already de-
clared levels (and labels) and sort them according to level, for "append" it
appends undeclared factor levels to declared levels (and labels) without sort-
ing, and for "no" this does not convert to factor in case of numeric SPSS levels
(not labels), and still converts to factor if the SPSS levels are characters and
to.data.frame=TRUE. For back compatibility with foreign versions <= 0.8-
68 use add.undeclared.levels="no" (not recommended as this may convert
some values with missing corresponding value labels to NA).

duplicated.value.labels
character: what to do with duplicated value labels for different lev-
els. For "append" (the default), the first original value label is
kept while further duplicated labels are renamed to paste0(label,
duplicated.value.labels.infix, level), for "condense", all levels with
identical labels are condensed into exactly the first of these levels in R. Back
compatibility with foreign versions <= 0.8-68 is not given as R versions >=
3.4.0 no longer support duplicated factor labels.

duplicated.value.labels.infix
character: the infix used for labels of factor levels with duplicated value labels
in SPSS (default "_duplicated_") if duplicated.value.labels="append".

... passed to as.data.frame if to.data.frame = TRUE.

Details

This uses modified code from the PSPP project (http://www.gnu.org/software/pspp/ for read-
ing the SPSS formats.

If the filename appears to be a URL (of schemes ‘http:’, ‘ftp:’ or ‘https:’) the URL is
first downloaded to a temporary file and then read. (‘https:’ is supported where supported by
download.file with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g.
to distinguish different types of missing data), and you will not want these variables converted
to factors. By setting max.value.labels you can specify that variables with a large number of
distinct values are not converted to factors even if they have value labels.

If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the
answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are
read that way by R. The default argument trim.values=TRUE causes trailing spaces to be ignored
when matching to value labels, as examples have been seen where the strings and the value labels
had different amounts of padding. See the examples for sub for ways to remove trailing spaces in
character data.

provides a list of translations from Windows codepage numbers to encoding names that iconv
is likely to know about and so suitable values for reencode. Automatic re-encoding is attempted
for apparent codepages of 200 or more in a UTF-8 or latin-1 locale: some other high-numbered
codepages can be re-encoded on most systems, but the encoding names are platform-dependent
(see iconvlist).
Value

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute "codepage" to the result.

There may be attributes "label.table" and "variable.labels". Attribute "label.table" is a named list of value labels with one element per variable, either NULL or a named character vector. Attribute "variable.labels" is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute "Missings". This is a named list with one list element per variable. Each element has an element type, a length-one character vector giving the type of missingness, and may also have an element value with the values corresponding to missingness. This is a complex subject (where the R and C source code for read.spss is the main documentation), but the simplest cases are types "one", "two" and "three" with a corresponding number (of real or string) values whose labels can be found from the "label.table" attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations.

Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, ....

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 and latin-1 locales: see argument reencode.

Author(s)

Saikat DebRoy and the R-core team

See Also

A different interface also based on the PSPP codebase is available in package memisc: see its help for spss.system.file.

Examples

(sav <- system.file("files", "electric.sav", package = "foreign"))
dat <- read.spss(file=sav)
str(dat) # list structure with attributes
dat <- read.spss(file=sav, to.data.frame=TRUE)
str(dat) # now a data.frame

### Now we use an example file that is not very well structured and
### hence may need some special treatment with appropriate argument settings.
### Expect lots of warnings as value labels (corresponding to R factor labels) are uncomplete,
### and an unsupported long string variable is present in the data
(sav <- system.file("files", "testdata.sav", package = "foreign"))
### Examples for `add.undeclared.levels`:

#### add.undeclared.levels = "sort" (default):
```r
x.sort <- read.spss(file=sav, to.data.frame = TRUE)
```

#### add.undeclared.levels = "append":
```r
x.append <- read.spss(file=sav, to.data.frame = TRUE,
  add.undeclared.levels = "append")
```

#### add.undeclared.levels = "no":
```r
x.no <- read.spss(file=sav, to.data.frame = TRUE,
  add.undeclared.levels = "no")
```

```r
levels(x.sort$factor_n_undeclared)
levels(x.append$factor_n_undeclared)
str(x.no$factor_n_undeclared)
```

### Examples for `duplicated.value.labels`:

#### duplicated.value.labels = "append" (default)
```r
x.append <- read.spss(file=sav, to.data.frame=TRUE)
```

#### duplicated.value.labels = "condense"
```r
x.condense <- read.spss(file=sav, to.data.frame=TRUE,
  duplicated.value.labels = "condense")
```

```r
levels(x.append$factor_n_duplicated)
levels(x.condense$factor_n_duplicated)
```

```r
as.numeric(x.append$factor_n_duplicated)
as.numeric(x.condense$factor_n_duplicated)
```

### Long Strings (>255 chars) are imported in consecutive separate variables

#### (see warning about subtype 14):
```r
x <- read.spss(file=sav, to.data.frame=TRUE, stringsAsFactors=FALSE)
```

```rncat.long.string <- function(x, w=70) cat(paste(strwrap(x, width=w), "\n"))
```

```r
# first part: x$string_500:
cat.long.string(x$string_500)
# second part: x$STRIN0:
cat.long.string(x$STRIN0)
```

```r
long.string <- apply(x[,c("string_500", "STRIN0")], 1, paste, collapse="")
cat.long.string(long.string)
```

---

**read.ssd**

Obtain a Data Frame from a SAS Permanent Dataset, via read.xport

---

**Description**

Generates a SAS program to convert the ssd contents to SAS transport format and then uses `read.xport` to obtain a data frame.

**Usage**

```r
read.ssd(libname, sectionnames,
  tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```
Arguments

libname character string defining the SAS library (usually a directory reference)
sectionnames character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended.
tmpXport character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.
tmpProgLoc character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.
sascmd character string giving full path to SAS executable.

Details

Creates a SAS program and runs it.
Error handling is primitive.

Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

Note

This requires SAS to be available. If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as .csv, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

read.xport

Examples

## if there were some files on the web we could get a real
## runnable example
## Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"
R> baseline <- read.ssd("trialdata", "baseline")
**read.systat**  

**Obtain a Data Frame from a Systat File**  

**Description**  

read.systat reads a rectangular data file stored by the Systat SAVE command as (legacy) *.sys or more recently *.syd files.

**Usage**  

```r
read.systat(file, to.data.frame = TRUE)
```

**Arguments**  

- `file` character variable with the name of the file to read  
- `to.data.frame` return a data frame (otherwise a list)

**Details**  

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is `FALSE`, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

**Value**  

A data frame (or list) with one component for each variable in the saved data set.

**Author(s)**  

Roger Bivand
References

Examples

```r
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[[1]])
str(iris.s)
summary(iris.s)
```

---

### read.xport

*Read a SAS XPORT Format Library*

**Description**

Reads a file as a SAS XPORT format library and returns a list of data.frames.

**Usage**

```r
read.xport(file, ...)
```

**Arguments**

- `file` character variable with the name of the file to read. The file must be in SAS XPORT format.
- `...` passed to `as.data.frame` when creating the data frames.

**Value**

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by \_A to \_Z by SAS) are mapped to R `NA`

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or ':: these are not treated as R missing values.

lookup.xport

Examples

## Not run: ## no XPORT file is installed
read.xport("test.xpt")

## End(Not run)

S3 read functions  Read an S3 Binary or data.dump File

Description

Reads binary data files or data.dump files that were produced in S version 3.

Usage

data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)

Arguments

file  the filename of the S-PLUS data.dump or binary file.
print  whether to print the name of each object as read from the file.
verbose  whether to print the name of every subitem within each object.
env  environment within which to create the restored object(s).

Details

read.S can read the binary files produced in some older versions of S-PLUS on either Windows
(versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether
the file was produced on a big- or little-endian machine and adapts itself accordingly.
data.restore can read a similar range of files produced by data.dump and for newer versions of
S-PLUS, those from data.dump(....... , oldStyle=TRUE).

Not all S3 objects can be handled in the current version. The most frequently encountered ex-
ceptions are functions and expressions; you will also have trouble with objects that contain model
formulas. In particular, comments will be lost from function bodies, and the argument lists of
functions will often be changed.

Value

For read.S, an R version of the S3 object.
For data.restore, the name of the file.

Author(s)

Duncan Murdoch
Examples

```r
## if you have an S-PLUS .Data file containing 'myobj'
## Not run: read.S(file.path(".Data", "myobj"))
data.restore("dumpdata", print = TRUE)
## End(Not run)
```

write.arff  Write Data into ARFF Files

Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

Usage

```r
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

Arguments

- `x`  
  the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.

- `file`  
  either a character string naming a file, or a connection. """ indicates output to the standard output connection.

- `eol`  
  the character(s) to print at the end of each line (row).

- `relation`  
  The name of the relation to be written in the file.

Details

relation will be passed through `make.names` before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have `X` prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

References

See Also

`read.arff`; functions `write.arff` and `read.arff` in package `RWeka` which provide some support for logicals via conversion to or from factors.

Examples

```r
write.arff(iris, file = "")
```
The function tries to write a data frame to a DBF file.

Usage

write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)

Arguments

dataframe a data frame object.
file a file name to be written to.
factor2char logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.
max_nchar The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

details

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase max_nchar only if you are sure the intended reader supports wider character fields.

Value

Invisible NULL.

Note

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0,-1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

try2 <- paste(tempfile(), ".dbf", sep = "")
write.dbf(warpbreaks, try2, factor2char = TRUE)
in2 <- read.dbf(try2)
str(in2)
unlink(c(try1, try2))

write.dta

Write Files in Stata Binary Format

Description

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be drop-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

Usage

write.dta(dataframe, file, version = 7L,
          convert.dates = TRUE, tz = "GMT",
          convert.factors = c("labels", "string", "numeric", "codes"))

Arguments

dataframe a data frame.
file character string giving filename.
version integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10.
convert.dates logical: convert Date and POSIXct objects: see section ‘Dates’.
tz timezone for date conversion.
convert.factors how to handle factors.
Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The abbreviate function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata ‘value labels’ for the factor levels. With convert.factors = "string", the factor levels are written as strings (the name of the value label is taken from the "val.labels" attribute if it exists or the variable name otherwise). With convert.factors = "numeric" the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, convert.factors = "codes" writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the "label.table" attribute contains value labels with names not already attached to a variable (not the variable name or name from "val.labels") then these will be written out as well.

If the "datalabel" attribute contains a string, it is written out as the dataset label otherwise the dataset label is "Written by R.".

If the "expansion.table" attribute contains a string, it is written out as the dataset label otherwise the dataset label is "Written by R.".

If the "val.labels" attribute contains a character vector with a string label for each value then this is written as the value labels. Otherwise the variable names are used.

For Stata 8 or later use the default version = 7 – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn’t have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

Value

NULL

Dates

Unless disabled by argument convert.dates = FALSE, R date and date-time objects (POSIXt classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

format xdate %td;
It is possible to pass objects of class POSIXct to Stata to be treated as one of its versions of date-times. Stata uses the number of milliseconds since 1960-01-01, either excluding (format %tc) or counting (format %tC) leap seconds. So either an object of class POSIXct can be passed to Stata with convert.dates = FALSE and converted in Stata, or 315619200 should be added and then multiplied by 1000 before passing to write.dta and assigning format %tc. Stata’s comments on the first route are at https://www.stata.com/manuals13/ddatetime.pdf, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

Examples

```r
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```
write.foreign

Details

The work for this function is done by foreign:::writeForeignStata, foreign:::writeForeignSAS and foreign:::writeForeignSPSS. To add support for another package, eg Systat, create a function writeForeignSystat with the same first three arguments as write.foreign. This will be called from write.foreign when package="Systat".

Numeric variables and factors are supported for all packages: dates and times (Date, dates, date, and POSIXt classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For package="SAS" there are optional arguments dataname = "rdata" taking a string that will be the SAS data set name, validvarname taking either "V6" or "V7", and libpath = NULL taking a string that will be the directory where the target SAS datset will be written when the generated SAS code been run.

For package="SPSS" there is an optional argument maxchars = 32L taking an integer that causes the variable names (not variable labels) to be abbreviated to not more than maxchars chars. For compatibility with SPSS version 12 and before, change this to maxchars = 8L. In single byte locales with SPSS versions 13 or later, this can be set to maxchars = 64L.

For package="SPSS", as a side effect, the decimal indicator is always set by SET DECIMAL=DOT. which may override user settings of the indicator or its default derived from the current locale.

Value

Invisible NULL.

Chapter 23

The lattice package

Description

The **lattice** add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland’s 1993 book *Visualizing Data*. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several ‘high-level’ generic functions (listed below in the “See Also” section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`, which also includes a discussion of the important topics of *conditioning* and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see `trellis.device`.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the `print.trellis` help page. See `update.trellis` to learn about manipulating a “trellis” object. Tools to augment lattice plots after they are drawn (including `locator`-like functionality) are described in the `trellis.focus` help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading
the PDF reference manual available at https://cran.r-project.org/package=lattice. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer’s ‘Use R’ series; see the “References” section below.

Note

High-level lattice functions like xyplot are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then print-ed or plot- ted to create the actual plot. Due to R’s automatic printing rule, it is usually not necessary to explicitly carry out the second step, and lattice functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often source) or in other contexts where automatic printing is suppressed (e.g., for or while loops). In such situations, an explicit call to print or plot is required.

The lattice package is based on the Grid graphics engine and requires the grid add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing par() settings usually has no effect on Lattice plots; lattice provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

Bell Lab’s Trellis Page contains several documents outlining the use of Trellis graphics; these provide a holistic introduction to the Trellis paradigm: http://web.archive.org/web/20081020164041/http://cm.bell-labs.com/cm/ms/departments/sia/project/trellis/display.writing.html

See Also

The following is a list of high-level functions in the lattice package and their default displays. In all cases, the actual display is produced by the so-called “panel” function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as “panel.” followed by the name of the corresponding high-level function; i.e., the default panel function for xyplot is panel.xyplot, the one for histogram is panel.histogram, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

Univariate:

barchart: Bar plots.
bwplot: Box-and-whisker plots.
densityplot: Kernel density estimates.
dotplot: Cleveland dot plots.
histogram: Histograms.
qqmath: Theoretical quantile plots.
stripplot: One-dimensional scatterplots.

Bivariate:

qq: Quantile plots for comparing two distributions.
xyplot: Scatterplots and time-series plots (and potentially a lot more).

Trivariate:

levelplot: Level plots (similar to image plots).
contourplot: Contour plots.
cloud: Three-dimensional scatter plots.
wireframe: Three-dimensional surface plots (similar to persp plots).

Hypervariate:

splom: Scatterplot matrices.
parallel: Parallel coordinate plots.

Miscellaneous:

rfs: Residual and fitted value plots (also see oneway).
tmd: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in panel.functions. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives lines, points, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like llines or panel.lines and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the latticeExtra package.

Description

This help page documents several commonly used high-level Lattice functions. `xyplot` produces bivariate scatterplots or time-series plots, `bwplot` produces box-and-whisker plots, `dotplot` produces Cleveland dot plots, `barchart` produces bar plots, and `stripplot` produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

Usage

```r
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)
```

```r
## S3 method for class 'formula'
xyplot(x,
data,
allow.multiple = is.null(groups) || outer,
outer = !is.null(groups),
auto.key = FALSE,
aspect = "fill",
panel = lattice.getOption("panel.xyplot"),
prepanel = NULL,
scales = list(),
strip = TRUE,
groups = NULL,
xlab,
xlim,
ylab,
ylim,
drop.unused.levels = lattice.getOption("drop.unused.levels"),
..., 
lattice.options = NULL,
default.scales,
default.prepanel = lattice.getOption("prepanel.default.xyplot"),
subscripts = !is.null(groups),
subset = TRUE)
```

```r
## S3 method for class 'formula'
```
dotplot(x,  
   data,  
   panel = lattice.getOption("panel.dotplot"),  
   default.prepanel = lattice.getOption("prepanel.default.dotplot"),  
   ...)  

## S3 method for class 'formula'  
barchart(x,  
   data,  
   panel = lattice.getOption("panel.barchart"),  
   default.prepanel = lattice.getOption("prepanel.default.barchart"),  
   box.ratio = 2,  
   ...)  

## S3 method for class 'formula'  
stripplot(x,  
   data,  
   panel = lattice.getOption("panel.stripplot"),  
   default.prepanel = lattice.getOption("prepanel.default.stripplot"),  
   ...)  

## S3 method for class 'formula'  
bwplot(x,  
   data,  
   allow.multiple = is.null(groups) || outer,  
   outer = FALSE,  
   auto.key = FALSE,  
   aspect = "fill",  
   panel = lattice.getOption("panel.bwplot"),  
   prepanel = NULL,  
   scales = list(),  
   strip = TRUE,  
   groups = NULL,  
   xlab,  
   xlim,  
   ylab,  
   ylim,  
   box.ratio = 1,  
   horizontal = NULL,  
   drop.unused.levels = lattice.getOption("drop.unused.levels"),  
   ...,  
   lattice.options = NULL,  
   default.scales,  
   default.prepanel = lattice.getOption("prepanel.default.bwplot"),  
   subscripts = !is.null(groups),  
   subset = TRUE)  

Arguments  

x  
All high-level function in lattice are generic. x is the object on which method  
dispatch is carried out.  
For the "formula" methods, x must be a formula describing the primary vari-
ables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form \( y \sim x \mid g1 \times g2 \times \ldots \) (or equivalently, \( y \sim x \mid g1 + g2 + \ldots \)), indicating that plots of \( y \) (on the y-axis) versus \( x \) (on the x-axis) should be produced conditional on the variables \( g1, g2, \ldots \). Here \( x \) and \( y \) are the primary variables, and \( g1, g2, \ldots \) are the conditioning variables. The conditioning variables may be omitted to give a formula of the form \( y \sim x \), in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., \( \sqrt{()} \), \( \log() \), etc. See the data argument below for rules regarding evaluation of the terms in the formula.

With the exception of \texttt{xyplot}, the functions documented here may also be supplied a formula of the form \( \sim x \mid g1 \times g2 \times \ldots \). In that case, \( y \) defaults to \texttt{names(x)} if \( x \) is named, and a factor with a single level otherwise.

Cases where \( x \) is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For \texttt{barchart} and \texttt{dotplot}, non-trivial methods exist for tables and arrays, documented at \texttt{barchart.table}.

The conditioning variables \( g1, g2, \ldots \) must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of \texttt{shingle} for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the \texttt{shingle} function; however, using \texttt{equal.count} may be more appropriate in many cases. Character variables are coerced to factors.

Extended formula interface: As a useful extension of the interface described above, the primary variable terms (both the LHS \( y \) and RHS \( x \)) may consist of multiple terms separated by a ‘+’ sign, e.g., \( y1 + y2 \sim x \mid a \times b \). This formula would be taken to mean that the user wants to plot both \( y1 \sim x \mid a \times b \) and \( y2 \sim x \mid a \times b \), but with the \( y1 \sim x \) and \( y2 \sim x \) superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the \texttt{groups} argument (see below) would produce, if \( y1 \) and \( y2 \) were concatenated to produce a longer vector, with the groups argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the \texttt{reshape} function. This feature cannot be used in conjunction with the \texttt{groups} argument.

To interpret \( y1 + y2 \) as a sum, one can either set \texttt{allow.multiple=FALSE} or use \texttt{I(y1+y2)}.

A variation on this feature is when the \texttt{outer} argument is set to \texttt{TRUE}. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

Primary variables: The \( x \) and \( y \) variables should both be numeric in \texttt{xyplot}, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of \( x \) and \( y \) should be numeric, and the other a factor or shingle. Which of these will happen is determined by the \texttt{horizontal} argument — if \texttt{horizontal=TRUE}, then \( y \) will be coerced to be a factor or shingle, otherwise \( x \). The default value of \texttt{horizontal} is \texttt{FALSE} if \( x \) is a factor or shingle, \texttt{TRUE} otherwise. (The functionality provided by \texttt{horizontal=FALSE} is not S-compatible.)
Note that the x argument used to be called formula in earlier versions (when the high-level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

**data**  
For the formula methods, a data frame (or more precisely, anything that is a valid envir argument in eval, e.g., a list or an environment) containing values for any variables in the formula, as well as groups and subset if applicable. If not found in data, or if data is unspecified, the variables are looked for in the environment of the formula. For other methods (where x is not a formula), data is usually ignored, often with a warning if it is explicitly specified.

**allow.multiple**  
Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to TRUE whenever sensible.

**outer**  
Logical flag controlling what happens with formulas using the extended interface described above (see the entry for x for details). Defaults to FALSE, except when groups is explicitly specified or grouping does not make sense for the default panel function.

**box.ratio**  
Applicable to barchart and bwplot. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the box.width argument in the respective default panel functions.

**horizontal**  
Logical flag applicable to bwplot, dotplot, barchart, and stripplot. Determines which of x and y is to be a factor or shingle (y if TRUE, x otherwise). Defaults to FALSE if x is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of scales in this case may be abbreviate = TRUE, in which case long labels which would usually overlap will be abbreviated. scales could also contain a minlength argument in this case, which would be passed to the abbreviate function.

**Common arguments:**  
The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

**panel**  
Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding x and y variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the panel argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “panel.” followed by the name of the corresponding high-level function (e.g., panel.xyplot, panel.barchart, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named x and y, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as xyplot) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a . . . argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.
Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the \( x \) and \( y \) arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, `lines` can be replaced by `llines` (or equivalently, `panel.lines`). Note that traditional graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the `groups` argument is not NULL. In that case, the panel function should also accept arguments named `groups` and `subscripts` (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `xyplot`, `barchart`, `dotplot`, and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the \( x \) and \( y \) data for that panel in the original data, BEFORE taking into account the effect of the `subset` argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of `subset`, in which case `subscripts` may have no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot`
calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

**aspect**
This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are "fill" (the default) which tries to make the panels as big as possible to fill the available space; "xy", which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Not all default `prepanel` functions produce sensible banking calculations.

**groups**
A variable or expression to be evaluated in `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

**auto.key**
A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns = 2)` will create a legend split into two columns (columns is documented in the entry for `key`).

More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `Legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (text) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified.

Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The `par.settings` argument, possibly in conjunction with `simpleTheme`, may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the
A function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx`, and `dy` (and less frequently, `xat` and `yat`). The return value of a user-supplied `prepanel` function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the `prepanel` function. This happens globally if the `relation` component of `scales` is "same", and on a per-panel basis otherwise.

The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation of `banking` for details.

If `xlim` or `ylim` is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first `n` integers, where `n` is the length of `xlim` or `ylim`, as the case may be. The elements of the character vector are used as the default labels for these `n` integers. Thus, to make this information consistent between panels, the `xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`. The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing else is appropriate, values of `NA` should be returned for the `xlim` and `ylim` components.

A logical flag or function. If `FALSE`, strips are not drawn. Otherwise, strips are drawn using the `strip` function, which defaults to `strip.default`. See documentation of `strip.default` to see the arguments that are available to the `strip` function. This description also applies to the `strip.left` argument (see ..., below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for `x` in the formula defining the plot. Can be specified as `NULL` to omit the label altogether. Finer control is possible, as described in the entry for `main`, with the modification that if the `label` component is omitted from the list, it is replaced by the default `xlab`.

Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for `y` in the formula defining the plot. Finer control is possible, see entries for `main` and `xlab`.

Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in `name=value` form, and may also contain two other lists called `x` and `y` of the same form (described below). Components of `x` and `y` affect the respective axes only, while those in `scales` affect both. When parameters are specified in both lists, the values in `x` or `y` are used. Note that certain high-level functions have defaults that are specific to a particular
axis (e.g., bwplot has alternating=FALSE for the categorical axis only); these

 can only be overridden by an entry in the corresponding component of scales.

 As a special exception, scales (or its x and y components) can also be a char-

acter string, in which case it is interpreted as the relation component.

The possible components are:

relation A character string that determines how axis limits are calculated for
each panel. Possible values are "same" (default), "free" and "sliced".

 For relation="same", the same limits, usually large enough to encompass
all the data, are used for all the panels. For relation="free", limits for
each panel is determined by just the points in that panel. Behavior for
relation="sliced" is similar, except that the length (max - min) of the

scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be
controlled by the prepanel function, which can be overridden by xlim,

ylim or scales$limits (except when relation="sliced", in which case
explicitly specified limits are ignored with a warning). When relation
is "free", xlim or ylim can be a list, in which case it is treated as if its
components were the limit values obtained from the prepanel calculations
for each panel (after being replicated if necessary).

tick.number An integer, giving the suggested number of intervals between
ticks. This is ignored for a factor, shingle, or character vector, for in these
cases there is no natural rule for leaving out some of the labels. But see
xlim.

draw A logical flag, defaulting to TRUE, that determines whether to draw the
axis (i.e., tick marks and labels) at all.

alternating Usually a logical flag specifying whether axis labels should al-
ternate from one side of the group of panels to the other. For finer control,
alternating can also be a vector (replicated to be as long as the number
of rows or columns per page) consisting of the following numbers

• 0: do not draw tick labels
• 1: bottom/left
• 2: top/right
• 3: both.

alternating applies only when relation="same". The default is TRUE,
or equivalently, c(1, 2)

limits Same as xlim and ylim.

at The location of tick marks along the axis (in native coordinates), or a list as
long as the number of panels describing tick locations for each panel.

labels Vector of labels (characters or expressions) to go along with at. Can
also be a list like at.

cex A numeric multiplier to control character sizes for axis labels. Can be a
vector of length 2, to control left/bottom and right/top labels separately.

font, fontface, fontfamily Specifies the font to be used for axis labels.

lineheight Specifies the line height parameter (height of line as a multiple of
the size of text); relevant for multi-line labels. (This is currently ignored for
ccloud.)

tck Usually a numeric scalar controlling the length of tick marks. Can also be
a vector of length 2, to control the length of left/bottom and right/top tick
marks separately.

col Color of tick marks and labels.
rot Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.

abbreviate A logical flag, indicating whether to abbreviate the labels using the abbreviate function. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength Argument passed to abbreviate if abbreviate=TRUE.

log Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x = list(log = 2)) is equivalent to y ~ log2(x).

See entry for equispaced.log below for details on how to control axis labeling.

equispaced.log A logical flag indicating whether tick mark locations should be equispaced when ‘log scales’ are in use. Defaults to TRUE.

Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If equispaced.log is FALSE, the choice made is similar to how log scales are annotated in traditional graphics. If TRUE, tick mark locations are chosen as ‘pretty’ equispaced values in the transformed scale, and labeled in the form "base"loc", where base is the base of the logarithm transformation, and loc are the locations in the transformed scale.

See also xscale.components.logpower in the latticeExtra package.

format The format to use for POSIXct variables. See strftime for description of valid values.

axis A character string, "r" (default) or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

subscripts A logical flag specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified, or if the panel function accepts an argument named subscripts. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using panel.identify.

subset An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If subscripts is TRUE, the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the drop.unused.levels argument.

xlim Normally a numeric vector (or a DateTime object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of x. The latter form is interpreted as a range containing c(1, length(xlim)), with the character vector determining labels at tick positions 1:length(xlim).

xlim could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaning-
ful only when \( \text{scales$\times$relation} \) is "free", in which case these are treated as if they were the corresponding limit components returned by prepanel calculations.

**ylim** Similar to **xlim**, applied to the y-axis.

**drop.unused.levels**

A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an **interaction** is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components cond and data, both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by `lattice.getOption("drop.unused.levels")`, which is initially set to \texttt{TRUE} for both components. Note that this argument does not control dropping of levels of the groups argument.

**default.scales** A list giving the default values of **scales** for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.

**default.prepanel**

A function or character string giving the name of a function that serves as the (component-wise) fallback prepanel function when the **prepanel** argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of `lattice.options`.

**lattice.options**

A list that could be supplied to `lattice.options`. These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the `par.settings` argument described below for a similar treatment of graphical settings.

... Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel function being used.

The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high-level functions, but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as “panel.” followed by the name of the high-level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

**as.table**: A logical flag that controls the order in which panels should be displayed: if \texttt{FALSE} (the default), panels are drawn left to right, bottom to top (as in a graph); if \texttt{TRUE}, left to right, top to bottom (as in a table).
between: A list with components x and y (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). x and y are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different between values for different pages.

key: A list that defines a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a "grob" (grid object) eventually plotted by the print method for "trellis" objects. The structure of the legend is constrained in the ways described below.

Although such a list can be and often is created explicitly, it is also possible to generate such a list using the `simpleKey` function; the latter is more convenient but less flexible. The `auto.key` argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by key, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0,0)`, `c(1,0)`, `c(1,1)` and `c(0,1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the "display area". Depending on the value of the "legend.bbox" option (see `lattice.getOption`), this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text")s is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in key and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- `cex=1` (text, lines, points)
- `col="black"` (text, rectangles, lines, points)
- `alpha=1` (text, rectangles, lines, points)
- `fill="transparent"` (lines, points)
- `lty=1` (lines)
In addition, the component border can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, border controls the border of the entire key (see below).

In addition, the component border can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, border controls the border of the entire key (see below).

angle and density are unimplemented. size determines the width of columns of rectangles and lines in character widths. type is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. height gives heights of rectangles as a fraction of the default.

Other possible components of key are:

reverse.rows Logical flag, defaulting to FALSE. If TRUE, all components are reversed after being replicated (the details of which may depend on the value of rep). This is useful in certain situations, e.g., with a grouped barchart with stack = TRUE with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless reverse.rows = TRUE. Note that in this case, unless all columns have the same number or rows, they will no longer be aligned.

between Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

title String or expression giving a title for the key.

rep Logical flag, defaults to TRUE. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying rep=FALSE, in which case the length of each column will be determined by components of that column alone.

cex.title Zoom factor for the title.

lines.title The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.

padding.text The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently \(0.2 \times "lines"\). This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

background Background color for the legend. Defaults to the global background color.
alpha.background  An alpha transparency value between 0 and 1 for the background.

color  Either a color for the border, or a logical flag. In the latter case, the border color is black if color is TRUE, and no border is drawn if it is FALSE (the default).

transparent=FALSE  Logical flag, whether legend should have a transparent background.

just  A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See grid.layout for more precise details.

columns  The number of column-blocks (drawn side by side) the legend is to be divided into.

between.columns  Space between column blocks, in addition to between.

divide  Number of point symbols to divide each line when type is "b" or "o" in lines.

legend:  The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.

If used, legend must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the space component of key. If key (or colorkey for levelplot and wireframe) is specified, their space component must not conflict with the name of any component of legend.

Each component of legend must have a component called fun. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called args. For components named "inside", there can be additional components called x, y and corner, which work in the same way as for key.

page:  A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

xlab.top, ylab.right:  Labels for the x-axis on top, and y-axis on the right. Similar to xlab and ylab, but less commonly used.

main:  Typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL.

main (as well as xlab, ylab and sub) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in plotmath. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for ylab). This feature can be used to provide column or row labels rather than a single axis label.

When main (etc.) is a list, the actual label should be specified as the label component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (xlab and ylab usually have defaults, but main and sub do not). Further named arguments are passed on to textGrob; this can include arguments controlling positioning like just and rot as well as graphical parameters such as col and font (see gpar for a full list).

main, sub, xlab, ylab, xlab.top, and ylab.right can also be arbitrary "grob"s (grid graphical objects).
sub: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for main for finer control options.

par.strip.text: A list of parameters to control the appearance of strip text. Notable components are col, cex, font, and lines. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "\n"-s) or if the default height seems too small or too large. Additionally, the lineheight component can control the space between multiple lines. The labels can be abbreviated when shown by specifying abbreviate = TRUE, in which case the components minlength and dot (passed along to the abbreviate function) can be specified to control the details of how this is done.

layout: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. layout determines this arrangement.
layout is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is c(0,n), where n is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via par("din")). If NA is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.
The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.

skip: A logical vector (default FALSE), replicated to be as long as the number of panels (spanning all pages). For elements that are TRUE, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

strip.left: strip.left can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for strip for detailed usage.

xlab.default, ylab.default: Fallback default for xlab and ylab when they are not specified. If NULL, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

xscale.components, yscale.components: Functions that determine axis annotation for the x and y axes respectively. See documentation for xscale.components.default, the default values of these arguments, to learn more.

axis: Function responsible for drawing axis annotation. See documentation for
axis.default, the default value of this argument, to learn more.

perm.cond: An integer vector, a permutation of 1:n, where n is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. perm.cond can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using perm.cond as the perm argument does in aperm.

index.cond: Whereas perm.cond permutes the dimensions of the multidimensional array of panels, index.cond can be used to subset (or reorder) margins of that array. index.cond can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. index.cond can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If index.cond is a list, it has to be as long as the number of conditioning variables, and the i-th component has to be a valid indexing vector for levels(g_i), where g_i is the i-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the subset and drop.unused.levels arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to TRUE.

Note that the components of index.cond are interpreted in the order of the conditioning variables in the original call, and is not affected by perm.cond. Another possibility is to specify index.cond as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a ... argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use perm.cond and index.cond to update an existing “trellis” object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the update.trellis method, both can be set to NULL, which reverts these back to their defaults.

par.settings: A list that could be supplied to trellis.par.set. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the lattice.options argument described above for a similar treatment of non-graphical options.

plot.args: A list containing possible arguments to plot.trellis, which will be used by the plot or print methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.
Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the formula method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables g1, g2, ..., a separate “packet” is produced, consisting of the points \((x, y)\) for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the layout argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for index.cond above).

The coordinate system used by lattice by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless as.table = TRUE, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to as.table=TRUE; this can be done by setting lattice.options(default.args = list(as.table = TRUE)). Default values can be set in this manner for the following arguments: as.table, aspect, between, page, main, sub, par.strip.text, layout, skip and strip. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with g1 varying fastest, followed by g2, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the index.cond and perm.cond arguments, possibly using the update (and other related) method(s).

Value

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The update method can be used to subsequently update components of the object, and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

Most of the arguments documented here are also applicable for the other high-level functions in the lattice package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

**Time series plotting methods**

**Description**

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

**Usage**

```r
## S3 method for class 'ts'
xyplot(x, data = NULL,
```
screens = if (superpose) 1 else colnames(x),
..., superpose = FALSE,
cut = FALSE,
type = "l",
col = NULL,
lty = NULL,
lwd = NULL,
pch = NULL,
cex = NULL,
fill = NULL,
auto.key = superpose,
panel = if (superpose) "panel.superpose"
  else "panel.superpose.plain",
par.settings = list(),
layout = NULL, as.table = TRUE,
xlab = "Time", ylab = NULL,
default.scales = list(y = list(relation =
  if (missing(cut)) "free" else "same")))

Arguments

x an object of class ts, which may be multi-variate, i.e. have a matrix structure with multiple columns.
data not used, and must be left as NULL.
... additional arguments passed to xyplot, which may pass them on to panel.xyplot.
screens factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. screens = c(1, 2, 1) would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below.
superpose overlays all series in one panel (via screens = 1) and uses grouped style settings (from trellis.par.get("superpose.line"), etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.
cut defines a cut-and-stack plot. cut can be a list of arguments to the function equal.count, i.e. number (number of intervals to divide into) and overlap (the fraction of overlap between cuts, default 0.5). If cut is numeric this is passed as the number argument.
cut = TRUE tries to choose an appropriate number of cuts (up to a maximum of 6), using banking, and assuming a square plot region. This should have the effect of minimising wasted space when aspect = "xy".
type, col, lty, lwd, pch, cex, fill graphical arguments, which are processed and eventually passed to panel.xyplot. These arguments can also be vectors or (named) lists, see Details for more information.
auto.key a logical, or a list describing how to draw a key. See the auto.key entry in xyplot. The default here is to draw lines, not points, and any specified style arguments should show up automatically.
panel the panel function. It is recommended to leave this alone, but one can pass a panel.groups argument which is handled by panel.superpose for each series.
par.settings  style settings beyond the standard col, lty, lwd, etc; see trellis.par.set and simpleTheme.

layout  numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.

as.table  to draw panels from top to bottom. The order is determined by the order of columns in x.

xlab, ylab  X axis and Y axis labels; see xyplot. Note in particular that ylab may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but NOTE in this case the vector should be reversed OR the argument as.table set to FALSE.

default.scales  scales specification. The default is set to have "free" Y axis scales unless cut is given. Note, users should pass the scales argument rather than default.scales.

Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., list(A = c(1,2), c(3,4)) in which c(3, 4) is the default value and c(1, 2) the value only for series A. The screens argument can be specified in a similar way.

Some examples are given below.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Author(s)

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <felix@nfrac.org>. The first two authors developed xyplot.ts in their zoo package, including the screens approach. The third author developed a different xyplot.ts for cut-and-stack plots in the latticeExtra package. The final author fused these together.

Examples

xyplot(ts(c(1:10,10:1)))

### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy", strip = FALSE, strip.left = TRUE, cut = list(number = 4, overlap = 0.05))
### A multivariate example; first juxtaposed, then superposed

```r
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
       type = c("l","g"), ylim = c(0, max(EuStockMarkets)))
```

### Examples using screens (these two are identical)

```r
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))
```

### Automatic group styles

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)
```

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE, xlim = extendrange(1996:1998),
       par.settings = standard.theme(color = FALSE))
```

### Specifying styles for series by name

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)
```

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
       auto.key = TRUE)
```

### Example with simpler data, few data points

```r
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
```

```r
xyplot(z, screens = list(a = "primary (a)", "other (b & c)",
                         type = list(a = c("p", "h"), b = c("p", "s"), "o"),
                         pch = list(a = 2, c = 3), auto.key = list(type = "o")))
```

---

**Description**

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

**Usage**

```r
## S3 method for class 'table'
barchart(x, data, groups = TRUE,
          origin = 0, stack = TRUE, ..., horizontal = TRUE)
```

```r
## S3 method for class 'array'
barchart(x, data, ...)
```

```r
## S3 method for class 'matrix'
barchart(x, data, ...)
```
## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)

### Arguments

- **x**: A table, array or matrix object.
- **data**: Should not be specified. If specified, will be ignored with a warning.
- **groups**: A logical flag, indicating whether to use the last dimension as a grouping variable in the display.
- **origin, stack**: Arguments to `panel.barchart`. The defaults for the table method are different.
- **horizontal**: Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
- **...**: Other arguments, passed to the underlying `formula` method.

### Details

The first dimension is used as the variable on the categorical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument beforehand using `t` or `aperm`). For more flexibility, use the formula method after converting the table to a data frame using the relevant `as.data.frame` method.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

default.prepanel =
  lattice.getOption("prepanel.default.densityplot"),
subscripts,
subset)

## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

Arguments

x  
The object on which method dispatch is carried out.

For the formula method, x can be a formula of the form \(~x \mid g1 \ast g2 \ast \ldots\)
indicating that histograms or kernel density estimates of the x variable should
be produced conditioned on the levels of the (optional) variables g1, g2, \ldots. x
should be numeric (or possibly a factor in the case of histogram), and each of
g1, g2, \ldots should be either factors or shingles.

As a special case, the right hand side of the formula can contain more than one
term separated by '+' signs (e.g., \(~x1 + x2 \mid g1 \ast g2\)). What happens in this
case is described in the documentation for xyplot. Note that in either form, all
the terms in the formula must have the same length after evaluation.

For the numeric and factor methods, x is the variable whose histogram or
Kernel density estimate is drawn. Conditioning is not allowed in these cases.

data  
For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see xyplot for details). data should not be specified
for the other methods, and is ignored with a warning if it is.

type  
A character string indicating the type of histogram that is to be drawn.
"percent" and "count" give relative frequency and frequency histograms re-
spectively, and can be misleading when breakpoints are not equally spaced.
"density" produces a density histogram.

type defaults to "density" when the breakpoints are unequally spaced, and
when breaks is NULL or a function, and to "percent" otherwise.

nint  
An integer specifying the number of histogram bins, applicable only when
breaks is unspecified or NULL in the call. Ignored when the variable being
plotted is a factor.

endpoints  
A numeric vector of length 2 indicating the range of x-values that is to be cov-
ered by the histogram. This applies only when breaks is unspecified and the
variable being plotted is not a factor. In do.breaks, this specifies the interval
that is to be divided up.

breaks  
Usually a numeric vector of length (number of bins + 1) defining the breakpoints
of the bins. Note that when breakpoints are not equally spaced, the only value
of type that makes sense is density.
When \texttt{breaks} is unspecified, the value of \texttt{latticegetOption("histogram.breaks")} is first checked. If this value is \texttt{NULL}, then the default is to use
\[
\texttt{breaks} = \text{seq_len}(1 + \text{nlevels}(x)) - 0.5
\]
when \(x\) is a factor, and
\[
\texttt{breaks} = \text{do.breaks}(\text{endpoints}, \text{nint})
\]
otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not \texttt{NULL}, or if \texttt{breaks} is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the \texttt{breaks} argument in \texttt{hist}. In particular, this allows specification of \texttt{breaks} as an integer giving the number of bins (similar to \texttt{nint}), as a character string denoting a method, or as a function.

When specified explicitly, a special value of \texttt{breaks} is \texttt{NULL}, in which case the number of bins is determined by \texttt{nint} and then breakpoints are chosen according to the value of \texttt{equal.widths}.

\texttt{equal.widths}  A logical flag, relevant only when \texttt{breaks=NULL}. If \texttt{TRUE}, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints).

\texttt{n}  Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to \texttt{density}.

\texttt{panel}  A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions \texttt{panel.histogram} and \texttt{panel.densityplot} are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

provide \texttt{allow.multiple}, \texttt{outer}, \texttt{auto.key}, \texttt{aspect}, \texttt{prepanel}, \texttt{scales}, \texttt{strip}, \texttt{groups}, \texttt{xlab}, \texttt{ylab}, \texttt{xlim}, \texttt{ylim}, \texttt{drop.unused.levels}, \texttt{lattice.options}, \texttt{default.scales}, \texttt{subscripts}, \texttt{subset}.

provide \texttt{xlab}, \texttt{ylab}, \texttt{xlim}, \texttt{ylim}, \texttt{drop.unused.levels}.
default.prepanel
  Fallback prepanel function. See xyplot.

weights
  numeric vector of weights for the density calculations, evaluated in the non-standard manner used for groups and terms in the formula, if any. If this is specified, it is subsetted using subscripts inside the panel function to match it to the corresponding x values.
  At the time of writing, weights do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).

bw, adjust, width
  Arguments controlling bandwidth. Passed on as arguments to density.

kernel, window
  The choice of kernel. Passed on as arguments to density.

give.Rkern
  Logical flag, passed on as argument to density. This argument is made available only for ease of implementation, and will produce an error if TRUE.

from, to, cut
  Controls range over which density is evaluated. Passed on as arguments to density.

na.rm
  Logical flag specifying whether NA values should be ignored. Passed on as argument to density, but unlike in density, the default is TRUE.

...
  Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

histogram draws Conditional Histograms, and densityplot draws Conditional Kernel Density Plots. The default panel function uses the density function to compute the density estimate, and all arguments accepted by density can be specified in the call to densityplot to control the output. See documentation of density for details.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

do.breaks is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

The form of the arguments accepted by the default panel function panel.histogram is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside histogram and passes only the breakpoints and the heights to the panel function, lattice simply passes along the original variable x along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

**Q-Q Plot with Theoretical Distribution**

**Description**

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

**Usage**

```r
qqmath(x, data, ...)
```

```r
# S3 method for class 'formula'
qqmath(x,
    data,
    allow.multiple = is.null(groups) || outer,
    outer = !is.null(groups),
    distribution = qnorm,
    f.value = NULL,
    auto.key = FALSE,
    aspect = "fill",
    panel = lattice.getOption("panel.qqmath"),
    prepanel = NULL,
    scales, strip, groups,
    xlab, xlim, ylab, ylim,
    drop.unused.levels = lattice.getOption("drop.unused.levels"),
    
```
## S3 method for class 'numeric'

`qqmath(x, data = NULL, ylab, ...)`

### Arguments

- **x**  
The object on which method dispatch is carried out. For the "formula" method, `x` should be a formula of the form `~ x | g1 * g2 * ...`, where `x` should be a numeric variable. For the "numeric" method, `x` should be a numeric vector.

- **data**  
For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see `xyplot` for details). `data` should not be specified for the other methods, and is ignored with a warning if it is.

- **distribution**  
A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are `qnorm`, `qunif`, etc. Distributions with other required arguments need to be provided as user-defined functions (see example with `qt`).

- **f.value**  
An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function `ppoints`, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the `quantile` function for the sample, and the function specified as the `distribution` argument for the theoretical distribution. `f.value` defaults to `NULL`, which has the effect of using `ppoints` for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for `qqnorm`, but different from the S-PLUS default of `f.value=ppoints`.

For large `x`, this argument can be used to restrict the number of points plotted. See also the `tails.n` argument in `panel.qqmath`.

- **panel**  
A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function `panel.qqmath` is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

- **allow.multiple**, **outer**  
See `xyplot`.

- **auto.key**  
See `xyplot`.

- **aspect**  
See `xyplot`.

- **prepanel**  
See `xyplot`.

- **scales**  
See `xyplot`.

- **strip**  
See `xyplot`.

- **groups**  
See `xyplot`.

- **xlab**, **ylab**  
See `xyplot`. 
qqmath produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of qqmath is different from the corresponding S-PLUS function, but is similar to qqnorm. See the entry for f.value for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not qqmath itself. In fact, both the arguments distribution and f.value are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for panel.qqmath for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

B_05_qq

Quantile-Quantile Plots of Two Samples

Description

Quantile-Quantile plots for comparing two Distributions

Usage

qq(x, data, ...)

## S3 method for class 'formula'

qq(x, data, aspect = "fill",
    panel = lattice.getOption("panel.qq"),
    prepanel, scales, strip,
    groups, xlab, xlim, ylab, ylim, f.value = NULL,
    drop.unused.levels = lattice.getOption("drop.unused.levels"),
    ...,
    lattice.options = NULL,
    qtype = 7,
    default.scales = list(),
    default.prepanel = lattice.getOption("prepanel.default.qq"),
    subscripts,
    subset)

Arguments

x

The object on which method dispatch is carried out.
For the "formula" method, x should be a formula of the form y ~ x | g1 * g2 * ...
where x should be a numeric variable, and y a factor, shingle, character, or
numeric variable, with the restriction that there must be exactly two levels of y,
which divide the values of x into two groups. Quantiles for these groups will be
plotted against each other along the two axes.

data

For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see xyplot for details).

f.value

An optional numeric vector of probabilities, quantiles corresponding to which
should be plotted. This can also be a function of a single integer (representing
sample size) that returns such a numeric vector. A typical value for this argument
is the function ppoints, which is also the S-PLUS default. If specified, the
probabilities generated by this function is used for the plotted quantiles, through
the quantile function.
f.value defaults to NULL, which is equivalent to

    f.value = function(n) ppoints(n, a = 1)

This has the effect of including the minimum and maximum data values in the
computed quantiles. This is similar to what happens for qqplot but different
from the default behaviour of qq in S-PLUS.

For large x, this argument can be used to restrict the number of quantiles plotted.

panel
A function, called once for each panel, that uses the packet (subset of panel
variables) corresponding to the panel to create a display. The default panel func-
tion panel.qq is documented separately, and has arguments that can be used to
customize its output in various ways. Such arguments can usually be directly
supplied to the high-level function.

qtype
The type argument for quantile.

aspect
See xyplot.

prepanel
See xyplot.

scales
See xyplot.

strip
See xyplot.

groups
See xyplot.

xlab, ylab
See xyplot.

xlim, ylim
See xyplot.

drop.unused.levels
See xyplot.

lattice.options
See xyplot.

default.scales
See xyplot.

subscripts
See xyplot.

subset
See xyplot.

default.prepanel
Fallback prepanel function. See xyplot.

... Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

qq produces Q-Q plots of two samples. The default behaviour of qq is different from the corre-
sponding S-PLUS function. See the entry for f.value for specifics.

This and all other high level Trellis functions have several arguments in common. These are ex-
tensively documented only in the help page for xyplot, which should be consulted to learn more
detailed usage.

Value

An object of class "trellis". The update method can be used to update components of the object
and the print method (usually called by default) will plot it on an appropriate plotting device.
Level plots and contour plots

contourplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

## S3 method for class 'matrix'
levelplot(x, data = NULL, aspect = "iso",
..., xlim, ylim,
row.values = seq_len(nrow(x)),
column.values = seq_len(ncol(x)))

## S3 method for class 'matrix'
contourplot(x, data = NULL, aspect = "iso",
..., xlim, ylim,
row.values = seq_len(nrow(x)),
column.values = seq_len(ncol(x)))

## S3 method for class 'array'
levelplot(x, data = NULL, ...)

## S3 method for class 'array'
contourplot(x, data = NULL, ...)

Arguments

x

for the formula method, a formula of the form \( z \sim x \times y | g1 \times g2 \times \ldots \), where \( z \) is a numeric response, and \( x, y \) are numeric values evaluated on a rectangular grid. \( g1, g2, \ldots \) are optional conditional variables, and must be either factors or shingles if present.

Calculations are based on the assumption that all \( x \) and \( y \) values are evaluated
on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the x and y values need not be equally spaced.

Both levelplot and wireframe have methods for matrix, array, and table objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used in filled.contour and image. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the dimnames may be duplicated; this is handled by calling make.unique to make the names unique (although the original labels are used for the x- and y-axes).

data
For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.

row.values, column.values
Optional vectors of values that define the grid when x is a matrix. row.values and column.values must have the same lengths as nrow(x) and ncol(x) respectively. By default, row and column numbers.

panel
panel function used to create the display, as described in xyplot

aspect
For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is aspect="fill", as described in xyplot.

at
A numeric vector giving breakpoints along the range of z. Contours (if any) will be drawn at these heights, and the regions in between would be colored using col.regions. In the latter case, values outside the range of at will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a zlim argument might have been used for. However, this also means that when supplying at explicitly, one has to be careful to include values outside the range of z to ensure that all the data are shown.

at can have length one only if region=FALSE.

col.regions
color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in col.regions, the colors are recycled. The actual color assignment is performed by level.colors, which is documented separately.

alpha.regions
Numeric, specifying alpha transparency (works only on some devices)

colorkey
A logical flag specifying whether a colorkey is to be drawn alongside the plot, or a list describing the colorkey. The list may contain the following components:

space: location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".

x, y: location, currently unused

col: A color ramp specification, as in the col.regions argument in level.colors

at: A numeric vector specifying where the colors change. must be of length 1 more than the col vector.

tri.lower, tri.upper: Logical or numeric controlling whether the first and last intervals should be triangular instead of rectangular. With the default value (NA), this happens only if the corresponding extreme at values are -Inf or Inf respectively, and the triangles occupy 5% of the total length
of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5% when specified as TRUE.

labels: A character vector for labelling the at values, or more commonly, a list describing characteristics of the labels. This list may include components labels, at, cex, col, rot, font, fontface and fontfamily.

title: Usually a character vector or expression providing a title for the colorkey, or a list controlling the title in further detail, or an arbitrary "grob". For details of how the list form is interpreted, see the entry for main in xyplot; generally speaking, the actual label should be specified as the label component (which may be unnamed if it is the first component), and the remaining arguments are used as appropriate in a call to textGrob. Further control of the placement of the title is possible through the component title.control. In particular, if a rot component is not specified, its default depends on the value of title.control$side (0 for top or bottom, and 90 for left or right).

title defaults to NULL, which means no title is drawn.

title: A list providing control over the placement of a title, if specified. Currently two components are honoured: side can take values "top", "bottom", "left", and "right", and specifies the side of the colorkey on which the title is to be placed. Defaults to the value of the "space" component. padding is a multiplier for the default amount of padding between the title and the colorkey.

tick.number: The approximate number of ticks desired.

tck: A (scalar) multiplier for tick lengths.

corner: Interacts with x, y; currently unimplemented

width: The width of the key

height: The length of key as a fraction of the appropriate side of plot.

raster: A logical flag indicating whether the colorkey should be rendered as a raster image using grid.raster. See also panel.levelplot.raster.

interpolate: Logical flag, passed to rasterGrob when raster=TRUE.

axis.line: A list giving graphical parameters for the color key boundary and tick marks. Defaults to trellis.par.get("axis.line").

axis.text: A list giving graphical parameters for the tick mark labels on the color key. Defaults to trellis.par.get("axis.text").

contour A logical flag, indicating whether to draw contour lines.

cuts The number of levels the range of z would be divided into.

labels Typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for panel.levelplot, to which this argument is passed on unchanged. That help page also documents the label.style argument, which affects how the labels are rendered.

pretty A logical flag, indicating whether to use pretty cut locations and labels.

region A logical flag, indicating whether regions between contour lines should be filled as in a level plot.

allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, la

These arguments are described in the help page for xyplot.

default.prepanel Fallback prepanel function. See xyplot.
Further arguments may be supplied. Some are processed by levelplot or contourplot, and those that are unrecognized are passed on to the panel function.

useRaster

A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to TRUE changes the default panel function from `panel.levelplot` to `panel.levelplot.raster`, and sets the default value of `colorkey$raster` to TRUE.

Note that `panel.levelplot.raster` provides only a subset of the features of `panel.levelplot`, but setting `useRaster=TRUE` will not check whether any of the additional features have been requested.

Not all devices support raster images. For devices that appear to lack support, `useRaster=TRUE` will be ignored with a warning.

Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

xlim, ylim, row.values, column.values)

Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula of the form \( z \sim x \times y \mid g_1 \times g_2 \times \ldots \),
where \( z \) is a numeric response, and \( x, y \) are numeric values. \( g_1, g_2, \ldots \), if present,
are conditioning variables used for conditioning, and must be either
factors or shingles. In the case of wireframe, calculations are based on
the assumption that the \( x \) and \( y \) values are evaluated on a rectangular grid defined
by their unique values. The grid points need not be equally spaced.

For wireframe, \( x, y \) and \( z \) may also be matrices (of the same dimension), in
which case they are taken to represent a 3-D surface parametrized on a 2-D grid
(e.g., a sphere). Conditioning is not possible with this feature. See details below.
Missing values are allowed, either as NA values in the z vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in z are.

Both wireframe and cloud have methods for matrix objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used in persp.

data for the “formula” methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. data should not be specified except when using the “formula” method.

row.values, column.values Optional vectors of values that define the grid when x is a matrix. row.values and column.values must have the same lengths as nrow(x) and ncol(x) respectively. By default, row and column numbers.

allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, These arguments are documented in the help page for xyplot. For the cloud.table method, groups must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.

type type of display in cloud (see panel.3dscatter for details). Defaults to “h” for the matrix method.

aspect, panel.aspect Unlike other high level functions, aspect is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the aspect argument in determining the aspect ratio of the panel (see xyplot for details) is played by panel.aspect, except that it can only be a numeric value.

For the matrix methods, the default y/x aspect is ncol(x) / nrow(x) and the z/x aspect is the smaller of the y/x aspect and 1.

panel panel function used to create the display. See panel.cloud for (non-trivial) details.

default.prepanel Fallback prepanel function. See xyplot.

scales a list describing the scales. As with other high level functions (see xyplot for details), this list can contain parameters in name=value form. It can also contain components with the special names x, y and z, which can be similar lists with axis-specific values overriding the ones specified in scales.

The most common use for this argument is to set arrows=FALSE, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by draw=FALSE. Another special component is distance, which specifies the relative distance of the axis label from the bounding box. If specified as a component of scales (as opposed to one of scales$z etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the x, y and z labels respectively.

Other components that work in the scales argument of xyplot etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)
Note, however, that for these functions scales cannot contain information that is specific to particular panels. If you really need that, consider using the scales.3d argument of panel.cloud.

**axs.default**
Unlike 2-D display functions, cloud does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in wireframe, which uses the same code. axs.default is intended to provide a different default for cloud. However, this feature has not yet been implemented.

**zlab**
Specifies a label describing the z variable in ways similar to xlab and ylab (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if zlab (and xlab and ylab) is a list, it can contain a component called rot, controlling the rotation for the label.

**zlim**
limits for the z-axis. Similar to xlim and ylim in other high level functions.

**drape**
logical, whether the wireframe is to be draped in color. If TRUE, the height of a facet is used to determine its color in a manner similar to the coloring scheme used in levelplot. Otherwise, the background color is used to color the facets. This argument is ignored if shade = TRUE (see panel.3dwire).

**at, col.regions, alpha.regions**
these arguments are analogous to those in levelplot. if drape=TRUE, at gives the vector of cutpoints where the colors change, and col.regions the vector of colors to be used in that case. alpha.regions determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for col.regions and alpha.regions is derived from the Trellis setting "regions".

**cuts**
if at is unspecified, the approximate number of cutpoints if drape=TRUE.

**pretty**
whether automatic choice of cutpoints should be prettified.

**colorkey**
logical indicating whether a color key should be drawn alongside, or a list describing such a key. See levelplot for details.

**...**
Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments distance, perspective, screen and R.mat are very important in determining the 3-D display. The argument shade can be useful for wireframe calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for panel.cloud.

Additionally, an argument called zoom may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default prepanel function.

**Details**

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the [-0.5, 0.5] cube (even smaller for non-default values of aspect). The viewing direction is given by a sequence of rotations specified by the screen argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of 1/distance from the origin. If perspective=FALSE, distance is set to 0 (i.e., the viewing point is at an infinite distance).

cloud draws a 3-D Scatter Plot, while wireframe draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by wireframe using the groups argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying groups with cloud results in a panel.superpose-like effect (via panel.3dscatter).
wireframe can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for `panel.3dwire`. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form \( f(u,v) = (x(u,v), y(u,v), z(u,v)) \), where values of \((u,v)\) lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula \( x \) of the form \( z \sim x \times y \), where \( x \), \( y \) and \( z \) are all matrices of the same dimension, representing the values of \( x(u,v) \), \( y(u,v) \) and \( z(u,v) \) evaluated on a discrete rectangular grid (the actual values of \((u,v)\) are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the \( z \) values, but the distances of \((x,y,z)\) from the origin.

Note that this feature does not work with groups, subscripts, subset, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Note**

There is a known problem with grouped `wireframe` displays when the \((x, y)\) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an `NA` response (\( z \)) in rows that were previously missing.

parallelplot(x, data = NULL, ..., groups = NULL, subset = TRUE)

### Arguments

- **x**: The object on which method dispatch is carried out.
  - For the "formula" method, a formula describing the structure of the plot, which should be of the form \( x \mid g_1 \times g_2 \times \ldots \), where \( x \) is a data frame or matrix. Each of \( g_1, g_2, \ldots \) must be either factors or shingles. The conditioning variables \( g_1, g_2, \ldots \) may be omitted.
  - For the data.frame methods, a data frame.

- **data**: For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated.

- **aspect**: aspect ratio of each panel (and subpanel), square by default for splom.

- **between**: to avoid confusion between panels and subpanels, the default is to show the panels of a splom plot with space between them.

- **panel**: For parallelplot, this has the usual interpretation, i.e., a function that creates the display within each panel.
  - For splom, the terminology is slightly complicated. The role played by the panel function in most other high-level functions is played here by the superpanel function, which is responsible for the display for each conditional data subset.
  - panel is simply an argument to the default superpanel function `panel.pairs`, and is passed on to it unchanged. It is used there to create each pairwise display.
  See `panel.pairs` for more useful options.

- **superpanel**: function that sets up the splom display, by default as a scatterplot matrix.

- **pscales**: a numeric value or a list, meant to be a less functional substitute for the scales argument in xyplot etc. This argument is passed to the superpanel function, and is handled by the default superpanel function `panel.pairs`. The help page for the latter documents this argument in more detail.

- **varnames**: A character or expression vector or giving names to be used for the variables in \( x \). By default, the column names of \( x \).

- **horizontal.axis**: logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).

- **auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset**: 
  See `xyplot` for more details.

- **default.prepanel**: fallback prepanel function. See `xyplot`.

- **...**: Further arguments. See corresponding entry in `xyplot` for non-trivial details.
Details

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both x- and y-limits from 0.5 to `ncol(z)` + 0.5. The only built-in option currently available is `panel.pairs`, which calls a further panel function for each pair (i, j) of variables in z inside a rectangle of unit width and height centered at c(i, j) (see `panel.pairs` for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and prepanel calculations. If you are trying to fine-tune your `splom` plot, definitely look at the `panel.pairs` help page. The scales argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

`parallelplot` draws Parallel Coordinate Plots. (Difficult to describe, see example.) These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class “trellis”. The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

`xyplot`, `Lattice`, `panel.pairs`, `panel.parallel`.

Examples

```R
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
    panel = panel.superpose,
    key = list(title = "Three Varieties of Iris",
               columns = 3,
               points = list(pch = super.sym$pch[1:3],
                              col = super.sym$col[1:3]),
               text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3]|Species, data = iris,
    layout=c(2,2), pscales = 0,
    varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
    page = function(...) {
      ltext(x = seq(.6, .8, length.out = 4),
            y = seq(.9, .6, length.out = 4),
            labels = c("Three", "Varieties", "of", "Iris"),
            cex = 2)
    })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
            horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```
Tukey Mean-Difference Plot

**Description**

tmd Creates Tukey Mean-Difference Plots from a trellis object returned by xyplot, qq or qqmath. The prepanel and panel functions are used as appropriate. The formula method for tmd is provided for convenience, and simply calls tmd on the object created by calling xyplot on that formula.

**Usage**

tmd(object, ...)

```r
## S3 method for class 'trellis'
tmd(object,
xlab = "mean",
ylab = "difference",
panel,
prepanel,
...)
```

```r
prepanel.tmd.qqmath(x,
f.value = NULL,
distribution = qnorm,
qtype = 7,
groups = NULL,
subscripts, ...)
```

```r
panel.tmd.qqmath(x,
f.value = NULL,
distribution = qnorm,
qtype = 7,
groups = NULL,
subscripts, ..., identifier = "tmd")
```

```r
panel.tmd.default(x, y, groups = NULL, ..., identifier = "tmd")
```

```r
prepanel.tmd.default(x, y, ...)
```

**Arguments**

- **object** An object of class "trellis" returned by xyplot, qq or qqmath.
- **xlab** x label
- **ylab** y label
- **panel** panel function to be used. See details below.
- **prepanel** prepanel function. See details below.
- **f.value, distribution, qtype** see panel.qqmath.
- **groups, subscripts** see xyplot.
Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by \( x=(x+y)/2 \) and \( y=y-x \), which are then plotted. The default panel function(s) add a reference line at \( y=0 \) as well.

tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. tmd uses these panel arguments to set up its own scales (using its prepanel argument) and display (using panel1). It is thus important to provide suitable prepanel and panel functions to tmd depending on the original call.

Such functions currently exist for xyplot, qq (the ones with default in their name) and qqmath, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the prepanel and panel arguments default to suitable choices.

tmd uses the update method for "trellis" objects, which processes all extra arguments supplied to tmd.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

**B_10_rfs**

*Residual and Fit Spread Plots*

**Description**

Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

**Usage**

```r
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
   distribution = qunif,
   panel, prepanel, strip, ...)
```
Arguments

- **model**: a fitted model object with methods `fitted.values` and `residuals`. Can be the value returned by `oneway`.
- **layout**: default layout is c(2,1).
- **xlab**: defaults to "f.value".
- **distribution**: the distribution function to be used for `qqmath`.
- **ylab, panel, prepanel, strip**: See `xyplot`.
- **...**: other arguments, passed on to `qqmath`.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

```

Fit One-way Model

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`.

Usage

```r
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

Arguments

- **formula**: formula of the form `y ~ x` where `y` is the numeric response and `x` is the grouping factor.
- **data**: data frame in which the model is to be evaluated.
- **location**: function or numeric giving the location statistic to be used for centering the observations, e.g. `median`, 0 (to avoid centering).
- **spread**: function or numeric giving the spread statistic to be used for scaling the observations, e.g. `sd`, 1 (to avoid scaling).
Value

A list with components

location vector of locations for each group.
spread vector of spreads for each group.
fitted.values vector of locations for each observation.
residuals residuals \( (y - \text{fitted.values}) \).
scaled.residuals residuals scaled by spread for their group.

---

Description

Initialization of a display device with appropriate graphical parameters.

Usage

trellis.device(device = getOption("device"),
               color = !(dev.name == "postscript"),
               theme = lattice.getOption("default.theme"),
               new = TRUE,
               retain = FALSE,
               ...
)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()

Arguments

device function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how \( \text{R} \) was compiled (see Devices), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.

color logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to \( \text{trellis.par.set} \) (and by arguments supplied directly in high level calls for some settings).
theme list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters.

A possible use of this argument is to change the default settings by specifying `lattice.options(default.theme = "col.whitebg")`.

For back-compatibility, this is initially (when lattice is loaded) set to `getOption(lattice.theme)`.

If theme is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use `.Device` inside the function to ascertain what device has been opened.

new logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.

retain logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).

name name of the device for which the setting is required, as returned by `.Device`

... additional parameters to be passed to the device function, most commonly file for non-screen devices, as well as height, width, etc. See the help file for individual devices for admissible arguments.

Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable "settings" list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly-supplants it (par settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a "trellis" object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default theme argument, e.g. by putting `lattice.options(default.theme = "standard.theme")` in a startup script (see the entry for theme above for details).

Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the theme argument to `trellis.par.set`, or even as theme in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`. 
col.whitebg returns a similar (but smaller) list that is suitable as the theme argument to trellis.device and trellis.par.set. It contains settings values which provide colors suitable for plotting on a white background. Note that the name col.whitebg is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

Note

Earlier versions of trellis.device had a bg argument to set the background color, but this is no longer supported. If supplied, the bg argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the theme argument instead.

trellis.par.get and trellis.par.set can be used to query and modify the settings after a device has been initialized. The par.settings argument to high level functions, described in xyplot, can be used to attach transient settings to a “trellis” object.

Description

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

Usage

trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)

Arguments

name A character string giving the name of a component. If unspecified in trellis.par.get(), the return value is a named list containing all the current settings (this can be used to get the valid values for name).
value a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in value will remain unchanged.
**theme**

A list describing how to change the settings, similar to what is returned by `trellis.par.get()`. This is purely for convenience, allowing multiple calls to `trellis.par.set` to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.

As in `trellis.device`, `theme` can also be a function that produces such a list when called. The function name can be supplied as a quoted string.

Multiple settings can be specified in `name = value` form. Equivalent to calling with `theme = list(...)`

**warn**

A logical flag, indicating whether a warning should be issued when `trellis.par.get` is called when no graphics device is open.

**strict**

Usually a logical flag, indicating whether the value should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from value but not currently NULL are retained. By specifying `strict = TRUE`, such values will be removed.

An even stricter interpretation is allowed by specifying `strict` as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use.

**x**

Optional list of components that change the settings (any valid value of `theme`). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

**Details**

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (color `postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a postscript device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to value.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```r
add.line <- trellis.par.get("add.line")
```
add.line$col <- "red"
trellis.par.set("add.line", add.line)
More convenient (but not S compatible) ways to do this are
trellis.par.set(list(add.line = list(col = "red")))
and
trellis.par.set(add.line = list(col = "red"))

The actual list of the components in trellis.settings has not been finalized, so I’m not attempting to list them here. The current value can be obtained by print(trellis.par.get()). Most names should be self-explanatory.

show.settings provides a graphical display summarizing some of the values in the current settings.

Value
trellis.par.get returns a list giving parameters for that component. If name is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

grid.pars Grid graphical parameters that are in effect globally unless overridden by specific settings.

fontsize A list of two components (each a numeric scalar), text and points, for text and symbols respectively.

clip A list of two components (each a character string, either "on" or "off"), panel and strip.

axis.components A list with four components (left, top, right, bottom), each a list giving numeric multipliers named tck, pad1, and pad2 for corresponding grid layout units.

layout.heights A list with numeric multipliers for grid layout heights.

layout.widths A list with numeric multipliers for grid layout widths.

Note
In some ways, trellis.par.get and trellis.par.set together are a replacement for the par function used in traditional R graphics. In particular, changing par settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system does have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the grid.pars component (see gpar for a list of valid parameter names).

```r
show.settings()

tp <- trellis.par.get()

unusual <- c("grid.pars", "fontsize", "clip", "axis.components",
             "layout.heights", "layout.widths")

for (u in unusual) tp[[u]] <- NULL

names.tp <- lapply(tp, names)

unames <- sort(unique(unlist(names.tp)))

ans <- matrix(0, nrow = length(names.tp), ncol = length(unames))

rownames(ans) <- names(names.tp)

colnames(ans) <- unames

for (i in seq(along = names.tp))
    ans[i,] <- as.numeric(unames %in% names.tp[[i]])

ans[ans == 0] <- NA

levelplot(t(ans), colorkey = FALSE,
          scales = list(x = list(rot = 90)),
          panel = function(x, y, z, ...) {
              panel.abline(v = unique(as.numeric(x)),
                           h = unique(as.numeric(y)),
                           col = "darkgrey")
              panel.xyplot(x, y, pch = 16 * z, ...)
         },
          xlab = "Graphical parameters",
          ylab = "Setting names")
```

---

**C_03_simpleTheme**  
*Function to generate a simple theme*

**Description**

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

**Usage**

```r
simpleTheme(col, alpha,
            cex, pch, lty, lwd, font, fill, border,
            col.points, col.line,
            alpha.points, alpha.line)
```

**Arguments**

col, col.points, col.line

A color specification. col is used for components "plot.symbol", "plot.line", "plot.polygon", "superpose.symbol", "superpose.line", and "superpose.polygon". col.points overrides col, but is used only for
"plot.symbol" and "superpose.symbol". Similarly, col.line overrides col for "plot.line" and "superpose.line". The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

alpha, alpha.points, alpha.line
A numeric alpha transparency specification. The same rules as col, etc., apply.

cex, pch, font
Parameters for points. Applicable for components plot.symbol (for which only the first component is used) and superpose.symbol (for which the arguments can be vectors).

lty, lwd
Parameters for lines. Applicable for components plot.line (for which only the first component is used) and superpose.line (for which the arguments can be vectors).

fill
fill color, applicable for components plot.symbol, plot.polygon, superpose.symbol, and superpose.polygon.

border
border color, applicable for components plot.polygon and superpose.polygon.

Details
The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see trellis.device for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the auto.key argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the par.settings argument, which is usually tedious to construct as it is a nested list. The simpleTheme function can be used in such situations as a wrapper that generates a suitable list given parameters in simple name-value form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

Value
A list that would work as the theme argument to trellis.device and trellis.par.set, or as the par.settings argument to any high level lattice function such as xyplot.

Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

     xlab = "Barley Yield (bushels/acre) ",
     aspect=0.5, layout = c(1,6))
Low-level Options Controlling Behaviour of Lattice

Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level may be useful in certain cases.

Usage

lattice.options(...)
lattice.getOption(name)

Arguments

name character giving the name of a setting
... new options can be defined, or existing ones modified, using one or more arguments of the form name = value or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

Details

These functions are modeled on options andgetOption, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

panel.error A function, or NULL. If the former, every call to the panel function will be wrapped inside tryCatch with the specified function as an error handler. The default is to use the panel.error function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to NULL, errors in panel functions will not be caught using tryCatch.

save.object Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to TRUE.

layout.widths, layout.heights Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the grid function unit (x, units, and optionally data). Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using trellis.par.set.

drop.unused.levels A list of two components named cond and data, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See xyplot for more details. Note that this does not control dropping of levels of the 'groups' argument.

legend.bbox A character string, either "full" or "panel". This determines the interpretation of x and y when space="inside" in key (determining the legend; see xyplot): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

default.args A list giving default values for various standard arguments: as.table, aspect, between, skip, strip, xscale.components, yscale.components, and axis.
highlight.gpar A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

banking The banking function. See `banking`.

axis.padding List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

skip.boundary.labels Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

interaction.sep The separator for creating interactions with the extended formula interface (see `xyplot`).

axis.units List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for `xyplot`. The options for the others have similarly patterned names.

Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

## S3 method for class 'trellis'
dim(x)
```

```r
## S3 method for class 'trellis'
dimnames(x)
```

```r
panel.error(e)
```

Arguments

- `x`, `object`:
  An object of class "trellis"

- `position`:
  A vector of 4 numbers, typically c(xmin, ymin, xmax, ymax) that give the lower-
  left and upper-right corners of a rectangle in which the Trellis plot of x is to be
  positioned. The coordinate system for this rectangle is [0-1] in both the x and y
  directions.

- `split`:
  A vector of 4 integers, c(x,y,nx,ny), that says to position the current plot at the
  x,y position in a regular array of nx by ny plots. (Note: this has origin at top
  left)

- `more`:
  A logical specifying whether more plots will follow on this page.

- `newpage`:
  A logical specifying whether the plot should be on a new page. This option is
  specific to lattice, and is useful for including lattice plots in an arbitrary grid
  viewport (see the details section).

- `packet.panel`:
  A function that determines which packet (data subset) is plotted in which panel.
  Panels are always drawn in an order such that columns vary the fastest, then
  rows and then pages. This function determines, given the column, row and page
  and other relevant information, the packet (if any) which should be used in
  that panel. By default, the association is determined by matching panel order
  with packet order, which is determined by varying the first conditioning variable
  the fastest, then the second, and so on. This association rule is encoded in
  the default, namely the function `packet.panel.default`, whose help page details
  the arguments supplied to whichever function is specified as the `packet.panel`
  argument.
draw.in  An optional (grid) viewport (used as the name argument in downViewport) in which the plot is to be drawn. If specified, the newpage argument is ignored. This feature is not well-tested.

panel.width, panel.height lists with 2 components, that should be valid x and units arguments to unit() (the data argument cannot be specified currently, but can be considered for addition if needed). The resulting unit object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.

Note that this option should not be used in conjunction with non-default values of the aspect argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).

save.object logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel’s data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the update method on the current plot, even if it was not assigned to a variable explicitly. For more details, see trellis.focus.

panel.error a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using tryCatch) and supplied as the only argument to panel.error. The default behaviour (implemented as the panel.error function) is to print the corresponding error message in the panel and continue. To stop execution on error, use panel.error = stop.

Normal error recovery and debugging tools are unhelpful when tryCatch is used. tryCatch can be completely bypassed by setting panel.error to NULL.

prefix A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently "::").

e an error condition caught by tryCatch

... extra arguments, ignored by the print method. All arguments to the plot method are passed on to the print method.

Details

This is the default print method for objects of class "trellis", produced by calls to functions like xyplot, bwplot etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments split and position.

When newpage = FALSE, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The draw.in argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in x (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.
Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see `trellis.focus`.

**Note**

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

**Examples**

```r
p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab = "Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

## Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport

## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
       layout = c(3, 2),
       panel = function(x, y, ...)
       {
         panel.xyplot(x, y, ...)
         fm <- lm(y ~ poly(x, panel.number()))
         llines(x, predict(fm))
       })

## Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:\n")
ltext(grid::grid.locator(), lab = "linear")

## End(Not run)

grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")
ggrid::seekViewport(trellis.vpname("panel", 2, 1))
```
grid::grid.text("quadratic")

grid::seekViewport(trellis.vpname("panel", 3, 1))
grid::grid.text("cubic")

grid::seekViewport(trellis.vpname("panel", 1, 2))
grid::grid.text("degree 4")

grid::seekViewport(trellis.vpname("panel", 2, 2))
grid::grid.text("degree 5")

grid::seekViewport(trellis.vpname("panel", 3, 2))
grid::grid.text("degree 6")

C_06_update.trellis  Retrieve and Update Trellis Object

Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

Usage

```r
## S3 method for class 'trellis'
update(object,
    panel,
    aspect,
    as.table,
    between,
    key,
    auto.key,
    legend,
    layout,
    main,
    page,
    par.strip.text,
    prepanel,
    scales,
    skip,
    strip,
    strip.left,
    sub,
    xlab,
    ylab,
    xlab.top,
    ylab.right,
    xlim,
    ylim,
    xscale.components,
    yscale.components,
    axis,
```
# S3 method for class 'trellis'
t(x)

## S3 method for class 'trellis'
x[i, j, ..., drop = FALSE]

## Arguments

- **object, x** The object to be updated, of class "trellis".
- **i, j** indices to be used. Names are not currently allowed.
- **drop** logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
- **panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip.text, prepanel** arguments that will be used to update object. See details below.
- **prefix** A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See `trellis.focus`.

## Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its print method. However, the object itself can be manipulated and modified to a large extent using the update method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the update method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the formula, data, groups, subscripts and subset). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by update, but the ones listed above should work. The purpose of these arguments are described in the help page for `xyplot`. Any other argument is added to the list of arguments to be passed to the panel function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The "[" method is a convenient shortcut for updating `index.cond`. The t method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate
2734

C_07_shingles

prefix argument. If trellis.last.object is called with arguments, these are used to update the
retrieved object before returning it.
Value
An object of class trellis, by default plotted by print.trellis. trellis.last.object returns
NULL is no saved object is available.

C_07_shingles

shingles

Description
Functions to handle shingles
Usage
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)
## S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)
## S3 method for class 'shingle'
print(x, showValues = TRUE, ...)
## S3 method for class 'shingleLevel'
as.character(x, ...)
## S3 method for class 'shingleLevel'
print(x, ...)


## S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)

### Arguments

- **x**: numeric variable or R object, shingle in `plot.shingle` and `x[]`. An object (list of intervals) of class 'shingleLevel' in `print.shingleLevel`
- **object**: shingle object to be summarized
- **showValues**: logical, whether to print the numeric part. If FALSE, only the intervals are printed
- **intervals**: numeric vector or matrix with 2 columns
- **subset**: logical vector
- **drop**: whether redundant shingle levels are to be dropped
- **panel, xlab, ylab**: standard Trellis arguments (see `xyplot`)
- **...**: other arguments, passed down as appropriate. For example, extra arguments to `equal.count` are passed on to `co.intervals`. Graphical parameters can be passed as arguments to the `plot` method.

### Details

A shingle is a data structure used in Trellis, and is a generalization of factors to 'continuous' variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the 'levels' of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

equal.count converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

shingle creates a shingle using the given `intervals`. If `intervals` is a vector, these are used to form 0 length intervals.

as.shingle returns `shingle(x)` if `x` is not a shingle.

is.shingle tests whether `x` is a shingle.

plot.shingle displays the ranges of shingles via rectangles. print.shingle and summary.shingle describe the shingle object.

### Value

- `x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.
D_draw.colorkey

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

Examples

z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))

D_draw.colorkey

Produce a colorkey typically for levelplot

Description

Creates (and optionally draws) a grid frame grob representing a color key that can be placed in other
grid-based plots. Primarily used by levelplot when a color key is requested.

Usage

draw.colorkey(key, draw = FALSE, vp = NULL)

Arguments

key A list determining the key. See documentation for levelplot, in particular the
section describing the colorkey argument, for details.
draw A scalar logical, indicating whether the grob is to be drawn.
vp The viewport in which to draw the grob, if applicable.

Value

A grid frame object (that inherits from "grob")

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

xyplot, levelplot
**D_draw.key**  
*Produce a Legend or Key*

**Description**

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

**Usage**

```r
draw.key(key, draw=FALSE, vp=NULL, ...)
```

**Arguments**

- `key`: A list determining the key. See documentation for `xyplot`, in particular the section describing the `key` argument, for details.
- `draw`: logical, whether the grob is to be drawn.
- `vp`: viewport
- `...`: ignored

**Value**

A Grid frame object (that inherits from ‘grob’).

`xyplot`

---

**D_level.colors**  
*A function to compute false colors representing a numeric or categorical variable*

**Description**

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

**Usage**

```r
level.colors(x, at, col.regions, colors = TRUE, ...)
```
Arguments

x
A numeric or factor variable.

at
A numeric variable of breakpoints defining intervals along the range of x.

col.regions
A specification of the colors to be assigned to each interval defined by at. This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below.

colors
logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by at) each value in x falls into is returned.

... Extra arguments, ignored.

Details

If at has length n, then it defines n-1 intervals. Values of x outside the range of at are not assigned to an interval, and the return value is NA for such values.

Colors are chosen by assigning a color to each of the n-1 intervals. If col.regions is a palette function (such as topo.colors, or the result of calling colorRampPalette), it is called with n-1 as an argument to obtain the colors. Otherwise, if there are exactly n-1 colors in col.regions, these get assigned to the intervals. If there are fewer than n-1 colors, col.regions gets recycled. If there are more, a more or less equally spaced (along the length of col.regions) subset is chosen.

Value

A vector of the same length as x. Depending on the colors argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of x fall in.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also

levelplot, colorRampPalette.

Examples

depth.col <-
  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
                col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
       strip = strip.custom(var.name = "Stations"),
       col = depth.col,
       panel = function(x, y, col, subscripts, ...) {
         panel.xyplot(x, y, pch = 21, col = "transparent",
                     fill = col[subscripts], ...)})
D_make.groups

Grouped data from multiple vectors

Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

Usage

make.groups(...)

Arguments

... one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

Value

When all the input arguments are vectors, a data frame with two columns

data all the vectors supplied, concatenated

which factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of rbind applied to them, along with an additional which column as described above.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

Lattice

Examples

```r
sim.dat <-
  make.groups(uniform = runif(200),
    exponential = rexp(175),
    lognormal = rlnorm(150),
    normal = rnorm(125))

types <- make.groups(sim.dat)
noteotypes <- levels(types)

qqmath(~data | which, sim.dat, scales = list(y = "free"))
```
Description

Simple interface to generate a list appropriate for `draw.key`

Usage

```r
simpleKey(text, points = TRUE,
          rectangles = FALSE,
          lines = FALSE,
          col, cex, alpha, font, fontface, fontfamily, lineheight, ...)
```

Arguments

- **text**: character or expression vector, to be used as labels for levels of the grouping variable
- **points**: logical
- **rectangles**: logical
- **lines**: logical
- **col, cex, alpha, font, fontface, fontfamily, lineheight**: Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in `trellis.par.get("add.text")`
- **...**: further arguments added to the list, eventually passed to `draw.key`

Details

A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable key argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

Value

A list that would work as the key argument to `xyplot`, etc.
D_strip.default

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, draw.key, trellis.par.get, and xyplot, specifically the entry for auto.key.

---

**D_strip.default**

**Default Trellis Strip Function**

Description

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

Usage

```r
strip.default(which.given, which.panel, var.name, factor.levels, shingle.intervals, strip.names = c(FALSE, TRUE), strip.levels = c(TRUE, FALSE), sep = " : ", style = 1, horizontal = TRUE, bg = trellis.par.get("strip.background")$col[which.given], fg = trellis.par.get("strip.shingle")$col[which.given], par.strip.text = trellis.par.get("add.text"))
```

strip.custom(...)

Arguments

- **which.given**: integer index specifying which of the conditioning variables this strip corresponds to.
- **which.panel**: vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of `which.packet`, which is a more accurate name.
- **var.name**: vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of `strip.names` and `style` (see below). By default, the names are shown for shingles, but not for factors.
factor.levels  vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with which.given. Whether these levels are shown on the strip depends on the values of strip.levels and style (see below). factor.levels may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in par.strip.text (see xyplot)

shingle.intervals
if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by printing levels(shingle)). Otherwise, it should be NULL

strip.names  a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when style is not one of 1 and 3.

strip.levels  a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.

sep  character or expression, serving as a separator if the name and level are both to be shown.

style  integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when shingle.intervals is non-null. The best way to find out what effect the value of style has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level. Note that unlike S-PLUS, the default value of style is 1. strip.names and strip.levels have no effect if style is not 1 or 3.

horizontal  logical, specifying whether the labels etc should be horizontal. horizontal=FALSE is useful for strips on the left of panels using strip.left=TRUE

par.strip.text  list with parameters controlling the text on each strip, with components col, cex, font, etc.

bg  strip background color.

fg  strip foreground color.

...  arguments to be passed on to strip.default, overriding whatever value it would have normally assumed

Details

default strip function for trellis functions. Useful mostly because of the style argument — non-default styles are often more informative, especially when the names of the levels of the factor x are
D_trellis.object

small. Traditional use is as strip = function(...) strip.default(style=2,...), though this can be simplified by the use of strip.custom.

Value

strip.default is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. strip.custom returns a function that is similar to strip.default, but with different defaults for the arguments specified in the call.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

xyplot, Lattice

Examples

## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = FALSE,
       strip.left = strip.custom(style = 4, horizontal = FALSE))

D_trellis.object A Trellis Plot Object

Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its print method.

Details

A trellis object, as returned by high level lattice functions like xyplot, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: as.table, layout, page, panel, prepanel, main, sub, par.strip.text, strip, skip, xlab ylab, par.settings, lattice.options and plot.args. Some other typical components are:

formula the Trellis formula used in the call
index.cond list with index for each of the conditioning variables
perm.cond permutation of the order of the conditioning variables
aspect.fill logical, whether aspect is "fill"
aspect.ratio numeric, aspect ratio to be used if aspect.fill is FALSE
call call that generated the object.

condlevels list with levels of the conditioning variables

legend list describing the legend(s) to be drawn

panel.args a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.

panel.args.common a list containing the arguments common to all the panel functions in name=value form

x.scales list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"

y.scales list describing y-scale, similar to x.scales

x.between numeric vector of interpanel x-space

y.between numeric vector of interpanel y-space

x.limits numeric vector of length 2 or list, giving x-axis limits

y.limits similar to x.limits

packet.sizes array recording the number of observations in each packet

Lattice, xyplot, print.trellis

E_interaction Functions to Interact with Lattice Plots

Description

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

Usage

panel.identify(x, y = NULL,
               subscripts = seq_along(x),
               labels = subscripts,
               n = length(x), offset = 0.5,
               threshold = 18, ## in points, roughly 0.25 inches
               panel.args = trellis.panelArgs(),
               ...)  
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
                       panel.args = trellis.panelArgs(),
                       ...)  
panel.identify.cloud(x, y, z, subscripts,
E_interaction

perspective, distance,
xlim, ylim, zlim,
screen, R.mat, aspect, scales.3d,
..., panel.3d.identify,
n = length(subscripts),
offset = 0.5,
threshold = 18,
labels = subscripts,
panel.args = trellis.panelArgs()
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
"figure", "panel", "strip", "strip.left",
"legend", "legend.region", "main", "sub",
"xlab", "ylab", "xlab.top", "ylab.right", "page"),
column, row,
side = c("left", "top", "right", "bottom", "inside"),
clip.off = FALSE, prefix)
trellis.grobname(name,
type = c("", "panel", "strip", "strip.left",
"key", "colorkey"),
group = 0,
which.given = lattice.getStatus("current.which.given",
prefix = prefix),
which.panel = lattice.getStatus("current.which.panel",
prefix = prefix),
column = lattice.getStatus("current.focus.column",
prefix = prefix),
row = lattice.getStatus("current.focus.row",
prefix = prefix),
prefix = lattice.getStatus("current.prefix"))
trellis.focus(name, column, row, side, clip.off,
highlight = interactive(), ..., prefix,
guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ..., prefix)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

Arguments

x, y, z variables defining the contents of the panel. In the case of trellis.panelArgs, a "trellis" object.
n the number of points to identify by default (overridden by a right click)
subscripts an optional vector of integer indices associated with each point. See details below.
labels an optional vector of labels associated with each point. Defaults to subscripts
distribution, groups typical panel arguments of panel.qqmath. These will usually be obtained from panel.args
offset the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The offset specifies (in "char" units) how far from the identified point the labels should be printed.

threshold threshold in grid’s "points" units. Points further than these from the mouse click position are not considered.

panel.args list that contains components names x (and usually y), to be used if x is missing. Typically, when called after trellis.focus, this would appropriately be the arguments passed to that panel.

perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d arguments as passed to panel.cloud. These are required to recompute the relevant three-dimensional projections in panel.identify.cloud.

panel.3d.identify the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to panel.identify is used.

name A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. trellis.vpname and trellis.focus deal with viewport names only, and only accept the values explicitly listed above. trellis.grobnname is meant to create names for grobs, and can currently accept any value.

If name, as well as column and row is missing in a call to trellis.focus, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.

When name is "panel", "strip", or "strip.left", column and row must also be specified. When name is "legend", side must also be specified.

column, row integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with as.table=TRUE.

guess logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to trellis.focus.

side character string, relevant only for legends (i.e., when name="legend"), indicating their position. Partial specification is allowed, as long as it is unambiguous.

clip.off logical, whether clipping should be off, relevant when name is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting clip.off=FALSE does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.

type A character string specifying whether the grob is specific to a particular panel or strip.

When type is "panel", "strip", or "strip.left", information about the panel is added to the grob name.

group An integer specifying whether the grob is specific to a particular group within the plot.

When group is greater than zero, information about the group is added to the grob name.
which.given, which.panel

Integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables. When which.panel has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.

prefix

A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the prefix argument in print.trellis.

Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last. For switchFocus, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.

highlight

Logical, whether the viewport being assigned focus should be highlighted. For trellis.focus, the default is TRUE in interactive mode, and trellis.switchFocus by default preserves the setting currently active.

packet.number

Integer, which panel to get data from. See packet.number for details on how this is calculated.

verbose

Whether details will be printed

... For panel.identify.qqmath, extra parameters are passed on to panel.identify. For panel.identify, extra arguments are treated as graphical parameters and are used for labelling. For trellis.focus and trellis.switchFocus, these are used (in combination with lattice.options) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for panel.link.splom.

Details

panel.identify is similar to identify. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to trellis.focus first is necessary.

panel.link.splom is meant for use with splom, and requires a panel to be chosen using trellis.focus before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. panel.brush.splom is a (misnamed) alias for panel.link.splom, retained for back-compatibility.

panel.identify.qqmath is a specialized wrapper meant for use with the display produced by qqmath. panel.identify.cloud is a specialized wrapper meant for use with the display produced by cloud. It would be unusual to call them except in a context where default panel function arguments are available through trellis.panelArgs (see below).

One way in which panel.identify etc. are different from identify is in how it uses the subscripts argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that subscripts is available is to specify subscripts = TRUE in the high level call such as xyplot. If subscripts is not explicitly specified in the call to panel.identify, but is available in panel.args, then those values will be used. Otherwise, they default to seq_along(x). In either case, the final return value will be the subscripts that were marked.
The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

trellis.focus can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, trellis.focus will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to trellis.focus, the desired viewport (typically panel or strip area) will be made the ‘current’ viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through trellis.currentLayout.

trellis.unfocus unsets the focus, and makes the toplevel viewport the current viewport.

trellis.switchFocus is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, trellis.panelArgs can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

trellis.panelArgs()

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). trellis.panelArgs can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the packet.number (as described under the panel entry in xyplot) and not the position in the layout, because a layout determines the panel only after the object has been printed.

It is usually not necessary to call trellis.vpname and trellis.grobname directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

Value

panel.identify returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of identify with pos=TRUE is not yet implemented, but can be considered for addition if requested.

trellis.panelArgs returns a named list of arguments that were available to the panel function for the chosen panel.

trellis.vpname and trellis.grobname return character strings.

trellis.focus has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components col and row giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is NULL. If click was outside a panel, both col and row are set to 0.
Note

The viewports created by lattice are accessible to the user through `trellis.focus` as described above. Functions from the grid package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` provides a portable way to access the appropriate viewports and grobs by name.

**F_1_panel.barchart**

**Default Panel Function for barchart**

**Description**

Default panel function for barchart.

**Usage**

```r
panel.barchart(x, y, box.ratio = 1, box.width,
horizontal = TRUE,
origin = NULL, reference = TRUE,
stack = FALSE,
groups = NULL,
col = if (is.null(groups)) plot.polygon$col
else superpose.polygon$col,
border = if (is.null(groups)) plot.polygon$border
else superpose.polygon$border,
lt = if (is.null(groups)) plot.polygon$lt
else superpose.polygon$lt,
```
lwd = if (is.null(groups)) plot.polygon$lwd
   else superpose.polygon$lwd,
   ..., identifier = "barchart")

Arguments

x Extent of Bars. By default, bars start at left of panel, unless origin is specified, in which case they start there.

y Horizontal location of bars. Possibly a factor.

box.ratio Ratio of bar width to inter-bar space.

box.width Thickness of bars in absolute units; overrides box.ratio. Useful for specifying thickness when the categorical variable is not a factor, as use of box.ratio alone cannot achieve a thickness greater than 1.

horizontal Logical flag. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.

origin The origin for the bars. For grouped displays with stack = TRUE, this argument is ignored and the origin set to 0. Otherwise, defaults to NULL, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, origin = 0 is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).

reference Logical, whether a reference line is to be drawn at the origin.

stack logical, relevant when groups is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.

groups Optional grouping variable.

col, border, lty, lwd Graphical parameters for the bars. By default, the trellis parameter plot.polygon is used if there is no grouping variable, otherwise superpose.polygon is used. col gives the fill color, border the border color, and lty and lwd the line type and width of the borders.

... Extra arguments will be accepted but ignored.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level barchart call directly.

barchart
**Examples**

```r
barchart(yield ~ variety | site, data = barley,
    groups = year, layout = c(1,6), origin = 0,
    ylab = "Barley Yield (bushels/acre),
    scales = list(x = list(abbreviate = TRUE,
                        minlength = 5)))
```

**F_1_panel.bwplot**  
**Default Panel Function for bwplot**

**Description**  
This is the default panel function for `bwplot`.

**Usage**

```r
panel.bwplot(x, y, box.ratio = 1,
    box.width = box.ratio / (1 + box.ratio),
    horizontal = TRUE,
    pch, col, alpha, cex,
    font, fontfamily, fontface,
    fill, varwidth = FALSE,
    notch = FALSE, notch.frac = 0.5,
    ...,
    levels.fos,
    stats = boxplot.stats,
    coef = 1.5,
    do.out = TRUE,
    identifier = "bwplot")
```

**Arguments**

- `x`, `y`  
  numeric vector or factor. Boxplots drawn for each unique value of `y` (`x`) if `horizontal` is `TRUE` (`FALSE`)

- `box.ratio`  
  ratio of box thickness to inter box space

- `box.width`  
  thickness of box in absolute units; overrides `box.ratio`. Useful for specifying thickness when the categorical variable is not a factor, as use of `box.ratio` alone cannot achieve a thickness greater than 1.

- `horizontal`  
  logical. If `FALSE`, the plot is 'transposed' in the sense that the behaviours of `x` and `y` are switched. `x` is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.

- `pch`, `col`, `alpha`, `cex`, `font`, `fontfamily`, `fontface`  
  graphical parameters controlling the dot. `pch="|"` is treated specially, by replacing the dot with a line (similar to `boxplot`)

- `fill`  
  color to fill the boxplot

- `varwidth`  
  logical. If `TRUE`, widths of boxplots are proportional to the number of points used in creating it.
notch
if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See boxplot.stats for the calculations used.

notch.frac
numeric in (0,1). When notch=TRUE, the fraction of the box width that the notches should use.

stats
a function, defaulting to boxplot.stats, that accepts a numeric vector and returns a list similar to the return value of boxplot.stats. The function must accept arguments coef and do.out even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot.

coeff, do.out
passed to stats

levels.fos
numeric values corresponding to positions of the factor or shingle variable. For internal use.

... further arguments, ignored.

identifier
A character string that is prepended to the names of grobs that are created by this panel function.

Details
Creates Box and Whisker plot of x for every level of y (or the other way round if horizontal=FALSE). By default, the actual boxplot statistics are calculated using boxplot.stats. Note that most arguments controlling the display can be supplied to the high-level bwplot call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters (“box.rectangle” for the box, “box.umbrella” for the whiskers and “plot.symbol” for the outliers).

Default Panel Function for cloud

Description

These are default panel functions controlling cloud and wireframe displays.

Usage

```r
panel.cloud(x, y, subscripts, z, groups = NULL,
            perspective = TRUE,
            distance = if (perspective) 0.2 else 0,
            xlim, ylim, zlim,
            panel.3d.cloud = "panel.3dscatter",
            panel.3d.wireframe = "panel.3dwire",
            screen = list(z = 40, x = -60),
            R.mat = diag(4), aspect = c(1, 1),
            par.box = NULL,
            xlab, ylab, zlab,
            xlab.default, ylab.default, zlab.default,
            scales.3d,
            proportion = 0.6,
            wireframe = FALSE,
            scpos,
            ...,
            at,
            identifier = "cloud")

panel.wireframe(...)

panel.3dscatter(x, y, z, rot.mat, distance,
                 groups, type = "p",
                 xlim, ylim, zlim,
                 xlim.scaled, ylim.scaled, zlim.scaled,
                 zero.scaled,
                 col, col.point, col.line,
                 lty, lwd, cex, pch, fill,
                 cross, ..., .scale = FALSE, subscripts,
                 identifier = "3dscatter")

panel.3dwire(x, y, z, rot.mat = diag(4), distance,
              shade = FALSE,
              shade.colors.palette = trellis.par.get("shade.colors")$palette,
              light.source = c(0, 0, 1000),
              xlim, ylim, zlim,
              xlim.scaled, ylim.scaled, zlim.scaled,
              col = if (shade) "transparent" else "black",
              lty = 1, lwd = 1,
              alpha,
              col.groups = superpose.polygon$col,
              polynum = 100,
```
...,
.scale = FALSE,
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha,
identifier = "3dwire")

Arguments

x, y, z numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For panel.cloud these are essentially the same as the data passed to the high level plot (except if formula was a matrix, the appropriate x and y vectors are generated). By the time they are passed to panel.3dscatter and panel.3dwire, they have been appropriately subsetted (using subscripts) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).

Further, for panel.3dwire, x and y are shorter than z and represent the sorted locations defining a rectangular grid. Also in this case, z may be a matrix if the display is grouped, with each column representing one surface.

In panel.cloud (called from wireframe) and panel.3dwire, x, y and z could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

subscripts index specifying which points to draw. The same x, y and z values (representing the whole data) are passed to panel.cloud for each panel. subscripts specifies the subset of rows to be used for the particular panel.

groups specification of a grouping variable, passed down from the high level functions.

perspective logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting distance to 0

distance numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / distance. This is described in a little more detail in the documentation for cloud

screen A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.

R.mat initial rotation matrix in homogeneous coordinates, to be applied to the data before screen rotates the view further.

par.box graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter box.3d.

xlim, ylim, zlim limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.

panel.3d.cloud, panel.3d.wireframe functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in cloud and wireframe. This function is called after the ‘back’ of the bounding box is drawn, but before the ‘front’ is drawn.
Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called xlim, ylim, zlim which give the bounding box ranges in the original data scale and xlim.scaled, ylim.scaled, zlim.scaled which give the bounding box ranges in the transformed scale. More arguments can be considered on request.

**aspect**

aspect as in cloud

**xlab, ylab, zlab**

Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to cloud directly.

**xlab.default**

for internal use

**ylab.default**

for internal use

**zlab.default**

for internal use

**scales.3d**

list defining the scales

**proportion**

numeric scalar, gives the length of arrows as a proportion of the sides

**scpos**

A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of panel.cloud to see the details of this enumeration.)

**wireframe**

logical, indicating whether this is a wireframe plot

**drape**

logical, whether the facets will be colored by height, in a manner similar to levelplot. This is ignored if shade=TRUE.

**at, col.regions, alpha.regions**

deals with specification of colors when drape = TRUE in wireframe. at can be a numeric vector, col.regions a vector of colors, and alpha.regions a numeric scalar controlling transparency. The resulting behaviour is similar to levelplot, at giving the breakpoints along the z-axis where colors change, and the other two determining the colors of the facets that fall in between.

**rot.mat**

4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and R.mat arguments to panel.cloud

**type**

Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean ‘points’ and ‘lines’ respectively, and "b" means ‘both’. "h" stands for ‘histogram’, and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing z = 0), or the lower (or upper) bounding box face, whichever is closer.

**xlim.scaled, ylim.scaled, zlim.scaled**

axis limits (after being scaled to the bounding box)

**zero.scaled**

z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when type = "h"

**cross**

logical, defaults to TRUE if pch = "+". panel.3dscatter can represent each point by a 3d ‘cross’ of sorts (it’s much easier to understand looking at an example than from a description). This is different from the usual pch argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.

This is useful for two reasons. It can be set to FALSE to use “+” as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.
shade logical, indicating whether the surface is to be colored using an illumination model with a single light source

shade.colors.palette a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits. All three numbers should be between 0 and 1. The shade.colors.palette function should return a valid color. The default function is obtained from the trellis settings.

light.source a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube

denumber quadrilateral faces are drawn in batches of denumber at a time. Drawing too few at a time increases the total number of calls to the underlying grid.polygon function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.

col.groups colors for different groups
col, col.point, col.line, lty, lwd, cex, pch, fill, alpha Graphical parameters. Some other arguments (such as lex for line width) may also be passed through the ... argument.

... other parameters, passed down when appropriate

.scale Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting .scale=TRUE may be helpful for calls to panel.3dscatter and panel.3dwire in user-supplied panel functions.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details These functions together are responsible for the content drawn inside each panel in cloud and wireframe. panel.wireframe is a wrapper to panel.cloud, which does the actual work.

panel.cloud is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether wireframe is TRUE, it calls either panel.3d.wireframe or panel.3d.cloud, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For cloud, the data is unstructured, and x, y and z are all passed to the panel.3d.cloud function. For wireframe, on the other hand, x and y are increasing vectors with unique values, defining a rectangular grid. z must be a matrix with length(x) * length(y) rows, and as many columns as the number of groups.

panel.3dscatter is the default panel.3d.cloud function. It has a type argument similar to panel.xyplot, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)
panel.3d.wire is the default panel.3d.wireframe function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about polygon facets, and draws them all at once. This avoids the overhead of drawing grid.polygon repeatedly, speeding up the rendering considerably. If shade = TRUE, these attempt to color the surface as being illuminated from a light source at light.source. palette.shade is a simple function that provides the default shading colors.

Multiple surfaces are drawn if groups is non-null in the call to wireframe, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

F_1_panel.densityplot  Default Panel Function for densityplot

Description
This is the default panel function for densityplot.

Usage
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE, groups = NULL, weights = NULL, jitter.amount, type, ..., identifier = "density")

Arguments
x data points for which density is to be estimated
darg list of arguments to be passed to the density function. Typically, this should be a list with zero or more of the following components: bw, adjust, kernel, window, width, give.Rkern, n, from, to, cut, na.rm (see density for details)
plot.points logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case panel.rug is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points.
ref logical, whether to draw x-axis
groups an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup
weights numeric vector of weights for the density calculations. If this is specified, the ... part must also include a subscripts argument that matches the weights to x.
jitter.amount when plot.points="jitter", the value to use as the amount argument to jitter.
F_1_panel.dotplot

Description

Default panel function for dotplot.

Usage

panel.dotplot(x, y, horizontal = TRUE,
              pch, col, lty, lwd,
              col.line, levels.fos,
              groups = NULL,
              ..., identifier = "dotplot")

Arguments

x, y
  variables to be plotted in the panel. Typically y is the ‘factor’
horizontal
  logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
pch, col, lty, lwd, col.line
  graphical parameters
levels.fos
  locations where reference lines will be drawn
groups
  grouping variable (affects graphical parameters)
...
  extra parameters, passed to panel.xyplot which is responsible for drawing the foreground points (panel.dotplot only draws the background reference lines).
identifier
  A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates (possibly grouped) Dotplot of x against y or vice versa

F_1_panel.histogram

Default Panel Function for histogram

Description

This is the default panel function for histogram.

Usage

```r
panel.histogram(x, 
    breaks, 
    equal.widths = TRUE, 
    type = "density", 
    nint = round(log2(length(x)) + 1), 
    alpha, col, border, lty, lwd, 
    ..., 
    identifier = "histogram")
```

Arguments

- `x` The data points for which the histogram is to be drawn
- `breaks` The breakpoints for the histogram
- `equal.widths` logical used when breaks==NULL
- `type` Type of histogram, possible values being "percent", "density" and "count"
- `nint` Number of bins for the histogram
- `alpha, col, border, lty, lwd` graphical parameters for bars; defaults are obtained from the plot.polygon settings.
- `...` other arguments, passed to `hist` when deemed appropriate
- `identifier` A character string that is prepended to the names of grobs that are created by this panel function.

`histogram`
F_1_panel.levelplot  

Panel Functions for levelplot and contourplot

Description

These are the default panel functions for levelplot and contourplot. Also documented is an alternative raster-based panel function for use with levelplot.

Usage

panel.levelplot(x, y, z, 
    subscripts, 
    at = pretty(z), 
    shrink, 
    labels, 
    label.style = c("mixed", "flat", "align"), 
    contour = FALSE, 
    region = TRUE, 
    col = add.line$col, 
    lty = add.line$lty, 
    lwd = add.line$lwd, 
    border = "transparent", 
    border.lty = 1, 
    border.lwd = 0.1, 
    ...,
    col.regions = regions$col, 
    alpha.regions = regions$alpha, 
    identifier = "levelplot")

panel.contourplot(...)

panel.levelplot.raster(x, y, z, 
    subscripts, 
    at = pretty(z), 
    ...,
    col.regions = regions$col, 
    alpha.regions = regions$alpha, 
    interpolate = FALSE, 
    identifier = "levelplot")

Arguments

x, y, z  Variables defining the plot.
subscripts  Integer vector indicating what subset of x, y and z to draw.
at  Numeric vector giving breakpoints along the range of z. See levelplot for details.
shrink  Either a numeric vector of length 2 (meant to work as both x and y components), or a list with components x and y which are numeric vectors of length 2. This
allows the rectangles to be scaled proportional to the z-value. The specification can be made separately for widths (x) and heights (y). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of z).

labels

Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the at values. Alternatively, labels can be a list with the following components:

labels: a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.

col, cex, alpha: graphical parameters for label texts

fontfamily, fontface, font: font used for the labels

label.style

Controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.

contour

A logical flag, specifying whether contour lines should be drawn.

region

A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.

col, lty, lwd

Graphical parameters for contour lines.

border

Border color for rectangles used when region=TRUE.

border.lty, border.lwd

Graphical parameters for the border

... Extra parameters.

col.regions

A vector of colors, or a function to produce a vector of colors, to be used if region=TRUE. Each interval defined by at is assigned a color, so the number of colors actually used is one less than the length of at. See level.colors for details on how the color assignment is done.

alpha.regions numeric scalar controlling transparency of facets

interpolate logical, passed to grid.raster.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

The same panel function is used for both levelplot and contourplot (which differ only in default values of some arguments). panel.contourplot is a simple wrapper to panel.levelplot.

When contour=TRUE, the contourLines function is used to calculate the contour lines. panel.levelplot.raster is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through grid.raster). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using panel.levelplot.raster, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see levelplot for details.

levelplot(volcano, panel = panel.levelplot.raster,
    col.regions = topo.colors, cuts = 30, interpolate = TRUE)

F_1_panel.pairs

Default Superpanel Function for splom

Description

This is the default superpanel function for splom.

Usage

panel.pairs(z,
    panel = lattice.getOption("panel.splom"),
    lower.panel = panel,
    upper.panel = panel,
    diag.panel = "diag.panel.splom",
    as.matrix = FALSE,
    groups = NULL,
    panel.subscripts,
    subscripts,
    pscales = 5,
    prepanel.limits = scale.limits,
    varnames = colnames(z),
    varname.col, varname.cex, varname.font,
    varname.fontfamily, varname.fontface,
    axis.text.col, axis.text.cex, axis.text.font,
    axis.text.fontfamily, axis.text.fontface,
    axis.text.lineheight,
    axis.line.col, axis.line.lty, axis.line.lwd,
    axis.line.alpha, axis.line.tck,
    ...
)

diag.panel.splom(x = NULL,
    varname = NULL, limits, at = NULL, labels = NULL,
    draw = TRUE, tick.number = 5,
    varname.col, varname.cex,
Arguments

z
The data frame used for the plot.

panel, lower.panel, upper.panel
The panel function used to display each pair of variables. If specified, lower.panel and upper.panel are used for panels below and above the diagonal respectively.

In addition to extra arguments not recognized by panel.pairs, the list of arguments passed to the panel function also includes arguments named i and j, with values indicating the row and column of the scatterplot matrix being plotted.

diag.panel
The panel function used for the diagonals. See arguments to diag.panel.splom to know what arguments this function is passed when called. Use diag.panel=NULL to suppress plotting on the diagonal panels.

as.matrix
logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to pairs). This is in essence the same functionality as provided by as.table for the panel layout

groups
Grouping variable, if any

panel.subscripts
logical specifying whether the panel function accepts an argument named subscripts.

subscripts
The indices of the rows of z that are to be displayed in this (super)panel.

pscales
Controls axis labels, passed down from splom. If pscales is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If pscales is a list, it should have one component for each column in z, each of which itself a list with the following valid components:
- at: a numeric vector specifying tick locations
- labels: character vector labels to go with at
- limits: numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)

These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use pscales=0 to suppress the axes entirely.

prepanel.limits
A function to calculate suitable axis limits given a single argument x containing a data vector. The return value of the function should be similar to the xlim or ylim argument documented in xyplot: that is, it should be a numeric or DateTime vector of length 2 defining a range, or a character vector representing levels of a factor.
Most high-level lattice plots (such as xyplot) use the prepanel function for deciding on axis limits from data. This function serves a similar function by calculating the per-variable limits. These limits can be overridden by the corresponding limits component in the pscales list.

`x`  
data vector corresponding to that row / column (which will be the same for diagonal `panels`).

`varname`  
(scalar) character string or expression that is to be written centred within the panel

`limits`  
numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)

`at`  
locations of tick marks

`labels`  
optional labels for tick marks

`draw`  
A logical flag specifying whether to draw the tick marks and labels. If `FALSE`, variable names are shown but axis annotation is omitted.

`tick.number`  
A Numeric scalar giving the suggested number of tick marks.

`varnames`  
A character or expression vector or giving names to be used for the variables in `x`. By default, the column names of `x`.

`varname.col`  
Color for the variable name in each diagonal panel. See `gpar` for details on this and the other graphical parameters listed below.

`varname.cex`  
Size multiplier for the variable name in each diagonal panel.

`varname.lineheight`  
Line height for the variable name in each diagonal panel.

`varname.font`, `varname.fontfamily`, `varname.fontface`  
Font specification for the variable name in each diagonal panel.

`axis.text.col`  
Color for axis label text.

`axis.text.cex`  
Size multiplier for axis label text.

`axis.text.font`, `axis.text.fontfamily`, `axis.text.fontface`  
Font specification for axis label text.

`axis.text.lineheight`  
Line height for axis label text.

`axis.text.alpha`  
Alpha-transparency for axis label text.

`axis.line.col`  
Color for the axes.

`axis.line.lty`  
Line type for the axes.

`axis.line.lwd`  
Line width for the axes.

`axis.line.alpha`  
Alpha-transparency for the axes.

`axis.line.tck`  
A numeric multiplier for the length of tick marks in diagonal panels.

...  
Further arguments, passed on to panel, lower.panel, upper.panel, and diag.panel from panel.pairs. Currently ignored by diag.panel.splom.

Details

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`.

splom

Examples

Cmat <- outer(1:6,1:6,
  function(i,j) rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE,
  panel = function(x, y, i, j, ...) {
    panel.fill(Cmat[i,j])
    panel.text(.5,.5, paste("(",i,"",j,")",sep=""))
  })

---

Default Panel Function for parallel

Description

This is the default panel function for parallel.

Usage

panel.parallel(x, y, z, subscripts,
  groups = NULL,
  col, lwd, lty, alpha,
  common.scale = FALSE,
  lower,
  upper,
  ..., horizontal.axis = TRUE,
  identifier = "parallel")

Arguments

x, y            dummy variables, ignored.
z             The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.
subscripts     The indices of the rows of z that are to be displayed in this panel.
groups         An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of z in the same group share parameters).
col, lwd, lty, alpha

graphical parameters (defaults to the settings for superpose.line). If groups is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame z.
common.scale  logical, whether a common scale should be used columns of z. Defaults to FALSE, in which case the horizontal range for each column is different (as determined by lower and upper).
lower, upper  numeric vectors replicated to be as long as the number of columns in z. Determines the lower and upper bounds to be used for scaling the corresponding columns of z after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.
...  other arguments (ignored)
horizontal.axis  logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for parallel

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

References

See Also

parallel

Description

This is the default panel function for qqmath.

Usage

panel.qqmath(x, f.value = NULL,
distribution = qnorm,
qtype = 7,
groups = NULL, ...,
tails.n = 0,
identifier = "qqmath")
Arguments

- **x**: vector (typically numeric, coerced if not) of data values to be used in the panel.
- **f.value**, **distribution**: Defines how quantiles are calculated. See `qqmath` for details.
- **qtype**: The type argument to be used in `quantile`
- **groups**: An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.
- **tails.n**: number of data points to represent exactly on each tail of the distribution. This reproduces the effect of `f.value = NULL` for the extreme data values, while approximating the remaining data. It has no effect if `f.value = NULL`. If `tails.n` is given, `qtype` is forced to be 1.
- **identifier**: A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

- `qqmath`

Examples

```r
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "+", distribution = qnorm,
      grid = TRUE, abline = c(0, 1),
      xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
      panel = function(..., f.value) {
        switch(panel.number(),
          panel.qqmath(..., f.value = NULL),
          panel.qqmath(..., f.value = ppoints(100)),
          panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
      }, layout = c(3, 1))[c(1,1,1)]
```
Default Panel Function for stripplot

Description

This is the default panel function for stripplot. Also see panel.superpose

Usage

```r
panel.stripplot(x, y, jitter.data = FALSE,
    factor = 0.5, amount = NULL,
    horizontal = TRUE, groups = NULL,
    ..., 
    identifier = "stripplot")
```

Arguments

- `x, y` coordinates of points to be plotted
- `jitter.data` whether points should be jittered to avoid overplotting. The actual jittering is performed inside `panel.xyplot`, using its `jitter.x` or `jitter.y` argument (depending on the value of `horizontal`).
- `factor, amount` amount of jittering, see `jitter`
- `horizontal` logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of `x` and `y` are switched. `x` is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- `groups` optional grouping variable
- `...` additional arguments, passed on to `panel.xyplot`
- `identifier` A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates stripplot (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`)

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

- `stripplot`, `jitter`
Default Panel Function for xyplot

Description

This is the default panel function for xyplot. Also see panel.superpose. The default panel functions for splom and qq are essentially the same function.

Usage

```r
panel.xyplot(x, y, type = "p", 
groups = NULL, 
pch, col, col.line, col.symbol, 
font, fontfamily, fontface, 
1ty, cex, fill, lwd, 
horizontal = FALSE, ..., 
grid = FALSE, abline = NULL, 
jitter.x = FALSE, jitter.y = FALSE, 
factor = 0.5, amount = NULL, 
identifier = "xyplot")

panel.splom(..., identifier = "splom")

panel.qq(..., identifier = "qq")
```

Arguments

- `x, y`: variables to be plotted in the scatterplot
- `type`: character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth", and "spline". If type has more than one element, an attempt is made to combine the effect of each of the components.

The behaviour if any of the first six are included in type is similar to the effect of type in plot (type "b" is actually the same as "o").  "r" adds a linear regression line (same as panel.lmline, except for default graphical parameters). "smooth" adds a loess fit (same as panel.loess). "spline" adds a cubic smoothing spline fit (same as panel.spline). "g" adds a reference grid using panel.grid in the background (but using the grid argument is now the preferred way to do so).  "a" has the effect of calling panel.average, which can be useful for creating interaction plots.  The effect of several of these specifications depend on the value of horizontal.

Type "s" (and "S") sorts the values along one of the axes (depending on horizontal); this is unlike the behavior in plot.  For the latter behavior, use type = "s" with panel = panel.points.

See example(xyplot) and demo(lattice) for examples.

- `groups`: an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup

- `col, col.line, col.symbol`: default colours are obtained from plot.symbol and plot.line using trellis.par.get.

- `font, fontface, fontfamily`: font used when pch is a character
pch, lty, cex, lwd, fill
other graphical parameters. fill serves the purpose of bg in points for certain values of pch

horizontal A logical flag controlling the orientation for certain type's, e.g., "h", "s", ans "S".

... Extra arguments, if any, for panel.xyplot. In most cases panel.xyplot ignores these. For types "r" and "smooth", these are passed on to panel.lmline and panel.loess respectively.

grid A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as type="g", but is the preferred alternative as the effect type="g" is conceptually different from that of other type values (which are all data-dependent). Using the grid argument also allows more flexibility.
Most generally, grid can be a list of arguments to be supplied to panel.grid, which is called with those arguments. Three shortcuts are available:
TRUE: roughly equivalent to list(h = -1, v = -1)
"h": roughly equivalent to list(h = -1, v = 0)
"v": roughly equivalent to list(h = 0, v = -1)
No grid is drawn if grid = FALSE.

abline A numeric vector or list, specifying arguments arguments for panel.abline, which is called with those arguments. If specified as a (possibly named) numeric vector, abline is coerced to a list. This allows arguments of the form abline = c(0, 1), which adds the diagonal line, or abline = c(h = 0, v = 0), which adds the x- and y-axes to the plot. Use the list form for finer control; e.g., abline = list(h = 0, v = 0, col = "grey").
For more flexibility, use panel.abline directly.

jitter.x, jitter.y logical, whether the data should be jittered before being plotted.

factor, amount controls amount of jittering.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details
Creates scatterplot of x and y, with various modifications possible via the type argument. panel.qq draws a 45 degree line before calling panel.xyplot.
Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. xyplot) call.

})[rep(1, length(types))]

---

Replacements of traditional graphics functions

Description

These functions are intended to replace common low level traditional graphics functions, primarily
for use in panel functions. The originals can not be used (at least not easily) because lattice panel
functions need to use grid graphics. Low level drawing functions in grid can be used directly as
well, and is often more flexible. These functions are provided for convenience and portability.

Usage

lplot.xy(xy, type, pch, lty, col, cex, lwd,
       font, fontfamily, fontface,
       col.line, col.symbol, alpha, fill,
       origin = 0, ..., identifier, name.type)

llines(x, ...)
lpoints(x, ...)
## Default S3 method:
```r
llines(x, y = NULL, type = "l",
       col, alpha, lty, lwd, ..., identifier, name.type)
```

## Default S3 method:
```r
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
         font, fontfamily, fontface, cex, ..., identifier, name.type)
```

## Default S3 method:
```r
ltext(x, y = NULL, labels = seq_along(x),
      col, alpha, cex, srt = 0,
      lineheight, font, fontfamily, fontface,
      adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)
```

## Default S3 method:
```r
lsegments(x0, y0, x1, y1, x2, y2,
          col, alpha, lty, lwd,
          font, fontface, ..., identifier, name.type)
```

## Default S3 method:
```r
lrect(xleft, ybottom, xright, ytop,
      x = (xleft + xright) / 2,
      y = (ybottom + ytop) / 2,
      width = xright - xleft,
      height = ytop - ybottom,
      col = "transparent",
      border = "black",
      lty = 1, lwd = 1, alpha = 1,
      just = "center",
      hjust = NULL, vjust = NULL,
      font, fontface,
      ..., identifier, name.type)
```

## Default S3 method:
```r
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
        angle = 30, code = 2, length = 0.25, unit = "inches",
        ends = switch(code, "first", "last", "both"),
        type = "open",
        col = add.line$col,
        alpha = add.line$alpha,
        lty = add.line$lty,
        lwd = add.line$lwd,
        fill = NULL,
        font, fontface,
        ..., identifier, name.type)
```

## Default S3 method:
```r
lpolygon(x, y = NULL,
         border = "black", col = "transparent", fill = NULL,
         font, fontface, ..., identifier, name.type)
```

panel.lines(...)  
panel.points(...)  
panel.segments(...)  
panel.text(...)  
panel.rect(...)  
panel.arrows(...)  
panel.polygon(...)
Arguments

\begin{itemize}
\item \texttt{x, y, x0, y0, x1, y1, x2, y2, xy} locations. \texttt{x2} and \texttt{y2} are available for \texttt{S} compatibility.
\item \texttt{length, unit} determines extent of arrow head. \texttt{length} specifies the length in terms of \texttt{unit}, which can be any valid grid unit as long as it doesn't need a data argument. \texttt{unit} defaults to inches, which is the only option in the base version of the function, \texttt{arrows}.
\item \texttt{angle, code, type, labels, srt, adj, pos, offset} arguments controlling behaviour. See respective base functions for details. For \texttt{larsrows and panel.larrows}, \texttt{type} is either "open" or "closed", indicating the type of arrowhead.
\item \texttt{ends} serves the same function as \texttt{code}, using descriptive names rather than integer codes. If specified, this overrides code.
\item \texttt{col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, col.symbol, border} graphical parameters. \texttt{fill} applies to points when \texttt{pch} is in \texttt{21:25} and specifies the fill color, similar to the \texttt{bg} argument in the base graphics function \texttt{points}. For devices that support alpha-transparency, a numeric argument \texttt{alpha} between 0 and 1 can control transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0. \texttt{fill, font and fontface} are included in \texttt{lrect, larsrows, lpolygon, and lsegments} only to ensure that they are not passed down (as \texttt{gpar} does not like them).
\item \texttt{origin} for \texttt{type="h" or type="H"}, the value to which lines drop down.
\item \texttt{xleft, ybottom, xright, ytop} see \texttt{rect}
\item \texttt{...} extra arguments, passed on to lower level functions as appropriate.
\item \texttt{identifier} A character string that is prepended to the name of the grob that is created.
\item \texttt{name.type} A character value indicating whether the name of the grob should have panel or strip information added to it. Typically either "panel", "strip", "strip.left", or "" (for no extra information).
\end{itemize}

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions \texttt{panel.*} are essentially identical to the \texttt{l*} versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

Note

There is a new \texttt{type="H"} option wherever appropriate, which is similar to \texttt{type="h"}, but with horizontal lines.

Description

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

Usage

panel.abline(a = NULL, b = 0,
    h = NULL, v = NULL,
    reg = NULL, coef = NULL,
    col, col.line, lty, lwd, alpha, type,
    ..., 
    reference = FALSE,
    identifier = "abline")

panel.refline(...)

panel.curve(expr, from, to, n = 101,
    curve.type = "l",
    col, lty, lwd, type,
    ..., 
    identifier = "curve")

panel.rug(x = NULL, y = NULL,
    regular = TRUE,
    start = if (regular) 0 else 0.97,
    end = if (regular) 0.03 else 1,
    x.units = rep("npc", 2),
    y.units = rep("npc", 2),
    col, col.line, lty, lwd, alpha,
    ..., 
    identifier = "rug")

panel.average(x, y, fun = mean, horizontal = TRUE,
    lwd, lty, col, col.line, type,
    ..., 
    identifier = "linejoin")

panel.linejoin(x, y, fun = mean, horizontal = TRUE,
    lwd, lty, col, col.line, type,
    ..., 
    identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
Arguments

\( x, y \) Variables defining the contents of the panel. In `panel.grid` these are optional and are used only to choose an appropriate method of \texttt{pretty}.

\( a, b \) Coefficients of the line to be added by `panel.abline`. \( a \) can be a vector of length 2, representing the coefficients of the line to be added, in which case \( b \) should be missing. \( a \) can also be an appropriate `regression` object, i.e., an object which has a \texttt{coef} method that returns a length 2 numeric vector. The corresponding line will be plotted. The \texttt{reg} argument overrides \( a \) if specified.

\texttt{coef} Coefficients of the line to be added as a vector of length 2.

\texttt{reg} A (linear) regression object, with a \texttt{coef} method that gives the coefficients of the corresponding regression line.

\( h, v \) For `panel.abline`, these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For `panel.grid`, these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. \( h=-1 \) and \( v=-1 \) are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using \texttt{pretty}, which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). \( h \) and \( v \) can be negative numbers other than \(-1\), in which case \(-h\) and \(-v\) (as appropriate) is supplied as the \texttt{n} argument to \texttt{pretty}.

If \( x \) and/or \( y \) are specified in `panel.grid`, they will be used to select an appropriate method for \texttt{pretty}. This is particularly useful while plotting date-time objects.

\texttt{reference} A logical flag determining whether the default graphical parameters for `panel.abline` should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The `panel.refline` function is a wrapper around `panel.abline` that calls it with \texttt{reference = TRUE}.

\texttt{expr} An expression considered as a function of \( x \), or a function, to be plotted as a curve.

\texttt{n} The number of points to use for drawing the curve.

\texttt{from, to} optional lower and upper x-limits of curve. If missing, limits of current panel are used.

\texttt{curve.type} Type of curve ("p" for points, etc), passed to \texttt{lines}.

\texttt{regular} A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).

\texttt{start, end} endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of \texttt{regular}, and cover 3% of the panel width and height.
x.units, y.units
Character vectors, replicated to be of length two. Specifies the (grid) units associated with start and end above. x.units and y.units are for the rug on the x-axis and y-axis respectively (and thus are associated with start and end values on the y and x scales respectively).

col, col.line, lty, lwd, alpha, border
Graphical parameters.

type
Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified type argument (perhaps meant for another function) does not affect the display.

fun
The function that will be applied to the subset of x values (or y if horizontal is FALSE) determined by the unique values of y (x).

horizontal
A logical flag. If FALSE, the plot is ‘transposed’ in the sense that the roles of x and y are switched; x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.

dmath
A vectorized function that produces density values given a numeric vector named x, e.g., dnorm.

args
A list giving additional arguments to be passed to dmath.

...
Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by col, col.line, and col.symbol, the last two overriding the first for lines and points respectively.

identifier
A character string that is prepended to the names of grobs that are created by this panel function.

Details

panel.abline adds a line of the form y = a + b * x, or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. panel.refline is similar, but uses the “reference.line” settings for the defaults.

panel.grid draws a reference grid.

panel.curve adds a curve, similar to what curve does with add = TRUE. Graphical parameters for the curve are obtained from the “add.line” setting.

panel.average treats one of x and y as a factor (according to the value of horizontal), calculates fun applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with panel.xyplot, and more commonly with panel.superpose to produce interaction plots.

panel.linejoin is an alias for panel.average. It is retained for back-compatibility, and may go away in future.

panel.mathdensity plots a (usually theoretical) probability density function. This can be useful in conjunction with histogram and densityplot to visually assess goodness of fit (note, however, that qqmath is more suitable for this).

panel.rug adds a rug representation of the (marginal) data to the panel, much like rug.

panel.lmline(x, y) is equivalent to panel.abline(lm(y ~ x)).

Examples

## Interaction Plot

bwplot(yield ~ site, barley, groups = year,
panel = function(x, y, groups, subscripts, ...) {
  panel.grid(h = -1, v = 0)
  panel.stripplot(x, y, ..., jitter.data = TRUE,
                  groups = groups, subscripts = subscripts)
  panel.superpose(x, y, ..., panel.groups = panel.average,
                  groups = groups, subscripts = subscripts)
},
auto.key =
  list(points = FALSE, lines = TRUE, columns = 2))

## Superposing a fitted normal density on a Histogram

histogram(~ height | voice.part, data = singer, layout = c(2, 4),
type = "density", border = "transparent", col.line = "grey60",
xlab = "Height (inches)",
ylab = "Density Histogram\nwith Normal Fit",
panel = function(x, ...) {
  panel.histogram(x, ...)
  panel.mathdensity(dmath = dnorm,
                   args = list(mean=mean(x),sd=sd(x)), ...)
})
Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

Usage

```r
panel.qqmathline(x, y = x,
    distribution = qnorm,
    probs = c(0.25, 0.75),
    qtype = 7,
    groups = NULL,
    ..., identifier = "qqmathline")
```

Arguments

- **x**: The original sample, possibly reduced to a fewer number of quantiles, as determined by the f.value argument to qqmath
- **y**: an alias for x for backwards compatibility
- **distribution**: quantile function for reference theoretical distribution.
`F_2_panel.smoothScatter`  

numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.

`qtype`  
the type of quantile computation used in `quantile`

`groups`  
on optional grouping variable. If non-null, a line will be drawn for each group.

`...`  
other arguments.

`identifier`  
A character string that is prepended to the names of grobs that are created by this panel function.

**Author(s)**

Deepayan Sarkar &lt;Deepayan.Sarkar@R-project.org&gt;

**See Also**

`prepanel.qqmathline`, `qqmath`, `quantile`

---

**F_2_panel.smoothScatter**

_Lattice panel function analogous to smoothScatter_

**Description**

This function allows the user to place smoothScatter plots in lattice graphics.

**Usage**

```r
panel.smoothScatter(x, y = NULL,
  nbin = 64, cuts = 255,
  bandwidth,
  colramp,
  nrpoints = 100,
  transformation = function(x) x^0.25,
  pch = ".",
  cex = 1, col="black",
  range.x,
  ...,
  raster = FALSE,
  subscripts,
  identifier = "smoothScatter")
```

**Arguments**

- `x`  
  Numeric vector containing x-values or n by 2 matrix containing x and y values.

- `y`  
  Numeric vector containing y-values (optional). The length of x must be the same as that of y.

- `nbin`  
  Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.

- `cuts`  
  number of cuts defining the color gradient
bandwidth  Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function bkde2D.

colramp  Function accepting an integer n as an argument and returning n colors.

nrpoints  Numeric vector of length 1 giving number of points to be superimposed on the density image. The first nrpoints points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose nrpoints = Inf.

transformation  Function that maps the density scale to the color scale.

pch, cex  graphical parameters for the nrpoints “outlying” points shown in the display

range.x  see bkde2D for details.

col  points color parameter

...  Further arguments that are passed on to panel.levelplot.

raster  logical; if TRUE, panel.levelplot.raster is used, making potentially smaller output files.

subscripts  ignored, but necessary for handling of ...in certain situations. Likely to be removed in future.

identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

This replicates the display part of the smoothScatter function by replacing standard graphics calls by grid-compatible ones.

Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

Examples

ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
   panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
F_2_panel.spline  Panel Function to Add a Spline Smooth

Description

A predefined panel function that can be used to add a spline smooth based on the provided data.

Usage

panel.spline(x, y, npoints = 101, lwd = plot.line$lwd, lty = plot.line$lty, col, col.line = plot.line$col, type, horizontal = FALSE, ..., keep.data = FALSE, identifier = "spline")

Arguments

x, y  Variables defining the data to be used.
npoints  The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.
lwd, lty, col, col.line  Graphical parameters for the added line. col.line overrides col.
type  Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.
horizontal  A logical flag controlling which variable is to be treated as the predictor (by default x) and which as the response (by default y). If TRUE, the plot is ‘transposed’ in the sense that y becomes the predictor and x the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in bwplot).
keep.data  Passed on to smooth.spline. The default here (FALSE) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to TRUE if the return value of panel.spline, which is the fitted model as returned by smooth.spline, is to be used for subsequent computations.
...  Extra arguments, passed on to smooth.spline and panel.lines as appropriate.
identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Value

The fitted model as returned by smooth.spline.

Lattice, smooth.spline, prepanel.spline

F_2_panel.superpose Panel Function for Display Marked by groups

Description
These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The x (and y where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

Usage

panel.superpose(x, y = NULL, subscripts, groups,
       panel.groups = "panel.xyplot",
       ..., 
       col, col.line, col.symbol,
       pch, cex, fill, font,
       fontface, fontfamily,
       lty, lwd, alpha,
       type = "p", grid = FALSE,
       distribute.type = FALSE)

panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
       col, col.line, col.symbol,
       pch, cex, fill, font,
       fontface, fontfamily,
       lty, lwd, alpha)

Arguments

x, y Coordinates of the points to be displayed. Usually numeric.

panel.groups The panel function to be used for each subgroup of points. Defaults to panel.xyplot.

To be able to distinguish between different levels of the originating group inside panel.groups, it will be supplied two special arguments called group.number and group.value which will hold the numeric code and factor level corresponding to the current level of groups. No special care needs to be taken when writing a panel.groups function if this feature is not used.

subscripts An integer vector of subscripts giving indices of the x and y values in the original data source. See the corresponding entry in xyplot for details.

groups A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of groups. The default graphical parameters are obtained from the "superpose.symbol" and "superpose.line" settings using trellis.par.get wherever appropriate.
type  Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the panel.groups function, which must know what to do with it. By default, panel.groups is panel.xyplot, whose help page describes the admissible values.

The functions panel.superpose and panel.superpose.2 differ only in the default value of distribute.type, which controls the way the type argument is interpreted. If distribute.type = FALSE, then the interpretation is the same as for panel.xyplot for each of the unique groups. In other words, if type is a vector, all the individual components are honoured concurrently. If distribute.type = TRUE, type is replicated to be as long as the number of unique values in groups, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying type as a list, each component being the desired type vector for the corresponding group.

If distribute.type = FALSE, any occurrence of "g" in type causes a grid to be drawn, and all such occurrences are removed before type is passed on to panel.groups.

grid  Logical flag specifying whether a background reference grid should be drawn. See panel.xyplot for details.

col  A vector color specification. See Details.

col.line  A vector color specification. See Details.

col.symbol  A vector color specification. See Details.

pch  A vector plotting character specification. See Details.

cex  A vector size factor specification. See Details.

fill  A vector fill color specification. See Details.

font, fontface, fontfamily  A vector color specification. See Details.

lty  A vector color specification. See Details.

lwd  A vector color specification. See Details.

alpha  A vector alpha-transparency specification. See Details.

...  Extra arguments. Passed down to panel.superpose from panel.superpose.2, and to panel.groups from panel.superpose.

distribute.type  logical controlling interpretation of the type argument.

Details

panel.superpose divides up the x (and optionally y) variable(s) by the unique values of groups[subscripts], and plots each subset with different graphical parameters. The graphical parameters (col.symbol, pch, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When panel.groups is called for the i-th level of groups, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the panel.groups function. With the default panel.groups, the col argument is overridden by col.line and col.symbol for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, col will still be supplied as an argument to panel.groups functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the
"superpose.line" and "superpose.symbol" settings as appropriate. The alpha parameter takes it default from the "superpose.line" setting.

panel.superpose and panel.superpose.2 differ essentially in how type is interpreted by default. The default behaviour in panel.superpose is the opposite of that in S, which is the same as that of panel.superpose.2.

panel.superpose.plain is the same as panel.superpose, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in xyplot.ts.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org> (panel.superpose.2 originally contributed by Neil Klepeis)

See Also

Different functions when used as panel.groups gives different types of plots, for example panel.xyplot, panel.dotplot and panel.average (This can be used to produce interaction plots).

See Lattice for an overview of the package, and xyplot for common arguments (in particular, the discussion of the extended formula interface and the groups argument).

F_2_panel.violin  Panel Function to create Violin Plots

Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to bwplot.

Usage

panel.violin(x, y, box.ratio = 1, box.width,
horizontal = TRUE,
alpha, border, lty, lwd, col,
varwidth = FALSE,
bw, adjust, kernel, window,
width, n = 50, from, to, cut,
na.rm, ..., identifier = "violin")

Arguments

x, y numeric vector or factor. Violin plots are drawn for each unique value of y (x) if horizontal is TRUE (FALSE)
box.ratio ratio of the thickness of each violin and inter violin space
box.width thickness of the violins in absolute units; overrides box.ratio. Useful for specifying thickness when the categorical variable is not a factor, as use of box.ratio alone cannot achieve a thickness greater than 1.
horizontal logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of \textit{x} and \textit{y} are switched. \textit{x} is now the ‘factor’. See documentation of \texttt{bwplot} for a fuller explanation.

\texttt{alpha, border, lty, lwd, col}
graphical parameters controlling the violin. Defaults are taken from the "plot.polygon" settings.

\texttt{varwidth} logical. If FALSE, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by \texttt{box.ratio}). If TRUE, densities across violins will have comparable scale.

\texttt{bw, adjust, kernel, window, width, n, from, to, cut, na.rm}
arguments to \texttt{density}, passed on as appropriate

\texttt{...}
arguments passed on to \texttt{density}.

\texttt{identifier} A character string that is prepended to the names of grobs that are created by this panel function.

### Details

Creates Violin plot of \textit{x} for every level of \textit{y}. Note that most arguments controlling the display can be supplied to the high-level (typically \texttt{bwplot}) call directly.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### See Also

\texttt{bwplot, density}

### Examples

```r
bwplot(voice.part ~ height, singer,
panel = function(..., box.ratio) {
  panel.violin(..., col = "transparent",
              varwidth = FALSE, box.ratio = box.ratio)
  panel.bwplot(..., fill = NULL, box.ratio = .1)
})
```

---

### Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.
Usage

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)  
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)  
prepanel.default.qq(x, y, ...)  
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)  
prepanel.default.cloud(perspective, distance,  
    xlim, ylim, zlim,  
    screen = list(z = 40, x = -60),  
    R.mat = diag(4),  
    aspect = c(1, 1), panel.aspect = 1,  
    ..., zoom = 0.8)  
prepanel.default.levelplot(x, y, subscripts, ...)  
prepanel.default.qqmath(x, f.value, distribution, qtype,  
    groups, subscripts, ..., tails.n = 0)  
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)  
prepanel.default.parallel(x, y, z, ..., horizontal.axis)  
prepanel.default.splo()
These are predefined prepanel functions available in Lattice.

Usage

prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
    probs = c(0.25, 0.75), qtype = 7,
    groups, subscripts,
    ...)
prepanel.loess(x, y, span, degree, family, evaluation,
    horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
    horizontal = FALSE, ..., keep.data = FALSE)

Arguments

  x, y          x and y values, numeric or factor
  distribution  quantile function for theoretical distribution. This is automatically passed in
                 when this is used as a prepanel function in qqmath.
  qtype         type of quantile
  probs         numeric vector of length two, representing probabilities. If used with
                 aspect="xy", the aspect ratio will be chosen to make the line passing through
                 the corresponding quantile pairs as close to 45 degrees as possible.
  span, degree, family, evaluation
  horizontal, npoints
  keep.data     Ignored. Present to capture argument of the same name in smooth.spline.
  groups, subscripts
  ...           Other arguments. These are passed on to other functions if appropriate (in par-
                 ticular, smooth.spline), and ignored otherwise.
Details

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, prepanel.lmline computes the dx and dy such that it reflects the slope of the linear regression line; for prepanel.qqmathline, this is the slope of the line passing through the quantile pairs specified by probs. For prepanel.loess and prepanel.spline, dx and dy reflect the piecewise slopes of the nonlinear smooth.

Value

usually a list with components xlim, ylim, dx and dy, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under xypplot. There are also several prepanel functions that serve as the default for high level functions, see prepanel.default.xyplot

G_axis.default

Default axis annotation utilities

Description

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The xscale.components and yscale.components arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the axis argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additonally be used as components of user written replacements.

Usage

xsclae.components.default(lim,
    packet.number = 0,
    packet.list = NULL,
    top = TRUE,
    ...
)y scale.components.default(lim,
    packet.number = 0,
    packet.list = NULL,
    right = TRUE,
    ...
)axis.default(side = c("top", "bottom", "left", "right"),
    scales, components, as.table,
    labels = c("default", "yes", "no"),
    ticks = c("default", "yes", "no"),
\ldots, \text{prefix})

**Arguments**

- **lim**
  - the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.

- **packet.number**
  - which packet (counted according to the packet order, described in \texttt{print.trellis}) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.

- **packet.list**
  - list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)

- **top, right**
  - the value of the top and right components of the result, as appropriate. See below for interpretation.

- **side**
  - on which side the axis is to be drawn. The usual partial matching rules apply.

- **scales**
  - the appropriate component of the scales argument supplied to the high level function, suitably standardized.

- **components**
  - list, similar to those produced by \texttt{xscale.components.default} and \texttt{yscale.components.default}.

- **as.table**
  - the as.table argument in the high level function.

- **labels**
  - whether labels are to be drawn. By default, the rules determined by scales are used.

- **ticks**
  - whether labels are to be drawn. By default, the rules determined by scales are used.

- **\ldots**
  - many other arguments may be supplied, and are passed on to other internal functions.

- **prefix**
  - A character string identifying the plot being drawn (see \texttt{print.trellis}). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.

**Details**

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

**Value**

\texttt{xscale.components.default} and \texttt{yscale.components.default} return a list of the form suitable as the components argument of \texttt{axis.default}. Valid components in the return value of \texttt{xscale.components.default} are:

- **num.limit**
  - A numeric limit for the box.
A list with two elements, ticks and labels. ticks must be a list with components at
and tck which give the location and lengths of tick marks. tck can be a vector, and will
be recycled to be as long as at. labels must be a list with components at, labels, and
check.overlap. at and labels give the location and labels of the tick labels; this is usually
the same as the location of the ticks, but is not required to be so. check.overlap is a logical
flag indicating whether overlapping of labels should be avoided by omitting some of the labels
while rendering.

top This can be a logical flag; if TRUE, top is treated as being the same as bottom; if FALSE, axis
annotation for the top axis is omitted. Alternatively, top can be a list like bottom.

Valid components in the return value of yscale.components.default are left and right. Their
interpretations are analogous to (respectively) the bottom and top components described above.

**G_banking**  

**Banking**

---

**Description**

Calculates banking slope
Usage

banking(dx, dy)

Arguments

dx, dy vector of consecutive x, y differences.

Details

banking is the banking function used when aspect = "xy" in high level Trellis functions. It is usually not very meaningful except with xyplot. It considers the absolute slopes (based on dx and dy) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs' website (see Lattice), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying lattice.options("banking").

## with and without banking

plot <- xyplot(sunspot.year ~ 1700:1988, xlab = "", type = "l",
               scales = list(x = list(alternating = 2)),
               main = "Yearly Sunspots")
print(plot, position = c(0, .3, 1, .9), more = TRUE)
print(update(plot, aspect = "xy", main = "", xlab = "Year"),
       position = c(0, 0, 1, .3))

## cut-and-stack plot (see also xyplot.ts)

xyplot(sunspot.year ~ time(sunspot.year) | equal.count(time(sunspot.year)),
       xlab = "", type = "l", aspect = "xy", strip = FALSE,
       scales = list(x = list(alternating = 2, relation = "sliced")),
       as.table = TRUE, main = "Yearly Sunspots")
G_latticeParseFormula  Parse Trellis formula

Description

This function is used by high level Lattice functions like xyplot to parse the formula argument and evaluate various components of the data.

Usage

latticeParseFormula(model, data, dimension = 2,
subset = TRUE, groups = NULL,
multiple, outer,
subscripts,
drop)

Arguments

model the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the dimension argument. The 2d formulas are of the form y ~ x | g1 * ... * gn, and the 3d formulas are of the form z ~ x * y | g1 * ... * gn. In the first form, y may be omitted. The conditioning variables g1, ..., gn can be omitted in either case.
data the environment/dataset where the variables in the formula are evaluated.
dimension dimension of the model, see above
subset index for choosing a subset of the data frame
groups the grouping variable, if present
multiple, outer logicals, determining how a '+' in the y and x components of the formula are processed. See xyplot for details
subscripts logical, whether subscripts are to be calculated
drop logical or list, similar to the drop.unused.levels argument in xyplot, indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

Value

Returns a list with several components, including left, right, left.name, right.name, condition for 2-D, and left, right.x, right.y, left.name, right.x.name, right.y.name, condition for 3-D. Other possible components are groups, subscr.

xyplot, Lattice
Associating Packets with Panels

Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

Usage

```r
packet.panel.default(layout, condlevels, page, row, column,
                       skip, all.pages.skip = TRUE)
```

Arguments

- `layout` the layout argument in high level functions, suitably standardized.
- `condlevels` a list of levels of conditioning variables, after relevant permutations and/or reordering of levels.
- `page, row, column` the location of the panel in the coordinate system of pages, rows and columns.
- `skip` the skip argument in high level functions.
- `all.pages.skip` whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is `p`, then the i-th conditioning variable will have level `condlevels[[i]][p[i]]`.

### `G_panel.axis`

#### Panel Function for Drawing Axis Ticks and Labels

**Description**

`panel.axis` is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. `current.panel.limits` can be used to retrieve a panel’s x and y limits.

**Usage**

```r
panel.axis(side = c("bottom", "left", "top", "right"),
           at,
           labels = TRUE,
           draw.labels = TRUE,
           check.overlap = FALSE,
           outside = FALSE,
           ticks = TRUE,
           half = !outside,
           which.half,
           tck = as.numeric(ticks),
           rot = if (is.logical(labels)) 0 else c(90, 0),
           text.col, text.alpha, text.cex, text.font,
           text.fontfamily, text.fontface, text.lineheight,
           line.col, line.lty, line.lwd, line.alpha)
```

`current.panel.limits(unit = "native")`
Arguments

- **side**: A character string indicating which side axes are to be drawn on. Partial specification is allowed.
- **at**: Numeric vector giving location of labels. Can be missing, in which case they are computed from the native coordinates of the active viewport.
- **labels**: The labels to go along with **at**, as a character vector or a vector of expressions. This only makes sense provided **at** is explicitly specified, as otherwise the provided labels may not match the computed **at** values. Alternatively, **labels** can be a logical flag: If **TRUE**, the labels are derived from **at**, otherwise, labels are empty.
- **draw.labels**: A logical indicating whether labels are to be drawn.
- **check.overlap**: A logical, whether to check for overlapping of labels. This also has the effect of removing **at** values that are ‘too close’ to the limits.
- **outside**: A logical flag, indicating whether to draw the labels outside the panel or inside. Note that **outside=TRUE** will only have a visible effect if clipping is disabled for the viewport (panel).
- **ticks**: Logical flag, whether to draw the tickmarks.
- **half**: Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in **splom**.
- **which.half**: Character string, either "lower" or "upper", indicating which half is to be used for tick locations if **half = TRUE**. Defaults to whichever is suitable for **splom**.
- **tck**: A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.
- **rot**: Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.
- **text.col**: Color for the axis label text. See **gpar** for more details on this and the other graphical parameters listed below.
- **text.alpha**: Alpha-transparency value for the axis label text.
- **text.cex**: Size multiplier for the axis label text.
- **text.font, text.fontfamily, text.fontface**: Font for the axis label text.
- **text.lineheight**: Line height for the axis label text.
- **line.col**: Color for the axis label text.
- **line.lty**: Color for the axis.
- **line.lwd**: Color for the axis.
- **line.alpha**: Alpha-transparency value for the axis.
- **unit**: Which grid **unit** the values should be in.

Details

**panel.axis** can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in **panel.pairs** for **splom**, as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots 'after the fact' by adding axes.
Value

current.panel.limits returns a list with components xlim and ylim, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by unit, by default "native".

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, xyplot, trellis.focus, unit

Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the panel, strip and axis functions. Note that this information is not available to the prepanel function, which is executed prior to the actual plotting.

Usage

current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)
trellis.currentLayout(which = c("packet", "panel"), prefix)

Arguments

which

whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

prefix

A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See trellis.focus.
G_Rows

Value

trellis.currentLayout returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. current.row and current.column return integer indices specifying which row and column in the layout are currently active. panel.number returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). packet.number gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. which.packet returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called panel.number and packet.number that were made available to panel and strip. If you have written such functions, it should be enough to replace instances of panel.number and packet.number by the corresponding function calls. You should also remove panel.number and packet.number from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

`xyplot`, `Lattice`
**Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

barley

**Format**

A data frame with 120 observations on the following 4 variables.

- **yield** Yield (averaged across three blocks) in bushels/acre.
- **variety** Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trebi".
- **year** Factor with levels 1932, 1931
- **site** Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crocketson", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

})
```

H_ethanol

*Engine exhaust fumes from burning ethanol*

Description

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

Usage

ethanol

Format

A data frame with 88 observations on the following 3 variables.

- **NOx**: Concentration of nitrogen oxides (NO and NO2) in micrograms/J.
- **C**: Compression ratio of the engine.
- **E**: Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.
H_melanoma

Melanoma skin cancer incidence

Description

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

Usage

melanoma
**H_singer**

**Format**
A data frame with 37 observations on the following 2 variables.

- **year**  Years 1936 to 1972.
- **incidence**  Rate of melanoma cancer per 100,000 population.

**Note**
This dataset is not related to the *melanoma* dataset in the *boot* package with the same name. The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (https://www.cancer.gov/).

**Author(s)**
Documentation contributed by Kevin Wright.

**Source**

**H_singer**  *Heights of New York Choral Society singers*

**Description**
Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**
singer
H_USMortality

Mortality Rates in US by Cause and Gender

Description

These datasets record mortality rates across all ages in the USA by cause of death, sex, and rural/urban status, 2011–2013. The two datasets represent the national aggregate rates and the region-wise rates for each administrative region under the Department of Health and Human Services (HHS).
Usage

USMortality
USRegionalMortality

Format

USRegionalMortality is a data frame with 400 observations on the following 6 variables.

Region  A factor specifying HHS Region. See details.
Status  A factor with levels Rural and Urban
Sex    A factor with levels Female and Male
Cause  Cause of death. A factor with levels Alzheimers, Cancer, Cerebrovascular diseases, Diabetes, Flu and pneumonia, Heart disease, Lower respiratory, Nephritis, Suicide, and Unintentional injuries
Rate   Age-adjusted death rate per 100,000 population
SE     Standard error for the rate

USMortality is a data frame with 40 observations, containing the same variables with the exception of Region.

Details

The region-wise data give estimated rates separately for each of 10 HHS regions. The location of the regional offices and their coverage area, available from https://www.hhs.gov/about/agencies/iea/regional-offices/index.html, is given below.

HHS Region 01 - Boston:  Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont
HHS Region 02 - New York: New Jersey, New York, Puerto Rico, and the Virgin Islands
HHS Region 03 - Philadelphia: Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia
HHS Region 04 - Atlanta: Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee
HHS Region 05 - Chicago: Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin
HHS Region 06 - Dallas: Arkansas, Louisiana, New Mexico, Oklahoma, and Texas
HHS Region 07 - Kansas City: Iowa, Kansas, Missouri, and Nebraska
HHS Region 08 - Denver: Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming
HHS Region 09 - San Francisco: Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and Republic of Palau
HHS Region 10 - Seattle: Alaska, Idaho, Oregon, and Washington

References

Examples

```r
dotplot(reorder(Cause, Rate) ~ Rate | Status, 
data = USMortality, groups = Sex, 
par.settings = simpleTheme(pch = 16), auto.key = list(columns = 2), 
scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
dotplot(reorder(Cause, Rate):Sex ~ Rate | Status, 
data = USRegionalMortality, groups = Sex, 
scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
```

Description

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

Usage

```r
lset(theme = col.whitebg())
```

Arguments

- `theme`: a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

Chapter 24

The mgcv package

anova.gam

Approximate hypothesis tests related to GAM fits

Description

Performs hypothesis tests relating to one or more fitted gam objects. For a single fitted gam object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to drop1 rather than anova.lm (i.e. it’s like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table or GLRT test: this latter approach should not be use to test the significance of terms which can be penalized to zero. Models to be compared should be fitted to the same data using the same smoothing parameter selection method.

Usage

## S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
freq = FALSE)
## S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3),...)

Arguments

object,... fitted model objects of class gam as produced by gam().
x an anova.gam object produced by a single model call to anova.gam().
dispersion a value for the dispersion parameter: not normally used.
test what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp". Reset to "Chisq" for extended and general families unless NULL.
freq whether to use frequentist or Bayesian approximations for parametric term p-values. See summary.gam for details.
digits number of digits to use when printing output.

2809
Details

If more than one fitted model is provided than anova.glm is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom (when possible this is a smoothing parameter uncertainty corrected version). For extended and general families this is set so that a GLRT test is used. The p-values resulting from the multi-model case are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to anova.gam, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notiona null model.

If only one model is provided then the significance of each model term is assessed using Wald like tests, conditional on the smoothing parameter estimates: see summary.gam and Wood (2013a,b) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but it is available in package RLRsim).

In the single model case print.anova.gam is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (freq=TRUE), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the paraPen argument will not be good.

Value

In the multi-model case anova.gam produces output identical to anova.glm, which it in fact uses.

In the single model case an object of class anova.gam is produced, which is in fact an object returned from summary.gam.

print.anova.gam simply produces tabulated output.

WARNING

If models ’a’ and ’b’ differ only in terms with no un-penalized components (such as random effects) then p values from anova(a,b) are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using ‘paraPen’: use freq=TRUE to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to drop1, not anova.lm.
bam

**Author(s)**

Simon N. Wood <simon.wood@r-project.org> with substantial improvements by Henric Nilsson.

**References**

**See Also**

`gam`, `predict.gam`, `gam.check`, `summary.gam`

**Examples**

```r
library(mgcv)
set.seed(0)
dat <- gamSim(5, n=200, scale=2)
b<-gam(y ~ x0 + s(x1) + s(x2) + s(x3), data=dat)
anova(b)
b1<-gam(y ~ x0 + s(x1) + s(x2), data=dat)
anova(b,b1,test="F")
```

**Description**

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM (the extended families listed in `family.mgcv` can also be used). The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like `gam`, except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data (see Wood, Goude and Shaw, 2015). The advantage of `bam` is much lower memory footprint than `gam`, but it can also be much faster, for large datasets. `bam` can also compute on a cluster set up by the `parallel` package.

An alternative fitting approach (Wood et al. 2017, Li and Wood, 2019) is provided by the `discrete=TRUE` method. In this case a method based on discretization of covariate values and C code level parallelization (controlled by the `nthreads` argument instead of the `cluster` argument) is used. This extends both the data set and model size that are practical.
Usage

```r
bam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL, 
na.action=na.omit, offset=NULL, method="fREML", control=list(), 
select=FALSE, scale=0, gamma=1, knots=NULL, sp=NULL, min.sp=NULL, 
paraPen=NULL, chunk.size=10000, rho=0, AR.start=NULL, discrete=FALSE, 
cluster=NULL, nthreads=1, gc.level=0, use.chol=FALSE, samfrac=1, 
coef=NULL, drop.unused.levels=TRUE, G=NULL, fit=TRUE, drop.intercept=NULL,...)
```

Arguments

- **formula**: A GAM formula (see `formula.gam` and also `gam.models`). This is exactly like the formula for a GLM except that smooth terms, `s` and `te` can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).

- **family**: This is a family object specifying the distribution and link to use in fitting etc. See `glm` and `family` for more details. The extended families listed in `family.mgcv` can also be used.

- **data**: A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`; typically the environment from which `gam` is called.

- **weights**: prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. `weights <- weights/mean(weights)`).

- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.

- **na.action**: a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.

- **offset**: Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of `lm` and `glm`).

- **method**: The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows’ Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation.

- **control**: A list of fit control parameters to replace defaults returned by `gam.control`. Any control parameters not supplied stay at their default values.

- **select**: Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See gamma to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.

- **scale**: If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for...
Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.

**gamma**
Increase above 1 to force smoother fits. gamma is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so \( \log(n)/2 \) is BIC like). \( n/\gamma \) can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.

**knots**
this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See **tpars** for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

**sp**
A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then \( \text{length}(\text{sp}) \) must correspond to the number of underlying smoothing parameters.

**min.sp**
Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters \( \text{full.sp} \), in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. \( \text{length}(\text{min.sp}) \) should always be the same as the total number of penalties (so it may be longer than \( \text{sp} \), if smooths share smoothing parameters).

**paraPen**
optional list specifying any penalties to be applied to parametric model terms. **gam.models** explains more.

**chunk.size**
The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to \( 4p \) if \( \text{chunk.size} < 4p \) where \( p \) is the number of coefficients.

**rho**
An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in **std.rsd** if non zero. Also usable with other models when **discrete=TRUE**, in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.

**AR.start**
logical variable of same length as data, **TRUE** at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If **NULL** then there are no breaks in AR1 correlation.

**discrete**
with method="fREML" it is possible to discretize covariates for storage and efficiency reasons. If **discrete** is **TRUE**, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins.

**cluster**
bam can compute the computationally dominant QR decomposition in parallel using **parLapply** from the **parallel** package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.

**nthreads**
Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If NA set to \( \max(1,\text{length(cluster)}) \). See details.

**gc.level**
to keep the memory footprint down, it can help to call the garbage collector often, but this takes a substantial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives
frequent garbage collection. 1 is in between. Not as much of a problem as it used to be.

**use.chol**

By default bam uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.

**samfrac**

For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. samfrac is the sampling fraction to use. 0.1 is often reasonable.

**coef**

initial values for model coefficients

**drop.unused.levels**

by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

**G**

if not NULL then this should be the object returned by a previous call to bam with fit=FALSE. Causes all other arguments to be ignored except sp, chunk.size, gamma,nthreads, cluster, rho, gc.level, samfrac, use.chol, method and scale (if >0).

**fit**

if FALSE then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the G argument to bam.

**drop.intercept**

Set to TRUE to force the model to really not have the a constant in the parametric model part, even with factor variables present.

... further arguments for passing on e.g. to gam.fit (such as mustart).

**Details**

When discrete=FALSE, bam operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using predict.gam. For each block the factor R, from the QR decomposition of the whole model matrix is updated, along with Q'y. and the sum of squares of y. At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudo-data, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified via the asymptotic multivariate normality of Q'z where z is the IRLS pseudodata.

For full method details see Wood, Goude and Shaw (2015).

Note that POI is not as stable as the default nested iteration used with gam, but that for very large, information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are typically much less costly in the multi-dimensional case.

If cluster is provided as a cluster set up using makeCluster (or makeForkCluster) from the parallel package, then the rate limiting QR decomposition of the model matrix is performed in parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine it is usually best to set the cluster size to the number of physical cores, which is often less than what
is reported by `detectCores`. Using more than the number of physical cores can result in no speed up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

When `discrete=TRUE` the covariate data are first discretized. Discretization takes place on a smooth by smooth basis, or in the case of tensor product smooths (or any smooth that can be represented as such, such as random effects), separately for each marginal smooth. The required spline bases are then evaluated at the discrete values, and stored, along with index vectors indicating which original observation they relate to. Fitting is by a version of performance oriented iteration/PQL using REML smoothing parameter selection on each iterative working model (as for the default method). The iteration is based on the derivatives of the REML score, without computing the score itself, allowing the expensive computations to be reduced to one parallel block Cholesky decomposition per iteration (plus two basic operations of equal cost, but easily parallelized). Unlike standard POI/PQL, only one step of the smoothing parameter update for the working model is taken at each step (rather than iterating to the optimal set of smoothing parameters for each working model). At each step a weighted model matrix crossproduct of the model matrix is required - this is efficiently computed from the pre-computed basis functions evaluated at the discretized covariate values. Efficient computation with tensor product terms means that some terms within a tensor product may be re-ordered for maximum efficiency. See Wood et al (2017) and Li and Wood (2019) for full details.

When `discrete=TRUE` parallel computation is controlled using the `nthreads` argument. For this method no cluster computation is used, and the `parallel` package is not required. Note that actual speed up from parallelization depends on the BLAS installed and your hardware. With the (R default) reference BLAS using several threads can make a substantial difference, but with a single threaded tuned BLAS, such as openblas, the effect is less marked (since cache use is typically optimized for one thread, and is then sub optimal for several). However the tuned BLAS is usually much faster than using the reference BLAS, however many threads you use. If you have a multi-threaded BLAS installed then you should leave `nthreads` at 1, since calling a multi-threaded BLAS from multiple threads usually slows things down: the only exception to this is that you might choose to form discrete matrix cross products (the main cost in the fitting routine) in a multi-threaded way, but use single threaded code for other computations: this can be achieved by e.g. `nthreads=c(2,1)`, which would use 2 threads for discrete inner products, and 1 for most code calling BLAS. Not that the basic reason that multi-threaded performance is often disappointing is that most computers are heavily memory bandwidth limited, not flop rate limited. It is hard to get data to one core fast enough, let alone trying to get data simultaneously to several cores.

discrete=TRUE will often produce identical results to the methods without discretization, since covariates often only take a modest number of discrete values anyway, so no approximation at all is involved in the discretization process. Even when some approximation is involved, the differences are often very small as the algorithms discretize marginally whenever possible. For example each margin of a tensor product smooth is discretized separately, rather than discretizing onto a grid of covariate values (for an equivalent isotropic smooth we would have to discretize onto a grid). The marginal approach allows quite fine scale discretization and hence very low approximation error. Note that when using the smooth `id` mechanism to link smoothing parameters, the discrete method cannot force the linked bases to be identical, so some differences to the none discrete methods will be noticeable.

The extended families given in `family.mgcv` can also be used. The extra parameters of these are estimated by maximizing the penalized likelihood, rather than the restricted marginal likelihood as in `gam`. So estimates may differ slightly from those returned by `gam`. Estimation is accomplished by a Newton iteration to find the extra parameters (e.g. the theta parameter of the negative binomial or the degrees of freedom and scale of the scaled t) maximizing the log likelihood given the model coefficients at each iteration of the fitting procedure.
Value

An object of class "gam" as described in *gamObject*. 

WARNINGS

The routine may be slower than optimal if the default "tp" basis is used.

Unless discrete=TRUE, you must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than ‘gam’ for the same dataset.

With discrete=TRUE, te terms are efficiently computed, but t2 are not.

**bam.update**

*Update a strictly additive bam model for new data.*

### Description

Gaussian with identity link models fitted by `bam` can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

### Usage

```r
bam.update(b, data, chunk.size=10000)
```

### Arguments

- `b` A `gam` object fitted by `bam` and representing a strictly additive model (i.e. gaussian errors, identity link).
- `data` Extra data to augment the original data used to obtain `b`. Must include a `weights` column if the original fit was weighted and a `AR.start` column if `AR.start` was non-NULL in original fit.
- `chunk.size` size of subsets of data to process in one go when getting fitted values.

### Details

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the same AR1 model for the residuals as that employed in the original model fit (see `rho` parameter of `bam`).

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).
Value

An object of class "gam" as described in gamObject.

WARNINGS

AIC computation does not currently take account of AR model, if used.

bandchol

Choleski decomposition of a band diagonal matrix

Description

Computes Choleski decomposition of a (symmetric positive definite) band-diagonal matrix, A.

Usage

`bandchol(B)`

Arguments

B

An n by k matrix containing the diagonals of the matrix A to be decomposed. First row is leading diagonal, next is first sub-diagonal, etc. sub-diagonals are zero padded at the end. Alternatively gives A directly, i.e. a square matrix with 2k-1 non zero diagonals (those from the lower triangle are not accessed).

Details

Calls `dpbtrf` from LAPACK. The point of this is that it has $O(k^2n)$ computational cost, rather than the $O(n^3)$ required by dense matrix methods.

Value

Let $R$ be the factor such that $t(R) \times R = A$. $R$ is upper triangular and if the rows of B contained the diagonals of A on entry, then what is returned is an n by k matrix containing the diagonals of $R$, packed as B was packed on entry. If B was square on entry, then $R$ is returned directly. See examples.

Examples

```r
require(mgcv)
## simulate a banded diagonal matrix
n <- 7;set.seed(8)
A <- matrix(0,n,n)
sdiag(A) <- runif(n);sdiag(A,1) <- runif(n-1)
sdiag(A,2) <- runif(n-2)
A <- crossprod(A)

## full matrix form...
```
bandchol(A)
chol(A) ## for comparison

## compact storage form...
B <- matrix(0,3,n)
B[1,] <- sdiag(A);B[2,1:(n-1)] <- sdiag(A,1)
B[3,1:(n-2)] <- sdiag(A,2)
bandchol(B)

betar

\textit{GAM beta regression family}

\textbf{Description}

Family for use with \texttt{gam} or \texttt{bam}, implementing regression for beta distributed data on $(0,1)$. A linear predictor controls the mean, $\mu$ of the beta distribution, while the variance is then $\mu(1-\mu)/(1+\phi)$, with parameter $\phi$ being estimated during fitting, alongside the smoothing parameters.

\textbf{Usage}

\texttt{betar(theta = NULL, link = "logit", eps=.Machine$double.eps*100)}

\textbf{Arguments}

- **theta**
  - the extra parameter ($\phi$ above).
- **link**
  - The link function: one of "logit", "probit", "cloglog" and "cauchit".
- **eps**
  - the response variable will be truncated to the interval $[\text{eps},1-\text{eps}]$ if there are values outside this range. This truncation is not entirely benign, but too small a value of eps will cause stability problems if there are zeroes or ones in the response.

\textbf{Details}

These models are useful for proportions data which can not be modelled as binomial. Note the assumption that data are in $(0,1)$, despite the fact that for some parameter values 0 and 1 are perfectly legitimate observations. The restriction is needed to keep the log likelihood bounded for all parameter values. Any data exactly at 0 or 1 are reset to be just above 0 or just below 1 using the eps argument (in fact any observation $<\text{eps}$ is reset to $\text{eps}$ and any observation $>1-\text{eps}$ is reset to $1-\text{eps}$). Note the effect of this resetting. If $\mu\phi > 1$ then impossible 0s are replaced with highly improbable eps values. If the inequality is reversed then 0s with infinite probability density are replaced with eps values having high finite probability density. The equivalent condition for 1s is $(1-\mu)\phi > 1$. Clearly all types of resetting are somewhat unsatisfactory, and care is needed if data contain 0s or 1s (often it makes sense to manually reset the 0s and 1s in a manner that somehow reflects the sampling setup).

\textbf{Value}

An object of class extended.family.

\textbf{WARNINGS}

Do read the details section if your data contain 0s and or 1s.
**Author(s)**

Natalya Pya (nat.pya@gmail.com) and Simon Wood (s.wood@r-project.org)

**Examples**

```r
library(mgcv)
## Simulate some beta data...
set.seed(3); n <- 400
dat <- gamSim(1, n = n)
mu <- binomial()$linkinv(dat$f/4-2)
phi <- .5
a <- mu*phi; b <- phi - a;
dat$y <- rbeta(n,a,b)

bm <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=betar(link="logit"),data=dat)

bm
plot(bm,pages=1)
```

---

**blas.thread.test**

**BLAS thread safety**

**Description**

Most BLAS implementations are thread safe, but some versions of OpenBLAS, for example, are not. This routine is a diagnostic helper function, which you will never need if you don’t set `nthreads>1`, and even then are unlikely to need.

**Usage**

```r
blas.thread.test(n=1000,nt=4)
```

**Arguments**

- `n` Number of iterations to run of parallel BLAS calling code.
- `nt` Number of parallel threads to use

**Details**

While single threaded OpenBLAS 0.2.20 was thread safe, versions 0.3.0-0.3.6 are not, and from version 0.3.7 thread safety of the single threaded OpenBLAS requires making it with the option `USE_LOCKING=1`. The reference BLAS is thread safe, as are MKL and ATLAS. This routine repeatedly calls the BLAS from multi-threaded code and is sufficient to detect the problem in single threaded OpenBLAS 0.3.x.

A multi-threaded BLAS is often no faster than a single-threaded BLAS, while judicious use of threading in the code calling the BLAS can still deliver a modest speed improvement. For this reason it is often better to use a single threaded BLAS and the codethreads options to `bam` or `gam`. For `bam(..., discrete=TRUE)` using several threads can be a substantial benefit, especially with the reference BLAS.

The MKL BLAS is multi-threaded by default. Under Linux setting environment variable `MKL_NUM_THREADS=1` before starting R gives single threaded operation.

Simon N. Wood <simon.wood@r-project.org>

Description
mgcv works largely because many people have reported bugs over the years. If you find something that looks like a bug, please report it, so that the package can be improved. mgcv does not have a large development budget, so it is a big help if bug reports follow the following guidelines.

The ideal report consists of an email to <simon.wood@r-project.org> with a subject line including mgcv somewhere, containing

1. The results of running sessionInfo in the R session where the problem occurs. This provides platform details, R and package version numbers, etc.
3. Short cut and paste-able code that produces the problem, including the code for loading/generating the data (using standard R functions like load, read.table etc).
4. Any required data files. If you send real data it will only be used for the purposes of debugging.

Of course if you have dug deeper and have an idea of what is causing the problem, that is also helpful to know, as is any suggested code fix. (Don’t send a fixed package .tar.gz file, however - I can’t use this).

Simon N. Wood <simon.wood@r-project.org>

Description
Given a Cholesky factor, R, of a matrix, A, choldrop finds the Cholesky factor of \( A[-k,-k] \), where \( k \) is an integer. cholup finds the factor of \( A + uu^T \) (update) or \( A - uu^T \) (downdate).

Usage
choldrop(R,k)
cholup(R,u,up)

Arguments
R Cholesky factor of a matrix, A.
k row and column of A to drop.
u vector defining rank one update.
up if TRUE compute update, otherwise downdate.
Details

First consider choldrop. If \( R \) is upper triangular then \( \text{t}([R[,-k]]\%*%R[,-k]) == A[-k,-k] \), but \( R[,-k] \) has elements on the first sub-diagonal, from its \( k \)th column onwards. To get from this to a triangular Cholesky factor of \( A[-k,-k] \) we can apply a sequence of Givens rotations from the left to eliminate the sub-diagonal elements. The routine does this. If \( R \) is a lower triangular factor then Givens rotations from the right are needed to remove the extra elements. If \( n \) is the dimension of \( R \) then the update has \( O(n^2) \) computational cost.

The routine uses hyperbolic rotations to do the downdating, see Golub and Van Loan (2013, section 6.5.4) for details. Downdating only works if \( A - uu^T \) is positive definite. Again the computational cost is \( O(n^2) \).

Note that the updates are vector oriented, and are hence not susceptible to speed up by use of an optimized BLAS. The updates are set up to be relatively Cache friendly, in that in the upper triangular case successive Givens rotations are stored for sequential application column-wise, rather than being applied row-wise as soon as they are computed. Even so, the upper triangular update is slightly slower than the lower triangular update.

References

Examples

```r
require(mgcv)
set.seed(0)
n <- 6
A <- crossprod(matrix(runif(n*n),n,n))
R0 <- chol(A)
k <- 3
Rd <- choldrop(R0,k)
range(Rd-chol(A[-k,-k]))
Rd;chol(A[-k,-k])

## same but using lower triangular factor A = LL'
L <- t(R0)
Ld <- choldrop(L,k)
range(Ld-t(chol(A[-k,-k])))
Ld;t(chol(A[-k,-k]))

## Rank one update example
u <- runif(n)
R <- cholup(R0,u,TRUE)
Ru <- chol(A+u %*% t(u)) ## direct for comparison
R;Ru
range(R-Ru)

## Downdate - just going back from R to R0
Rd <- cholup(R,u,FALSE)
```
choose.k

Basis dimension choice for smooths

Description

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size, k. When setting up models in the mgcv package, using s or te terms in a model formula, k must be chosen: the defaults are essentially arbitrary.

In practice k-1 (or k) sets the upper limit on the degrees of freedom associated with an s smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For te smooths the upper limit of the degrees of freedom is given by the product of the k values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the fx=TRUE option, in which case it is unpenalized.

So, exact choice of k is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of k informally. If the effective degrees of freedom for a model term are estimated to be much less than k-1 then this is unlikely to be very worthwhile, but as the EDF approach k-1, checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased k to see if there is pattern in the residuals that could potentially be explained by increasing k. Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect k and refit the original model. If there are no statistically important changes as a result of doing this, then k was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when k is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

gam.check runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which k is too low. Grossly too small k will also be visible from partial residuals available with plot.gam.

One scenario that can cause confusion is this: a model is fitted with k=10 for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with k=20 and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with k=20 contains a larger subspace of functions with EDF 8.7 than did the function space with k=10: one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

       data=dat,method="REML")
b

# edf substantially up, -ve REML substantially down
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
       data=dat,method="REML")
b

# slight edf increase and -ve REML change
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
       data=dat,method="REML")
b

# definitely stabilized (but really k around 20 would have been fine)

columb

Reduced version of Columbus OH crime data

Description

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

Usage

data(columb)
data(columb.polys)
concurvity

Format

columb is a 49 row data frame with the following columns

area  land area of district
home.value   housing value in 1000USD.
income  household income in 1000USD.
crime  residential burglaries and auto thefts per 1000 households.
open.space  measure of open space in district.
district  code identifying district, and matching names(columb.polys).

columb.polys contains the polygons defining the areas in the format described below.

Details

The data frame columb relates to the districts whose boundaries are coded in columb.polys. columb.polys[[i]] is a 2 column matrix, containing the vertices of the polygons defining the boundary of the ith district. columb.polys[[2]] has an artificial hole inserted to illustrate how holes in districts can be specified. Different polygons defining the boundary of a district are separated by NA rows in columb.polys[[1]], and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). names(columb.polys) matches columb$district (order unimportant).

Source

The data are adapted from the columbus example in the spdep package, where the original source is given as:

Examples

## see ?mrf help files

<table>
<thead>
<tr>
<th>concurvity</th>
<th>GAM concurvity measures</th>
</tr>
</thead>
</table>

Description

Produces summary measures of concurvity between gam components.

Usage

concurvity(b,full=TRUE)

Arguments

b  An object inheriting from class "gam".
full  If TRUE then concurvity of each term with the whole of the rest of the model is considered. If FALSE then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered.
Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term, \( f \), in the model can be decomposed into a part, \( g \), that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term’s own space. If \( g \) makes up a large part of \( f \) then there is a concurvity problem. The indices used are all based on the square of \( \|g\|/\|f\| \), that is the ratio of the squared Euclidean norms of the vectors of \( f \) and \( g \) evaluated at the observed covariate values.

The three measures are as follows

- **worst** This is the largest value that the square of \( \|g\|/\|f\| \) could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.
- **observed** This just returns the value of the square of \( \|g\|/\|f\| \) according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.
- **estimate** This is the squared F-norm of the basis for \( g \) divided by the F-norm of the basis for \( f \). It is a measure of the extent to which the \( f \) basis can be explained by the \( g \) basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.

**Value**

If `full=TRUE` a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If `full=FALSE` a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

**Examples**

```
library(mgcv)
## simulate data with concurvity...
set.seed(8);n<- 200
f2 <- function(x) 0.2 * x^11 + (10 * (1 - x))^6 + 10 * 
(10 + x)^3 * (1 - x)^10

## make covariate x a smooth function of t + noise...
```
```r
x <- f2(t) + rnorm(n)*3
## simulate response dependent on t and x...
y <- sin(4*pi*t) + exp(x/20) + rnorm(n)*.3
## fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")
## assess concurvity between each term and `rest of model'...
concurvity(b)
## ... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)
```

---

**Description**

The `cox.ph` family implements the Cox Proportional Hazards model with Peto’s correction for ties, optional stratification, and estimation by penalized partial likelihood maximization, for use with `gam`. In the model formula, event time is the response. Under stratification the response has two columns: time and a numeric index for stratum. The `weights` vector provides the censoring information (0 for censoring, 1 for event). `cox.ph` deals with the case in which each subject has one event/censoring time and one row of covariate values. When each subject has several time dependent covariates see `cox.pht`.

See example below for conditional logistic regression.

**Usage**

```r
cox.ph(link="identity")
```

**Arguments**

- `link` currently (and possibly for ever) only "identity" supported.

**Details**

Used with `gam` to fit Cox Proportional Hazards models to survival data. The model formula will have event/censoring times on the left hand side and the linear predictor specification on the right hand side. Censoring information is provided by the `weights` argument to `gam`, with 1 indicating an event and 0 indicating censoring.

Stratification is possible, allowing for different baseline hazards in different strata. In that case the response has two columns: the first is event/censoring time and the second is a numeric stratum index. See below for an example.

Prediction from the fitted model object (using the `predict` method) with `type="response"` will predict on the survivor function scale. This requires evaluation times to be provided as well as covariates (see example). Also see example code below for extracting the cumulative baseline hazard/survival directly. The `fitted.values` stored in the model object are survival function estimates for each subject at their event/censoring time.
deviance, martingale, score, or schoenfeld residuals can be extracted. See Klein and Moeschberger (2003) for descriptions. The score residuals are returned as a matrix of the same dimension as the model matrix, with a "terms" attribute, which is a list indicating which model matrix columns belong to which model terms. The score residuals are scaled. For parametric terms this is by the standard deviation of associated model coefficient. For smooth terms the sub matrix of score residuals for the term is postmultiplied by the transposed Cholesky factor of the covariance matrix for the term's coefficients. This is a transformation that makes the coefficients approximately independent, as required to make plots of the score residuals against event time interpretable for checking the proportional hazards assumption (see Klein and Moeschberger, 2003, p376). Penalization causes drift in the score residuals, which is also removed, to allow the residuals to be approximately interpreted as unpenalized score residuals. Schoenfeld and score residuals are computed by strata. See the examples for simple PH assumption checks by plotting score residuals, and Klein and Moeschberger (2003, section 11.4) for details. Note that high correlation between terms can undermine these checks.

Estimation of model coefficients is by maximising the log-partial likelihood penalized by the smoothing penalties. See e.g. Hastie and Tibshirani, 1990, section 8.3. for the partial likelihood used (with Peto’s approximation for ties), but note that optimization of the partial likelihood does not follow Hastie and Tibshirani. See Klein and Moeschberger (2003) for estimation of residuals, the cumulative baseline hazard, survival function and associated standard errors (the survival standard error expression has a typo).

The percentage deviance explained reported for Cox PH models is based on the sum of squares of the deviance residuals, as the model deviance, and the sum of squares of the deviance residuals when the covariate effects are set to zero, as the null deviance. The same baseline hazard estimate is used for both.

This family deals efficiently with the case in which each subject has one event/censoring time and one row of covariate values. For studies in which there are multiple time varying covariate measures for each subject then the equivalent Poisson model should be fitted to suitable pseudodata using bam(..., discrete=TRUE). See cox.pht.

Value

An object inheriting from class general.family.

t[ii] <- 1.5 + rexp(sum(ii),h1[ii]); d <- as.numeric(t<20)

b <- gam(t~s(x0)+s(x1)+s(x2)+s(x3),family=cox.ph,weights=d)
plot(b,pages=1)
ph.resid(b) ## The checking plot picks up the problem in s(x2)
```

## conditional logistic regression models are often estimated using the
## Cox proportional hazards partial likelihood with a strata for each
## case-control group. A dummy vector of times is created (all equal).
## The following compares to ‘clogit’ for a simple case. Note that
## the gam log likelihood is not exact if there is more than one case
## per stratum, corresponding to clogit’s approximate method.

```r
library(survival);library(mgcv)
infert$dumt <- rep(1,nrow(infert))
mg <- gam(cbind(dumt,stratum) ~ spontaneous + induced, data=infert,
          family=cox.ph,weights=case)
ms <- clogit(case ~ spontaneous + induced + strata(stratum), data=infert,
             method="approximate")
summary(mg)$p.table[1:2,]; ms
```

---

**Additive Cox proportional hazard models with time varying covariates**

**Description**

The `cox.ph` family only allows one set of covariate values per subject. If each subject has several time varying covariate measurements then it is still possible to fit a proportional hazards regression model, via an equivalent Poisson model. The recipe is provided by Whitehead (1980) and is equally valid in the smooth additive case. Its drawback is that the equivalent Poisson dataset can be quite large.

The trick is to generate an artificial Poisson observation for each subject in the risk set at each non-censored event time. The corresponding covariate values for each subject are whatever they are at the event time, while the Poisson response is zero for all subjects except those experiencing the event at that time (this corresponds to Peto’s correction for ties). The linear predictor for the model must include an intercept for each event time (the cumulative sum of the exponential of these is the Breslow estimate of the baseline hazard).

Below is some example code employing this trick for the `pbcseq` data from the `survival` package. It uses `bam` for fitting with the `discrete=TRUE` option for efficiency: there is some approximation involved in doing this, and the exact equivalent to what is done in `cox.ph` is rather obtained by using `gam` with `method="REML"` (taking some 14 times the computational time for the example below).

The function `tdpois` in the example code uses crude piecewise constant interpolation for the covariates, in which the covariate value at an event time is taken to be whatever it was the previous time that it was measured. Obviously more sophisticated interpolation schemes might be preferable.

**cSplineDes**

*Evaluate cyclic B spline basis*

**Description**

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.

**Usage**

```r
cSplineDes(x, knots, ord = 4, derivs=0)
```

**Arguments**

- `x` covariate values for smooth.
- `knots` The knot locations: the range of these must include all the data.
- `ord` order of the basis. 4 is a cubic spline basis. Must be >1.
- `derivs` order of derivative of the spline to evaluate, between 0 and ord-1. Recycled to length of x.

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with length(x) rows and length(knots)-1 columns.

dDeta Obtaining derivative w.r.t. linear predictor

Description

INTERNAL function. Distribution families provide derivatives of the deviance and link w.r.t. mu = inv_link(eta). This routine converts these to the required derivatives of the deviance w.r.t. eta, the linear predictor.

Usage

dDeta(y, mu, wt, theta, fam, deriv = 0)

Arguments

y vector of observations.
mu if eta is the linear predictor, mu = inv_link(eta). In a traditional GAM mu=E(y).
wt vector of weights.
theta vector of family parameters that are not regression coefficients (e.g. scale parameters).

fam the family object.

deriv the order of derivative of the smoothing parameter score required.

Value

A list of derivatives.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for vis.gam and plot.gam.

Usage

exclude.too.far(g1, g2, d1, d2, dist)

Arguments

g1 co-ordinates of grid relative to first axis.

g2 co-ordinates of grid relative to second axis.
d1 co-ordinates of data relative to first axis.
d2 co-ordinates of data relative to second axis.
dist how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and dist is a distance within this unit square.

Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in g1 and g2 lies exactly in the unit square (i.e. on [0,1] by [0,1]). These scalings are applied to g1, g2, d1 and d2. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than dist the corresponding entry in the returned array is set to TRUE (otherwise to FALSE). The distance calculations are performed in compiled code for speed without storage overheads.

Value

A logical array with TRUE indicating a node in the grid defined by g1, g2 that is ‘too far’ from any datum.

plot(gx[!tf],gy[!tf],pch=".");points(x,y,col=2)
```

extract.lme.cov

```
extract.lme.cov
Extract the data covariance matrix from an lme object
```

Description

This is a service routine for `gamm`. Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

Usage

```r
extract.lme.cov(b, data=NULL, start.level=1)
extract.lme.cov2(b, data=NULL, start.level=1)
```

Arguments

- `b` A fitted model object returned by a call to `lme`.
- `data` The data frame/model frame that was supplied to `lme`, but with any rows removed by the na action dropped. Uses the data stored in the model object if not supplied.
- `start.level` The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.
Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extracts that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The extract.lme.cov calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. extract.lme.cov2 is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

gamm uses extract.lme.cov2.

extract.lme.cov does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. extract.lme.cov2 does deal with this situation.

Value

For extract.lme.cov an estimated covariance matrix.

For extract.lme.cov2 a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

\section*{Description}

As well as the standard families documented in \texttt{family} (see also \texttt{glm}) which can be used with functions \texttt{gam}, \texttt{bam} and \texttt{gamm}, \texttt{mgcv} also supplies some extra families, most of which are currently only usable with \texttt{gam}, although some can also be used with \texttt{bam}. These are described here.

\section*{Details}

The following families are in the exponential family given the value of a single parameter. They are usable with all modelling functions.

- \texttt{Tweedie} An exponential family distribution for which the variance of the response is given by the mean response to the power $p$. $p$ is in $(1,2)$ and must be supplied. Alternatively, see \texttt{tw} to estimate $p$ (\texttt{gam} only).
- \texttt{negbin} The negative binomial. Alternatively see \texttt{nb} to estimate the theta parameter of the negative binomial (\texttt{gam} only).

The following families are for regression type models dependent on a single linear predictor, and with a log likelihood which is a sum of independent terms, each corresponding to a single response observation. Usable with \texttt{gam}, with smoothing parameter estimation by "REML" or "ML" (the latter does not integrate the unpenalized and parameteric effects out of the marginal likelihood optimized for the smoothing parameters). Also usable with \texttt{bam}.

- \texttt{ocat} for ordered categorical data.
- \texttt{tw} for Tweedie distributed data, when the power parameter relating the variance to the mean is to be estimated.
- \texttt{nb} for negative binomial data when the theta parameter is to be estimated.
- \texttt{betar} for proportions data on (0,1) when the binomial is not appropriate.
- \texttt{scat} scaled t for heavy tailed data that would otherwise be modelled as Gaussian.
- \texttt{ziP} for zero inflated Poisson data, when the zero inflation rate depends simply on the Poisson mean.

The following families implement more general model classes. Usable only with \texttt{gam} and only with REML smoothing parameter estimation.

- \texttt{cox.ph} the Cox Proportional Hazards model for survival data.
- \texttt{gammals} a gamma location-scale model, where the mean and standard deviation are modelled with separate linear predictors.
- \texttt{gaulss} a Gaussian location-scale model where the mean and the standard deviation are both modelled using smooth linear predictors.
- \texttt{gevlss} a generalized extreme value (GEV) model where the location, scale and shape parameters are each modelled using a linear predictor.
- \texttt{gumbls} a Gumbel location-scale model (2 linear predictors).
• **shash** Sinh-arcsinh location scale and shape model family (4 linear predictors).
• **ziplss** a ‘two-stage’ zero inflated Poisson model, in which ‘potential-presence’ is modelled with one linear predictor, and Poisson mean abundance given potential presence is modelled with a second linear predictor.
• **mvn**: multivariate normal additive models.
• **multinom**: multinomial logistic regression, for unordered categorical responses.

**FFdes**

*Level 5 fractional factorial designs*

**Description**

Computes level 5 fractional factorial designs for up to 120 factors using the algorithm of Sanchez and Sanchez (2005), and optionally central composite designs.

**Usage**

`FFdes(size=5,ccd=FALSE)`

**Arguments**

- **size**: number of factors up to 120.
- **ccd**: if TRUE, adds points along each axis at the same distance from the origin as the points in the fractional factorial design, to create the outer points of a central composite design. Add central points to complete.

**Details**

Basically a translation of the code provided in the appendix of Sanchez and Sanchez (2005).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

FFdes(5)
FFdes(5,TRUE)
```

---

**fix.family.link**  Modify families for use in GAM fitting and checking

**Description**

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.

**Usage**

```r
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)
```

**Arguments**

- `fam`  A family.

**Details**

Consider the first 3 function first.

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions `dvar`, `d2var`, `d3var`, `d2link`, `d3link`, `d4link` and for RE/ML `ls`, then these functions simply return the family unmodified: this allows non-standard links to be used with `gam` when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then `d4link` and `d3var` can be dummy, as they are ignored. Similarly `ls` is only needed for RE/ML.

The `dvar` function is a function of a mean vector, `mu`, and returns a vector of corresponding first derivatives of the family variance function. The `d2link` function is also a function of a vector of mean values, `mu`: it returns a vector of second derivatives of the link, evaluated at `mu`. Higher derivatives are defined similarly.
If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var` function if your family only requires links that occur in one of the standard families. The second two functions are useful for investigating the distribution of residuals and are used by `qq.gam`. If possible the functions add quantile (`qf`) or random deviate (`rd`) generating functions to the family. If a family already has `qf` or `rd` functions then it is left unmodified. `qf` functions are only available for some families, and for quasi families neither type of function is available.

**Value**

A family object with extra component functions `dvar`, `d2var`, `d2link`, `d3link`, `d4link`, `ls`, and possibly `qf` and `rd`, depending on which functions are called. `fix.family.var` also adds a variable `scale` set to negative to indicate that family has a free scale parameter.

**fixDependence**

*Detect linear dependencies of one matrix on another*

**Description**

Identifies columns of a matrix `X2` which are linearly dependent on columns of a matrix `X1`. Primarily of use in setting up identifiability constraints for nested GAMs.

**Usage**

```r
fixDependence(X1, X2, tol = .Machine$double.eps^.5, rank.def = 0, strict = FALSE)
```

**Arguments**

- `X1` A matrix.
- `X2` A matrix, the columns of which may be partially linearly dependent on the columns of `X1`.
- `tol` The tolerance to use when assessing linear dependence.
- `rank.def` If the degree of rank deficiency in `X2`, given `X1`, is known, then it can be supplied here, and `tol` is then ignored. Unused unless positive and not greater than the number of columns in `X2`.
- `strict` if `TRUE` then only columns individually dependent on `X1` are detected, if `FALSE` then enough columns to make the reduced `X2` full rank and independent of `X1` are detected.

**Details**

The algorithm uses a simple approach based on QR decomposition: see Wood (2017, section 5.6.3) for details.
Value
A vector of the columns of X2 which are linearly dependent on columns of X1 (or which need to be deleted to achieve independence and full rank if strict==FALSE). NULL if the two matrices are independent.

fixDependence(X1,X2,strict=TRUE)

formula.gam  GAM formula

Description
Description of gam formula (see Details), and how to extract it from a fitted gam object.

Usage
## S3 method for class 'gam'
formula(x,...)

Arguments
x  fitted model objects of class gam (see gamObject) as produced by gam().
...  un-used in this case

Details
gam will accept a formula or, with some families, a list of formulae. Other mgcv modelling functions will not accept a list. The list form provides a mechanism for specifying several linear predictors, and allows these to share terms: see below.

The formulae supplied to gam are exactly like those supplied to glm except that smooth terms, s, te, ti and t2 can be added to the right hand side (and . is not supported in gam formulae).

Smooth terms are specified by expressions of the form:
s(x1,x2,...,k=12,fx=FALSE,bs="tp",by=z,id=1)
where $x_1$, $x_2$, etc. are the covariates which the smooth is a function of, and $k$ is the dimension of the basis used to represent the smooth term. If $k$ is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for $k$, but if not informal checking is easy: see choose.k and gam.check.

fx is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by $k$ (almost always $k-1$). bs indicates the basis to use for the smooth: the built in options are described in smooth.terms, and user defined smooths can be added (see user.defined.smooth). If bs is not supplied then the default “tp” (tp.s) basis is used. by can be used to specify a variable by which the smooth should be multiplied. For example gam(y~s(x,by=z)) would specify a model $E(y) = f(x)z$ where $f(\cdot)$ is a smooth function. The by option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for ‘varying coefficient models’: see gam.models. id is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

te(x,z,bs=c("tp","tp"),m=c(2,3),k=c(5,10))

which would specify a tensor product smooth of the two covariates x and z constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. te provides further information. ti terms are a variant designed to be used as interaction terms when the main effects (and any lower order interactions) are present. t2 produces tensor product smooths that are the natural low rank analogue of smoothing spline anova models.

s, te, ti and t2 terms accept an sp argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If sp is supplied then it over-rides whatever is in the sp argument to gam, if it is not supplied then it defaults to all negative, but does not over-ride the sp argument to gam.

Formulae can involve nested or “overlapping” terms such as y~s(x)+s(z)+s(x,z) or y~s(x,z)+s(z,v) but nested models should really be set up using ti terms: see gam.side for further details and examples.

Smooth terms in a gam formula will accept matrix arguments as covariates (and corresponding by variable), in which case a ‘summation convention’ is invoked. Consider the example of s(X,Z,by=L) where X, Z and L are n by m matrices. Let F be the n by m matrix that results from evaluating the smooth at the values in X and Z. Then the contribution to the linear predictor from the term will be rowSums(F*L) (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see linear.functional.terms for more information and examples (including functional linear models/signal regression).

Note that gam allows any term in the model formula to be penalized (possibly by multiple penalties), via the paraPen argument. See gam.models for details and example code.

When several formulae are provided in a list, then they can be used to specify multiple linear predictors for families for which this makes sense (e.g. mvn). The first formula in the list must include a response variable, but later formulae need not (depending on the requirements of the family). Let the linear predictors be indexed, 1 to d where d is the number of linear predictors, and the indexing is in the order in which the formulae appear in the list. It is possible to supply extra formulae specifying that several linear predictors should share some terms. To do this a formula is supplied in which the response is replaced by numbers specifying the indices of the linear predictors which will share the terms specified on the r.h.s. For example 1+3~s(x)+z-1 specifies that linear
predictors 1 and 3 will share the terms \( s(x) \) and \( z \) (but we don’t want an extra intercept, as this would usually be unidentifiable). Note that it is possible that a linear predictor only includes shared terms: it must still have its own formula, but the r.h.s. would simply be \(-1\) (e.g. \( y \sim -1 \) or \( \sim -1 \)).

**Value**

Returns the model formula, \( x \texttt{formula} \). Provided so that \texttt{anova} methods print an appropriate description of the model.

**WARNING**

A \texttt{gam} formula should not refer to variables using e.g. \texttt{dat["x"]}.

\texttt{gam}

---

**formXtViX**

*Form component of GAMM covariance matrix*

**Description**

This is a service routine for \texttt{gamm}. Given, \( V \), an estimated covariance matrix obtained using \texttt{extract.lme.cov2} this routine forms a matrix square root of \( X^T V^{-1} X \) as efficiently as possible, given the structure of \( V \) (usually sparse).

**Usage**

\texttt{formXtViX(V,X)}

**Arguments**

\begin{itemize}
  \item \( V \) A data covariance matrix list returned from \texttt{extract.lme.cov2}
  \item \( X \) A model matrix.
\end{itemize}

**Details**

The covariance matrix returned by \texttt{extract.lme.cov2} may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix, \( R \) such that \texttt{crossprod(R)} gives \( X^T V^{-1} X \).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

Examples

```r
require(mgcv)
library(nlme)
data(ergoStool)
b <- lme(effort ~ Type, data=ergoStool, random=~1|Subject)
V1 <- extract.lme.cov(b, ergoStool)
V2 <- extract.lme.cov2(b, ergoStool)
X <- model.matrix(b, data=ergoStool)
crossprod(formXtViX(V2, X))
t(X)
```

---

**fs.test**

*FELSPLINE test function*

Description

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

Usage

```r
fs.test(x,y,r0=.1,r=.5,l=3,b=1,exclude=TRUE)
fs.boundary(r0=.1,r=.5,l=3,n.theta=20)
```

Arguments

- `x, y`: Points at which to evaluate the test function.
- `r0`: The test domain is a sort of bent sausage. This is the radius of the inner bend.
- `r`: The radius of the curve at the centre of the sausage.
- `l`: The length of an arm of the sausage.
- `b`: The rate at which the function increases per unit increase in distance along the centre line of the sausage.
- `exclude`: Should exterior points be set to NA?
- `n.theta`: How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve.
Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

Value

fs_test returns function evaluations, or NAs for points outside the boundary. fs_boundary returns a list of x, y points to be jointed up in order to define/draw the boundary.

Examples

```r
require(mgcv)
## plot the function, and its boundary...
fsb <- fs_boundary()
m<-300;n<-150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsb$x,fsb$y,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```
Arguments

sp  The logs of the smoothing parameters
G  a list returned by mgcv:::gam.setup
family  The family object for the GAM.
control  a list returned be gam.control
gamma  the degrees of freedom inflation factor (usually 1).
...  other arguments, typically for passing on to gam.fit.

Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by gam.fit.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

gam  Generalized additive models with integrated smoothness estimation

Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM and a variety of other models estimated by a quadratically penalised likelihood type approach (see family.mgcv). The degree of smoothness of model terms is estimated as part of fitting. gam can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Confidence/credible intervals are readily available for any quantity predicted using a fitted model.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate), and users can add smooths. Linear functionals of smooths can also be included in models. For an overview of the smooths available see smooth.terms. For more on specifying models see gam.models, random.effects and linear.functional.terms. For more on model selection see gam.selection. Do read gam.check and choose.k.

See package gam, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see bam, for mixed GAM see gamm and random.effects.

Usage

gam(formula,family=gaussian(),data=list(),weights=NULL,subset=NULL, na.action,offset=NULL,method="GCV.Cp", optimizer=c("outer","newton"),control=list(),scale=0, select=FALSE,knots=NULL,sp=NULL,min.sp=NULL,H=NULL,gamma=1, fit=TRUE,paraPen=NULL,G=NULL,in.out,drop.unused.levels=TRUE, drop.intercept=NULL,discrete=FALSE,...)
Arguments

formula A GAM formula, or a list of formulae (see formula.gam and also gam.models).
These are exactly like the formula for a GLM except that smooth terms, s, te, ti and t2, can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).

family This is a family object specifying the distribution and link to use in fitting etc (see glm and family). See family.mgcv for a full list of what is available, which goes well beyond exponential family. Note that quasi families actually result in the use of extended quasi-likelihood if method is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6).

data A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from environment(formula): typically the environment from which gam is called.

weights prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to re-weight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. weights <- weights/mean(weights)).

subset an optional vector specifying a subset of observations to be used in the fitting process.

na.action a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.

offset Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula (this used to conform to the behaviour of lm and glm).

control A list of fit control parameters to replace defaults returned by gam.control. Values not set assume default values.

method The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows’ Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Beyond the exponential family "REML" is the default, and the only other option is "ML".

optimizer An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by method). "perf" (deprecated) for performance iteration. "outer" for the more stable direct approach. "outer" can use several alternative optimizers, specified in the second element of optimizer: "newton" (default), "bfgs", "optim", "nlm" and "nlm.fd" (the latter is based entirely on finite differenced derivatives and is very slow). "efs" for the extended Fellner Schall method of Wood and Fasiolo (2017).

scale If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.

select If this is TRUE then gam can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding
smoothing parameter is estimated as zero then the extra penalty has no effect. Use \textit{gamma} to increase level of penalization.

\textbf{knots}  
this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the $k$ value supplied (note that the number of knots is not always just $k$). See \textit{tprs} for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

\textbf{sp}  
A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then $\text{length(sp)}$ must correspond to the number of underlying smoothing parameters.

\textbf{min.sp}  
Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters \texttt{full.sp}, in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. $\text{length(min.sp)}$ should always be the same as the total number of penalties (so it may be longer than \texttt{sp}, if smooths share smoothing parameters).

\textbf{H}  
A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.

\textbf{gamma}  
Increase this beyond 1 to produce smoother models. \textit{gamma} multiplies the effective degrees of freedom in the GCV or UBRE/AIC. \texttt{coden/gamma} can be viewed as an effective sample size in the GCV score, and this also enables it to be used with REML/ML. Ignored with P-RE/ML or the \texttt{efs} optimizer.

\textbf{fit}  
If this argument is \texttt{TRUE} then \texttt{gam} sets up the model and fits it, but if it is \texttt{FALSE} then the model is set up and an object \texttt{G} containing what would be required to fit is returned is returned. See argument \texttt{G}.

\textbf{paraPen}  
onoptional list specifying any penalties to be applied to parametric model terms. \texttt{gam.models} explains more.

\textbf{G}  
Usually \texttt{NULL}, but may contain the object returned by a previous call to \texttt{gam} with \texttt{fit=FALSE}, in which case all other arguments are ignored except for \texttt{sp}, \texttt{gamma}, \texttt{in.out}, \texttt{scale}, \texttt{control}, \texttt{method optimizer} and \texttt{fit}.

\textbf{in.out}  
onoptional list for initializing outer iteration. If supplied then this must contain two elements: \texttt{sp} should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); \texttt{scale} is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the the initial value of the scale parameter, if this is to be estimated by RE/ML.

\textbf{drop.unused.levels}  
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

\textbf{drop.intercept}  
Set to \texttt{TRUE} to force the model to really not have the a constant in the parametric model part, even with factor variables present. Can be vector when \texttt{formula} is a list.
Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = \alpha + f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables $y_i \sim \text{Poi}$, and $f_1$ and $f_2$ are smooth functions of covariates $x_1$ and $x_2$. The log is an example of a link function. Note that to be identifiable the model requires constraints on the smooth functions. By default these are imposed automatically and require that the function sums to zero over the observed covariate values (the presence of a metric by variable is the only case which usually suppresses this).

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex over-fitting estimates of $f_1$ and $f_2$. For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggliness’. To control the trade-off between penalizing wiggliness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The mgcv implementation of gam represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

gam in mgcv solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where $D$ is the deviance, $n$ the number of data, $s$ the scale parameter and $DoF$ the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when $s$ is known.

Alternatives are GACV, or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice. The main computational challenge solved by the mgcv package is to optimize the smoothness selection criteria efficiently and reliably.

Broadly gam works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (design matrix) and a set of penalty matrices for the smooth terms. The linear identifiability constraints are also obtained at this point. The model is fit using gam.fit, gam.fit3 or variants, which are modifications of glm.fit. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Re-weighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is possible in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS step a working penalized linear model is estimated, and the smoothing parameter
estimation can be performed for each such working model. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. This option is available in bam and gamm but is deprecated for gam.

(ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and gam.fit3 or one of its variants is used in place of gam.fit. gam uses the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see smooth.terms for an overview and smooth.construct for how to add smooth classes). The choice of the basis dimension (k in the s, te, ti and t2 terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by k-1 or occasionally k). Of course the \( k \) should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that gam assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end gam allows the non smooth model components to be penalized via argument paraPen and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in linear.functional.terms. link{family.mgcv} details what is available beyond GLMs and the exponential family.

Details of the default underlying fitting methods are given in Wood (2011 and 2004). Some alternative methods are discussed in Wood (2000 and 2006).

gam() is not a clone of Trevor Hastie’s original (as supplied in S-PLUS or package gam). The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no lo smooths, but instead (a) s terms can have more than one argument, implying an isotropic smooth and (b) te, ti or t2 smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. (vii) Models beyond the exponential family are available. See package gam, for GAMs via the original Hastie and Tibshirani approach.

**Value**

If fit=FALSE the function returns a list \( G \) of items needed to fit a GAM, but doesn’t actually fit it. Otherwise the function returns an object of class "gam" as described in gamObject.

**WARNINGS**

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See choose.k and gam.check.

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.
For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

Front end design inspired by the S function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

---

**Description**

Takes a fitted gam object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate. Care should be taken in interpreting the results when applied to gam objects returned by `gamm`.

**Usage**

```r
gam.check(b, old.style=FALSE,
        type=c("deviance","pearson","response"),
        k.sample=5000,k.rep=200,
        rep=0, level=.9, rl.col=2, rep.col="gray80", ...)
```

---

**Some diagnostics for a fitted gam model**
Arguments

- **b**: a fitted `gam` object as produced by `gam()`.
- **old.style**: If you want old fashioned plots, exactly as in Wood, 2006, set to `TRUE`.
- **type**: type of residuals, see `residuals.gam`, used in all plots.
- **k.sample**: Above this k testing uses a random sub-sample of data.
- **k.rep**: how many re-shuffles to do to get p-value for k testing.
- **rep, level, rl.col, rep.col**: arguments passed to `qq.gam()` when `old.style` is false, see there.
- **...**: extra graphics parameters to pass to plotting functions.

Details

Checking a fitted `gam` is like checking a fitted `glm`, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. `choose.k` provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the k-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled k.rep times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than k.sample data, the tests are based of k.sample randomly sampled data. Low p-values may indicate that the basis dimension, k, has been set too low, especially if the reported edf is close to k’, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect k and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low k. See `choose.k` for fuller discussion.

The QQ plot produced is usually created by a call to `qq.gam`, and plots deviance residuals against approximate theoretical quantilies of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using `qq.gam`. Note that residuals for models fitted to
binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

Take care when interpreting results from applying this function to a model fitted using `gamm`. In this case the returned `gam` object is based on the working model used for estimation, and will treat all the random effects as part of the error. This means that the residuals extracted from the `gam` object are not standardized for the family used or for the random effects or correlation structure. Usually it is necessary to produce your own residual checks based on consideration of the model structure you have used.

**Value**

A vector of reference quantiles for the residual distribution, if these can be computed.

**References**

https://www.maths.ed.ac.uk/~swood34/

**See Also**

`choose.k`, `gam`, `magic`

**Examples**

```r
library(mgcv)
set.seed(8)
dat <- gamSim(1, n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
gam.check(b,pch=19,cex=.3)
```

---

**Description**

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see `gam` arguments `method` and `optimizer`.
Usage

gam.control(nthreads=1,irls.reg=0.0,epsilon = 1e-07, maxit = 200,
mgcv.tol=1e-7,mgcv.half=15, trace = FALSE,
rank.tol=.Machine$double.eps^0.5,nlm=list(),
optim=list(),newton=list(),outerPIsteps=0,
idLinksBases=TRUE, scalePenalty=TRUE, efs.lspmax=15,
es.tol=.1,keepData=FALSE, scale.est="fletcher",
edge.correct=FALSE)

Arguments

nthreads Some parts of some smoothing parameter selection methods (e.g. REML) can use some parallelization in the C code if your R installation supports openMP, and nthreads is set to more than 1. Note that it is usually better to use the number of physical cores here, rather than the number of hyper-threading cores.

irls.reg For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and irls.reg is the size of the penalty.

epsilon This is used for judging conversion of the GLM IRLS loop in gam.fit or gam.fit3.

maxit Maximum number of IRLS iterations to perform.

gmcv.tol The convergence tolerance parameter to use in GCV/UBRE optimization.

mgcv.half If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.

trace Set this to TRUE to turn on diagnostic output.

rank.tol The tolerance used to estimate the rank of the fitting problem.

nlm list of control parameters to pass to nlm if this is used for outer estimation of smoothing parameters (not default). See details.

optim list of control parameters to pass to optim if this is used for outer estimation of smoothing parameters (not default). See details.

newton list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.

outerPIsteps The number of performance iteration steps used to initialize outer iteration.

idLinksBases If smooth terms have their smoothing parameters linked via the id mechanism (see s), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set scalePenalty to FALSE as well in this case).

scalePenalty gamm is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accommodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set idLinksBases to FALSE.
**gam.control**

**efs.lspmax**  
maximum log smoothing parameters to allow under extended Fellner Schall smoothing parameter optimization.

**efs.tol**  
change in REML to count as negligible when testing for EFS convergence. If the step is small and the last 3 steps led to a REML change smaller than this, then stop.

**keepData**  
Should a copy of the original data argument be kept in the gam object? Strict compatibility with class glm would keep it, but it wastes space to do so.

**scale.est**  
How to estimate the scale parameter for exponential family models estimated by outer iteration. See *gam.scale*.

**edge.correct**  
With RE/ML smoothing parameter selection in gam using the default Newton RE/ML optimizer, it is possible to improve inference at the 'completely smooth' edge of the smoothing parameter space, by decreasing smoothing parameters until there is a small increase in the negative RE/ML (e.g. 0.02). Set to TRUE or to a number representing the target increase to use. Only changes the corrected smoothing parameter matrix, Vc.

**Details**

Outer iteration using *newton* is controlled by the list *newton* with the following elements:  
- **conv.tol** (default 1e-6) is the relative convergence tolerance;  
- **maxNstep** is the maximum length allowed for an element of the Newton search direction (default 5);  
- **maxSstep** is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2);  
- **maxHalf** is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using *nlm* is used for fitting, then the control list *nlm* stores control arguments for calls to routine *nlm*. The list has the following named elements:  
- (i) **ndigit** is the number of significant digits in the GCV/UBRE score - by default this is worked out from epsilon;  
- (ii) **gradtol** is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to 10*epsilon;  
- (iii) **stepmax** is the maximum allowable log smoothing parameter step - defaults to 2;  
- (iv) **steptol** is the minimum allowable step length - defaults to 1e-4;  
- (v) **iterlim** is the maximum number of optimization steps allowed - defaults to 200;  
- (vi) **check.analyticals** indicates whether the built in exact derivative calculations should be checked numerically - defaults to FALSE. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using *optim* is controlled using list *optim*, which currently has one element:  
- **factr** which takes default value 1e7.

*gam*, *gam.fit*, *glm.control*
GAM convergence and performance issues

Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The fitting methods used by \texttt{gam} opt for certainty of convergence over speed of fit. \texttt{bam} opts for speed.

\texttt{gam} uses a nested iteration method (see \texttt{gam.outer}), in which each trial set of smoothing parameters proposed by an outer Newton algorithm require an inner Newton algorithm (penalized iteratively re-weighted least squares, \texttt{PIRLS}) to find the corresponding best fit model coefficients. Implicit differentiation is used to find the derivatives of the coefficients with respect to log smoothing parameters, so that the derivatives of the smoothness selection criterion can be obtained, as required by the outer iteration. This approach is less expensive than it at first appears, since excellent starting values for the inner iteration are available as soon as the smoothing parameters start to converge. See Wood (2011) and Wood, Pya and Saefken (2016).

\texttt{bam} uses an alternative approach similar to ‘performance iteration’ or ‘PQL’. A single \texttt{PIRLS} iteration is run to find the model coefficients. At each step this requires the estimation of a working penalized linear model. Smoothing parameter selection is applied directly to this working model at each step (as if it were a Gaussian additive model). This approach is more straightforward to code and in principle less costly than the nested approach. However it is not guaranteed to converge, since the smoothness selection criterion is changing at each iteration. It is sometimes possible for the algorithm to cycle around a small set of smoothing parameter, coefficient combinations without ever converging. \texttt{bam} includes some checks to limit this behaviour, and the further checks in the algorithm used by \texttt{bam(...,discrete=TRUE)} actually guarantee convergence in some cases, but in general guarantees are not possible. See Wood, Goude and Shaw (2015) and Wood et al. (2017).

\texttt{gam} when used with ‘general’ families (such as \texttt{multinom} or \texttt{cox.ph}) can also use a potentially faster scheme based on the extended Fellner-Schall method (Wood and Fasiolo, 2017). This also operates with a single iteration and is not guaranteed to converge, theoretically.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the “\texttt{bfgs}” method option in \texttt{gam} argument \texttt{optimizer}: this can be faster than the default. (ii) Try using \texttt{bam} (iii) For large datasets it may be worth changing the smoothing basis to use \texttt{bs=“cr”} (see \texttt{s} for details) for 1-d smooths, and to use \texttt{te} smooths in place of \texttt{s} smooths for smooths of more than one variable. This is because the default thin plate regression spline basis ”\texttt{tp}” is costly to set up for large datasets.

If you have convergence problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with \texttt{fx=TRUE} so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing \texttt{maxit} in \texttt{gam.control}, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the \texttt{min.sp} argument of \texttt{gam}: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions \texttt{k} in the specification of \texttt{s} and \texttt{te} model terms: this obviously changes the model being fitted somewhat.

Usually, a major contributer to fitting difficulties is that the model is a very poor description of the data.
Please report convergence problems, especially if you there is no obvious pathology in the data/model that suggests convergence should fail.

gam.fit

GAM P-IRLS estimation with GCV/UBRE smoothness estimation

Description

This is an internal function of package mgcv. It is a modification of the function glm.fit, designed to be called from gam when performance iteration is selected (not the default). The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine magic. For further information on usage see code for gam. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see gam.control). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

Usage

```r
gam.fit(G, start = NULL, etastart = NULL,
 mustart = NULL, family = gaussian(),
 control = gam.control(), gamma=1,
 fixedSteps=(control$maxit+1),...)
```
Arguments

G  An object of the type returned by `gam` when `fit=FALSE`.
start  Initial values for the model coefficients.
etastart  Initial values for the linear predictor.
mustart  Initial values for the expected response.
family  The family object, specifying the distribution and link to use.
control  Control option list as returned by `gam.control`.
gamma  Parameter which can be increased to up the cost of each effective degree of freedom in the GCV or AIC/UBRE objective.
fixedSteps  How many steps to take: useful when only using this routine to get rough starting values for other methods.
...  Other arguments: ignored.

Value

A list of fit information.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

gam.fit3, gam, magic

Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them.
by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for \texttt{gam}.

**Usage**

\[
\text{Usage:} \\
\text{gam.fit3}(x, y, sp, Eb ,UrS=list(), \\
\hspace{1em} \text{weights} \hspace{1em} \text{rep(1, nobs)}, \hspace{1em} \text{start} \hspace{1em} \text{NULL, etastart} \hspace{1em} \text{NULL,} \\
\hspace{1em} \text{mustart} \hspace{1em} \text{NULL, offset} \hspace{1em} \text{rep(0, nobs)}, \hspace{1em} U1 \hspace{1em} \text{diag(ncol(x))}, \\
\hspace{1em} \text{Mp} \hspace{1em} -1, \hspace{1em} \text{family} \hspace{1em} \text{gaussian()}, \hspace{1em} \text{control} \hspace{1em} \text{gam.control()}, \\
\hspace{1em} \text{intercept} \hspace{1em} \text{TRUE, deriv} \hspace{1em} 2, \hspace{1em} \text{gamma} \hspace{1em} 1, \hspace{1em} \text{scale} \hspace{1em} 1, \\
\hspace{1em} \text{printWarn} \hspace{1em} \text{TRUE, scoreType="REML", null.coef} \hspace{1em} \text{rep(0, ncol(x))}, \\
\hspace{1em} \text{pearson.extra} \hspace{1em} 0, \hspace{1em} \text{dev.extra} \hspace{1em} 0, \hspace{1em} \text{n.true} \hspace{1em} -1, \hspace{1em} S1=\text{NULL,}\ldots)
\]

**Arguments**

- **x**: The model matrix for the GAM (or any penalized GLM).
- **y**: The response variable.
- **sp**: The log smoothing parameters.
- **Eb**: A balanced version of the total penalty matrix: used for numerical rank determination.
- **UrS**: List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.
- **weights**: prior weights for fitting.
- **start**: optional starting parameter guesses.
- **etastart**: optional starting values for the linear predictor.
- **mustart**: optional starting values for the mean.
- **offset**: the model offset
- **U1**: An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.
- **Mp**: The dimension of the total penalty null space — required for ML smoothness estimation only.
- **family**: the family - actually this routine would never be called with \texttt{gaussian()}.
- **control**: control list as returned from \texttt{glm.control}.
- **intercept**: does the model have and intercept, \texttt{TRUE} or \texttt{FALSE}.
- **deriv**: Should derivatives of the GCV and UBRE/AIC scores be calculated? \texttt{0}, \texttt{1} or \texttt{2}, indicating the maximum order of differentiation to apply.
- **gamma**: The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.
- **scale**: The scale parameter - needed for the UBRE/AIC score.
- **printWarn**: Set to \texttt{TRUE} to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.
- **scoreType**: specifies smoothing parameter selection criterion to use.
null.coef  coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.

pearson.extra  Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.

dev.extra  Extra component to add to deviance for REML/ML type smoothness selection criteria.

n.true  Number of data to assume in smoothness selection criteria. <=0 indicates that it should be the number of rows of X.

S1  A smooth list suitable for passing to gam.fit5.

...  Other arguments: ignored.

Details

This routine is basically glm.fit with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O’Sullivan et al. (1986), and is here termed ‘outer’ iteration.

Note that use of non-standard families with this routine requires modification of the families as described in fix.family.link.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

The routine has been modified from glm.fit in R 2.0.1, written by the R core (see glm.fit for further credits).

gam.fit, gam, magic
gam.fit5.post.proc  Post-processing output of gam.fit5

Description

INTERNAL function for post-processing the output of gam.fit5.

Usage

gam.fit5.post.proc(object, Sl, L, lsp0, S, off)

Arguments

- object: output of gam.fit5.
- Sl: penalty object, output of Sl.setup.
- L: matrix mapping the working smoothing parameters.
- lsp0: log smoothing parameters.
- S: penalty matrix.
- off: vector of offsets.

Value

A list containing:

- R: unpivoted Choleski of estimated expected hessian of log-likelihood.
- Vb: the Bayesian covariance matrix of the model parameters.
- Ve: "frequentist" alternative to Vb.
- Vc: corrected covariance matrix.
- F: matrix of effective degrees of freedom (EDF).
- edf: diag(F).
- edf2: diag(2F-FF).

Simple posterior simulation with gam fits

Description

GAM coefficients can be simulated directly from the Gaussian approximation to the posterior for the coefficients, or using a simple Metropolis Hastings sampler. See also `ginla`.

Usage

```r
gam.mh(b, ns=10000, burn=1000, t.df=40, rw.scale=.25, thin=1)
```

Arguments

- `b`: a fitted model object from `gam`, `bam` fits are not supported.
- `ns`: the number of samples to generate.
- `burn`: the length of any initial burn in period to discard (in addition to codens).
- `t.df`: degrees of freedom for static multivariate t proposal. Lower for heavier tailed proposals.
- `rw.scale`: Factor by which to scale posterior covariance matrix when generating random walk proposals. Negative or non finite to skip the random walk step.
- `thin`: retain only every `thin` samples.

Details

Posterior simulation is particularly useful for making inferences about non-linear functions of the model coefficients. Simulate random draws from the posterior, compute the function for each draw, and you have a draw from the posterior for the function. In many cases the Gaussian approximation to the posterior of the model coefficients is accurate, and samples generated from it can be treated as samples from the posterior for the coefficients. See example code below. This approach is computationally very efficient.

In other cases the Gaussian approximation can become poor. A typical example is in a spatial model with a log or logit link when there is a large area of observations containing only zeroes. In this case the linear predictor is poorly identified and the Gaussian approximation can become useless (an example is provided below). In that case it can sometimes be useful to simulate from the posterior using a Metropolis Hastings sampler. A simple approach alternates fixed proposals, based on the Gaussian approximation to the posterior, with random walk proposals, based on a shrunken version of the approximate posterior covariance matrix. `gam.mh` implements this. The fixed proposal often promotes rapid mixing, while the random walk component ensures that the chain does not become stuck in regions for which the fixed Gaussian proposal density is much lower than the posterior density.

The function reports the acceptance rate of the two types of step. If the random walk acceptance probability is higher than a quarter then `rw.step` should probably be increased. Similarly if the acceptance rate is too low, it should be decreased. The random walk steps can be turned off altogether (see above), but it is important to check the chains for stuck sections if this is done.

Value

A list containing the retained simulated coefficients in matrix bs and two entries for the acceptance probabilities.

gam.models

**Specifying generalized additive models**

**Description**

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let $y_i$ denote an independent random variable with mean $\mu_i$ and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = X_i \beta + f_1(x_{i1}, x_{i2}) + f_2(x_{i3}) + L_i f_3(x_4) + \ldots$$

where $g$ is a known smooth monotonic ‘link’ function, $X_i \beta$ is the parametric part of the linear predictor, the $x_j$ are predictor variables, the $f_j$ are smooth functions and $L_i$ is some linear functional of $f_3$. There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam` always applies such constraints unless there is a by variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for gam. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.
Models with simple smooth terms

Consider the example model.

\[ g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i}) \]

where the response variables \( y_i \) has expectation \( \mu_i \) and \( g \) is a link function.

The \texttt{gam} formula for this would be

\[ y \sim x1 + x2 + s(x3) + s(x4, x5). \]

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in \texttt{s} and \texttt{te}, and further discussion of basis dimension choice can be found in \texttt{choose.k}. For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

\[ y \sim x1 + x2 + s(x3, bs="\text{cr}", k=20) + s(x4, x5, k=25, fx=\text{TRUE}). \]

The above assumes that \( x_4 \) and \( x_5 \) are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see \texttt{te}).

\[ y \sim x1 + x2 + s(x3) + te(x4, x5) \]

would generate a tensor product smooth of \( x_4 \) and \( x_5 \). By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

\[ y \sim x1 + x2 + s(x3) + te(x4, x5, bs=c("\text{cr}", "\text{ps}") , k=c(6,7)) \]

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

Nested terms/functional ANOVA

Sometimes it is interesting to specify smooth models with a main effects + interaction structure such as

\[ E(y_i) = f_1(x_i) + f_2(z_i) + f_3(x_i, z_i) \]

or

\[ E(y_i) = f_1(x_i) + f_2(z_i) + f_3(v_i) + f_4(x_i, z_i) + f_5(z_i, v_i) + f_6(x_i, v_i) + f_7(x_i, z_i, v_i) \]

for example. Such models should be set up using \texttt{ti} terms in the model formula. For example:

\[ y \sim ti(x) + ti(z) + ti(x, z), \text{ or} \]

\[ y \sim ti(x) + ti(z) + ti(v) + ti(x, z) + ti(x, v) + ti(z, v) + ti(x, z, v). \]

The \texttt{ti} terms produce interactions with the component main effects excluded appropriately. (There is in fact no need to use \texttt{ti} terms for the main effects here, \texttt{s} terms could also be used.)

gam allows nesting (or ‘overlap’) of \texttt{te} and \texttt{s} smooths, and automatically generates side conditions to make such models identifiable, but the resulting models are much less stable and interpretable than those constructed using \texttt{ti} terms.

‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The \texttt{s} and \texttt{te} terms used to specify smooths accept an argument \texttt{by}, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a \texttt{by} variable is numeric, then its \texttt{i}\textsuperscript{th} element multiplies the \texttt{i}\textsuperscript{th} row of the model matrix corresponding to the smooth term concerned.
Factor smooth interactions (see also `factor.smooth.interaction`). If a by variable is a factor then it generates an indicator vector for each level of the factor, unless it is an ordered factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the id argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter). ordered by variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see b3 example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor by variables.

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where $f$ is a smooth function, and $z_i$ is a numeric variable. The appropriate formula is:

$$y \sim s(x, \text{by}=z)$$

- the by argument ensures that the smooth function gets multiplied by covariate $z$. Note that when using factor by variables, centering constraints are applied to the smooths, which usually means that the by variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor by variables.

by variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a by variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the by variable is a constant vector, or, (ii) for a matrix by variable, $L$, if $L%*%rep(1,\text{ncol}(L))$ is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute "always.apply".

### Linking smooths with ‘id’

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the id argument to `s` or `te` terms. Smooths which share an id will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an id have the same basis functions as the first smooth occurring with that id. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that $E(y_i) \equiv \mu_i$ and

$$g(\mu_i) = f_1(x_1i) + f_2(x_2i, x_3i) + f_3(x_4i)$$

but that $f_1$ and $f_3$ should have the same smoothing parameters (and $x_2$ and $x_3$ are on different scales). Then the `gam` formula

$$y \sim s(x_1, \text{id}=1) + \text{te}(x_2, x_3) + s(x_4, \text{id}=1)$$

would achieve the desired result. id can be numbers or character strings. Giving an id to a term with a factor by variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term ids are not supported by `gam`.

### Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic
regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in mgcv using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any by variable matrix must be of the same dimension. Consider, for example the term

\[ s(X, Z, \text{by}=L) \]

where \( X, Z \) and \( L \) are \( n \times p \) matrices. Let \( f \) denote the thin plate regression spline specified. The resulting contribution to the \( i^{th} \) element of the linear predictor is

\[ \sum_{j=1}^{p} L_{ij} f(X_{ij}, Z_{ij}) \]

If no \( L \) is supplied then all its elements are taken as 1. In R code terms, let \( F \) denote the \( n \times p \) matrix obtained by evaluating the smooth at the values in \( X \) and \( Z \). Then the contribution of the term to the linear predictor is \( \text{rowSums}(L \times F) \) (note that it’s element by element multiplication here!).

The summation convention applies to \( \text{te} \) terms as well as \( s \) terms. More details and examples are provided in linear.functional.terms.

Random effects

Random effects can be added to gam models using \( s(...) \text{bs}=\text{"re"} \) terms (see smooth.construct.re.smooth.spec), or the paraPen argument to \( \text{gam} \) covered below. See \( \text{gam.vcomp}, \text{random.effects} \) and \( \text{smooth.construct.re.smooth.spec} \) for further details. An alternative is to use the approach of \( \text{gamm} \).

Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, by variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, \( \text{gam} \) also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix \( X \), and want to penalize the corresponding coefficients, \( \beta \) with two penalties \( \beta^T S_1 \beta \) and \( \beta^T S_2 \beta \). Then something like the following would be appropriate:

\[ \text{gam}(y \sim X - 1, \text{paraPen=list}(X=\text{list}(S1,S2))) \]

The paraPen argument should be a list with elements having names corresponding to the terms being penalized. Each element of paraPen is itself a list, with optional elements \( L \), rank and \( sp \): all other elements must be penalty matrices. If present, rank is a vector giving the rank of each penalty matrix (if absent this is determined numerically). \( L \) is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. \( sp \) is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of paraPen is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated
scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’
example below.
P-values for penalized parametric terms should be treated with caution. If you must have them,
then use the option freq=TRUE in \texttt{anova.gam} and \texttt{summary.gam}, which will tend to give reasonable
results for random effects implemented this way, but not for terms with a rank deficient penalty (or
penalties with a wide eigen-spectrum).

gam.outer

Minimize GCV or UBRE score of a GAM using ‘outer’ iteration

Description

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using newton (default), bfgs, optim or nlm. Exact (first and second) derivatives of the score can be used by fitting with gam.fit3. This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for gam.
Usage

gam.outer(lsp, fscale, family, control, method, optimizer,
    criterion, scale, gamma, G, start=NULL, ...)

Arguments

lsp The log smoothing parameters.
fscale Typical scale of the GCV or UBRE/AIC score.
family the model family.
control control argument to pass to `gam.fit` if pure finite differencing is being used.
method method argument to `gam` defining the smoothness criterion to use (but depending on whether or not scale known).
optimizer The argument to `gam` defining the numerical optimization method to use.
criterion Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".
scale Supplied scale parameter. Positive indicates known.
gamma The degree of freedom inflation factor for the GCV/UBRE/AIC score.
G List produced by `mgcv:::gam.setup`, containing most of what’s needed to actually fit a GAM.
start starting parameter values.
... other arguments, typically for passing on to `gam.fit3` (ultimately).

Details

See Wood (2008) for full details on ‘outer iteration’.

See Also

gam.fit3, gam, magic
Finding stable orthogonal re-parameterization of the square root penalty.

Description

INTERNAL function for finding an orthogonal re-parameterization which avoids "dominant machine zero leakage" between components of the square root penalty.

Usage

gam.reparam(rS, lsp, deriv)

Arguments

rS  list of the square root penalties: last entry is root of fixed penalty, if fixed.penalty==TRUE (i.e. length(rS)>length(sp)). The assumption here is that rS[[1]] are in a null space of total penalty already; see e.g. totalPenaltySpace and mini.roots.

lsp  vector of log smoothing parameters.

deriv  if deriv==1 also the first derivative of the log-determinant of the penalty matrix is returned, if deriv>1 also the second derivative is returned.

Value

A list containing

• S: the total penalty matrix similarity transformed for stability.

• rS: the component square roots, transformed in the same way.

• Qs: the orthogonal transformation matrix $S = t(Qs)\%*%S0\%*%Qs$, where S0 is the untransformed total penalty implied by sp and rS on input.

• det: log|S|.

• det1: dlog|S|/dlog(sp) if deriv>0.

• det2: hessian of log|S| wrt log(sp) if deriv>1.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.
Description

Scale parameter estimation in `gam` depends on the type of `family`. For extended families then the RE/ML estimate is used. For conventional exponential families, estimated by the default outer iteration, the scale estimator can be controlled using argument `scale.est` in `gam.control`. The options are "fletcher" (default), "pearson" or "deviance". The Pearson estimator is the (weighted) sum of squares of the pearson residuals, divided by the effective residual degrees of freedom. The Fletcher (2012) estimator is an improved version of the Pearson estimator. The deviance estimator simply substitutes deviance residuals for Pearson residuals.

Usually the Pearson estimator is recommended for GLMs, since it is asymptotically unbiased. However, it can also be unstable at finite sample sizes, if a few Pearson residuals are very large. For example, a very low Poisson mean with a non-zero count can give a huge Pearson residual, even though the deviance residual is much more modest. The Fletcher (2012) estimator is designed to reduce these problems.

For performance iteration the Pearson estimator is always used.

`gamm` uses the estimate of the scale parameter from the underlying call to `lme`. `bam` uses the REML estimator if the method is "fREML". Otherwise the estimator is a Pearson estimator.

`gam.control`

Description

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.
Smoothness selection criteria

Given a model structure specified by a gam model formula, gam() attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows’ Cp (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The method argument to gam selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these ‘flat’ regions can be separated from regions of lower score by a small ‘lip’. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see gam arguments method and optimizer) and see if the estimates change, or try changing some or all of the smoothing parameters ‘manually’ (argument sp of gam, or sp arguments to s or te).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as ‘completely smooth’ and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby ‘selected out’ of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes cs.smooth and tprs.smooth (specified by "cs" and "ts" respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively ‘completely smooth’ according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the ‘completely smooth’ functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The select argument to gam turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposiong the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as
the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

**Interactive term selection**

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated \( \theta \) parameter is a special case: the GCV score is not informative, because of the \( \theta \) estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by `summary.gam`, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

**Caveats/platitudes**

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn’t fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with ‘everything in’ and hoping that automatic selection will find the right structure is not often successful.

Examples

## an example of automatic model selection via null space penalization
library(mgcv)
set.seed(3);n<-200
dat <- gamSim(1,n=n,scale=.15, dist="poisson") ## simulate data
dat$x4 <- runif(n, 0, 1);dat$x5 <- runif(n, 0, 1) ## spurious
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3)+s(x4)+s(x5),data=dat,
   family=poisson, select=TRUE, method="REML")
summary(b)
plot(b,pages=1)

Description

GAM formulae with repeated variables may only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from mgcv:::gam.setup and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

Usage

gam.side(sm,Xp,tol=.Machine$double.eps^.5,with.pen=FALSE)

Arguments

sm      A list of smooth objects as returned by smooth.construct.
Xp      The model matrix for the strictly parametric model components.
tol     The tolerance to use when assessing linear dependence of smooths.
with.pen Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints.
Details

Models such as $y = s(x) + s(z) + s(x,z)$ can be estimated by \texttt{gam}, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using \texttt{fixDependence}. This makes the routine rather general, and not dependent on any particular basis.

\texttt{Xp} is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute "\texttt{del.index}", listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

WARNINGS

Much better statistical stability will be obtained by using models like $y = s(x) + s(z) + ti(x,z)$ or $y = ti(x) + ti(z) + ti(x,z)$ rather than $y = s(x) + s(z) + s(x,z)$, since the former are designed not to require further constraint.

gam.vcomp

Report gam smoothness estimates as variance components

Description

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

Usage

gam.vcomp(x,rescale=TRUE,conf.lev=.95)

Arguments

x
rescale
conf.lev

a fitted model object of class gam as produced by gam().
the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if TRUE this rescaling is reversed, so that the variance components are on the original scale.
when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at.

Details

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term’s coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth’s coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for gam models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by gam in which random effects have been incorporated.
Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

For models in which there are more smoothing parameters than actually estimated (e.g. if some were fixed, or smoothing parameters are linked) then a list is returned. The vc element is as above, the all element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

gam2objective  

Objective functions for GAM smoothing parameter estimation

Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by `optim` or `nlm`. Not normally called directly, but rather service routines for `gam.outer`.

Usage

```r
gam2objective(lsp, args, ...)  
gam2derivative(lsp, args, ...)
```

Arguments

- `lsp` The log smoothing parameters.
- `args` List of arguments required to call `gam.fit3`.
- `...` Other arguments for passing to `gam.fit3`.

Details

gam2objective and gam2derivative are functions suitable for calling by `optim`, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.
gam4objective is an equivalent to gam2objective, suitable for optimization by `nlm` - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.
The basic idea of optimizing smoothing parameters `outer` to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

Transform derivatives wrt mu to derivatives wrt linear predictor

Description
Mainly intended for internal use in specifying location scale models. Let \( g(\mu) = lp \), where \( lp \) is the linear predictor, and \( g \) is the link function. Assume that we have calculated the derivatives of the log-likelihood wrt \( \mu \). This function uses the chain rule to calculate the derivatives of the log-likelihood wrt \( lp \). See \texttt{trind.generator} for array packing conventions.

Usage
\[
\text{gamlss.etamu}(l1, l2, l3 = \text{NULL}, l4 = \text{NULL}, ig1, g2, g3 = \text{NULL}, \\
g4 = \text{NULL}, i2, i3 = \text{NULL}, i4 = \text{NULL}, \text{deriv} = 0)
\]

Arguments
- \( l1 \): array of 1st order derivatives of log-likelihood wrt \( \mu \).
- \( l2 \): array of 2nd order derivatives of log-likelihood wrt \( \mu \).
- \( l3 \): array of 3rd order derivatives of log-likelihood wrt \( \mu \).
- \( l4 \): array of 4th order derivatives of log-likelihood wrt \( \mu \).
- \( ig1 \): reciprocal of the first derivative of the link function wrt the linear predictor.
- \( g2 \): array containing the 2nd order derivative of the link function wrt the linear predictor.
- \( g3 \): array containing the 3rd order derivative of the link function wrt the linear predictor.
- \( g4 \): array containing the 4th order derivative of the link function wrt the linear predictor.
- \( i2 \): two-dimensional index array, such that \( l2[,i2[i,j]] \) contains the partial w.r.t. params indexed by \( i,j \) with no restriction on the index values (except that they are in 1,..,ncol(l1)).
- \( i3 \): third-dimensional index array, such that \( l3[,i3[i,j,k]] \) contains the partial w.r.t. params indexed by \( i,j,k \).
- \( i4 \): third-dimensional index array, such that \( l4[,i4[i,j,k,l]] \) contains the partial w.r.t. params indexed by \( i,j,k,l \).
- \( \text{deriv} \): if \( \text{deriv} = 0 \) only first and second order derivatives will be calculated. If \( \text{deriv} = 1 \) the function goes up to 3rd order, and if \( \text{deriv} = 2 \) it provides also 4th order derivatives.

Value
A list where the arrays \( l1, l2, l3, l4 \) contain the derivatives (up to order four) of the log-likelihood wrt the linear predictor.

Author(s)
Simon N. Wood <simon.wood@r-project.org>.
gamlss.gH

Calculating derivatives of log-likelihood wrt regression coefficients

Description

Mainly intended for internal use with location scale model families. Given the derivatives of the log-likelihood wrt the linear predictor, this function obtains the derivatives and Hessian wrt the regression coefficients and derivatives of the Hessian w.r.t. the smoothing parameters. For input derivative array packing conventions see trind.generator.

Usage

gamlss.gH(X, jj, l1, l2, i2, l3 = 0, i3 = 0, l4 = 0, i4 = 0, d1b = 0, d2b = 0, deriv = 0, fh = NULL, D = NULL)

Arguments

X  matrix containing the model matrices of all the linear predictors.
jj  list of index vectors such that X[,jj[[i]]] is the model matrix of the i-th linear predictor.
l1  array of 1st order derivatives of each element of the log-likelihood wrt each parameter.
l2  array of 2nd order derivatives of each element of the log-likelihood wrt each parameter.
i2  two-dimensional index array, such that l2[,i2[[i,j]]] contains the partial w.r.t. params indexed by i,j with no restriction on the index values (except that they are in 1,...,ncol(l1)).
l3  array of 3rd order derivatives of each element of the log-likelihood wrt each parameter.
i3  third-dimensional index array, such that l3[,i3[[i,j,k]]] contains the partial w.r.t. params indexed by i,j,k.
l4  array of 4th order derivatives of each element of the log-likelihood wrt each parameter.
i4  third-dimensional index array, such that l4[,i4[[i,j,k,l]]] contains the partial w.r.t. params indexed by i,j,k,l.
d1b  first derivatives of the regression coefficients wrt the smoothing parameters.
d2b  second derivatives of the regression coefficients wrt the smoothing parameters.
deriv  if deriv==0 only first and second order derivatives will be calculated. If deriv==1 the function return also the diagonal of the first derivative of the Hessian, if deriv==2 it return the full 3rd order derivative and if deriv==3 it provides also 4th order derivatives.
fh  eigen-decomposition or Cholesky factor of the penalized Hessian.
D  diagonal matrix, used to provide some scaling.

gamm

Generalized Additive Mixed Models

Description
Fits the specified generalized additive mixed model (GAMM) to data, by a call to lme in the normal errors identity link case, or by a call to gammPQL (a modification of glmmPQL from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than gam, and not quite as numerically robust.

To use lme4 in place of nlme as the underlying fitting engine, see gamm4 from package gamm4.

Smooths are specified as in a call to gam as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for lme are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of gam and lme.

Usage
gamm(formula,random=NULL,correlation=NULL,family=gaussian(),data=list(),weights=NULL,subset=NULL,na.action,knots=NULL,control=list(niterEM=0,optimMethod="L-BFGS-B",returnObject=TRUE),niterPQL=20,verbosePQL=TRUE,method="ML",drop.unused.levels=TRUE,mustart=NULL, etastart=NULL,...)

Arguments

formula
A GAM formula (see also formula.gam and gam.models). This is like the formula for a glm except that smooth terms (s, te etc.) can be added to the right hand side of the formula. Note that ids for smooths and fixed smoothing parameters are not supported. Any offset should be specified in the formula.
random
The (optional) random effects structure as specified in a call to \texttt{lme}: only the \texttt{list} form is allowed, to facilitate manipulation of the random effects structure within \texttt{gamm} in order to deal with smooth terms. See example below.

correlation
An optional \texttt{corStruct} object (see \texttt{corClasses}) as used to define correlation structures in \texttt{lme}. Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of \texttt{lme}). This is a GEE approach to correlation in the generalized case. See examples below.

family
A family as used in a call to \texttt{glm} or \texttt{gam}. The default \texttt{gaussian} with identity link causes \texttt{gamm} to fit by a direct call to \texttt{lme} provided there is no offset term, otherwise \texttt{gammPQL} is used.

data
A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from \texttt{environment(formula)}, typically the environment from which \texttt{gamm} is called.

weights
In the generalized case, weights with the same meaning as \texttt{glm} weights. An \texttt{lme} type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for \texttt{lme} for details of how to use such an argument).

subset
an optional vector specifying a subset of observations to be used in the fitting process.

na.action
a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.

knots
this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.

control
A list of fit control parameters for \texttt{lme} to replace the defaults returned by \texttt{lmeControl}. Note the setting for the number of EM iterations used by \texttt{lme}: smooths are set up using custom \texttt{pdMat} classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include \texttt{niterEM=0}, as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The \texttt{optimMethod} option is only used if your version of \texttt{R} does not have the \texttt{nlminb} optimizer function.

niterPQL
Maximum number of PQL iterations (if any).

verbosePQL
Should PQL report its progress as it goes along?

method
Which of "ML" or "REML" to use in the Gaussian additive mixed model case when \texttt{lme} is called directly. Ignored in the generalized case (or if the model has an offset), in which case \texttt{gammPQL} is used.

drop.unused.levels
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

mustart
starting values for mean if PQL used.

etastart
starting values for linear predictor if PQL used (over-rides \texttt{mustart} if supplied).

... further arguments for passing on e.g. to \texttt{lme}
Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as lme. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in glmmPQL by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the nlme library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using lme or gammPQL in gamm can be found in Wood (2004,2006a,b). In addition gamm obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in gam, although adaptive smoothing bases are not available. Prediction from the returned gam object is straightforward using predict.gam, but this will set the random effects to zero. If you want to predict with random effects set to their predicted values then you can adapt the prediction code given in the examples below.

In the event of lme convergence failures, consider modifying options(mgcv.vc.logrange): reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See notExp2 for more information on this option. Failing that, you can try increasing the niterEM option in control: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of gamm works best with R 2.2.0 or above and nlme, 3.1-62 and above, since these use an improved optimizer.

Value

Returns a list with two items:

- **gam**: an object of class gam, less information relating to GCV/UBRE model selection. At present this contains enough information to use predict, summary and print methods and vis.gam, but not to use e.g. the anova method function to compare models. This is based on the working model when using gammPQL.
- **lme**: the fitted model object returned by lme or gammPQL. Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to lme and gammPQL are constructed.

WARNINGS

gamm has a somewhat different argument list to gam, gam arguments such as gamma supplied to gamm will just be ignored.

gamm performs poorly with binary data, since it uses PQL. It is better to use gam with s(\ldots,bs="re") terms, or gamm4.
gamm assumes that you know what you are doing! For example, unlike \texttt{glmmPQL} from \texttt{MASS} it will return the complete \texttt{lme} object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument \texttt{random}.

gamm is not as numerically stable as \texttt{gam}: an \texttt{lme} call will occasionally fail. See details section for suggestions, or try the ‘gamm4’ package.

gamm is usually much slower than \texttt{gam}, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see \texttt{memory.limit}).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the \texttt{gam} object part of the returned object is not complete in the sense of having all the elements defined in \texttt{gamObject} and does not inherit from \texttt{glm}: hence e.g. multi-model \texttt{anova} calls will not work. It is also based on the working model when PQL is used.

The parameterization used for the smoothing parameters in \texttt{gamm}, bounds them above and below by an effective infinity and effective zero. See \texttt{notExp2} for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

### gammals

**Gamma location-scale model family**

**Description**

The **gammals** family implements gamma location scale additive models in which the log of the mean and the log of the scale parameter (see details) can depend on additive smooth predictors. Useable only with **gam**, the linear predictors are specified via a list of formulae.

**Usage**

```r
gammals(link=list("identity","log"),b=-7)
```
Arguments

link   two item list specifying the link for the mean and the standard deviation. See details for meaning which may not be intuitive.

b      The minimum log scale parameter.

Details

Used with `gam` to fit gamma location - scale models parameterized in terms of the log mean and the log scale parameter (the response variance is the squared mean multiplied by the scale parameter). Note that identity links mean that the linear predictors give the log mean and log scale directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument b: if \( \eta \) is the linear predictor for the log scale parameter, \( \phi \), then \[
\log \phi = b + \log(1 + e^{\eta})
\]
gam is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the log mean on the right hand side. The second is one sided, specifying the linear predictor for the log scale on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean (on original, not log, scale), and the second column is the log scale. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response". The first column is on the original data scale when type="response" and on the log mean scale of the linear predictor when type="link". The second column when type="response" is again the log scale parameter, but is on the linear predictor when type="link".

The null deviance reported for this family computed by setting the fitted values to the mean response, but using the model estimated scale.

Value

An object inheriting from class `general.family`.

References

Examples

```r
library(mgcv)
## simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 * (10 * x)^3 * (1 - x)^10
f3 <- function(x) 0 * x
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- exp((f0(x0)+f2(x2))/5)
theta <- exp(f1(x1))/2-2
y <- rgamma(n,shape=1/th, scale=mu*theta)

b1 <- gam(list(y~s(x0)+s(x2),~s(x1)+s(x3)), family=gammals)
plot(b1, pages=1)
```
summary(b1)
gam.check(b1)
plot(mu,fitted(b1)[,1]);abline(0,1,col=2)
plot(log(th),fitted(b1)[,2]);abline(0,1,col=2)

---

gamObject

Fitted gam object

Description

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

Value

A `gam` object has the following elements:

- **aic**: AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE.
- **assign**: Array whose elements indicate which model term (listed in `pterms`) each parameter relates to: applies only to non-smooth terms.
- **boundary**: Did parameters end up at boundary of parameter space?
- **call**: The matched call (allows `update` to be used with `gam` objects, for example).
- **cmX**: Column means of the model matrix (with elements corresponding to smooths set to zero) — useful for componentwise CI calculation.
- **coefficients**: The coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.
- **control**: The `gam` control list used in the fit.
- **converged**: Indicates whether or not the iterative fitting method converged.
- **data**: The original supplied data argument (for class "glm" compatibility). Only included if `gam` control argument element `keepData` is set to `TRUE` (default is `FALSE`).
- **db.drho**: Matrix of first derivatives of model coefficients w.r.t. log smoothing parameters.
- **deviance**: Model deviance (not penalized deviance).
- **df.null**: Null degrees of freedom.
- **df.residual**: Effective residual degrees of freedom of the model.
- **edf**: Estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.
- **edf1**: Similar, but using alternative estimate of EDF. Useful for testing.
if estimation is by ML or REML then an edf that accounts for smoothing parameter uncertainty can be computed, this is it. edf1 is a heuristic upper bound for edf2.

family object specifying distribution and link used.

fitted model predictions of expected value for each datum.

the model formula.

full array of smoothing parameters multiplying penalties (excluding any contribution from min.sp argument to gam). May be larger than sp if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the sp argument of gam.

Degrees of freedom matrix. This may be removed at some point, and should probably not be used.

The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.

array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.

number of iterations of P-IRLS taken to get convergence.

fitted model prediction of link function of expected value for each datum.

One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "lme.ML" or "lme.REML", depending on the fitting criterion used.

A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: full.rank, The apparent rank of the problem given the model matrix and constraints; rank, The numerical rank of the problem; fully.converged, TRUE if multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; hess.pos.def, Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; iter, How many iterations were required to find the smoothing parameters?; score.calls, and how many times did the GCV/UBRE score have to be evaluated?; rms.grad, root mean square of the gradient of the GCV/UBRE score at convergence.

Minimum possible degrees of freedom for whole model.

model frame containing all variables needed in original model fit.

The na.action used in fitting.

number of parametric, non-smooth, model terms including the intercept.

deviance for single parameter model.

model offset.

optimizer argument to gam, or "magic" if it's a pure additive model.

If 'outer' iteration has been used to fit the model (see gam argument optimizer) then this is present and contains whatever was returned by the optimization routine used (currently nlm or optim).

If the paraPen argument to gam was used then this provides information on the parametric penalties. NULL otherwise.

one sided formula containing variables needed for prediction, used by predict.gam
prior.weights  prior weights on observations.
ptersms terms object for strictly parametric part of model.
R Factor R from QR decomposition of weighted model matrix, unpivoted to be in same column order as model matrix (so need not be upper triangular).
rank apparent rank of fitted model.
reml.scale The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness estimation.
residuals the working residuals for the fitted model.
rV If present, rV%*%t(rV)*sig2 gives the estimated Bayesian covariance matrix.
scale when present, the scale (as sig2)
scale.estimated TRUE if the scale parameter was estimated, FALSE otherwise.
sig2 estimated or supplied variance/scale parameter.
smooth list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the smooth.construct objects.
sp estimated smoothing parameters for the model. These are the underlying smoothing parameters, subject to optimization. For the full set of smoothing parameters multiplying the penalties see full.sp. Divide the scale parameter by the smoothing parameters to get, variance components, but note that this is not valid for smooths that have used rescaling to improve conditioning.
terms terms object of model model frame.
var.summary A named list of summary information on the predictor variables. If a parametric variable is a matrix, then the summary is a one row matrix, containing the observed data value closest to the column median, for each matrix column. If the variable is a factor the then summary is the modal factor level, returned as a factor, with levels corresponding to those of the data. For numerics and matrix arguments of smooths, the summary is the mean, nearest observed value to median and maximum, as a numeric vector. Used by vis.gam, in particular.
Ve frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI’s as smooths are usually biased.
Vp estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.
Vc Under ML or REML smoothing parameter estimation it is possible to correct the covariance matrix Vp for smoothing parameter uncertainty. This is the corrected version.
weights final weights used in IRLS iteration.
y response data.

WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

gamSim

Simulate example data for GAMs

Description

Function used to simulate data sets to illustrate the use of gam and gamm. Mostly used in help files to keep down the length of the example code sections.

Usage

gamSim(eg=1,n=400,dist="normal",scale=2,verbose=TRUE)

Arguments

eg numeric value specifying the example required.
n number of data to simulate.
dist character string which may be used to specify the distribution of the response.
scale Used to set noise level.
verbose Should information about simulation type be printed?

Details

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

Value

Depends on eg, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.
gaulss

Gaussian location-scale model family

Description

The gaulss family implements Gaussian location scale additive models in which the mean and the logb of the standard deviation (see details) can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae.

Usage

gaulss(link=list("identity","logb"),b=0.01)

Arguments

  link        two item list specifying the link for the mean and the standard deviation. See details.
  b           The minimum standard deviation, for the "logb" link.

Details

Used with gam to fit Gaussian location-scale models. gam is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the mean on the right hand side. The second is one sided, specifying the linear predictor for the standard deviation on the right hand side.

Link functions "identity", "inverse", "log" and "sqrt" are available for the mean. For the standard deviation only the "logb" link is implemented: $\eta = \log(\sigma - b)$ and $\sigma = b + \exp(\eta)$. This link is designed to avoid singularities in the likelihood caused by the standard deviation tending to zero. Note that internally the family is parameterized in terms of the $\tau = \sigma^{-1}$, i.e. the standard deviation of the precision, so the link and inverse link are coded to reflect this, however the relationships between the linear predictor and the standard deviation are as given above.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the inverse of the standard deviation. Predictions using predict.gam will also produce 2 column matrices for type "link" and "response". The second column when type="response" is again on the reciprocal standard deviation scale (i.e. the square root precision scale). The second column when type="link" is $\log(\sigma - b)$. Also plot.gam will plot smooths relating to $\sigma$ on the $\log(\sigma - b)$ scale (so high values correspond to high standard deviation and low values to low standard deviation). Similarly the smoothing penalties are applied on the (log) standard deviation scale, not the log precision scale.

Examples

## see ?gam

gaulss(link=list("identity","logb"),b=0.01)

See Also

gam, gamm

Author(s)

Simon N. Wood <simon.wood@r-project.org>
The null deviance reported for this family is the sum of squares of the difference between the response and the mean response divided by the standard deviation of the response according to the model. The deviance is the sum of squares of residuals divided by model standard deviations.

**Value**

An object inheriting from class `general.family`.

**References**

**Examples**

```r
library(mgcv);library(MASS)
b <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
data=mcycle,family=gaulss())
summary(b)
plot(b,pages=1,scale=0)
```

**get.var**  
*Get named variable or evaluate expression from list or data.frame*

**Description**

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then NULL is returned. The routine is useful for processing `gam` formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

**Usage**

```r
get.var(txt,data,vecMat=TRUE)
```

**Arguments**

- `txt`: a text string which is either the name of a variable in `data` or when parsed is an expression that can be evaluated in `data`. It can also be neither in which case the function returns NULL.
- `data`: A data frame or list.
- `vecMat`: Should matrices be coerced to numeric vectors?

**Value**

The evaluated variable or NULL. May be coerced to a numeric vector if it’s a matrix.

gevlss

Generalized Extreme Value location-scale model family

Description
The gevlss family implements Generalized Extreme Value location scale additive models in which
the location, scale and shape parameters depend on additive smooth predictors. Usable only with
gam, the linear predictors are specified via a list of formulae.

Usage
gevlss(link=list("identity","identity","logit"))

Arguments
link three item list specifying the link for the location scale and shape parameters.
See details.

Details
Used with gam to fit Generalized Extreme Value location scale and shape models. gam is called with
a list containing 3 formulae: the first specifies the response on the left hand side and the structure
of the linear predictor for the location parameter on the right hand side. The second is one sided,
specifying the linear predictor for the log scale parameter on the right hand side. The third is one
sided specifying the linear predictor for the shape parameter.

Link functions "identity" and "log" are available for the location (mu) parameter. There is
no choice of link for the log scale parameter (\(\rho = \log \sigma\)). The shape parameter (xi) defaults to a
modified logit link restricting its range to (-1,.5), the upper limit is required to ensure finite variance,
while the lower limit ensures consistency of the MLE (Smith, 1985).

The fitted values for this family will be a three column matrix. The first column is the location
parameter, the second column is the log scale parameter, the third column is the shape parameter.
This family does not produce a null deviance. Note that the distribution for \(\xi = 0\) is approximated
by setting \(\xi\) to a small number.
The derivative system code for this family is mostly auto-generated, and the family is still somewhat experimental.

The GEV distribution is rather challenging numerically, and for small datasets or poorly fitting models improved numerical robustness may be obtained by using the extended Fellner-Schall method of Wood and Fasiolo (2017) for smoothing parameter estimation. See examples.

Value
An object inheriting from class `general.family`.

References

Examples

```r
library(mgcv)
Fi.gev <- function(z, mu, sigma, xi) {
  ## GEV inverse cdf.
  xi[abs(xi)<1e-8] <- 1e-8 ## approximate xi=0, by small xi
  x <- mu + ((-log(z))^(-xi)-1)*sigma/xi
}

## simulate test data...
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 *(10 * (1 - x))^6 + 10 *
                   (10 * x)^3 *(1 - x)^10
set.seed(1)
n <- 500
x0 <- runif(n);x1 <- runif(n);x2 <- runif(n)
mu <- f2(x2)
rho <- f0(x0)
xi <- (f1(x1)-4)/9
y <- Fi.gev(runif(n),mu,exp(rho),xi)
dat <- data.frame(y,x0,x1,x2);pairs(dat)

## fit model....
b <- gam(list(y~s(x2),~s(x0),~s(x1)),family=gevlss,data=dat)

## same fit using the extended Fellner-Schall method which
## can provide improved numerical robustness...
b <- gam(list(y~s(x2),~s(x0),~s(x1)),family=gevlss,data=dat, optimizer="efs")

## plot and look at residuals...
plot(b,pages=1,scale=0)
summary(b)
```
```r
par(mfrow=c(2,2))
mu <- fitted(b)[,1]; rho <- fitted(b)[,2]
xi <- fitted(b)[,3]
## Get the predicted expected response...
fv <- mu + exp(rho) * (gamma(1-xi)-1)/xi
rsd <- residuals(b)
plot(fv,rsd); qqnorm(rsd)
plot(fv,residuals(b,"pearson"))
plot(fv,residuals(b,"response"))
```

---

**ginla**

GAM Integrated Nested Laplace Approximation Newton Enhanced

**Description**

Apply Integrated Nested Laplace Approximation (INLA, Rue et al. 2009) to models estimable by `gam` or `bam`, using the INLA variant described in Wood (2019). Produces marginal posterior densities for each coefficient, selected coefficients or linear transformations of the coefficient vector.

**Usage**

```r
ginla(G,A=NULL,nk=16,nb=100,J=1,interactive=FALSE,int=0,approx=0)
```

**Arguments**

- `G` A pre-fit `gam` object, as produced by `gam(...,fit=FALSE)` or `bam(...,discrete=TRUE,fit=FALSE)`.
- `A` Either a matrix of transforms of the coefficients that are of interest, or an array of indices of the parameters of interest. If `NULL` then distributions are produced for all coefficients.
- `nk` Number of values of each coefficient at which to evaluate its log marginal posterior density. These points are then spline interpolated.
- `nb` Number of points at which to evaluate posterior density of coefficients for returning as a gridded function.
- `J` How many determinant updating steps to take in the log determinant approximation step. Not recommended to increase this.
- `interactive` If this is `>0` or `TRUE` then every approximate posterior is plotted in red, overlaid on the simple Gaussian approximate posterior. If `2` then waits for user to press return between each plot. Useful for judging whether anything is gained by using INLA approach.
- `int` 0 to skip integration and just use the posterior modal smoothing parameter. >0 for integration using the CCD approach proposed in Rue et al. (2009).
- `approx` 0 for full approximation; 1 to update Hessian, but use approximate modes; 2 as 1 and assume constant Hessian. See details.
Details

Let $\beta$, $\theta$ and $y$ denote the model coefficients, hyperparameters/smoothing parameters and response data, respectively. In principle, INLA employs Laplace approximations for $\pi(\beta_i|\theta, y)$ and $\pi(\theta|y)$ and then obtains the marginal posterior distribution $\pi(\beta_i|y)$ by intergrating the approximations to $\pi(\beta_i|\theta, y)\pi(\theta|y)$ w.r.t $\theta$ (marginals for the hyperparameters can also be produced). In practice the Laplace approximation for $\pi(\beta_i|\theta, y)$ is too expensive to compute for each $\beta_i$ and must itself be approximated. To this end, there are two quantities that have to be computed: the posterior mode $\beta^*|\beta_i$ and the determinant of the Hessian of the joint log density $\log \pi(\beta, \theta, y)$ w.r.t. $\beta$ at the mode. Rue et al. (2009) originally approximated the posterior conditional mode by the conditional mode implied by a simple Gaussian approximation to the posterior $\pi(\beta|y)$. They then approximated the log determinant of the Hessian as a function of $\beta_i$ using a first order Taylor expansion, which is cheap to compute for the sparse model representaiton that they use, but not when using the dense low rank basis expansions used by `gam`. They also offer a more expensive alternative approximation based on computing the log determinant with respect only to those elements of $\beta$ with sufficiently high correlation with $\beta_i$ according to the simple Gaussian posterior approximation: efficiency again seems to rest on sparsity. Wood (2018) suggests computing the required posterior modes exactly, and basing the log determinant approximation on a BFGS update of the Hessian at the unconditional model. The latter is efficient with or without sparsity, whereas the former is a ’for free’ improvement. Both steps are efficient because it is cheap to obtain the Cholesky factor of $H[-i,-i]$ from that of $H$ - see `choldrop`. This is the approach taken by this routine.

The `approx` argument allows two further approximations to speed up computations. For `approx==1` the exact posterior conditional modes are not used, but instead the conditional modes implied by the simple Gaussian posterior approximation. For `approx==2` the same approximation is used for the modes and the Hessian is assumed constant. The latter is quite fast as no log joint density gradient evaluations are required.

Note that for many models the INLA estimates are very close to the usual Gaussian approximation to the posterior, the `interactive` argument is useful for investigating this issue.

`bam` models are only supported with the `discrete=TRUE` option. The `discrete=FALSE` approach would be too inefficient. AR1 models are not supported (related arguments are simply ignored).

Value

A list with elements `beta` and `density`, both of which are matrices. Each row relates to one coefficient (or linear coefficient combination) of interest. Both matrices have `nb` columns. If `int!=0` then a further element `reml` gives the integration weights used in the CCD integration, with the central point weight given first.

WARNINGS

This routine is still somewhat experimental, so details are liable to change. Also currently not all steps are optimally efficient.

The routine is written for relatively expert users.

`ginla` is not designed to deal with rank deficient models.

---

**gumbls**  

### Gumbel location-scale model family

**Description**

The gumbls family implements Gumbel location scale additive models in which the location and scale parameters (see details) can depend on additive smooth predictors. Useable only with *gam*, the linear predictors are specified via a list of formulae.

**Usage**

```r
gumbls(link=list("identity","log"),b=-7)
```

**Arguments**

- `link`: two item list specifying the link for the location \( \mu \) and log scale parameter \( \beta \). See details for meaning, which may not be intuitive.
- `b`: The minimum log scale parameter.

**Details**

Let \( z = (y - \mu) e^{-\beta} \), then the log Gumbel density is \( l = -\beta - z - e^{-z} \). The expected value of a Gumbel r.v. is \( \mu + \gamma e^\beta \) where \( \gamma \) is Eulers constant (about 0.57721566). The corresponding variance is \( \pi^2 e^{2\beta} / 6 \).
gumbls is used with \texttt{gam} to fit Gumbel location-scale models parameterized in terms of location parameter $\mu$ and the log scale parameter $\beta$. Note that identity link for the scale parameter means that the corresponding linear predictor gives $\beta$ directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument \texttt{b}: if $\eta$ is the linear predictor for the log scale parameter, $\beta$, then $\beta = b + \log(1 + e^\eta)$.

\texttt{gam} is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for location parameter, $\mu$, on the right hand side. The second is one sided, specifying the linear predictor for the log scale parameter, $\beta$, on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the log scale parameter, $\beta$. Predictions using \texttt{predict.gam} will also produce 2 column matrices for type "link" and "response". The first column is on the original data scale when type="response" and on the log mean scale of the linear predictor when type="link". The second column when type="response" is again the log scale parameter, but is on the linear predictor when type="link".

**Value**

An object inheriting from class \texttt{general.family}.

**References**

**Examples**

```r
library(mgcv)
## simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
       (10 * x)^3 * (1 - x)^10
n <- 400; set.seed(9)
x0 <- runif(n);x1 <- runif(n);
x2 <- runif(n);x3 <- runif(n);
mu <- f0(x0)+f1(x1)
beta <- exp(f2(x2)/5)
y <- mu - beta*log(-log(runif(n))) ## Gumbel quantile function

b <- gam(list(y~s(x0)+s(x1),~s(x2)+s(x3)),family=gumbls)
plot(b,pages=1,scale=0)
summary(b)
gam.check(b)
```

---

**identifiability**

\textbf{Identifiability constraints}
Description

Smooth terms are generally only identifiable up to an additive constant. In consequence sum-to-zero identifiability constraints are imposed on most smooth terms. The exceptions are terms with by variables which cause the smooth to be identifiable without constraint (that doesn’t include factor by variables), and random effect terms. Alternatively smooths can be set up to pass through zero at a user specified point.

Details

By default each smooth term is subject to the sum-to-zero constraint

\[ \sum f(x_i) = 0. \]

The constraint is imposed by reparameterization. The sum-to-zero constraint causes the term to be orthogonal to the intercept: alternative constraints lead to wider confidence bands for the constrained smooth terms.

No constraint is used for random effect terms, since the penalty (random effect covariance matrix) anyway ensures identifiability in this case. Also if a by variable means that the smooth is anyway identifiable, then no extra constraint is imposed. Constraints are imposed for factor by variables, so that the main effect of the factor must usually be explicitly added to the model (the example below is an exception).

Occasionally it is desirable to substitute the constraint that a particular smooth curve should pass through zero at a particular point: the `pc` argument to `s`, `te`, `ti` and `t2` allows this: if specified then such constraints are always applied.

Simon N. Wood (s.wood@r-project.org)

Examples

```r
## Example of three groups, each with a different smooth dependence on x
## but each starting at the same value...
require(mgcv)
set.seed(53)
n <- 100;x <- runif(3*n);z <- runif(3*n)
fac <- factor(rep(c("a","b","c"),each=100))
y <- c(sin(x[1:100]*4),exp(3*x[101:200])/10-.1,exp(-10*(x[201:300]-.5))/(1+exp(-10*(x[201:300]-.5)))-0.9933071) + z*(1-z)*5 + rnorm(100)*.4

## 'pc' used to constrain smooths to 0 at x=0...
b <- gam(y~s(x,by=fac,pc=0)+s(z))
plot(b,pages=1)
```

Description

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as ‘inside’ if they are interior to an odd number of polygons.
Usage

in.out(bnd, x)

Arguments

bnd   A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed. Alternatively can be a lists where bnd[[i]][[1]], bnd[[i]][[2]] defines the ith boundary loop.

x     A two column matrix. Each row is a point to test for inclusion in the region defined by bnd. Can also be a 2-vector, defining a single point.

Details

The algorithm works by counting boundary crossings (using compiled C code).

Value

A logical vector of length nrow(x). TRUE if the corresponding row of x is inside the boundary and FALSE otherwise.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

Examples

library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd, type="n")
polygon(bnd)
x <- seq(7.9, 8.7, length=20)
y <- seq(13.7, 14.3, length=20)
gr <- as.matrix(expand.grid(x, y))
inside <- in.out(bnd, gr)
points(gr, col=as.numeric(inside)+1)

influence.gam

Extract the diagonal of the influence/hat matrix for a GAM

Description

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted gam object.

Usage

## S3 method for class 'gam'
influence(model,...)
**initial.sp**

**Arguments**

model fitted model objects of class `gam` as produced by `gam()`.

... un-used in this case

**Details**

Simply extracts hat array from fitted model. (More may follow!)

**Value**

An array (see above).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**

`gam`

**Description**

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

**Usage**

`initial.sp(X, S, off, expensive=FALSE, XX=FALSE)`

**Arguments**

X is the model matrix.

S is a list of of penalty matrices. `S[[i]]` is the ith penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of `S[[i]]` occupies element `off[i], off[i]` of the ith penalty matrix. Each `S[[i]]` must be positive semi-definite.

off is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving `S[[i]]`.

expensive if TRUE then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.

XX if TRUE then X contains `X^T X`, rather than `X`. 
Details

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.’s away from 0 and 1. Usually only called by `magic` and `gam`.

Value

An array of initial smoothing parameter estimates.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

See Also

`magic`, `gam.outer`, `gam`, `inSide` Are points inside boundary?

Description

Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

Usage

`inSide(bnd, x, y)`

Arguments

- `bnd` This should have two equal length columns with names matching whatever is supplied in `x` and `y`. This may contain several sections of boundary separated by `NA`. Alternatively `bnd` may be a list, each element of which contains 2 columns named as above. See below for details.
- `x` `x` co-ordinates of points to be tested.
- `y` `y` co-ordinates of points to be tested.

Details

Segments of boundary are separated by `NA`s, or are in separate list elements. The boundary co-ordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).

The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner ‘islands’ completely enclosed in the outer loop.

The routine calls compiled C code and operates by an exhaustive search for each point in `x`, `y`.
**Value**

The function returns a logical array of the same dimension as \( x \) and \( y \). TRUE indicates that the corresponding \( x, y \) point lies inside the boundary.

**Examples**

```
require(mgcv)
m <- 300;n <- 150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
x <- rep(xm,n);y<rep(yn,rep(m,n))
er <- matrix(fs.test(x,y),m,n)
bnd <- fs.boundary()
in.bnd <- inSide(bnd,x,y)
plot(x,y,col=as.numeric(in.bnd)+1,pch=".")
lines(bnd$x,bnd$y,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")
## check boundary details ...
plot(x,y,col=as.numeric(in.bnd)+1,pch=",",ylim=c(-1,0),xlim=c(3,3.5))
lines(bnd$x,bnd$y,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=",")
```

---

**interpret.gam**

**Interpret a GAM formula**

**Description**

This is an internal function of package mgcv. It is a service routine for gam which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

**Usage**

```
interpret.gam(gf, extra.special = NULL)
```

**Arguments**

- `gf` A GAM formula as supplied to `gam` or `gamm`, or a list of such formulae, as supplied for some `gam` families.
- `extra.special` Name of any extra special in formula in addition to s, te, ti and t2.
Value

An object of class `split.gam.formula` with the following items:

- **pf**: A model formula for the strictly parametric part of the model.
- **pfok**: TRUE if there is a pf formula.
- **smooth.spec**: A list of class `xx.smooth.spec` objects where `xx` depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)
- **full.formula**: An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.
- **fake.formula**: A formula suitable for use in evaluating a model frame.
- **response**: Name of the response variable.

`gam` `gamm`

---

**Description**

Facilities to auto-generate model specification code and associated data to simulate with GAMs in JAGS (or BUGS). This is useful for inference about models with complex random effects structure best coded in JAGS. It is a very inefficient approach to making inferences about standard GAMs. The idea is that `jagam` generates template JAGS code, and associated data, for the smooth part of the model. This template is then directly edited to include other stochastic components. After simulation with the resulting model, facilities are provided for plotting and prediction with the model smooth components.

**Usage**

```r
jagam(formula, family=gaussian, data=list(), file, weights=NULL, na.action, offset=NULL, knots=NULL, sp=NULL, drop.unused.levels=TRUE, control=gam.control(), centred=TRUE, sp.prior = "gamma", diagonalize=FALSE)

sim2jam(sam, pregam, edf.type=2, burnin=0)
```
Arguments

**formula**
A GAM formula (see `formula.gam` and also `gam.models`). This is exactly like the formula for a GLM except that smooth terms, s, te, ti and t2 can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).

**family**
This is a family object specifying the distribution and link function to use. See `glm` and `family` for more details. Currently only gaussian, poisson, binomial and Gamma families are supported, but the user can easily modify the assumed distribution in the JAGS code.

**data**
A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`: typically the environment from which `jagam` is called.

**file**
Name of the file to which JAGS model specification code should be written. See `setwd` for setting and querying the current working directory.

**weights**
Prior weights on the data.

**na.action**
a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The ‘factory-fresh’ default is ‘na.omit’.

**offset**
Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in `formula`: this conforms to the behaviour of `lm` and `glm`.

**control**
A list of fit control parameters to replace defaults returned by `gam.control`. Any control parameters not supplied stay at their default values. little effect on `jagam`.

**knots**
This is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See `tprs` for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

**sp**
A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula (without forgetting null space penalties). Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then `length(sp)` must correspond to the number of underlying smoothing parameters.

**drop.unused.levels**
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

**centred**
Should centring constraints be applied to the smooths, as is usual with GAMS? Only set this to `FALSE` if you know exactly what you are doing. If `FALSE` there is a (usually global) intercept for each smooth.

**sp.prior**
"gamma" or "log.uniform" prior for the smoothing parameters? Do check that the default parameters are appropriate for your model in the JAGS code.

**diagonalize**
Should smooths be re-parameterized to have i.i.d. Gaussian priors (where possible)? For Gaussian data this allows efficient conjugate samplers to be used, and it can also work well with GLMs if the JAGS "glm" module is loaded, but otherwise it is often better to update smoothers blockwise, and not do this.
jags sample object, containing at least fields b (coefficients) and rho (log smoothing parameters). May also contain field mu containing monitored expected response.

standard mgcv GAM setup data, as returned in jagam return list.

Since EDF is not uniquely defined and may be affected by the stochastic structure added to the JAGS model file, 3 options are offered. See details.

the amount of burn in to discard from the simulation chains. Limited to .9 of the chain length.

Details

Smooths are easily incorporated into JAGS models using multivariate normal priors on the smooth coefficients. The smoothing parameters and smoothing penalty matrices directly specify the prior multivariate normal precision matrix. Normally a smoothing penalty does not correspond to a full rank precision matrix, implying an improper prior inappropriate for Gibbs sampling. To rectify this problem the null space penalties suggested in Marra and Wood (2011) are added to the usual penalties.

In an additive modelling context it is usual to centre the smooths, to avoid the identifiability issues associated with having an intercept for each smooth term (in addition to a global intercept). Under Gibbs sampling with JAGS it is technically possible to omit this centring, since we anyway force propriety on the priors, and this propriety implies formal model identifiability. However, in most situations this formal identifiability is rather artificial and does not imply statistically meaningful identifiability. Rather it serves only to massively inflate confidence intervals, since the multiple intercept terms are not identifiable from the data, but only from the prior. By default then, jagam imposes standard GAM identifiability constraints on all smooths. The centred argument does allow you to turn this off, but it is not recommended. If you do set centred=FALSE then chain convergence and mixing checks should be particularly stringent.

The final technical issue for model setup is the setting of initial conditions for the coefficients and smoothing parameters. The approach taken is to take the default initial smoothing parameter values used elsewhere by mgcv, and to take a single PIRLS fitting step with these smoothing parameters in order to obtain starting values for the smooth coefficients. In the setting of fully conjugate updating the initial values of the coefficients are not critical, and good results are obtained without supplying them. But in the usual setting in which slice sampling is required for at least some of the updates then very poor results can sometimes be obtained without initial values, as the sampler simply fails to find the region of the posterior mode.

The sim2jam function takes the partial gam object (pregam) from jagam along with simulation output in standard rjags form and creates a reduced version of a gam object, suitable for plotting and prediction of the model’s smooth components. sim2gam computes effective degrees of freedom for each smooth, but it should be noted that there are several possibilities for doing this in the context of a model with a complex random effects structure. The simplest approach (edf.type=0) is to compute the degrees of freedom that the smooth would have had if it had been part of an unweighted Gaussian additive model. One might choose to use this option if the model has been modified so that the response distribution and/or link are not those that were specified to jagam. The second option is (edf.type=1) uses the edf that would have been computed by gam had it produced these estimates - in the context in which the JAGS model modifications have all been about modifying the random effects structure, this is equivalent to simply setting all the random effects to zero for the effective degrees of freedom calculation. The default option (edf.type=2) is to base the EDF on the sample covariance matrix, Vp, of the model coefficients. If the simulation output (sim) includes a mu field, then this will be used to form the weight matrix W in \( W X = t(X) W X + X \), where the EDF is computed from \( rowSums(Vp*W*X)*scale \). If mu is not supplied then it is estimated from the the model matrix X and the mean of the simulated coefficients, but the resulting W may not be
strictly compatible with the $V_p$ matrix in this case. In the situation in which the fitted model is very different in structure from the regression model of the template produced by `jagam` then the default option may make no sense, and indeed it may be best to use option 0.

**Value**

For `jagam` a three item list containing

- `pregam` standard mgcv GAM setup data.
- `jags.data` list of arguments to be supplied to JAGS containing information referenced in model specification.
- `jags.ini` initialization data for smooth coefficients and smoothing parameters.

For `sim2jam` an object of class "jam": a partial version of an mgcv `gamObject`, suitable for plotting and predicting.

**WARNINGS**

Gibb's sampling is a very slow inferential method for standard GAMs. It is only likely to be worthwhile when complex random effects structures are required above what is possible with direct GAMM methods.

Check that the parameters of the priors on the parameters are fit for your purpose.

**k.check**  
*Checking smooth basis dimension*

**Description**

Takes a fitted **gam** object produced by **gam()** and runs diagnostic tests of whether the basis dimension choices are adequate.

**Usage**

```r
k.check(b, subsample=5000, n.rep=400)
```

**Arguments**

- **b**: a fitted **gam** object as produced by **gam()**.
- **subsample**: above this number of data, testing uses a random sub-sample of data of this size.
- **n.rep**: how many re-shuffles to do to get p-value for k testing.

**Details**

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the \( k \)-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled \( n \cdot \text{rep} \) times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than \( \text{subsample} \) data, the tests are based of \( \text{subsample} \) randomly sampled data. Low p-values may indicate that the basis dimension, \( k \), has been set too low, especially if the reported edf is close to \( k \cdot \), the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an \( \text{NA} \) p-value.

Doubling a suspect \( k \) and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low \( k \). See **choose.k** for fuller discussion.

**Value**

A matrix containing the output of the tests described above.
ldetS

Getting log generalized determinant of penalty matrices

Description

INTERNAL function calculating the log generalized determinant of penalty matrix S stored blockwise in an Sl list (which is the output of Sl.setup).

Usage

ldetS(Sl, rho, fixed, np, root = FALSE, repara = TRUE, nt = 1, deriv=2, sparse=FALSE)

Arguments

Sl  the output of Sl.setup.
rho the log smoothing parameters.
fixed an array indicating whether the smoothing parameters are fixed (or free).
np number of coefficients.
root indicates whether or not to return the matrix square root, E, of the total penalty S_tot.
repara if TRUE multi-term blocks will be re-parameterized using gam.reparam, and a re-parameterization object supplied in the returned object.
nt number of parallel threads to use.
deriv order of derivative to use
sparse should E be sparse?
**Value**

A list containing:

- `ldetS`: the log-determinant of S.
- `ldetS1`: the gradient of the log-determinant of S.
- `ldetS2`: the Hessian of the log-determinant of S.
- `S1`: with modified rS terms, if needed and rho added to each block
- `rp`: a re-parameterization list.
- `rp`: E a total penalty square root such that t(E)%*%E = S_tot (if root==TRUE).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

**ldTweedie**  
*Log Tweedie density evaluation*

**Description**

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter, phi, and p, or w.r.t. rho=log(phi) and theta where p = (a+b*exp(theta))/(1+exp(theta)).

**Usage**

```r
ldTweedie(y, mu=y, p=1.5, phi=1, rho=NA, theta=NA, a=1.001, b=1.999, all.derivs=FALSE)
```

**Arguments**

- `y`: values at which to evaluate density.
- `mu`: corresponding means (either of same length as y or a single value).
- `p`: the variance of y is proportional to its mean to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.
- `phi`: The scale parameter. Variance of y is phi*mu^p.
- `rho`: optional log scale parameter. Over-rides phi if theta also supplied.
- `theta`: parameter such that p = (a+b*exp(theta))/(1+exp(theta)). Over-rides p if rho also supplied.
- `a`: lower limit parameter (>1) used in definition of p from theta.
- `b`: upper limit parameter (<2) used in definition of p from theta.
- `all.derivs`: if TRUE then derivatives w.r.t. mu are also returned. Only available with rho and phi parameterization.
Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1.

ldTweedie is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on p the calculation of Tweedie densities is less straightforward. If you really need this case then the tweedie package is the place to start.

The rho, theta parameterization is useful for optimization of p and phi, in order to keep p bounded well away from 1 and 2, and phi positive. The derivatives near p=1 tend to infinity.

Note that if p and phi (or theta and rho) both contain only a single unique value, then the underlying code is able to use buffering to avoid repeated calls to expensive log gamma, di-gamma and tri-gamma functions (mu can still be a vector of different values). This is much faster than is possible when these parameters are vectors with different values.

Value

A matrix with 6 columns, or 10 if all.derivs=TRUE. The first is the log density of y (log probability if p=1). The second and third are the first and second derivatives of the log density w.r.t. phi. 4th and 5th columns are first and second derivative w.r.t. p, final column is second derivative w.r.t. phi and p.

If rho and theta were supplied then derivatives are w.r.t. these. In this case, and if all.derivs=TRUE then the 7th column is the derivative w.r.t. mu, the 8th is the 2nd derivative w.r.t. mu, the 9th is the mixed derivative w.r.t. theta and mu and the 10th is the mixed derivative w.r.t. rho and mu.

plot(y,fy,type="l",ylim=c(0,3),main="Tweedie density as p changes")
for (i in 2:length(p)) {
  fy <- exp(ldTweedie(y,mu=2,p=p[i],phi=phi)[,1])
  plot(y,fy,type="l",ylim=c(0,3),main=paste("Tweedie density as p",p[i]))
  points(y,fy,pch=16,col=i)
  box()
}
```
linear.functional.terms

### Description

gam allows the response variable to depend on linear functionals of smooth terms. Specifically
dependencies of the form

$$g(\mu_i) = \ldots + \sum_j L_{ij} f(x_{ij}) + \ldots$$

are allowed, where the $x_{ij}$ are covariate values and the $L_{ij}$ are fixed weights. i.e. the response can
depend on the weighted sum of the same smooth evaluated at different covariate values. This allows,
for example, for the response to depend on the derivatives or integrals of a smooth (approximated
by finite differencing or quadrature, respectively). It also allows dependence on predictor functions
(sometimes called `signal regression`).

The mechanism by which this is achieved is to supply matrices of covariate values to the model
smooth terms specified by s or te terms in the model formula. Each column of the covariate matrix
gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of
evaluated smooth values be F (F will have the same dimension as the covariate matrices). In the
absense of a by variable then these columns are simply summed and added to the linear predictor.
i.e. the contribution of the term to the linear predictor is rowSums(F). If a by variable is present
then it must be a matrix, L,say, of the same dimension as F (and the covariate matrices), and it
contains the weights $L_{ij}$ in the summation given above. So in this case the contribution to the linear
predictor is rowSums(L*F).

Note that if a L1 (i.e. rowSums(L)) is a constant vector, or there is no by variable then the smooth
will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also
that for centred smooths it can be worth replacing the constant term in the model with rowSums(L)
in order to ensure that predictions are automatically on the right scale.

predict.gam can accept matrix predictors for prediction with such terms, in which case its newdata
argument will need to be a list. However when predicting from the model it is not necessary to
provide matrix covariate and by variable values. For example to simply examine the underlying
smooth function one would use vectors of covariate values and vector by variables, with the by
variable and equivalent of L1, above, set to vectors of ones.

The mechanism is usable with random effect smooths which take factor arguments, by using a trick
to create a 2D array of factors. Simply create a factor vector containing the columns of the factor
matrix stacked end to end (column major order). Then reset the dimensions of this vector to create
the appropriate 2D array: the first dimension should be the number of response data and the second
the number of columns of the required factor matrix. You can not use matrix or data.matrix to
set up the required matrix of factor levels. See example below.

Examples

### matrix argument `linear operator' smoothing

```r
library(mgcv)
set.seed(0)

n<-400
sig<-2
x <- runif(n, 0, .9)
f2 <- function(x) 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
x1 <- x + .1
f <- f2(x) + f2(x1) ## response is sum of f at two adjacent x values
y <- f + rnorm(n)*sig
X <- matrix(c(x,x1),n,2) ## matrix covariate contains both x values
b <- gam(y~s(X))
plot(b) ## reconstruction of f
plot(f,fitted(b))
```

## example of prediction with summation convention...
```r
predict(b,list(X=X[1:3,]))
```

## example of prediction that simply evaluates smooth (no summation)... 
```r
predict(b,data.frame(X=c(.2,.3,.7)))
```

### Simple random effect model example.

```r
set.seed(7)
n <- 200
x <- runif(n) ## a continuous covariate

fac <- factor(sample(letters,n*2,replace=TRUE))
dim(fac) <- c(n,2)

nb <- length(levels(fac))
b <- rnorm(nb)
y <- 20*(x-.3)^4 + b[fac[,1]] - b[fac[,2]] + rnorm(n)*.5

L <- matrix(-1,n,2);L[,1] <- 1 ## the differencing 'by' variable

mod <- gam(y ~ s(x) + s(fac,by=L,bs="re"),method="REML")
gam.vcomp(mod)
plot(mod,page=1)
```

## example of prediction using matrices...
### Multivariate Integral Example

Function `test1` will be integrated (by midpoint quadrature) over 100 equal area sub-squares covering the unit square. Noise is added to the resulting simulated data.

#### Function `test1`

```r
test1 <- function(x, z, sx = 0.3, sz = 0.4) {
  (pi^sx^sz)*(1.2*exp(-(x-0.2)^2/sx^2-(z-0.3)^2/sz^2) +
       0.8*exp(-(x-0.7)^2/sx^2-(z-0.8)^2/sz^2))
}
```

#### Integration Grid

- **Integration Grid**
  - `ig` integration grid within square
    - `mx` = `(1:ig-.5)/ig`
    - `ix` = `rep(mx, ig)`
  - `mz` = `(1:ig-.5)/ig`
  - `iz` = `rep(mz, rep(ig, ig))`

- **Observation Grid**
  - `og` observation grid
    - `mx` = `(1:og-1)/og`
    - `ox` = `rep(mx, og)`
  - `mz` = `(1:og-1)/og`
  - `oz` = `rep(mz, rep(og, og))`

- **x, z grid**
  - `x` = `ox + ix/og`
  - `z` = `oz + iz/og`

#### Creating Matrix Covariates

- **Matrix `X`**
  - `X <- matrix(x, og^2, ig^2, byrow=TRUE)`
- **Matrix `Z`**
  - `Z <- matrix(z, og^2, ig^2, byrow=TRUE)`

#### Simulated Test Data

- **Quadrature Square Area**
  - `dA <- 1/(og*ig)^2`
- **Evaluate on Grid**
  - `F <- test1(X, Z)`
- **Integrate by Midpoint Quadrature**
  - `f <- rowSums(F)*dA`
  - `y <- f + rnorm(og^2)*5e-4`

#### Fit Models

- **Model `L`**
  - `L <- X*0 + dA`
- **Model `L1`**
  - `L1 <- rowSums(L)`

- **Model with Smooths**
  - `b <- gam(y ~ s(X, Z, by=L) + L1 - 1)`
  - `b1 <- gam(y ~ te(X, Z, by=L) + L1 - 1)`

#### Plot Results
old.par<-par(mfrow=c(2,2))
x<-runif(n);z<-runif(n);
xs<-seq(0,1,length=30);zs<-seq(0,1,length=30)
pr<-data.frame(x=rep(xs,30),z=rep(zs,rep(30,30)))
truth<-matrix(test1(pr$x,pr$z),30,30)
contour(xs,zs,truth)
plot(b)
vis.gam(b,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")
vis.gam(b1,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")

####################################
## A "signal" regression example...
####################################

rf <- function(x=seq(0,1,length=100)){
  ## generates random functions...
  m <- ceiling(runif(1)*5) # number of components
  f <- x*0;
  mu <- runif(m,min(x),max(x));sig <- (runif(m)+.5)*(max(x)-min(x))/10
  for (i in 1:m) f <- f + dnorm(x,mu[i],sig[i])
  f
}

x <- seq(0,1,length=100) # evaluation points

example functional predictors...
par(mfrow=c(3,3));for (i in 1:9) plot(x,rf(x),type="l",xlab="x")

## simulate 200 functions and store in rows of L...
L <- matrix(NA,200,100)
for (i in 1:200) L[i,] <- rf() # simulate the functional predictors

f2 <- function(x) {
  ## the coefficient function
  (0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10)/10
}
f <- f2(x) # the true coefficient function

y <- L%*%f + rnorm(200)*20 # simulated response data

## Now fit the model E(y) = L%*%f(x) where f is a smooth function.
## The summation convention is used to evaluate smooth at each value
## in matrix X to get matrix F, say. Then rowSum(L*F) gives E(y).
## create matrix of eval points for each function. Note that
## `smoothCon' is smart and will recognize the duplication...
X <- matrix(x,200,100,byrow=TRUE)

b <- gam(y~s(X,by=L,k=20))
par(mfrow=c(1,1))
plot(b,shade=TRUE);lines(x,f,col=2)
Description

Function to extract the log-likelihood for a fitted gam model (note that the models are usually fitted by penalized likelihood maximization). Used by AIC. See details for more information on AIC computation.

Usage

```r
## S3 method for class 'gam'
logLik(object,...)
```

Arguments

- `object`: fitted model objects of class gam as produced by `gam()`.
- `...`: un-used in this case

Details

Modification of `logLik.glm` which corrects the degrees of freedom for use with gam objects.

The function is provided so that AIC functions correctly with gam objects, and uses the appropriate degrees of freedom (accounting for penalization). See e.g. Wood, Pya and Saefken (2016) for a derivation of an appropriate AIC.

For `gaussian` family models the MLE of the scale parameter is used. For other families with a scale parameter the estimated scale parameter is used. This is usually not exactly the MLE, and is not the simple deviance based estimator used with glm models. This is because the simple deviance based estimator can be badly biased in some cases, for example when a Tweedie distribution is employed with low count data.

There are two possible AIC’s that might be considered for use with GAMs. Marginal AIC is based on the marginal likelihood of the GAM, that is the likelihood based on treating penalized (e.g. spline) coefficients as random and integrating them out. The degrees of freedom is then the number of smoothing/variance parameters + the number of fixed effects. The problem with Marginal AIC is that marginal likelihood underestimates variance components/oversmooths, so that the approach favours simpler models excessively (substituting REML does not work, because REML is not comparable between models with different unpenalized/fixed components). Conditional AIC uses the likelihood of all the model coefficients, evaluated at the penalized MLE. The degrees of freedom to use then is the effective degrees of freedom for the model. However, Greven and Kneib (2010) show that the neglect of smoothing parameter uncertainty can lead to this conditional AIC being excessively likely to select larger models. Wood, Pya and Saefken (2016) propose a simple correction to the effective degrees of freedom to fix this problem. mgcv applies this correction whenever possible: that is when using ML or REML smoothing parameter selection with `gam` or `bam`. The correction is not computable when using the Extended Fellner Schall or BFGS optimizer (since the correction requires an estimate of the covariance matrix of the log smoothing parameters).

Value

Standard `logLik` object: see `logLik`.

ls.size Size of list elements

Description

Produces a named array giving the size, in bytes, of the elements of a list.

Usage

ls.size(x)

Arguments

x A list.

Value

A numeric vector giving the size in bytes of each element of the list x. The elements of the array have the same names as the elements of the list. If x is not a list then its size in bytes is returned, un-named.

magic

Stable Multiple Smoothing Parameter Estimation by GCV or UBRE

Description

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton’s method in multidimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

Usage

magic(y,X,sp,S,off,L=NULL,lsp0=NULL,rank=NULL,H=NULL,C=NULL,
w=NULL,gamma=1,sc...
H is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.

C is the optional matrix specifying any linear equality constraints on the fitting problem. If \( \mathbf{b} \) is the parameter vector then the parameters are forced to satisfy \( \mathbf{C} \mathbf{b} = \mathbf{0} \).

\( \mathbf{w} \) is the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of \( \mathbf{y} \), specifically \( \mathbf{V}^{-1} = \mathbf{w}^\prime \mathbf{w} \). If \( \mathbf{w} \) is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of \( \mathbf{y} \). See below for an example using this.

gamma is an inflation factor for the model degrees of freedom in the GCV or UBRE score.

gcv should be set to TRUE if GCV is to be used, FALSE for UBRE.

ridge.parameter It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.

control is a list of iteration control constants with the following elements:

- **tol** The tolerance to use in judging convergence.
- **step.half** If a trial step fails then the method tries halving it up to a maximum of step.half times.
- **rank.tol** is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than rank_tol multiplied by the largest singular value of the problem is set to zero.

**extra.rss** is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with n.score, this is useful for certain methods for dealing with very large data sets.

**n.score** number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.

**nthreads** magic can make use of multiple threads if this is set to >1.

Details The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

\[
\text{minimise } \| \mathbf{W} (\mathbf{X} \mathbf{b} - \mathbf{y}) \|^2 + \mathbf{b}' \mathbf{H} \mathbf{b} + \sum_{i=1}^{m} \theta_i \mathbf{S}_i \mathbf{b}
\]

possibly subject to constraints \( \mathbf{C} \mathbf{b} = \mathbf{0} \). \( \mathbf{X} \) is a design matrix, \( \mathbf{b} \) a parameter vector, \( \mathbf{y} \) a data vector, \( \mathbf{W} \) a weight matrix, \( \mathbf{S}_i \) a positive semi-definite matrix of coefficients defining the ith penalty with associated smoothing parameter \( \theta_i \), \( \mathbf{H} \) is the positive semi-definite offset penalty matrix and \( \mathbf{C} \) a matrix of coefficients defining any linear equality constraints on the problem. \( \mathbf{X} \) need not be of full column rank.

The \( \theta_i \) are chosen to minimize either the GCV score:
$$V_g = \frac{n\|W(y - Ay)\|^2}{[tr(I - \gamma A)]^2}$$

or the UBRE score:

$$V_u = \frac{\|W(y - Ay)\|^2}{n - 2\phi tr(I - \gamma A)/n + \phi}$$

where $\gamma$ is gamma, the inflation factor for degrees of freedom (usually set to 1) and $\phi$ is scale, the scale parameter. $A$ is the hat matrix (influence matrix) for the fitting problem (i.e. the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through $A$.

The method operates by Newton or steepest descent updates of the logs of the $\theta_i$. A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small $\theta_i$, it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a $\log(\theta_i)$ change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal $b$ parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

Value

The function returns a list with the following items:

- **b**: The best fit parameters given the estimated smoothing parameters.
- **scale**: the estimated (GCV) or supplied (UBRE) scale parameter.
- **score**: the minimized GCV or UBRE score.
- **sp**: an array of the estimated smoothing parameters.
- **sp.full**: an array of the smoothing parameters that actually multiply the elements of $S$ (same as sp if L was NULL). This is $\exp(L%*%\log(sp))$.
- **rV**: a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters $b$ is given by $rV%*%t(rV)*scale$.
- **gcv.info**: is a list of information about the performance of the method with the following elements:
  - **full.rank**: The apparent rank of the problem: number of parameters less number of equality constraints.
  - **rank**: The estimated actual rank of the problem (at the final iteration of the method).
  - **fully.converged**: is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it converged by failing to decrease the score along the search direction.
**hess.pos.def** is TRUE if the hessian of the UBRE or GCV score was positive definite at convergence.

**iter** is the number of Newton/Steepest descent iterations taken.

**score.calls** is the number of times that the GCV/UBRE score had to be evaluated.

**rms.grad** is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.

**R** The factor R from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to X. So it may not be upper triangular.

Note that some further useful quantities can be obtained using **magic.post.proc**.

G <- gam(y~s(x, k=20), fit=FALSE)
## fit using magic, with weight *matrix*
mgfit <- magic(G$y, G$X, G$sp, G$S, G$off, rank=G$rank, C=G$C, w=w)
## Modify previous gam object using new fit, for plotting...
mg.stuff <- magic.post.proc(G$X, mgfit, w)
b$edf <- mg.stuff$edf; b$Vp <- mg.stuff$Vb
b$coefficients <- mgfit$b
plot(b); lines(x, f-mean(f), col=2); title("Known correlation")
```

---

### `magic.post.proc`

**Auxilliary information from magic fit**

**Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

**Usage**

```r
magic.post.proc(X, object, w=NULL)
```

**Arguments**

- **X** is the model matrix.
- **object** is the list returned by `magic` after fitting the model with model matrix `X`.
- **w** is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to magic, if one was.). If `w` is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If `w` is a matrix then `t(w)%*%w` should typically give the inverse of the covariance matrix of the response data supplied to magic.
Details

object contains \( rV \) (\( V \), say), and scale (\( \phi \), say) which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is \( VV'\phi \). The vector of estimated degrees of freedom for each parameter is the leading diagonal of \( VV'X'W'WX \) where \( W \) is either the weight matrix \( w \) or the matrix \( \text{diag}(w) \). The hat/influence matrix is given by \( WXV'X'W' \).

The frequentist parameter estimator covariance matrix is \( VV'X'W'WXV'X'W' \phi \); it is sometimes useful for testing terms for equality to zero.

Value

A list with three items:

- \( Vb \) the Bayesian covariance matrix of the model parameters.
- \( Ve \) the frequentist covariance matrix for the parameter estimators.
- \( \text{hat} \) the leading diagonal of the hat (influence) matrix.
- \( \text{edf} \) the array giving the estimated degrees of freedom associated with each parameter.

Description

This page provides answers to some of the questions that get asked most often about mgcv

FAQ list

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the `summary.gam` Alternatively, simple random effects can be fitted with `gam`, which makes comparison straightforward. Package `gamm4` is an alternative, which allows AIC type model selection for generalized models.

2. **How do I get the equation of an estimated smooth?** This slightly misses the point of semi-parametric modelling: the idea is that we estimate the form of the function from data without assuming that it has a particular simple functional form. Of course for practical computation the functions do have underlying mathematical representations, but they are not very helpful, when written down. If you do need the functional forms then see chapter 5 of Wood (2017). However for most purposes it is better to use `predict.gam` to evaluate the function for whatever argument values you need. If derivatives are required then the simplest approach is to use finite differencing (which also allows SEs etc to be calculated).
3. Some of my smooths are estimated to be straight lines and their confidence intervals vanish at some point in the middle. **What is wrong?** Nothing. Smooths are subject to sum-to-zero identifiability constraints. If a smooth is estimated to be a straight line then it consequently has one degree of freedom, and there is no choice about where it passes through zero — so the CI must vanish at that point.

4. **How do I test whether a smooth is significantly different from a straight line?** See `tprs` and the example therein.

5. **An example from an mgcv hlpfile gives an error - is this a bug?** It might be, but first please check that the version of mgcv you have loaded into R corresponds to the version from which the hlpfile came. Many such problems are caused by trying to run code only supported in a later mgcv version in an earlier version. Another possibility is that you have an object loaded whose name clashes with an mgcv function (for example you are trying to use the mgcv `multinom` function, but have another object called `multinom` loaded.)

6. **Some code from Wood (2006) causes an error: why?** The book was written using mgcv version 1.3. To allow for REML estimation of smoothing parameters in versions 1.5; some changes had to be made to the syntax. In particular the function `gam.method` no longer exists. The smoothness selection method (GCV, REML etc) is now controlled by the `method` argument to `gam` while the optimizer is selected using the `optimizer` argument. See `gam` for details.

7. **Why is a model object saved under a previous mgcv version not usable with the current mgcv version?** I’m sorry about this issue, I know it’s really annoying. Here’s my defence. Each mgcv version is run through an extensive test suite before release, to ensure that it gives the same results as before, unless there are good statistical reasons why not (e.g. improvements to p-value approximation, fixing of an error). However it is sometimes necessary to modify the internal structure of model objects in a way that makes an old style object unusable with a newer version. For example, bug fixes or new R features sometimes require changes in the way that things are computed which in turn require modification of the object structure. Similarly improvements, such as the ability to compute smoothing parameters by RE/ML require object level changes. The only fix to this problem is to access the old object using the original mgcv version (available on CRAN), or to recompute the fit using the current mgcv version.

8. **When using gamm or gamm4, the reported AIC is different for the gam object and the lme or lmer object. Why is this?** There are several reasons for this. The most important is that the models being used are actually different in the two representations. When treating the GAM as a mixed model, you are implicitly assuming that if you gathered a replicate dataset, the smooths in your model would look completely different to the smooths from the original model, except for having the same degree of smoothness. Technically you would expect the smooths to be drawn afresh from their distribution under the random effects model. When viewing the gam from the usual penalized regression perspective, you would expect smooths to look broadly similar under replication of the data. i.e. you are really using Bayesian model for the smooths, rather than a random effects model (it’s just that the frequentist random effects and Bayesian computations happen to coincide for computing the estimates). As a result of the different assumptions about the data generating process, AIC model comparisons can give rather different answers depending on the model adopted. Which you use should depend on which model you really think is appropriate. In addition the computations of the AICs are different. The mixed model AIC uses the marginal likelihood and the corresponding number of model parameters. The gam model uses the penalized likelihood and the effective degrees of freedom.

9. **What does ’mgcv’ stand for? ’Mixed GAM Computation Vehicle’, is my current best effort (let me know if you can do better). Originally it stood for ’Multiple GCV’, which has long since ceased to be usefully descriptive, (and I can’t really change ’mgcv’ now without causing disruption). On a bad inbox day ’Mad GAM Computing Vulture’.
10. **My new method is failing to beat mgcv, what can I do?** If speed is the problem, then make sure that you use the slowest basis possible ("tp") with a large sample size, and experiment with different optimizers to find one that is slow for your problem. For prediction error/MSE, then leaving the smoothing basis dimensions at their arbitrary defaults, when these are inappropriate for the problem setting, is a good way of reducing performance. Similarly, using p-splines in place of derivative penalty based splines will often shave a little more from the performance here. Unlike REML/ML, prediction error based smoothness selection criteria such as Mallows Cp and GCV often produce a small proportion of severe overfits, so careful choice of smoothness selection method can help further. In particular GCV etc. usually result in worse confidence interval and p-value performance than ML or REML. If all this fails, try using a really odd simulation setup for which mgcv is clearly not suited: for example poor performance is almost guaranteed for small noisy datasets with large numbers of predictors.

**mgcv.package**

*Mixed GAM Computation Vehicle with GCV/AIC/REML smoothness estimation and GAMMs by REML/PQL*

**Description**

mgcv provides functions for generalized additive modelling (**gam** and **bam**) and generalized additive mixed modelling (**gamm**, and **random.effects**). The term GAM is taken to include any model dependent on unknown smooth functions of predictors and estimated by quadratically penalized (possibly quasi-) likelihood maximization. Available distributions are covered in **family.mgcv** and available smooths in **smooth.terms**.

Particular features of the package are facilities for automatic smoothness selection (Wood, 2004, 2011), and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available. In addition to the main modelling functions, **jagam** provided facilities to ease the set up of models for use with JAGS, while **ginla** provides marginal inference via a version of Integrated Nested Laplace Approximation.

**Details**

mgcv provides generalized additive modelling functions **gam**, **predict.gam** and **plot.gam**, which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other
functions such as `summary.gam` and `anova.gam` are also provided, for extracting information from a fitted `gamObject`.

Use of `gam` is much like use of `glm`, except that within a `gam` model formula, isotropic smooths of any number of predictors can be specified using `s` terms, while scale invariant smooths of any number of predictors can be specified using `te`, `ti` or `t2` terms. `smooth` terms provides an overview of the built in smooth classes, and `random.effects` should be referred to for an overview of random effects terms (see also `mrf` for Markov random fields). Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE or (RE)ML. See `gam`, `gam.models`, `linear.functional.terms` and `gam.selection` for some discussion of model specification and selection. For detailed control of fitting see `gam.convergence`, `gam` arguments method and optimizer and `gam.control`. For checking and visualization see `gam.check`, `choose.k`, `vis.gam` and `plot.gam`. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see `smooth.construct`, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals (see Marra and Wood, 2012). The Bayesian covariance matrix for the model coefficients is returned in `Vp` of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas (see Wood, 2013a,b). Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

For large datasets (that is large n) see `bam` which is a version of `gam` with a much reduced memory footprint.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`. See also `mgcv.FAQ`.

**Description**

`mgcv` can make some use of multiple cores or a cluster.

- **bam** can use an openMP based parallelization approach alongside discretisation of covariates to achieve substantial speed ups. This is selected using the `discrete=TRUE` option to `bam`, with the number of threads controlled via the `nthreads` argument. This is the approach that scales best. See example below.

Alternatively, function `bam` can use the facilities provided in the `parallel` package. See examples below. Note that most multi-core machines are memory bandwidth limited, so parallel speed up tends to be rather variable.

Function `gam` can use parallel threads on a (shared memory) multi-core machine via openMP (where this is supported). To do this, set the desired number of threads by setting `nthreads` to the number of cores to use, in the `control` argument of `gam`. Note that, for the most part, only the dominant $O(np^2)$ steps are parallelized ($n$ is number of data, $p$ number of parameters). For additive Gaussian models estimated by GCV, the speed up can be disappointing as these employ an $O(p^3)$ SVD step that can also have substantial cost in practice.

`magic` can also use multiple cores, but the same comments apply as for the GCV Gaussian additive model.

If `control$nthreads` is set to more than the number of cores detected, then only the number of detected cores is used. Note that using virtual cores usually gives very little speed up, and can even slow computations slightly. For example, many Intel processors reporting 4 cores actually have 2 physical cores, each with 2 virtual cores, so using 2 threads gives a marked increase in speed, while using 4 threads makes little extra difference.

Note that on Intel and similar processors the maximum performance is usually achieved by disabling Hyper-Threading in BIOS, and then setting the number of threads to the number of physical cores used. This prevents the operating system scheduler from sending 2 floating point intensive threads
to the same physical core, where they have to share a floating point unit (and cache) and therefore slow each other down. The scheduler tends to do this under the manager - worker multi-threading approach used in mgcv, since the manager thread looks very busy up to the point at which the workers are set to work, and at the point of scheduling the scheduler has no way of knowing that the manager thread actually has nothing more to do until the workers are finished. If you are working on a many cored platform where you can not disable hyper-threading then it may be worth setting the number of threads to one less than the number of physical cores, to reduce the frequency of such scheduling problems.

mgcv’s work splitting always makes the simple assumption that all your cores are equal, and you are not sharing them with other floating point intensive threads.

In addition to hyper-threading several features may lead to apparently poor scaling. The first is that many CPUs have a Turbo mode, whereby a few cores can be run at higher frequency, provided the overall power used by the CPU does not exceed design limits, however it is not possible for all cores on the CPU to run at this frequency. So as you add threads eventually the CPU frequency has to be reduced below the Turbo frequency, with the result that you don’t get the expected speed up from adding cores. Secondly, most modern CPUs have their frequency set dynamically according to load. You may need to set the system power management policy to favour high performance in order to maximize the chance that all threads run at the speed you were hoping for (you can turn off dynamic power control in BIOS, but then you turn off the possibility of Turbo also).

Because the computational burden in mgcv is all in the linear algebra, then parallel computation may provide reduced or no benefit with a tuned BLAS. This is particularly the case if you are using a multi threaded BLAS, but a BLAS that is tuned to make efficient use of a particular cache size may also experience loss of performance if threads have to share the cache.

 ,data=dat,family=poisson(),chunk.size=5000,cluster=cl))

fv <- predict(b3,cluster=cl)  ## parallel prediction
if (!is.null(cl)) stopCluster(cl)
b3

## Alternative, better scaling example, using the discrete option with bam...

system.time(b4 <- bam(y ~ s(x0,bs=bs,k=7)+s(x1,bs=bs,k=7)+s(x2,bs=bs,k=k)
 ,data=dat,family=poisson(),discrete=TRUE,nthreads=2))

mini.roots

Obtain square roots of penalty matrices

Description

INTERNAL function to obtain square roots, B[i], of the penalty matrices S[i]'s having as few columns as possible.

Usage

mini.roots(S, off, np, rank = NULL)

Arguments

S  
  a list of penalty matrices, in packed form.
off  
  a vector where the i-th element is the offset for the i-th matrix. The elements in columns 1:off[i] of B[i] will be equal to zero.
np  
  total number of parameters.
rank  
  here rank[i] is optional supplied rank of S[i]. Set rank[i] < 1, or rank=NULL to estimate.

Value

A list of matrix square roots such that S[i]=B[i]%*%t(B[i]).

Author(s)

Simon N. Wood <simon.wood@r-project.org>.
Description

If there are missing values in the response or covariates of a GAM then the default is simply to use only the ‘complete cases’. If there are many missing covariates, this can get rather wasteful. One possibility is then to use imputation. Another is to substitute a simple random effects model in which the by variable mechanism is used to set $s(x)$ to zero for any missing $x$, while a Gaussian random effect is then substituted for the ‘missing’ $s(x)$. See the example for details of how this works, and `gam.models` for the necessary background on by variables.

Examples

## The example takes a couple of minutes to run...

```r
require(mgcv)
par(mfrow=c(4,4),mar=c(4,4,1,1))
for (sim in c(1,7)) {  # cycle over uncorrelated and correlated covariates
  n <- 350; set.seed(2)
  # simulate data but randomly drop 300 covariate measurements
  # leaving only 50 complete cases...
  dat <- gamSim(sim,n=n,scale=3)  # 1 or 7
  drop <- sample(1:n,300)  # to
  for (i in 2:5) dat[drop[1:75+(i-2)*75],i] <- NA
  # process data.frame producing binary indicators of missingness,
  # mx0, mx1 etc. For each missing value create a level of a factor
  # idx0, idx1, etc. So idx0 has as many levels as x0 has missing
  # values. Replace the NA’s in each variable by the mean of the
  # non missing for that variable...
  dname <- names(dat)[2:5]
  dat1 <- dat
  for (i in 1:4) {
    by.name <- paste("m",dname[i],sep="")
    dat1[[by.name]] <- is.na(dat1[[dname[i]]])
    dat1[[dname[i]]][dat1[[by.name]]] <- mean(dat1[[dname[i]]],na.rm=TRUE)
    lev <- rep(1,n); lev[dat1[[by.name]]] <- 1:sum(dat1[[by.name]])
    id.name <- paste("id",dname[i],sep="")
    dat1[[id.name]] <- factor(lev)
    dat1[[by.name]] <- as.numeric(dat1[[by.name]])
  }
  ## Fit a gam, in which any missing value contributes zero
  ## to the linear predictor from its smooth, but each
```
## missing has its own random effect, with the random effect
## variances being specific to the variable. e.g.
## for s(x0, by=ordered(!mx0)), declaring the `by' as an ordered
## factor ensures that the smooth is centred, but multiplied
## by zero when mx0 is one (indicating a missing x0). This means
## that any value (within range) can be put in place of the
## NA for x0. s(idx0, bs="re", by=mx0) produces a separate Gaussian
## random effect for each missing value of x0 (in place of s(x0),
## effectively). The `by' variable simply sets the random effect to
## zero when x0 is non-missing, so that we can set idx0 to any
## existing level for these cases.

b <- bam(y~s(x0, by=ordered(!mx0))+s(x1, by=ordered(!mx1))+
  s(x2, by=ordered(!mx2))+s(x3, by=ordered(!mx3))+
  s(idx0, bs="re", by=mx0)+s(idx1, bs="re", by=mx1)+
  s(idx2, bs="re", by=mx2)+s(idx3, bs="re", by=mx3)
  , data=dat1, discrete=TRUE)

for (i in 1:4) plot(b, select=i) ## plot the smooth effects from b

## fit the model to the 'complete case' data...
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), data=dat, method="REML")
plot(b2) ## plot the complete case results

---

### model.matrix.gam

Extract model matrix from GAM fit

#### Description

Obtains the model matrix from a fitted gam object.

#### Usage

```r
## S3 method for class 'gam'
model.matrix(object, ...)
```

#### Arguments

- **object**: fitted model object of class `gam` as produced by `gam()`.
- **...**: other arguments, passed to `predict.gam`.

#### Details

Calls `predict.gam` with no newdata argument and type="lpmatrix" in order to obtain the model matrix of object.

#### Value

A model matrix.
Author(s)
Simon N. Wood <simon.wood@r-project.org>

References

See Also
gam

Examples
require(mgcv)
n <- 15
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=6),knots=list(x=seq(0,1,length=6)))
model.matrix(mod)

Description
Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the gam, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

Usage
mono.con(x, up=TRUE, lower=NA, upper=NA)

Arguments
x The array of knot locations.
up If TRUE then the constraints imply increase, if FALSE then decrease.
lower This specifies the lower bound on the spline unless it is NA in which case no lower bound is imposed.
upper This specifies the upper bound on the spline unless it is NA in which case no upper bound is imposed.

details
Consider the natural cubic spline passing through the points \( \{x_i, y_i : i = 1 \ldots n\} \). Then it is possible to find a relatively small set of linear constraints on \( p \) sufficient to ensure monotonicity (and bounds if required): \( Ap \geq b \). Details are given in Wood (1994).
mroot

Value

A list containing constraint matrix A and constraint vector b.

mroot

Smallest square root of matrix

Description

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleski decomposition or singular value decomposition to do this.

Usage

mroot(A, rank=NULL, method="chol")

Arguments

A The positive semi-definite matrix, a square root of which is to be found.
rank if the rank of the matrix A is known then it should be supplied. NULL or <1 imply that it should be estimated.
method "chol" to use pivoted choleski decompositon, which is fast but tends to overestimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank.

Details

The function uses SVD, or a pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

Value

A matrix, B with as many columns as the rank of A, and such that A = BB'.
Author(s)
Simon N. Wood <simon.wood@r-project.org>

Examples

```r
require(mgcv)
set.seed(0)
a <- matrix(runif(24),6,4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
tol <- 100*Machine$double.eps
svd.err <- max(abs(A-B%*%t(B)));
if (svd.err>tol) warning("mroot (svd) suspect")
```

multinom

GAM multinomial logistic regression

Description

Family for use with `gam`, implementing regression for categorical response data. Categories must be coded 0 to K, where K is a positive integer. `gam` should be called with a list of K formulae, one for each category except category zero (extra formulae for shared terms may also be supplied: see `formula.gam`). The first formula also specifies the response variable.

Usage

```r
multinom(K=1)
```

Arguments

- `K` There are K+1 categories and K linear predictors.

Details

The model has K linear predictors, $\eta_j$, each dependent on smooth functions of predictor variables, in the usual way. If response variable, y, contains the class labels 0,...,K then the likelihood for y>0 is $\exp(\eta_y) / \{1 + \sum_j \exp(\eta_j)\}$. If y=0 the likelihood is $1 / \{1 + \sum_j \exp(\eta_j)\}$. In the two class case this is just a binary logistic regression model. The implementation uses the approach to GAMLSS models described in Wood, Pya and Saefken (2016).

The residuals returned for this model are simply the square root of -2 times the deviance for each observation, with a positive sign if the observed y is the most probable class for this observation, and a negative sign otherwise.

Use `predict` with `type="response"` to get the predicted probabilities in each category.

Note that the model is not completely invariant to category relabelling, even if all linear predictors have the same form. Realistically this model is unlikely to be suitable for problems with large numbers of categories. Missing categories are not supported.
Value

An object of class general.family.

pc <- apply(pp,1,function(x) which(max(x)==x)[1])-1
plot(gr,col=pc+3,pch=19)
Description

Family for use with \texttt{gam} implementing smooth multivariate Gaussian regression. The means for each dimension are given by a separate linear predictor, which may contain smooth components. Extra linear predictors may also be specified giving terms which are shared between components (see \texttt{formula.gam}). The Choleski factor of the response precision matrix is estimated as part of fitting.

Usage

\texttt{mvn(d=2)}

Arguments

d \indent The dimension of the response (>1).

Details

The response is \texttt{d} dimensional multivariate normal, where the covariance matrix is estimated, and the means for each dimension have separate linear predictors. Model specification is via a list of \texttt{gam} like formulae - one for each dimension. See example.

Currently the family ignores any prior weights, and is implemented using first derivative information sufficient for BFGS estimation of smoothing parameters. "response" residuals give raw residuals, while "deviance" residuals are standardized to be approximately independent standard normal if all is well.

Value

An object of class \texttt{general.family}.

negbin

**GAM negative binomial families**

Description

The `gam` modelling function is designed to be able to use the `negbin` family (a modification of MASS library `negative.binomial` family by Venables and Ripley), or the `nb` function designed for integrated estimation of parameter theta. \( \theta \) is the parameter such that \( \text{var}(y) = \mu + \mu^2/\theta \), where \( \mu = E(y) \).

Two approaches to estimating theta are available (with `gam` only):

- With `negbin` then if ‘performance iteration’ is used for smoothing parameter estimation (see `gam`), then smoothing parameters are chosen by GCV and \( \theta \) is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection with the `nb` family then \( \theta \) is estimated alongside the smoothing parameters by ML or REML.

To use the first option, set the optimizer argument of `gam` to "perf" (it can sometimes fail to converge).

Usage

```r
negbin(theta = stop("'theta' must be specified"), link = "log")
nb(theta = NULL, link = "log")
```
Arguments

theta Either i) a single value known value of theta or ii) two values of theta specifying the endpoints of an interval over which to search for theta (this is an option only for negbin, and is deprecated). For nb then a positive supplied theta is treated as a fixed known parameter, otherwise it is estimated (the absolute value of a negative theta is taken as a starting value).

link The link function: one of "log", "identity" or "sqrt"

Details

nb allows estimation of the theta parameter alongside the model smoothing parameters, but is only usable with gam or bam (not gamm).

For negbin, if a single value of theta is supplied then it is always taken as the known fixed value and this is useable with bam and gamm. If theta is two numbers (theta[2]>theta[1]) then they are taken as specifying the range of values over which to search for the optimal theta. This option is deprecated and should only be used with performance iteration estimation (see gam argument optimizer), in which case the method of estimation is to choose \( \hat{\theta} \) so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial).

In this case \( \theta \) estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the \( \theta \) estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except \( \theta \) and then searching for the \( \hat{\theta} \) which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter <1.

Value

For negbin an object inheriting from class family, with additional elements

dvar the function giving the first derivative of the variance function w.r.t. mu.
d2var the function giving the second derivative of the variance function w.r.t. mu.
getTheta A function for retrieving the value(s) of theta. This also useful for retrieving the estimate of theta after fitting (see example).

For nb an object inheriting from class extended.family.

WARNINGS

gamm does not support theta estimation

The negative binomial functions from the MASS library are no longer supported.

dat <- gamSim(1,n=n)
g <- exp(dat$f/5)
## negative binomial data...
dat$y <- rnbinom(g,size=3,mu=g)
## known theta fit ...
b0 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(3),data=dat)
plot(b0,pages=1)
print(b0)

## same with theta estimation...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=nb(),data=dat)
plot(b,pages=1)
print(b)
b$family$getTheta(TRUE) ## extract final theta estimate

## another example...
set.seed(1)
f <- dat$f
f <- f - min(f)+5;g <- f^2/10
dat$y <- rnbinom(g,size=3,mu=g)
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=nb(link="sqrt"),
          data=dat,method="REML")
plot(b2,pages=1)
print(b2)
rm(dat)
```

Description

`new.name` obtains a name for a new variable that is not already in use.

Usage

```r
new.name(proposed,old.names)
```

Arguments

- `proposed` (a suggested name)
- `old.names` (an array of names that must not be duplicated)

Value

A name that is not in `old.names`. 
notExp

gamm

Examples

```
require(mgcv)
old <- c("a","tuba","is","tubby")
new.name("tubby",old)
```

Description
It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter \( a \) should be non-negative then we use \( a = \exp(b) \) and optimize with respect to the unconstrained parameter \( b \). This often works well, but it does imply a rather limited working range for \( b \): using 8 byte doubles, for example, if \( b \)'s magnitude gets much above 700 then \( a \) overflows or underflows. This can cause problems for numerical optimization methods.

notExp is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than \( \exp \). It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

notLog is the inverse function of notExp.

The major use of these functions was originally to provide more robust pdMat classes for lme for use by gamm. Currently the notExp2 and notLog2 functions are used in their place, as a result of changes to the nlme optimization routines.

Usage

```
notExp(x)
notLog(x)
```

Arguments

- \( x \) Argument array of real numbers (notExp) or positive real numbers (notLog).

Value

An array of function values evaluated at the supplied argument values.

notExp2

Alternative to log parameterization for variance components

Description

notLog2 and notExp2 are alternatives to log and exp or notLog and notExp for re-parameterization of variance parameters. They are used by the pdTens and pdIdnot classes which in turn implement smooths for gamm.

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.
This reparameterization was made necessary by some modifications to the underlying optimization method in \texttt{lme} introduced in \texttt{nlme} 3.1-62. It is possible that future releases will return to the \texttt{notExp} parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

**Usage**

\begin{verbatim}
notExp2(x,d=.Options$mgcv.vc.logrange,b=1/d)
notLog2(x,d=.Options$mgcv.vc.logrange,b=1/d)
\end{verbatim}

**Arguments**

- \texttt{x} : Argument array of real numbers (\texttt{notExp}) or positive real numbers (\texttt{notLog}).
- \texttt{d} : the range of \texttt{notExp2} runs from \text{exp}(-d) to \text{exp}(d). To change the range used by \texttt{gamm} reset \texttt{mgcv.vc.logrange} using \texttt{options}.
- \texttt{b} : determines the period of the cycle of \texttt{notExp2}.

**Value**

An array of function values evaluated at the supplied argument values.

null.space.dimension

The basis of the space of un-penalized functions for a TPRS

Description
The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. null.space.dimension finds the dimension of this space, $M$, given the number of covariates that the smoother is a function of, $d$, and the order of the smoothing penalty, $m$. If $m$ does not satisfy $2m > d$ then the smallest possible dimension for the null space is found given $d$ and the requirement that the smooth should be visually smooth.

Usage
null.space.dimension(d,m)

Arguments
- **d**: a positive integer - the number of variables of which the t.p.s. is a function.
- **m**: a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

Details
Thin plate splines are only visually smooth if the order of the wiggliness penalty, $m$, satisfies $2m > d + 1$. If $2m < d + 1$ then this routine finds the smallest $m$ giving visual smoothness for the given $d$, otherwise the supplied $m$ is used. The null space dimension is given by:

$$M = (m + d - 1)!/(d!(m - 1)!)$$

which is the value returned.

Value
An integer (array), the null space dimension $M$.

tprs

Examples
```r
require(mgcv)
null.space.dimension(2,0)
```
**Description**

Family for use with `gam` or `bam`, implementing regression for ordered categorical data. A linear predictor provides the expected value of a latent variable following a logistic distribution. The probability of this latent variable lying between certain cut-points provides the probability of the ordered categorical variable being of the corresponding category. The cut-points are estimated along side the model smoothing parameters (using the same criterion). The observed categories are coded 1, 2, 3, ... up to the number of categories.

**Usage**

```r
ocat(theta=NULL,link="identity",R=NULL)
```

**Arguments**

- `theta`: cut point parameter vector (dimension R-2). If supplied and all positive, then taken to be the cut point increments (first cut point is fixed at -1). If any are negative then absolute values are taken as starting values for cutpoint increments.
- `link`: The link function: only "identity" allowed at present (possibly for ever).
- `R`: the number of categories.

**Details**

Such cumulative threshold models are only identifiable up to an intercept, or one of the cut points. Rather than remove the intercept, `ocat` simply sets the first cut point to -1. Use `predict.gam` with type="response" to get the predicted probabilities in each category.

**Value**

An object of class `extended.family`.

dat <- gamSim(1,n=n)
dat$f <- dat$f - mean(dat$f)
```
The one standard error rule for smoother models

Description

The ‘one standard error rule’ (see e.g. Hastie, Tibshirani and Friedman, 2009) is a way of producing smoother models than those directly estimated by automatic smoothing parameter selection methods. In the single smoothing parameter case, we select the largest smoothing parameter within one standard error of the optimum of the smoothing parameter selection criterion. This approach can be generalized to multiple smoothing parameters estimated by REML or ML.

Details

Under REML or ML smoothing parameter selection an asymptotic distributional approximation is available for the log smoothing parameters. Let $\rho$ denote the log smoothing parameters that we want to increase to obtain a smoother model. The large sample distribution of the estimator of $\rho$ is $N(\rho, V)$ where $V$ is the matrix returned by sp.vcov. Drop any elements of $\rho$ that are already at ‘effective infinity’, along with the corresponding rows and columns of $V$. The standard errors of the log smoothing parameters can be obtained from the leading diagonal of $V$. Let the vector of these be $d$. Now suppose that we want to increase the estimated log smoothing parameters by an amount $\alpha d$. We choose $\alpha$ so that $\alpha d^T V^{-1} d = \sqrt{2p}$, where $p$ is the dimension of $d$ and $2p$ the variance of a chi-squared r.v. with $p$ degrees of freedom.

The idea is that we increase the log smoothing parameters in proportion to their standard deviation, until the RE/ML is increased by 1 standard deviation according to its asymptotic distribution.

Simon N. Wood <simon.wood@r-project.org>
Penalized Constrained Least Squares Fitting

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

Usage

pcls(M)

Arguments

M is the single list argument to pcls. It should have the following elements:

y The response data vector.

w A vector of weights for the data (often proportional to the reciprocal of the variance).

X The design matrix for the problem, note that ncol(M$X) must give the number of model parameters, while nrow(M$X) should give the number of data.

C Matrix containing any linear equality constraints on the problem (e.g. C in $Cp = c$). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector c, it is defined implicitly by the initial parameter estimates p.
S A list of penalty matrices. S[[i]][][] is the smallest contiguous matrix including all the non-zero elements of the ith penalty matrix. The first parameter it penalizes is given by off[[i]]+1 (starting counting at 1).

off Offset values locating the elements of S in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)

sp An array of smoothing parameter estimates.

p An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.

Ain Matrix for the inequality constraints Ain p > bin.

bin vector in the inequality constraints.

Details

This solves the problem:

\[
\text{minimise } \| W^{1/2}(Xp - y) \|^2 + \sum_{i=1}^{m} \lambda_i p' S_i p
\]

subject to constraints C p = c and Ain p > bin, w.r.t. p given the smoothing parameters \lambda_i. X is a design matrix, p a parameter vector, y a data vector, W a diagonal weight matrix, S_i a positive semi-definite matrix of coefficients defining the ith penalty and C a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the \lambda_i. Note that X must be of full column rank, at least when projected into the null space of any equality constraints. Ain is a matrix of coefficients defining the inequality constraints, while bin is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e. X'X is not formed explicitly. See Gill et al. 1981.

Value

The function returns an array containing the estimated parameter vector.

Overflow proof pdMat class for multiples of the identity matrix

Description

This set of functions is a modification of the pdMat class pdIdent from library nlme. The modification is to replace the log parameterization used in pdMat with a notLog2 parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the pdTens class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the pdTens class it is easy to do so.

Usage

pdIdnot(value = numeric(0), form = NULL, nam = NULL, data = sys.frame(sys.parent()))

Arguments

value Initialization values for parameters. Not normally used.
form A one sided formula specifying the random effects structure.
nam a names argument, not normally used with this class.
data data frame in which to evaluate formula.

Details

The following functions are provided: Dim.pdIdnot, coef.pdIdnot, corMatrix.pdIdnot, logDet.pdIdnot, pdConstruct.pdIdnot, pdFactor.pdIdnot, pdMatrix.pdIdnot, solve.pdIdnot, summary.pdIdnot. (e.g. mgcv:::coef.pdIdnot to access.)

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is initialised with estimates of the scaled covariance matrix itself.

Value

A class pdIdnot object, or related quantities. See the nlme documentation for further details.

**pdTens**

*Functions implementing a pdMat class for tensor product smooths*

**Description**

This set of functions implements an nlme library pdMat class to allow tensor product smooths to be estimated by lme as called by gamm. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It's not possible to transform the problem to make the required random effects covariance matrix look like one of the standard pdMat classes: hence the need for the pdTens class. A notLog2 parameterization ensures that the parameters are positive.

These functions (pdTens, pdConstruct.pdTens, pdFactor.pdTens, pdMatrix.pdTens, coef.pdTens and summary.pdTens) would not normally be called directly.

**Usage**

```r
pdTens(value = numeric(0), form = NULL,
       nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

- `value`: Initialization values for parameters. Not normally used.
- `form`: A one sided formula specifying the random effects structure. The formula should have an attribute `S` which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects.
- `nam`: a names argument, not normally used with this class.
- `data`: data frame in which to evaluate formula.

**Details**

If using this class directly note that it is worthwhile scaling the S matrices to be of 'moderate size', for example by dividing each matrix by its largest singular value: this avoids problems with lme defaults (smooth.construct.tensor.smooth.spec does this automatically).

This appears to be the minimum set of functions required to implement a new pdMat class.

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes initialzed with its inverse.
pen.edf

Value

A class pdTens object, or its coefficients or the matrix it represents or the factor of that matrix. pdFactor returns the factor as a vector (packed column-wise) (pdMatrix always returns a matrix).

---

pen.edf Extract the effective degrees of freedom associated with each penalty in a gam fit

Description

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for t2 terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. te terms).

Usage

pen.edf(x)

Arguments

x an object inheriting from gam

Details

Useful for models containing t2 terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

Value

A vector of EDFs, named with labels identifying which penalty each EDF relates to.

t2

Examples

```r
require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400, scale=2) ## simulate data
## following 't2' smooth basically separates smooth
## of x0,x1 into main effects + interaction....

b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
data=dat,method="ML")
pen.edf(b)
## label "rr" indicates interaction edf (range space times range space)
## label "nr" (null space for x0 times range space for x1) is main
## effect for x1.
## label "rn" is main effect for x0
## clearly interaction is negligible

## second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)
+s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)
## In this case the EDF is negligible for all terms in the t2 smooth
## apart from the 'main effects' (r2 and 2r). To understand the labels
## consider the following 2 examples....
## "r1" relates to the interaction of the range space of the first
## marginal smooth and the first basis function of the null
## space of the second marginal smooth
## "2r" relates to the interaction of the second basis function of
## the null space of the first marginal smooth with the range
## space of the second marginal smooth.
```

place.knots

Automatically place a set of knots evenly through covariate values

Description
Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

Usage

`place.knots(x, nk)`
Arguments

- `x` array of covariate values (need not be sorted).
- `nk` integer indicating the required number of knots.

Details

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

Value

An array of knot locations.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

See Also

smooth.construct.cc.smooth.spec

Examples

```
require(mgcv)
x<-runif(30)
place.knots(x,7)
rm(x)
```

Description

Takes a fitted `gam` object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

Usage

```r
## S3 method for class 'gam'
plot(x,residuals=FALSE,rug=NULL,se=TRUE,pages=0,select=NULL,scale=-1,
n=100,n2=40,n3=3,pers=FALSE,theta=30,phi=30,jit=FALSE,xlab=NULL,
 ylab=NULL,main=NULL,ylim=NULL,xlim=NULL,too.far=0.1,
 all.terms=FALSE,shade=FALSE,shade.col="gray80",shift=0,
 trans=I,seWithMean=FALSE,unconditional=FALSE,by.resids=FALSE,
scheme=0,...)
```
Arguments

**x**
a fitted `gam` object as produced by `gam()`.

**residuals**
If `TRUE` then partial residuals are added to plots of 1-D smooths. If `FALSE` then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If `TRUE` then the residuals are the working residuals from the IRLS iteration weighted by the (square root) IRLS weights, in order that they have constant variance if the model is correct. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals).

**rug**
When `TRUE` the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth. The default of NULL sets rug to `TRUE` when the dataset size is <= 10000 and `FALSE` otherwise.

**se**
When `TRUE` (default) upper and lower lines are added to the 1-d plots at standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlayed on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also `shade`, below.

**pages**
(default 0) the number of pages over which to spread the output. For example, if pages=1 then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.

**select**
Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set `select=2`.

**scale**
set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if `ylim` supplied.

**n**
n number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.

**n2**
Square root of number of points used to grid estimates of 2-d functions for contouring.

**n3**
Square root of number of panels to use when displaying 3 or 4 dimensional functions.

**pers**
Set to `TRUE` if you want perspective plots for 2-d terms.

**theta**
One of the perspective plot angles.

**phi**
The other perspective plot angle.

**jit**
Set to `TRUE` if you want rug plots for 1-d terms to be jittered.

**xlab**
If supplied then this will be used as the x label for all plots.

**ylab**
If supplied then this will be used as the y label for all plots.

**main**
Used as title (or z axis label) for plots if supplied.

**ylim**
If supplied then this pair of numbers are used as the y limits for each plot.

**xlim**
If supplied then this pair of numbers are used as the x limits for each plot.

**too.far**
If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before
deciding what to exclude, and **too.far** is a distance within the unit square. Setting to zero can make plotting faster for large datasets, but care then needed with interpretation of plots.

```r
all.terms
```
if set to **TRUE** then the partial effects of parametric model components are also plotted, via a call to **termplot**. Only terms of order 1 can be plotted in this way.

```r
shade
```
Set to **TRUE** to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using **termplot**).

```r
shade.col
```
define the color used for shading confidence bands.

```r
shift
```
constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with **trans**.

```r
trans
```
monotonic function to apply to each smooth (after any shift), before plotting. Monotonicity is not checked, but default plot limits assume it. **shift** and **trans** are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.

```r
seWithMean
```
if **TRUE** the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If **FALSE** then the uncertainty relates purely to the centred smooth itself. If **seWithMean=2** then the intervals include the uncertainty in the mean of the fixed effects (but not in the mean of any uncentred smooths or random effects). Marra and Wood (2012) suggests that **TRUE** results in better coverage performance, and this is also suggested by simulation.

```r
unconditional
```
if **TRUE** then the smoothing parameter uncertainty corrected covariance matrix is used to compute uncertainty bands, if available. Otherwise the bands treat the smoothing parameters as fixed.

```r
by.resids
```
Should partial residuals be plotted for terms with by variables? Usually the answer is no, they would be meaningless.

```r
scheme
```
Integer or integer vector selecting a plotting scheme for each plot. See details.

```r
...
```
other graphics parameters to pass on to plotting commands. See details for smooth plot specific options.

### Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by **termplot**.

For smooth terms **plot.gam** actually calls plot method functions depending on the class of the smooth. Currently **random.effects**, Markov random fields (**mrf**), **Spherical.Spline** and **factor.smooth.interaction** terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled $s(\text{cov}, \text{edf})$ where **cov** is the covariate name, and **edf** the estimated (or user defined for regression splines) degrees of freedom of the smooth. **scheme == 0** produces a smooth curve with dashed curves indicating 2 standard error bounds. **scheme == 1** illustrates the error bounds using a shaded region.

For schemes of 0, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like $s(\text{var1}, \text{var2}, \text{edf})$, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When **se=TRUE** estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If **se** is a positive number then contour plots are at plus or minus **se** multiplied by the s.e. Contour levels are chosen to try and
ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths scheme==1 produces a perspective plot, while scheme==2 produces a heatmap, with overlaid contours and scheme==3 a greyscale heatmap (contour.col controls the contour colour).

Smooths of 3 and 4 variables are displayed as tiled heatmaps with overlaid contours. In the 3 variable case the third variable is discretized and a contour plot of the first 2 variables is produced for each discrete value. The panels in the lower and upper rows are labelled with the corresponding third variable value. The lowest value is bottom left, and highest at top right. For 4 variables, two of the variables are coarsely discretized and a square array of image plots is produced for each combination of the discrete values. The first two arguments of the smooth are the ones used for the image/contour plots, unless a tensor product term has 2D marginals, in which case the first 2D marginal is image/contour plotted. n3 controls the number of panels. See also vis.gam.

Fine control of plots for parametric terms can be obtained by calling termplot directly, taking care to use its terms argument.

Note that, if seWithMean=TRUE, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka’s (1988) results presented in Marra and Wood (2012). There are two possible variants of this approach. In the default variant the extra uncertainty is in the mean of all other terms in the model (fixed and random, including uncentred smooths). Alternatively, if seWithMean=2 then only the uncertainty in parametric fixed effects is included in the extra uncertainty (this latter option actually tends to lead to wider intervals when the model contains random effects).

Several smooth plots methods using image will accept an hcolors argument, which can be anything documented in heat.colors (in which case something like hcolors=rainbow(50) is appropriate), or the grey function (in which case something like hcolors=grey(0:50/50) is needed). Another option is contour.col which will set the contour colour for some plots. These options are useful for producing grey scale pictures instead of colour.

Sometimes you may want a small change to a default plot, and the arguments to plot.gam just won’t let you do it. In this case, the quickest option is sometimes to clone the smooth.construct and Predict.matrix methods for the smooth concerned, modifying only the returned smoother class (e.g. to foo.smooth). Then copy the plot method function for the original class (e.g. mgcv:::plot.mgcv.smooth), modify the source code to plot exactly as you want and rename the plot method function (e.g. plot.foo.smooth). You can then use the cloned smooth in models (e.g. s(x,bs="foo")), and it will automatically plot using the modified plotting function.

Value

The function’s main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

WARNING

Note that the behaviour of this function is not identical to plot.gam() in S-PLUS.

Plotting can be slow for models fitted to large datasets. Set rug=FALSE to improve matters. If it’s still too slow set too.far=0, but then take care not to overinterpret smooths away from supporting data.
Plots of 2-D smooths with standard error contours shown can not easily be customized.
The function can not deal with smooths of more than 2 variables!

Author(s)

Simon N. Wood <simon.wood@r-project.org>
Henric Nilsson <henric.nilsson@statisticon.se> donated the code for the shade option.
The design is inspired by the S function of the same name described in Chambers and Hastie (1993)
(but is not a clone).

---

**polys.plot**  
Plot geographic regions defined as polygons

**Description**

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

**Usage**

polys.plot(pc,z=NULL,scheme="heat",lab="",...)

**Arguments**

- **pc**:
  A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several polygons, then each of these must be separated by an NA row in the matrix. See `mrf` for an example.
z  A vector of values associated with each area (item) of pc. If the vector elements have names then these are used to match elements of z to areas defined in pc. Otherwise pc and z are assumed to be in the same order. If z is NULL then polygons are not filled.

scheme  One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of z.

lab  label for plot.

...  other arguments to pass to plot (currently only if z is NULL).

Details

Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing mrf smooths.

Value

Simply produces a plot.

Author(s)

Simon Wood <simon.wood@r-project.org>

See Also

mrf and columb.polys.

Examples

## see also ?mrf for use of z
require(mgcv)
data(columb.polys)
polys.plot(columb.polys)
Usage

```r
## S3 method for class 'bam'
predict(object, newdata, type = "link", se.fit = FALSE, terms = NULL,
         exclude = NULL, block.size = 50000, newdata.guaranteed = FALSE,
         na.action = na.pass, cluster = NULL, discrete = TRUE, n.threads = 1,
         gc.level = 0, ...)```

Arguments

- **object**: a fitted `bam` object as produced by `bam`.
- **newdata**: A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If `newdata` is provided then it should contain all the variables needed for prediction: a warning is generated if not.
- **type**: When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When `type = "terms"` each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. `type = "terms"` is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When `type = "response"` predictions on the scale of the response are returned (possibly with approximate standard errors). When `type = "lpmatrix"` then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case `se.fit` is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).
- **se.fit**: when this is TRUE (not default) standard error estimates are returned for each prediction.
- **terms** if `type = "terms"` or `type = "iterms"` then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If `NULL` then all terms are included.
- **exclude** if `type = "terms"` or `type = "iterms"` then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If `NULL` then no terms are excluded. To avoid supplying covariate values for excluded terms, set `newdata.guaranteed = TRUE`, but note that this skips all checks of `newdata`.
- **block.size**: maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.
- **newdata.guaranteed**: Set to TRUE to turn off all checking of `newdata` except for sanity of factor levels: this can speed things up for large prediction tasks, but `newdata` must be complete, with no NA values for predictors required in the model.
- **na.action**: what to do about NA values in `newdata`. With the default `na.pass`, any row of `newdata` containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). `na.exclude` or `na.omit` result in the dropping of `newdata` rows, if they contain any NA values for required predictors. If `newdata` is missing then NA handling is determined from `object$na.action`. 
predict.bam

cluster
predict.bam can compute in parallel using parLapply from the parallel package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for bam.

discrete
if TRUE then discrete prediction methods used with model fitted by discrete methods. FALSE for regular prediction. See details.

n.threads
if se.fit=TRUE and discrete prediction is used then parallel computation can be used to speed up se calcualtion. This specifies number of threads to use.

gc.level
increase from 0 to up the level of garbage collection if default does not give enough.

... other arguments.

Details
The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters \( V_p \) in the fitted bam object.

To facilitate plotting with termplot, if object possesses an attribute "para.only" and type="terms" then only parametric terms of order 1 are returned (i.e. those that termplot can handle).

Note that, in common with other prediction functions, any offset supplied to bam as an argument is always ignored when predicting, unlike offsets specified in the bam model formula.

See the examples in predict.gam for how to use the lpmatrix for obtaining credible regions for quantities derived from the model.

When discrete=TRUE the prediction data in newdata is discretized in the same way as is done when using discrete fitting methods with bam. However the discretization grids are not currently identical to those used during fitting. Instead, discretization is done afresh for the prediction data. This means that if you are predicting for a relatively small set of prediction data, or on a regular grid, then the results may in fact be identical to those obtained without discretization. The disadvantage to this approach is that if you make predictions with a large data frame, and then split it into smaller data frames to make the predictions again, the results may differ slightly, because of slightly different discretization errors.

Value
If type="lpmatrix" then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if se.fit is TRUE then a 2 item list is returned with items (both arrays) fit and se.fit containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether type is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

newdata can be a data frame, list or model.frame: if it’s a model frame then all variables must be supplied.

WARNING
Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples in predict.gam.
Author(s)
Simon N. Wood <simon.wood@r-project.org>

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

------
predict.gam Prediction from fitted GAM model

Description
Takes a fitted gam object produced by gam() and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

Usage
## S3 method for class 'gam'
predict(object, newdata, type = "link", se.fit = FALSE, terms = NULL,
       exclude = NULL, block.size = NULL, newdata.guaranteed = FALSE,
       na.action = na.pass, unconditional = FALSE, items.type = NULL, ...)

Arguments

object

A fitted `gam` object as produced by `gam()`.

eventdata

A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If `newdata` is provided then it should contain all the variables needed for prediction: a warning is generated if not. See details for use with `link(linear.functional.terms)`.

type

When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When `type="terms"` each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. `type="iterms"` is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When `type="response"` predictions on the scale of the response are returned (possibly with approximate standard errors). When `type="lpmatrix"` then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case `se.fit` is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).

se.fit

when this is TRUE (not default) standard error estimates are returned for each prediction.

terms

if `type="terms"` or `type="iterms"` then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If NULL then all terms are included.

exclude

if `type="terms"` or `type="iterms"` then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If NULL then no terms are excluded. Note that this is the term names as it appears in the model summary, see example. You can avoid providing the covariates for the excluded terms by setting `newdata.guaranteed=TRUE`, which will avoid all checks on `newdata`.

block.size

maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this. If NULL then block size is 1000 if new data supplied, and the number of rows in the model frame otherwise.

newdata.guaranteed

Set to TRUE to turn off all checking of `newdata` except for sanity of factor levels: this can speed things up for large prediction tasks, but `newdata` must be complete, with no NA values for predictors required in the model.

na.action

what to do about NA values in `newdata`. With the default `na.pass`, any row of `newdata` containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). `na.exclude` or `na.omit` result in the dropping of `newdata` rows, if they contain any NA values for required predictors. If `newdata` is missing then NA handling is determined from `object$na.action`.

unconditional

if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used, when available, otherwise the covariance matrix conditional on the estimated smoothing parameters is used.
iterms.type if type="iterms" then standard errors can either include the uncertainty in the overall mean (default, with fixed and random effects included) or the uncertainty in the mean of the non-smooth fixed effects only (iterms.type=2).

... other arguments.

Details

The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters \( \varphi \) in the fitted gam object.

When predicting from models with \texttt{linear.functional.terms} then there are two possibilities. If the summation convention is to be used in prediction, as it was in fitting, then newdata should be a list, with named matrix arguments corresponding to any variables that were matrices in fitting. Alternatively one might choose to simply evaluate the constituent smooths at particular values in which case arguments that were matrices can be replaced by vectors (and newdata can be a dataframe). See \texttt{linear.functional.terms} for example code.

To facilitate plotting with \texttt{termplot}, if object possesses an attribute "para.only" and type="terms" then only parametric terms of order 1 are returned (i.e. those that \texttt{termplot} can handle).

Note that, in common with other prediction functions, any offset supplied to \texttt{gam} as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the \texttt{lpmatrix} for obtaining credible regions for quantities derived from the model.

Value

If type="lpmatrix" then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if se.fit is TRUE then a 2 item list is returned with items (both arrays) fit and se.fit containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether type is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

newdata can be a data frame, list or model.frame: if it’s a model frame then all variables must be supplied.

WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples.

Note that the behaviour of this function is not identical to \texttt{predict.gam()} in Splus.

Type="terms" does not exactly match what \texttt{predict.lm} does for parametric model components.

Author(s)

Simon N. Wood \(<\text{simon.wood}@\text{r-project.org}>\)

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

plot(x.mesh, df, type="l", ylim=range(c(df+2*df.sd, df-2*df.sd)))
lines(x.mesh, df+2*df.sd, lty=2); lines(x.mesh, df-2*df.sd, lty=2)
}
```

---

### Description

Takes smooth objects produced by smooth.construct methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function `PredictMat`.  

### Usage

```r
Predict.matrix(object, data)
Predict.matrix2(object, data)
```
Arguments

object is a smooth object produced by a smooth.construct method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate Predict.matrix function to produce a prediction matrix for new covariate values. Further details are given in smooth.construct.

data A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for smooth.construct and smooth.construct2.

Details

Smooth terms in a GAM formula are turned into smooth specification objects of class xx.smooth.spec during processing of the formula. Each of these objects is converted to a smooth object using an appropriate smooth.construct function. The Predict.matrix functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new smooth.construct method function and a corresponding Predict.matrix method function: see the example code provided for smooth.construct for details.

Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object. If the smooth class is one which generates offsets the corresponding offset is returned as attribute "offset" of the matrix.

Predict.matrix.cr.smooth

**Predict matrix method functions**

### Description

The various built-in smooth classes for use with `gam` have associate `Predict.matrix` method functions to enable prediction from the fitted model.

### Usage

```r
## S3 method for class 'cr.smooth'
Predict.matrix(object, data)
## S3 method for class 'cs.smooth'
Predict.matrix(object, data)
## S3 method for class 'cyclic.smooth'
Predict.matrix(object, data)
## S3 method for class 'pspline.smooth'
Predict.matrix(object, data)
## S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
## S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
## S3 method for class 'ts.smooth'
Predict.matrix(object, data)
## S3 method for class 't2.smooth'
Predict.matrix(object, data)
```

### Arguments

- `object`: a smooth object, usually generated by a `smooth.construct` method having processed a smooth specification object generated by an `s` or `te` term in a `gam` formula.
- `data`: A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for `smooth.construct` and `smooth.construct2`.

### Details

The `Predict.matrix` function is not normally called directly, but is rather used internally by `predict.gam` etc. to predict from a fitted `gam` model. See `Predict.matrix` for more details, or the specific smooth.construct pages for details on a particular smooth class.

### Value

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

Examples

## see smooth.construct

-----

**Predict.matrix.soap.film**

*Prediction matrix for soap film smooth*

Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the `Predict.matrix` method function required by `gam`.

Usage

```r
## S3 method for class 'soap.film'
Predict.matrix(object, data)
## S3 method for class 'sw'
Predict.matrix(object, data)
## S3 method for class 'sf'
Predict.matrix(object, data)
```

Arguments

- `object` A class "soap.film", "sf" or "sw" object.
- `data` A list list or data frame containing the arguments of the smooth at which predictions are required.

Details

The smooth object will be largely what is returned from `smooth.construct.so.smooth.spec`, although elements X and S are not needed, and need not be present, of course.

Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

---

print.gam *Print a Generalized Additive Model object.*

**Description**

The default print method for a gam object.

**Usage**

```r
## S3 method for class 'gam'
print(x, ...)
```

**Arguments**

- `x, ...`: fitted model objects of class `gam` as produced by `gam()`.

**Details**

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See `gamObject` (or `names(x)`) for a listing of what the object contains. `summary.gam` provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBR(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

If rank deficiency of the model was detected then the apparent rank is reported, along with the length of the coefficient vector (rank in absence of rank deficiency). Rank deficiency occurs when not all coefficients are identifiable given the data. Although the fitting routines (except `gamm`) deal gracefully with rank deficiency, interpretation of rank deficient models may be difficult.

psum.chisq

Evaluate the c.d.f. of a weighted sum of chi-squared deviates

Description

Evaluates the c.d.f. of a weighted sum of chi-squared random variables by the method of Davies (1973, 1980). That is it computes

\[ P(q < \sum_{i=1}^{r} \lambda_i X_i + \sigma Z) \]

where \( X_j \) is a chi-squared random variable with \( \text{df}[j] \) (integer) degrees of freedom and non-centrality parameter \( \text{nc}[j] \), while \( Z \) is a standard normal deviate.

Usage

psum.chisq(q,lb,df=rep(1,length(lb)),nc=rep(0,length(lb)),sigz=0,
lower.tail=FALSE,tol=2e-5,nlim=100000,trace=FALSE)

Arguments

q is the vector of quantile values at which to evaluate.

lb contains \( \lambda_i \), the weight for deviate i. Weights can be positive and/or negative.

df is the integer vector of chi-squared degrees of freedom.

nc is the vector of non-centrality parameters for the chi-squared deviates.

sigz is the multiplier for the standard normal deviate. Non-positive to exclude this term.

lower.tail indicates whether lower or upper tail probabilities are required.

tol is the numerical tolerance to work to.

nlim is the maximum number of integration steps to allow.

trace can be set to TRUE to return some trace information and a fault code as attributes.
Details

This calls a C translation of the original Algol60 code from Davies (1980), which numerically inverts the characteristic function of the distribution (see Davies, 1973). Some modifications have been made to remove goto statements and global variables, to use a slightly more efficient sorting of lb and to use R functions for log(1+x). In addition the integral and associated error are accumulated in single terms, rather than each being split into 2, since only their sums are ever used. If q is a vector then psum.chisq calls the algorithm separately for each q[i].

If the Davies algorithm returns an error then an attempt will be made to use the approximation of Liu et al (2009) and a warning will be issued. If that is not possible then an NA is returned. A warning will also be issued if the algorithm detects that round off errors may be significant.

If trace is set to TRUE then the result will have two attributes. "ifault" is 0 for no problem, 1 if the desired accuracy can not be obtained, 2 if round-off error may be significant, 3 is invalid parameters have been supplied or 4 if integration parameters can not be located. "trace" is a 7 element vector: 1. absolute value sum; 2. total number of integration terms; 3. number of integrations; 4. integration interval in main integration; 5. truncation point in initial integration; 6. sd of convergence factor term; 7. number of cycles to locate integration parameters. See Davies (1980) for more details.

Note that for vector q these attributes relate to the final element of q.

psum.chisq(q,lb,df,nc)

## same by simulation...
psc.sim <- function(q,lb,df=lb*0+1,nc=df*0,ns=10000) {
  r <- length(lb); p <- q
  X <- rowSums(rep(lb,each=ns) * matrix(rchisq(r*ns,rep(df,each=ns),rep(nc,each=ns)),ns,r))
  apply(matrix(q),1,function(q) mean(X>q))
} ## psc.sim

psum.chisq(q,lb,df,nc)
psc.sim(q,lb,df,nc,100000)
```
**Description**

Takes a fitted gam object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

**Usage**

```r
qq.gam(object, rep=0, level=.9, s.rep=10,
       type=c("deviance","pearson","response"),
       pch=".", rl.col=2, rep.col="gray80", ...)
```

**Arguments**

- `object` a fitted gam object as produced by `gam()` (or a glm object).
- `rep` How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.
- `level` If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated.
- `s.rep` how many times to randomize uniform quantiles to data under direct computation.
- `type` what sort of residuals should be plotted? See `residuals.gam`.
- `pch` plot character to use. 19 is good.
- `rl.col` color for the reference line on the plot.
- `rep.col` color for reference bands or replicate reference plots.
- `...` extra graphics parameters to pass to plotting functions.

**Details**

QQ-plots of the the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the
quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficients and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended). Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

plot(b,residuals=TRUE,pch=19,cex=.3)
```

random.effects

### Random effects in GAMs

**Description**

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. `gamm` and `gamm4` from the `gamm4` package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with `gam` by making use of `s(...,bs="re")` terms in a model: see `smooth.construct.re.smooth.spec`, for full details. The basic idea is that, e.g., `s(x,z,g,bs="re")` generates an i.i.d. Gaussian random effect with model matrix given by `model.matrix(~x:z:g-1)` — in principle such terms can take any number of arguments. This simple approach is sufficient for implementing a wide range of commonly used random effect structures. For example if `g` is a factor then `s(g,bs="re")` produces a random coefficient for each level of `g`, with the random coefficients all modelled as i.i.d. normal. If `g` is a factor and `x` is numeric, then `s(x,g,bs="re")` produces an i.i.d. normal random slope relating the response to `x` for each level of `g`. If `h` is another factor then `s(h,g,bs="re")` produces a random interaction between `h` and `g`. In general, one can include terms such as `s(x0,g1:z2,bs="re")` to include an interaction between `x0` and `g1` with random coefficient for each level of `z2`. The smoothness of each of these random components can vary, using `s(...,k)` and `s(...,bs="rep")` terms.
random.effects

produces the usual i.i.d. normal g - h interaction. Note that a rather useful approximate test for zero random effect is also implemented for such terms based on Wood (2013). If the precision matrix is known to within a multiplicative constant, then this can be supplied via the xt argument of s. See smooth.construct.re.smooth.spec for details and example. Some models require differences between different levels of the same random effect: these can be implemented as described in linear.functional.terms.

Alternatively, but less straightforwardly, the paraPen argument to gam can be used: see gam.models. If smoothing parameter estimation is by ML or REML (e.g. gam(...,method="REML") then this approach is a completely conventional likelihood based treatment of random effects.

gam can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However gam is often faster and more reliable than gamm or gamm4, when the number of random effects is modest.

To facilitate the use of random effects with gam, gam.vcomp is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see summary.gam and anova.gam.

### residuals.gam

**Generalized Additive Model residuals**

#### Description

Returns residuals for a fitted gam model object. Pearson, deviance, working and response residuals are available.

#### Usage

```r
## S3 method for class 'gam'
residuals(object, type = "deviance", ...)
```

#### Arguments

- **object**
  a gam fitted model object.
- **type**
  the type of residuals wanted. Usually one of "deviance", "pearson", "scaled.pearson", "working", or "response".
- **...**
  other arguments.
Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter); \( \frac{(y - \mu)}{\sqrt{V(\mu)}} \), where \( y \) is data, \( \mu \) is model fitted value and \( V \) is model mean-variance relationship. Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

Families can supply their own residual function, which is used in place of the standard function if present, (e.g. \texttt{cox.ph}).

Value

A vector of residuals.

\texttt{gam}

---

**rig**

Generate inverse Gaussian random deviates

Description

Generates inverse Gaussian random deviates.

Usage

\texttt{rig(n,mean,scale)}

Arguments

- \texttt{n} \texttt{the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required.}
- \texttt{mean} \texttt{vector of mean values.}
- \texttt{scale} \texttt{vector of scale parameter values (lambda, see below)}

Details

If \( x \) if the returned vector, then \( E(x) = \texttt{mean} \) while \( \texttt{var(x)} = \texttt{scale*mean^3} \). For density and distribution functions see the \texttt{statmod} package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that \texttt{scale} here is the scale parameter in the GLM sense, which is the reciprocal of the usual ‘lambda’ parameter.
**Value**

A vector of inverse Gaussian random deviates.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

[https://www.maths.ed.ac.uk/~swood34/](https://www.maths.ed.ac.uk/~swood34/)

**Examples**

```r
require(mgcv)
set.seed(7)
## An inverse.gaussian GAM example, by modify 'gamSim' output...
dat <- gamSim(1,n=400,dist="normal",scale=1)
dat$f <- dat$f/4  # true linear predictor
Ey <- exp(dat$f); scale <- .5  # mean and GLM scale parameter
# simulate inverse Gaussian response...
big <- gam(y~ s(x0)+ s(x1)+s(x2)+s(x3),family=inverse.gaussian(link=log),
data=dat,method="REML")
plot(big,pages=1)
gam.check(big)
summary(big)
```

---

**rmvn**

Generate from or evaluate multivariate normal or t densities.

**Description**

Generates multivariate normal or t random deviates, and evaluates the corresponding log densities.

**Usage**

```r
rmvn(n,mu,V)
r.mvt(n,mu,V,df)
dmvm(x,mu,V,R=NULL)
d.mvt(x,mu,V,df,df,R=R=NULL)
```

**Arguments**

- `n` number of simulated vectors required.
- `mu` the mean of the vectors: either a single vector of length p=ncol(V) or an n by p matrix.
- `V` A positive semi definite covariance matrix.
- `df` The degrees of freedom for a t distribution.
- `x` A vector or matrix to evaluate the log density of.
- `R` An optional Cholesky factor of V (not pivoted).
Details

Uses a ‘square root’ of $V$ to transform standard normal deviates to multivariate normal with the correct covariance matrix.

Value

An $n$ row matrix, with each row being a draw from a multivariate normal or t density with covariance matrix $V$ and mean vector $\mu$. Alternatively each row may have a different mean vector if $\mu$ is a vector.

For density functions, a vector of log densities.

Author(s)

crossprod(sweep(z,2,colMeans(z)))/n  ## observed covariance matrix
colMeans(z)  ## observed mu
dmvn(z,mu,V)
```

Rrank

Find rank of upper triangular matrix

Description

Finds rank of upper triangular matrix $R$, by estimating condition number of upper rank by rank block, and reducing rank until this is acceptably low. Assumes $R$ has been computed by a method that uses pivoting, usually pivoted QR or Choleski.

Usage

```
Rrank(R,tol=.Machine$double.eps^.9)
```

Arguments

- **R**: An upper triangular matrix, obtained by pivoted QR or pivoted Choleski.
- **tol**: the tolerance to use for judging rank.

Details

The method is based on Cline et al. (1979) as described in Golub and van Loan (1996).
Author(s)
Simon N. Wood <simon.wood@r-project.org>

References

Examples
```r
set.seed(0)
n <- 10; p <- 5
x <- runif(n*(p-1))

qrX <- qr(X,LAPACK=TRUE)
Rrank(qr.R(qrX))
```

---

**rTweedie**

*Generate Tweedie random deviates*

Description
Generates Tweedie random deviates, for powers between 1 and 2.

Usage
```r
rTweedie(mu, p=1.5, phi=1)
```

Arguments
- **mu**: vector of expected values for the deviates to be generated. One deviate generated for each element of mu.
- **p**: the variance of a deviate is proportional to its mean, mu to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.
- **phi**: The scale parameter. Variance of the deviates is given by phi*mu^p.

Details
A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution, with mean mu^(2-p)/(2-p)*phi. The Gamma random variables that are summed have shape parameter (2-p)/(p-1) and scale parameter phi*(p-1)*mu*(p-1) (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of rtweedie from the tweedie package.

Value
A vector of random deviates from a Tweedie distribution, expected value vector mu, variance vector phi*mu^p.

s

Defining smooths in GAM formulae

Description

Function used in definition of smooth terms within gam model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

Usage

```r
s(..., k=-1,fx=FALSE,bs="tp",m=NA,by=NA,xt=NULL,id=NULL,sp=NULL,pc=NULL)
```

Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. s(log(x)) is fine, but s(I(x/sd(x))) is not (see predict.gam).

k the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. k should not be less than the dimension of the null space of the penalty for the term (see null.space.dimension), but will be reset if it is. See choose.k for further information.

fx indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
bs a two letter character string indicating the (penalized) smoothing basis to use. (e.g. "tp" for thin plate regression spline, "cr" for cubic regression spline). see \texttt{smooth.terms} for an over view of what is available.

m The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.r.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). For the numeric by variable case the resulting smooth is not usually subject to a centering constraint (so the by variable should not be added as an additional main effect). In the factor by variable case a replicate of the smooth is produced for each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See \texttt{gam.models} for further details. A by variable may also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see \texttt{gam.models} and \texttt{linear.functional.terms} for details).

xt Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis. If \texttt{xt$sumConv} exists and is FALSE then the summation convention for matrix arguments is turned off.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An id with a factor by variable causes the smooths at each factor level to have the same smoothing parameter.

sp any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to \texttt{gam}. Ignored by gamm.

pc If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See \texttt{identifiability}.

Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in \texttt{smooth.construct}.

Value

A class \texttt{xx.smooth.spec} object, where \texttt{xx} is a basis identifying code given by the bs argument of \texttt{s}. These smooth.spec objects define smooths and are turned into bases and penalties by \texttt{smooth.construct} method functions.

The returned object contains the following items:

term An array of text strings giving the names of the covariates that the term is a function of.
bs.dim  The dimension of the basis used to represent the smooth.
fixed  TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline
dim  The dimension of the smoother - i.e. the number of covariates that it is a function of.
p.order  The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.
by  is the name of any by variable as text ("NA" for none).
label  A suitable text label for this smooth term.
xt  The object passed in as argument xt.
id  An identifying label or number for the smooth, linking it to other smooths. Defaults to NULL for no linkage.
sp  array of smoothing parameters for the term (negative for auto-estimation). Defaults to NULL.

scat

GAM scaled t family for heavy tailed data

Description

Family for use with gam or bam, implementing regression for the heavy tailed response variables, y, using a scaled t model. The idea is that \((y - \mu)/\sigma \sim t_\nu\) where \(\mu\) is determined by a linear predictor, while \(\sigma\) and \(\nu\) are parameters to be estimated alongside the smoothing parameters.

Usage

scat(theta = NULL, link = "identity", min.df = 3)

Arguments

- theta: the parameters to be estimated \(\nu = b + \exp(\theta_1)\) (where ‘b’ is min.df) and \(\sigma = \exp(\theta_2)\). If supplied and both positive, then taken to be fixed values of \(\nu\) and \(\sigma\). If any negative, then absolute values taken as starting values.
- link: The link function: one of "identity", "log" or "inverse".
- min.df: minimum degrees of freedom. Should not be set to 2 or less as this implies infinite response variance.

Details

Useful in place of Gaussian, when data are heavy tailed. min.df can be modified, but lower values can occasionally lead to convergence problems in smoothing parameter estimation. In any case min.df should be >2, since only then does a t random variable have finite variance.

Value

An object of class extended.family.

**sdiag**  
*Extract or modify diagonals of a matrix*

**Description**

Extracts or modifies sub- or super- diagonals of a matrix.

**Usage**

```
sdiag(A, k = 0)  
sdiag(A, k = 0) <- value
```

**Arguments**

- `A`: a matrix
- `k`: sub- (negative) or super- (positive) diagonal of a matrix. 0 is the leading diagonal.
- `value`: single value, or vector of the same length as the diagonal.

**Value**

A vector containing the requested diagonal, or a matrix with the requested diagonal replaced by `value`.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```r
require(mgcv)
A <- matrix(1:35, 7, 5)
A
sdiag(A, 1) ## first super diagonal
sdiag(A, -1) ## first sub diagonal

sdiag(A) <- 1 ## leading diagonal set to 1
sdiag(A, 3) <- c(-1, -2) ## set 3rd super diagonal
```
shash

Sinh-arcsinh location scale and shape model family

Description
The shash family implements the four-parameter sinh-arcsinh (shash) distribution of Jones and Pewsey (2009). The location, scale, skewness and kurtosis of the density can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae. It is worth carefully considering whether the data are sufficient to support estimation of such a flexible model before using it.

Usage
shash(link = list("identity", "logeb", "identity", "identity"),
     b = 1e-2, phiPen = 1e-3)

Arguments
link vector of four characters indicating the link function for location, scale, skewness and kurtosis parameters.
b positive parameter of the logeb link function, see Details.
phiPen positive multiplier of a ridge penalty on kurtosis parameter. Do not touch it unless you know what you are doing, see Details.

Details
The density function of the shash family is
\[ p(y|\mu, \sigma, \epsilon, \delta) = C(z) \text{exp} - S(z)^2 / 2 \sigma^2 (1 + z^2)^{1/2}, \]
where \( C(z) = 1 + S(z)^2 / 2, S(z) = \sinh z \cosh z - 1)(z) - \epsilon \) and \( z = (y - \mu) / (\sigma \delta) \). Here \( \mu \) and \( \sigma > 0 \) control, respectively, location and scale, \( \epsilon \) determines skewness, while \( \delta > 0 \) controls tailweight. shash can model skewness to either side, depending on the sign of \( \epsilon \). Also, shash can have tails that are lighter (\( \delta > 1 \)) or heavier (\( 0 < \delta < 1 \)) than a normal. For fitting purposes, here we are using \( \tau = \log(\sigma) \) and \( \phi = \log(\delta) \).

The link function used for \( \tau \) is logeb with is \( \eta = \logexp(\tau) - b \) so that the inverse link is \( \tau = \log(\sigma) = \logexp(\eta) + b \). The point is that we are don’t allow \( \sigma \) to become smaller than a small constant \( b \). The likelihood includes a ridge penalty \(-\phiPen * \phi^2\), which shrinks \( \phi \) toward zero. When sufficient data is available the ridge penalty does not change the fit much, but it is useful to include it when fitting the model to small data sets, to avoid \( \phi \) diverging to +infinity (a problem already identified by Jones and Pewsey (2009)).

Value
An object inheriting from class genral.family.

## Single index models with mgcv

Single index models contain smooth terms with arguments that are linear combinations of other covariates, e.g. \( s(X\alpha) \) where \( \alpha \) has to be estimated. For identifiability, assume \( \|\alpha\| = 1 \) with positive first element. One simple way to fit such models is to use `gam` to profile out the smooth model coefficients and smoothing parameters, leaving only the \( \alpha \) to be estimated by a general purpose optimizer.

Example code is provided below, which can be easily adapted to include multiple single index terms, parametric terms and further smooths. Note the initialization strategy. First estimate \( \alpha \) without penalization to get starting values and then do the full fit. Otherwise it is easy to get trapped in a local optimum in which the smooth is linear. An alternative is to initialize using fixed penalization (via the `sp` argument to `gam`).

### Sl.inirep

**Re-parametrizing model matrix X**

**Description**

INTERNAL routine to apply initial Sl re-parameterization to model matrix X, or, if inverse==TRUE, to apply inverse re-parametrization to parameter vector or covariance matrix.

**Usage**

```r
Sl.inirep(Sl,X,l,r,nt=1)
Sl.initial.repara(Sl, X, inverse = FALSE, both.sides = TRUE, cov = TRUE, nt = 1)
```

**Arguments**

- `Sl` the output of Sl.setup.
- `X` the model matrix.
- `l` if non-zero apply transform (positive) or inverse transform from left. 1 or -1 of transform, 2 or -2 for transpose.
- `r` if non-zero apply transform (positive) or inverse transform from right. 1 or -1 of transform, 2 or -2 for transpose.
- `inverse` if TRUE an inverse re-parametrization is performed.
- `both.sides` if inverse==TRUE and both.sides==FALSE then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If both.sides==FALSE, X is a vector and inverse==FALSE then X is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix).
- `cov` boolean indicating whether X is a covariance matrix.
- `nt` number of parallel threads to be used.

**Value**

A re-parametrized version of X.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.
**Sl.repara**

*Applying re-parameterization from log-determinant of penalty matrix to model matrix.*

---

**Description**

INTERNAL routine to apply re-parameterization from log-determinant of penalty matrix, `ldetS` to model matrix, `X`, blockwise.

**Usage**

```r
Sl.repara(rp, X, inverse = FALSE, both.sides = TRUE)
```

**Arguments**

- **rp**: reparameterization.
- **X**: if `X` is a matrix it is assumed to be a model matrix whereas if `X` is a vector it is assumed to be a parameter vector.
- **inverse**: if `TRUE` an inverse re-parameterization is performed.
- **both.sides**: if `inverse==TRUE` and `both.sides==FALSE` then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If `both.sides==FALSE`, `X` is a vector and `inverse==FALSE` then `X` is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix).

**Value**

A re-parametrized version of `X`.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

**Sl.setup**

*Setting up a list representing a block diagonal penalty matrix*

---

**Description**

INTERNAL function for setting up a list representing a block diagonal penalty matrix from the object produced by `gam.setup`.

**Usage**

```r
Sl.setup(G, cholesky=FALSE, no.repara=FALSE, sparse=FALSE)
```

**Arguments**

- **G**: the output of `gam.setup`.
- **cholesky**: re-parameterize using Cholesky only.
- **no.repara**: set to `TRUE` to turn off all initial reparameterization.
- **sparse**: sparse setup?
slanczos

Value

A list with an element for each block. For block, b, \( S[[b]] \) is a list with the following elements

- **repara**: should re-parameterization be applied to model matrix, etc? Usually FALSE if non-linear in coefficients.
- **start, stop**: such that \( \text{start:stop} \) are the indexes of the parameters of this block.
- **S**: a list of penalty matrices for the block (\( \text{dim} = \text{stop-start+1} \)) If \( \text{length}(S) = 1 \) then this will be an identity penalty. Otherwise it is a multiple penalty, and an \( rS \) list of square root penalty matrices will be added. \( S \) (if \( \text{repara}==\text{TRUE} \)) and \( rS \) (always) will be projected into range space of total penalty matrix.
- **rS**: square root of penalty matrices if multiple penalties are used.
- **D**: a reparameterization matrix for the block. Applies to cols/params in \( \text{start:stop} \). If numeric then \( X[,\text{start:stop}]%*%\text{diag}(D) \) is re-parametrization of \( X[,\text{start:stop}] \), and \( \text{b.orig} = D*\text{b.repara} \) (where \( \text{b.orig} \) is the original parameter vector). If matrix then \( X[,\text{start:stop}]%*%D \) is re-parametrization of \( X[,\text{start:stop}] \), and \( \text{b.orig} = D*\text{b.repara} \) (where \( \text{b.orig} \) is the original parameter vector).

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

desc slanczos

Compute truncated eigen decomposition of a symmetric matrix

desc Usage

uses slanczos(A,k=10,kl=-1, tol=.Machine$double.eps^.5,nt=1)

Arguments

- **A**: A symmetric matrix.
- **k**: Must be non-negative. If \( \text{k1} \) is negative, then the \( k \) largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If \( \text{k1} \) is non-negative then the \( k \) highest eigenvalues are found together with their eigenvectors and the \( k \) lowest eigenvalues with eigenvectors are also returned.
- **kl**: If \( \text{k1} \) is non-negative then the \( k \) lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the \( k \) highest eigenvalues + vectors). negative \( \text{k1} \) signals that the \( k \) largest magnitude eigenvalues should be returned, with eigenvectors.
- **tol**: tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by \( \text{tol} \) (or the machine precision!).
- **nt**: number of threads to use for leading order iterative multiplication of \( A \) by vector. May show no speed improvement on two processor machine.
Details

If \( k_1 \) is non-negative, returns the highest \( k \) and lowest \( k_1 \) eigenvalues, with their corresponding eigenvectors. If \( k_1 \) is negative, returns the largest magnitude \( k \) eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of \( A \), as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small \( k \) and \( k_1 \) the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner triadiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

Value

A list with elements `values` (array of eigenvalues); `vectors` (matrix with eigenvectors in its columns); `iter` (number of iterations required).

```
smooth.construct

Description

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. New smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function (see example code below).

In practice, `smooth.construct` is usually called via `smooth.construct2` and the wrapper function `smoothCon`, in order to handle by variables and centering constraints (see the `smoothCon` documentation if you need to handle these things directly, for a user defined smooth class).

Usage

`smooth.construct(object, data, knots)`
`smooth.construct2(object, data, knots)`

Arguments

- `object` is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If `object` is not class `tensor.smooth.spec` it will have the following elements:
  - `term` The names of the covariates for this smooth, in an array.
  - `bs.dim` Argument `k` of the `s` term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for `cc` terms). `bs.dim<0` indicates that the constructor should set this to the default value.
  - `fixed` TRUE if the term is to be unpenalized, otherwise FALSE.
  - `dim` the number covariates of which this smooth is a function.
  - `p.order` the order of the smoothness penalty or `NA` for autoselection of this. This is argument `m` of the `s` term that generated object.
  - `by` the name of any by variable to multiply this term as supplied as an argument to `s`. "NA" if there is no such term.
  - `label` A suitable label for use with this term.
  - `xt` An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).
  - `id` Any identity associated with this term — used for linking bases and smoothing parameters. `NULL` by default, indicating no linkage.
  - `sp` Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless `NULL` (default), over-rides `sp` argument to `gam`.

If `object` is of class `tensor.smooth.spec` then it was generated by a `te` term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

- `margin` is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.
- `term` is the array of names of the covariates that are arguments of the smooth.
by is the name of any by variable, or "NA".

fx is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

label A suitable label for use with this term.

dim is the number of covariates of which this smooth is a function.

mp TRUE if multiple penalties are to be used.

np TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

id Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

sp Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides sp argument to gam.

data For smooth.construct a data frame or list containing the evaluation of the elements of object$term, with names given by object$term. The last entry will be the by variable, if object$by is not "NA". For smooth.construct2 data need only be an object within which object$term can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

knots an optional data frame or list containing the knots relating to object$term. If it is NULL then the knot locations are generated automatically. The structure of knots should be as for data, depending on whether smooth.construct or smooth.construct2 is used.

Details

There are built in methods for objects with the following classes: tp.smooth.spec (thin plate regression splines: see tprs); ts.smooth.spec (thin plate regression splines with shrinkage-to-zero); cr.smooth.spec (cubic regression splines: see cubic.regression.spline; cs.smooth.spec (cubic regression splines with shrinkage-to-zero); cc.smooth.spec (cyclic cubic regression splines); ps.smooth.spec (Eilers and Marx (1986) style P-splines: see p.spline); cp.smooth.spec (cyclic P-splines); ad.smooth.spec (adaptive smooths of 1 or 2 variables: see adaptive.smooth); re.smooth.spec (simple random effect terms); mrf.smooth.spec (Markov random field smoothers for smoothing over discrete districts); tensor.smooth.spec (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default mgcv.smooth method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for mgcv:::plot.sos.smooth, mgcv:::plot.random.effect, mgcv:::plot.mgcv.smooth for example code.

Value

The input argument object, assigned a new class to indicate what type of smooth it is and with at least the following items added:

X The model matrix from this term. This may have an "offset" attribute: a vector of length nrow(X) containing any contribution of the smooth to the model offset term. by variables do not need to be dealt with here, but if they are then an item by.done must be added to the object.
smooth.construct

S A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.

rank An array giving the ranks of the penalties.

null.space.dim The dimension of the penalty null space (before centering).

The following items may be added:

C The matrix defining any identifiability constraints on the term, for use when fitting. If this is NULL then smoothCon will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied C has an attribute "always.apply" then it is never ignored, even if any by variables of a smooth imply that no constraint is actually needed. Code for creating C should check whether the specification object already contains a zero row matrix, and leave this unchanged if it is (since this signifies no constraint should be produced).

Cp An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.

no.rescale if this is non-NULL then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because gamm requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.

df the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is null then smoothCon will set it to the basis dimension. smoothCon will reduce this by the number of constraints.

te.ok 0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 is it can be used but not plotted. Set to 1 if NULL.

plot.me Set to FALSE if this smooth should not be plotted by plot.gam. Set to TRUE if NULL.

side.constrain Set to FALSE to ensure that the smooth is never subject to side constraints as a result of nesting.

L smooths may depend on fewer ‘underlying’ smoothing parameters than there are elements of S. In this case L is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the S[[i]]. L=NULL signifies that there is one smoothing parameter per S[[i]].

Usually the returned object will also include extra information required to define the basis, and used by Predict.matrix methods to make predictions using the basis. See the Details section for links to the information included for the built in smooth classes.

tensor.smooth returned objects will additionally have each element of the margin list updated in the same way. tensor.smooths also have a list, XP, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.
**WARNING**

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

smooth.construct.ad.smooth.spec

Adaptive smooths in GAMs

Description

gam can use adaptive smooths of one or two variables, specified via terms like s(...,bs="ad",...). (gamm can not use such terms — check out package AdaptFit if this is a
The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the k argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the m argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables k is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making k a two element vector. Similarly, in the two dimensional case m is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then m specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument xt with a character vector xt$bs specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting m=10 for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

Usage

```r
## S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- **object** a smooth specification object, usually generated by a term `s(..., bs="ad", ...)`
- **data** a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- **knots** a list containing any knots supplied for basis setup — in same order and with same names as data. Can be `NULL`

Details

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

Value

An object of class "pspline.smooth" in the 1D case or "tensor.smooth" in the 2D case.
Examples

```r

```
smooth.construct.bs.smooth.spec

Penalized B-splines in GAMs

Description

gam can use smoothing splines based on univariate B-spline bases with derivative based penalties, specified via terms like s(x,bs="bs",m=c(3,2)). m[1] controls the spline order, with m[1]=3 being a cubic spline, m[1]=2 being quadratic, and so on. The integrated square of the m[2]th derivative is used as the penalty. So m=c(3,2) is a conventional cubic spline. Any further elements of m, after the first 2, define the order of derivative in further penalties. If m is supplied as a single number, then it is taken to be m[1] and m[2]=m[1]-1, which is only a conventional smoothing spline in the m=3, cubic spline case. Notice that the definition of the spline order in terms of m[1] is intuitive, but differs to that used with the tprs and p.spline bases. See details for options for controlling the interval over which the penalty is evaluated (which can matter if it is necessary to extrapolate).

Usage

## S3 method for class 'bs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'Bspline.smooth'
Predict.matrix(object, data)

Arguments

object a smooth specification object, usually generated by a term s(x,bs="bs",...)
data a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.

Details

The basis and penalty are sparse (although sparse matrices are not used to represent them). m[2]>m[1] will generate an error, since in that case the penalty would be based on an undefined derivative of the basis, which makes no sense. The terms can have multiple penalties of different orders, for example s(x,bs="bs",m=c(3,2,1,0)) specifies a cubic basis with 3 penalties: a conventional cubic spline penalty, an integrated square of first derivative penalty, and an integrated square of function value penalty.
The default basis dimension, $k$, is the larger of 10 and $m[1]$. $m[1]$ is the lower limit on basis dimension. If knots are supplied, then the number of supplied knots should be $k + m[1] + 1$, and the range of the middle $k-m[1]+1$ knots should include all the covariate values. Alternatively, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (making this range too wide mean that there is no information about some basis coefficients, because the corresponding basis functions have a span that includes no data). Unlike P-splines, splines with derivative based penalties can have uneven knot spacing, without a problem.

Another option is to supply 4 knots. Then the outer 2 define the interval over which the penalty is to be evaluated, while the inner 2 define an interval within which all but the outermost 2 knots should lie. Normally the outer 2 knots would be the interval over which predictions might be required, while the inner 2 knots define the interval within which the data lie. This option allows the penalty to apply over a wider interval than the data, while still placing most of the basis functions where the data are. This is useful in situations in which it is necessary to extrapolate slightly with a smooth. Only applying the penalty over the interval containing the data amounts to a model in which the function could be less smooth outside the interval than within it, and leads to very wide extrapolation confidence intervals. However the alternative of evaluating the penalty over the whole real line amounts to asserting certainty that the function has some derivative zeroed away from the data, which is equally unreasonable. It is preferable to build a model in which the same smoothness assumptions apply over both data and extrapolation intervals, but not over the whole real line. See example code for practical illustration.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior $k-m[1]+1$ knots — the interval over which the penalty is evaluated). Such extrapolation is not allowed in basis construction, but is when predicting.

It is possible to set a `deriv` flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it.

**Value**

An object of class "Bspline.smooth". See `smooth.construct`, for the elements that this object will contain.

**WARNING**

$m[1]$ directly controls the spline order here, which is intuitively sensible, but different to other bases.

smooth.construct.cr.smooth.spec

Penalized Cubic regression splines in GAMs

Description

gam can use univariate penalized cubic regression spline smooths, specified via terms like s(x,bs="cr"). s(x,bs="cs") specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) s(x,bs="cc") specifies a cyclic penalized cubic regression spline smooth.

‘Cardinal’ spline bases are used: Wood (2017) sections 5.3.1 and 5.3.2 gives full details. These bases have very low setup costs. For a given basis dimension, k, they typically perform a little less well than thin plate regression splines, but a little better than p-splines. See te to use these bases in tensor product smooths of several variables.

Default k is 10.

Usage

## S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)

## S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)

## S3 method for class 'cc.smooth.spec'
smooth.construct(object, data, knots)

Arguments

object a smooth specification object, usually generated by a term s(...,bs="cr"),...), s(...,bs="cs",...) or s(...,bs="cc",...)

data a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots

A list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details.

Details

The constructor is not normally called directly, but is rather used internally by gam. To use for basis setup it is recommended to use smooth.construct2.

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of x then there would be a knot at every 10th (ordered) x value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

Value

An object of class "cr.smooth" "cs.smooth" or "cyclic.smooth". In addition to the usual elements of a smooth class documented under smooth.construct, this object will contain:

xp giving the knot locations used to generate the basis.

F For class "cr.smooth" and "cs.smooth" objects t(F) transforms function values at the knots to second derivatives at the knots.

BD class "cyclic.smooth" objects include matrix BD which transforms function values at the knots to second derivatives at the knots.

plot(b,select=2,shade=TRUE);plot(fitted(b),residuals(b))

smooth.construct.ds.smooth.spec

Low rank Duchon 1977 splines

Description
Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like `s(x,z,bs="ds",m=c(1,.5)` in a `gam` model formula. In the notation of Duchon (1977) `m` is given by `m[1]` (default value 2), while `s` is given by `m[2]` (default value 0).

Duchon’s (1977) construction generalizes the usual thin plate spline penalty as follows. The usual TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial mth order derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the fourier frequencies, raised to the power 2s. `s` is a user selected constant taking integer values divided by 2. If `d` is the number of arguments of the smooth, then it is required that `-d/2 < s < d/2`. To obtain continuous functions we further require that `m + s > d/2`. If `s`=0 then the usual thin plate spline is recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003) to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is used here. For large datasets the same subsampling approach as is used in the `tprs` case is employed here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin plate splines, while still yielding continuous functions. For example, we can set `m = 1` and `s = d/2 - .5` in order to use first derivative penalization for any `d` (which has the advantage that the dimension of the null space of unpenalized functions is only `d+1`).

Usage
## S3 method for class 'ds.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'duchon.spline'
Predict.matrix(object, data)
Arguments

object: a smooth specification object, usually generated by a term `s(..., bs="ds", ...)`.

data: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.

knots: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be `NULL`.

Details

The default basis dimension for this class is $k = M + k_{\text{def}}$ where $M$ is the null space dimension (dimension of unpenalized function space) and $k_{\text{def}}$ is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not affect the state of R's RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, $k$. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, $k$. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

Value

An object of class "duchon.spline". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

shift: A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.

$X_u$: A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

$U_Z$: The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.
null.space.dimension

The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

## S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'fs.interaction'
Predict.matrix(object, data)

Arguments

*object*  For the smooth.construct method a smooth specification object, usually generated by a term \( s(x, \ldots, bs="fs",) \), May have a gamm attribute: see details.

*data* a list containing just the data (including any by variable) required by this term, with names corresponding to object$term.

*knots* a list containing any knots supplied for smooth basis setup.

Details

This class produces a smooth for each level of a single factor variable. Within a gam formula this is done with something like \( s(x, fac, bs="fs") \), which is almost equivalent to \( s(x, by=fac, id=1) \) (with the gam argument select=TRUE). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with gamm, where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) gamm only allows one conditioning factor for smooths, so \( s(x)+s(z, fac, bs="fs")+s(v, fac, bs="fs") \) is OK, but \( s(x)+s(z, fac1, bs="fs")+s(v, fac2, bs="fs") \) is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction. To facilitate this the constructor is called from gamm with an attribute "gamm" attached to the smooth specification object. The result differs from that resulting from the case where this is not done.

Note that gamm4 from the gamm4 package suffers from none of the restrictions that apply to gamm, and "fs" terms can be used without side-effects. Constructor is still called with a smooth specification object having a "gamm" attribute.

Any singly penalized basis can be used to smooth at each factor level. The default is "tp", but alternatives can be supplied in the xt argument of s (e.g. \( s(x, fac, bs="fs", xt="cr") \) or \( s(x, fac, bs="fs", xt=list(bs="cr")) \). The k argument to \( s(\ldots, bs="fs") \) refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently gamm (or gamm4) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down k.

The plot method for this class has two schemes. scheme==0 is in colour, while scheme==1 is black and white.

Value

An object of class "fs.interaction" or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves. The contents of an "fs.interaction" object will depend on whether or not smooth.construct was called with an object with attribute gamm: see below.

smooth.construct.gp.smooth.spec

Low rank Gaussian process smooths

Description

Gaussian process/kriging models based on simple covariance functions can be written in a very
similar form to thin plate and Duchon spline models (e.g. Handcock, Meier, Nychka, 1994), and
low rank versions produced by the eigen approximation method of Wood (2003). Kammann and
Wand (2003) suggest a particularly simple form of the Matern covariance function with only a
single smoothing parameter to estimate, and this class implements this and other similar models.
Usually invoked by an s(...) term in a gam formula. Argument m selects the covariance
function, sets the range parameter and any power parameter. If m is not supplied then it defaults to NA
and the covariance function suggested by Kammann and Wand (2003) along with their suggested
range parameter is used. Otherwise \( \text{abs}(m[1]) \) between 1 and 5 selects the correlation function from respectively, spherical, power exponential, and Matern with kappa = 1.5, 2.5 or 3.5. The sign of \( m[1] \) determines whether a linear trend in the covariates is added to the Gaussian process (positive), or not (negative). The latter ensures stationarity. \( m[2] \), if present, specifies the range parameter, with non-positive or absent indicating that the Kammann and Wand estimate should be used. \( m[3] \) can be used to specify the power for the power exponential which otherwise defaults to 1.

Usage

```r
## S3 method for class 'gp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'gp.smooth'
Predict.matrix(object, data)
```

Arguments

- `object`: a smooth specification object, usually generated by a term `s(..., bs="ms", ...)`.
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`.

Details

Let \( \rho > 0 \) be the range parameter, \( 0 < \kappa \leq 2 \) and \( d \) denote the distance between two points. Then the correlation functions indexed by \( m[1] \) are:

1. \( 1 - 1.5d/\rho + 0.5(d/\rho)^3 \) if \( d \leq \rho \) and 0 otherwise.
2. \( \exp(-d/\rho^\kappa) \).
3. \( \exp(-d/\rho)(1 + d/\rho) \).
4. \( \exp(-d/\rho)(1 + d/\rho + (d/\rho)^2/3) \).
5. \( \exp(-d/\rho)(1 + d/\rho + 2(d/\rho)^2/5 + (d/\rho)^3/15) \).

See Fahrmeir et al. (2013) section 8.1.6, for example. Note that setting \( r \) to too small a value will lead to unpleasant results, as most points become all but independent (especially for the spherical model. Note: Wood 2017, Figure 5.20 right is based on a buggy implementation).

The default basis dimension for this class is \( k=M+k\.def \) where \( M \) is the null space dimension (dimension of unpenalized function space) and \( k\.def \) is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 ‘knots’ from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied
as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, k. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, k. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

**Value**

An object of class "gp.smooth". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

- `shift` A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
- `Xu` A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
- `UZ` The matrix mapping the smoother parameters back to the parameters of a full GP smooth.
- `null.space.dimension` The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.
- `gp.defn` the type, range parameter and power parameter defining the correlation function.

smooth.construct.mrf.smooth.spec

*Markov Random Field Smooths*

Description

For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for mgcv. See details for how to deal with regions with missing data.

Usage

```r
## S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'mrf.smooth'
Predict.matrix(object, data)
```

Arguments

- **object**
  - For the smooth.construct method a smooth specification object, usually generated by a term \( s(x, \ldots, bs=\text{mrf}, xt=\text{list(polys=foo)}) \). \( x \) is a factor variable giving labels for geographic districts, and the \( xt \) argument is obligatory: see details. For the Predict.Matrix method an object of class "mrf.smooth" produced by the smooth.construct method.

- **data**
  - a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots

If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).

Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the xt argument to s. This must contain at least one of the elements polys, nb or penalty.

polys contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. names(polys) must correspond to the levels of the argument of the smooth, in any order (i.e. it gives the area labels). polys[[i]] is a 2 column matrix the rows of which specify the vertices of the polygon(s) defining the boundary of the ith area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any polys[[i]] should not be a hole. An example of the structure is provided by colomb.polys (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix.

Plotting of the smooth is not possible without a polys object.

If polys is the only element of xt provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one or more vertices.

nb is a named list defining the neighbourhood structure. names(nb) must correspond to the levels of the covariate of the smooth (i.e. the area labels), but can be in any order. nb[[i]] is a numeric vector indexing the neighbours of the ith area (and should not include i). All indices are relative to nb itself, but can be translated using names(nb). See example code. As an alternative each nb[[i]] can be an array of the names of the neighbours, but these will be converted to the arrays of numeric indices internally.

If no penalty is provided then it is computed automatically from this list. The ith row of the penalty matrix will be zero everywhere, except in the ith column, which will contain the number of neighbours of the ith geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

penalty if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite.

Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2017) Section 5.4.2. See Wood (2017, section 5.8.1).

Note that smooths of this class have a built in plot method, and that the utility function in.out can be useful for working with discrete area data. The plot method has two schemes, scheme==0 is colour, scheme==1 is grey scale.

The situation in which there are areas with no data requires special handling. You should set drop.unused.levels=FALSE in the model fitting function, gam, bam or gamm, having first ensured that any fixed effect factors do not contain unobserved levels. Also make sure that the basis dimension is set to ensure that the total number of coefficients is less than the number of observations.

Value

An object of class "mrf.smooth" or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in data.

smooth.construct.ps.smooth.spec

P-splines in GAMs

Description

gam can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like s(x,bs="ps"). These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like s(x,bs="cp",...). These bases can be used in tensor product smooths (see te).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed (but see also d.spline). This often provides a useful way of ‘taming’ an otherwise poorly behave smooth. However, in regular use, splines with derivative based penalties (e.g. "tp" or "cr" bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

Usage

## S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)

## S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)

Arguments

object a smooth specification object, usually generated by a term s(x,bs="ps",...) or s(x,bs="cp",...)
data a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.

Details

A smooth term of the form s(x,bs="ps",m=c(2,3)) specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If m is a single number then it is taken as the basis order and penalty order. The default is the ‘cubic spline like’ m=c(2,2).

The default basis dimension, k, is the larger of 10 and m[1]+1 for a "ps" terms and the larger of 10 and m[1] for a "cp" term. m[1]+1 and m[1] are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. k+1) for a "cp" smooth. For the "ps" basis the number of supplied knots should be k + m[1] + 2, and the range of the middle k-m[1] knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don’t make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions...
have a span that includes no data!). Note that P-splines don’t make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior k-m[1] knots). Such extrapolation is not allowed in basis construction, but is when predicting.

For the "ps" basis it is possible to set flags in the smooth specification object, requesting setup according to the SCOP-spline monotonic smoother construction of Pya and Wood (2015). As yet this is not supported by any modelling functions in mgcv (see package scam). Similarly it is possible to set a deriv flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it. See examples below.

Value

An object of class "pspline.smooth" or "cp.smooth". See smooth.construct, for the elements that this object will contain.

```

smooth.construct.re.smooth.spec

*Simple random effects in GAMs*
Description

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x, bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

Usage

```r
## S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'random.effect'
Predict.matrix(object, data)
```

Arguments

- `object`: For the `smooth.construct` method a smooth specification object, usually generated by a term `s(x,...,bs="re",)`. For the `predict.Matrix` method an object of class "random.effect" produced by the `smooth.construct` method.
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: generically a list containing any knots supplied for basis setup — unused at present.

Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x,z,bs="re")`. This will result in the model matrix component corresponding to `~x:z-1` being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x,bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x,v,w,bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

Some models require differences between the coefficients corresponding to different levels of the same random effect. See `linear.functional.terms` for how to implement this.

If the random effect precision matrix is of the form \( \sum_j \lambda_j S_j \) for known matrices \( S_j \) and unknown parameters \( \lambda_j \), then a list containing the \( S_j \) can be supplied in the `xt` argument of `s`. In this case an array `rank` should also be supplied in `xt` giving the ranks of the \( S_j \) matrices. See simple example below.

Note that smooth `id`s are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when
gamm4 or gamm may be better alternatives. Note also that gam will not support models with more coefficients than data.

The situation in which factor variable random effects intentionally have unobserved levels requires special handling. You should set drop.unused.levels=FALSE in the model fitting function, gam, bam or gamm, having first ensured that any fixed effect factors do not contain unobserved levels.

The implementation is designed so that supplying random effect factor levels to predict.gam that were not levels of the factor when fitting, will result in the corresponding random effect (or interactions involving it) being set to zero (with zero standard error) for prediction. See random.effects for an example. This is achieved by the predict.matrix method zeroing any rows of the prediction matrix involving factors that are NA. predict.gam will set any factor observation to NA if it is a level not present in the fit data.

Value
An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

gam.vcomp(b)
Description

Sets up basis functions and wiggliness penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The so version sets up the full smooth. The sf version sets up just the boundary interpolating soap film, while the sw version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with gamm and gamm4. To use these to simply set up a basis, then call via the wrapper smooth.construct2 or smoothCon.

Usage

```r
## S3 method for class 'so.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sw.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- **object**: A smooth specification object as produced by a `s(..., bs="so", xt=list(bnd=bnd, ...))` term in a gam formula. Note that the `xt` argument to `s` *must* be supplied, and should be a list, containing at least a boundary specification list (see details). `xt` may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the `k` argument of `s`, either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops.

- **data**: A list or data frame containing the arguments of the smooth.

- **knots**: list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the *interior* basis dimension (i.e. it is *not* supplied via argument `k` of `s`).

Details

For soap film smoothers the following *must* be supplied:

- `k` the basis dimension for each boundary loop smooth.
- `xt$bnd` the boundary specification for the smooth.
• knots the locations of the interior knots for the smooth.

When used in a GAM then k and xt are supplied via s while knots are supplied in the knots argument of gam.

The bnd element of the xt list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number of boundary loops. Each boundary loop list may also contain a column f giving known boundary conditions on a loop.

The bndSpec element of xt, if non-NULL, should contain

• bs the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument m must be supplied.
• knot.space set to "even" to get even knot spacing with the "cc" basis.
• m 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints get awkward).

Note that the function locator provides a simple means for defining boundaries graphically, using something like bnd <- as.data.frame(locator(type="l")), after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don’t want to smooth across, but doesn’t follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element nmax (default 200) of the list supplied as argument xt of s in a gam formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth \( f(x, y) \) is defined as the solution of

\[
f_{xx} + f_{yy} = g
\]

subject to the condition that \( f = s \) on the boundary curve, where \( s \) is a smooth function (usually a cyclic penalized regression spline). The function \( g \) is defined as the solution of

\[
g_{xx} + g_{yy} = 0
\]

where \( g = 0 \) on the boundary curve and \( g(x_k, y_k) = c_k \) at the ‘knots’ of the surface; the \( c_k \) are model coefficients.

In the simplest case, estimation of the coefficients of \( f \) (boundary coefficients plus \( c_k \)'s) is by minimization of

\[
\|z - f\|^2 + \lambda_s J_s(s) + \lambda_f J_f(f)
\]

where \( J_s \) is usually some cubic spline type wiggliness penalty on the boundary smooth and \( J_f \) is the integral of \((f_{xx} + f_{yy})^2\) over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The \( \lambda \)'s are smoothing parameters, selectable by GCV, REML, AIC, etc. \( z \) represents noisy observations of \( f \).
Value

A list with all the elements of object plus

sd  A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix.

X  The model matrix: this will have an "offset" attribute, if there are any known boundary conditions.

S  List of smoothing penalty matrices (in smallest non-zero submatrix form).

irng  A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.

In addition there are all the elements usually added by smooth.construct methods.

WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

smooth.construct.sos.smooth.spec
Splines on the sphere

Description

gam can use isotropic smooths on the sphere, via terms like s(la,lo,bs="sos",m=2,k=100).
There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees)
and the second longitude (in degrees). m (default 0) is an integer in the range -1 to 4 determining
the order of the penalty used. For \( m > 0 \), \((m+2)/2\) is the penalty order, with \( m=2 \) equivalent to the usual second derivative penalty. \( m=0 \) signals to use the 2nd order spline on the sphere, computed by Wendelberger's (1981) method. \( m = -1 \) results in a Duchon spline being used (with \( m=2 \) and \( s=1/2 \)), following an unpublished suggestion of Jean Duchon.

\( k \) (default 50) is the basis dimension.

**Usage**

```r
## S3 method for class 'sos.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sos.smooth'
Predict.matrix(object, data)
```

**Arguments**

- `object` a smooth specification object, usually generated by a term `s(...,bs="sos",...)`.
- `data` a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots` a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`.

**Details**

For \( m > 0 \), the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of \( A \) — the \( A \) given in the 1981 paper is correct). For \( m=0 \) (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For \( m = -1 \) a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a "normal" thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon. \( m = -2 \) is the same but with first derivative penalization.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. `theta`, `phi` give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. lat, lon gridlines are also plotted.

`scheme==1` is as `scheme==0`, but in black and white, without the image plot. `scheme>1` calls the default plotting method with `scheme` decremented by 2.

**Value**

An object of class "sos.smooth". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:
A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.

smooth.construct.t2.smooth.spec

Tensor product smoothing constructor

### Description

### Usage
```r
## S3 method for class 't2.smooth.spec'
smooth.construct(object, data, knots)
```

### Arguments
- **object**: a smooth specification object of class t2.smooth.spec, usually generated by a term like t2(x,z) in a `gam` model formula
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.

### Details
Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic...
smoothing is inappropriate. See \texttt{t2, te, smooth.construct} and \texttt{smooth.terms}. The construction employed here produces tensor smooths for which the smoothing penalties are non-overlapping portions of the identity matrix. This makes their estimation by mixed modelling software rather easy.

**Value**

An object of class "t2.smooth".

**smooth.construct.tp.smooth.spec**

*Penalized thin plate regression splines in GAMs*

**Description**

*smooth.construct.tp.smooth.spec* can use isotropic smooths of any number of variables, specified via terms like s(x, z, bs="tp", m=3) (or just s(x, z) as this is the default basis). These terms are based on thin plate regression splines. m specifies the order of the derivatives in the thin plate spline penalty.

If m is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth: this is useful if you need to test whether a smooth could be replaced by a linear term, or construct models with odd nesting structures.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).
The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason
the default behaviour is to randomly subsample \texttt{max.knots} unique data locations if there are more
than \texttt{max.knots} such, and to use the sub-sample for basis construction. The sampling is always
done with the same random seed to ensure repeatability (does not reset R RNG). \texttt{max.knots} is 2000,
by default. Both seed and \texttt{max.knots} can be modified using the \texttt{xt} argument to \texttt{s}. Alternatively the
user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high
enough smoothing parameter, rather than being shrunk towards a function in the penalty null space
(see details).

### Usage

```r
## S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

### Arguments

- **object**: a smooth specification object, usually generated by a term
  \texttt{s(...,bs="tp","...)} or \texttt{s(...,bs="ts","...)}
- **data**: a list containing just the data (including any by variable) required by this term,
  with names corresponding to \texttt{object$term} (and \texttt{object$by}). The by variable
  is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with
  same names as \texttt{data}. Can be \texttt{NULL}

### Details

The default basis dimension for this class is \(k = M + k.def\) where \(M\) is the null space dimension (dimen-
sion of unpenalized function space) and \(k.def\) is 8 for dimension 1, 27 for dimension 2 and 100 for
higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized
regression smoothers, results are statistically insensitive to the exact choice, provided it is not so
small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by
its smoothing parameter).

The default is to set \(m\) (the order of derivative in the thin plate spline penalty) to the smallest value
satisfying \(2m > d+1\) where \(d\) if the number of covariates of the term: this yields 'visually smooth'
functions. In any case \(2m \geq d\) must be satisfied.

The constructor is not normally called directly, but is rather used internally by \texttt{gam}. To use for basis
setup it is recommended to use \texttt{smooth.construct2}.

For these classes the specification \texttt{object} will contain information on how to handle large datasets
in their \texttt{xt} field. The default is to randomly subsample 2000 'knots' from which to produce a tprs
basis, if the number of unique predictor variable combinations in excess of 2000. The default can
be modified via the \texttt{xt} argument to \texttt{s}. This is supplied as a list with elements \texttt{max.knots} and seed
containing a number to use in place of 2000, and the random number seed to use (either can be
missing).

For these bases \texttt{knots} has two uses. Firstly, as mentioned already, for large datasets the calculation
of the \texttt{tp} basis can be time-consuming. The user can retain most of the advantages of the t.p.r.s.
approach by supplying a reduced set of covariate values from which to obtain the basis - typically
the number of covariate values used will be substantially smaller than the number of data, and
substantially larger than the basis dimension, \(k\). This approach is the one taken automatically if the
number of unique covariate values (combinations) exceeds max.knots. The second possibility is to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, k. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Value
An object of class "tprs.smooth" or "ts.smooth". In addition to the usual elements of a smooth class documented under smooth.construct, this object will contain:

shift A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.

Xu A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

UZ The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.

null.space.dimension The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

smooth.info

Generic function to provide extra information about smooth specification

Description

Takes a smooth specification object and adds extra basis specific information to it before smooth constructor called. Default method returns supplied object unmodified.

Usage

smooth.info(object)

Arguments

object is a smooth specification object

Details

Sometimes it is necessary to know something about a smoother before it is constructed, beyond what is in the initial smooth specification object. For example, some smooth terms could be set up as tensor product smooths and it is useful for bam to take advantage of this when discrete covariate methods are used. However, bam needs to know whether a smoother falls into this category before it is constructed in order to discretize its covariates marginally instead of jointly. Rather than bam having a hard coded list of such smooth classes it is preferable for the smooth specification object to report this themselves. smooth.info method functions are the means for achieving this. When interpreting a gam formula the smooth.info function is applied to each smooth specification object as soon as it is produced (in interpret.gam).

Value

A smooth specification object, which may be modified in some way.
smooth.terms

Description

Smooth terms are specified in a `gam` formula using `s`, `te`, `ti` and `t2` terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see `user.defined.smooth`). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by `s` terms, or as building blocks for tensor product smoothing via `te`, `ti` or `t2` terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the mgcv package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in gam models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in `linear.functional.terms`.

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** `bs="tp"`. These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See `tprs` for further details.

`bs="ts"` is as "tp" but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.
Duchon splines bs="ds". These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See Duchon.spline for further details.

Cubic regression splines bs="cr". These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional itergrated square second derivative cubic spline penalty. For details see cubic.regression.spline and e.g. Wood (2006a).
b3="cs" specifies a shrinkage version of "cr".
b3="cc" specifies a cyclic cubic regression splines (see cyclic.cubic.spline). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

Splines on the sphere bs="sos". These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See Spherical.Spline for details.

P-splines bs="ps". These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.
b3="cp" gives a cyclic version of a P-spline (see cyclic.p.spline).

Random effects bs="re". These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See smooth.construct.re.smooth.spec.

Markov Random Fields bs="mrf". These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See mrf for details and an example.

Gaussian process smooths bs="gp". Gaussian process models with a variety of simple correlation functions can be represented as smooths. See gp.smooth for details.

Soap film smooths bs="so" (actually not single penalized, but bs="sw" and bs="sf" allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See soap for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via te, ti or t2 terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006b) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions.

te te smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See Wood (2006b).
ti smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable an interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predictor $f_1(x) + f_2(z) + f_3(x,z)$, we might use model formula $y \sim s(x) + s(z) + \text{ti}(x,z)$ or $y \sim \text{ti}(x) + \text{ti}(z) + \text{ti}(x,z)$. A similar construction involving te terms instead will be much less statistically stable.

t2 uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the gamm4 package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See Wood, Scheipl and Faraway (2012/13).

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see te for an example of this). Note that te terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

Adaptive smoothers bs="ad" Univariate and bivariate adaptive smooths are available (see adaptive.smooth). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by gamm.

Factor smooth interactions bs="fs" Smooth factor interactions are often produced using by variables (see gam.models), but a special smoother class (see factor.smooth.interaction) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The "fs" smoothers are set up to be efficient when used with gamm, and have penalties on each null space component (i.e. they are fully ‘random effects’).

smooth2random

Convert a smooth to a form suitable for estimating as random effect

Description
A generic function for converting mgcv smooth objects to forms suitable for estimation as random effects by e.g. lme. Exported mostly for use by other package developers.

Usage
smooth2random(object, vnames, type = 1)

Arguments
object an mgcv smooth object.
vnames a vector of names to avoid as dummy variable names in the random effects form.
type 1 for lme, otherwise lmer.

Details
There is a duality between smooths and random effects which means that smooths can be estimated using mixed modelling software. This function converts standard mgcv smooth objects to forms suitable for estimation by lme, for example. A service routine for gamm exported for use by package developers. See examples for creating prediction matrices for new data, corresponding to the random and fixed effect matrices returned when type=2.

Value
A list.

rand a list of random effects, including grouping factors, and a fixed effects matrix. Grouping factors, model matrix and model matrix name attached as attributes, to each element. Alternatively, for type=2 a list of random effect model matrices, each corresponding to an i.i.d. Gaussian random effect with a single variance component.

smooth2random

trans.U A matrix, trans.U, that transforms coefs, in order [rand1, rand2,... fix] back to original parameterization. If null, then not needed. If null then taken as identity.

Xf A matrix for the fixed effects, if any.

fixed TRUE/FALSE, indicating if term was unpenalized or not. If unpenalized then other stuff may not be returned (it’s not a random effect).

rind an index vector such that if br is the vector of random coefficients for the term, br[rind] is the coefs in order for this term.

pen.ind index of which penalty penalizes each coefficient: 0 for unpenalized.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

Examples

## Simple type 1 'lme' style...
library(mgcv)
x <- runif(30)
sm <- smoothCon(s(x),data.frame(x=x))[[1]]
smooth2random(sm,"")

## Now type 2 'lme4' style...
z <- runif(30)
dat <- data.frame(x=x,z=z)
sm <- smoothCon(t2(x,z),dat)[[1]]
re <- smooth2random(sm,"",2)
str(re)

## For prediction after fitting we might transform parameters back to original parameterization using 'rind', 'trans.D' and 'trans.U', and call PredictMat(sm,newdata) to get the prediction matrix to multiply these transformed parameters by.
## Alternatively we could obtain fixed and random effect Prediction matrices corresponding to the results from smooth2random, which can be used with the fit parameters without transforming them.
## The following shows how...
s2rPred <- function(sm,re,data) {
  ## Function to aid prediction from smooths represented as type==2 random effects. re must be the result of smooth2random(sm,...,type=2).
  X <- PredictMat(sm,data) ## get prediction matrix for new data
  ## transform to r.e. parameterization
  if (!is.null(re$trans.U)) X <- X%*%re$trans.U
  X <- t(t(X)*re$trans.D)
  ## re-order columns according to random effect re-ordering...
  X[,re$rind] <- X[,re$pen.ind!=0]}

smoothCon

Prediction/Construction wrapper functions for GAM smooth terms

Description
Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

Usage
smoothCon(object, data, knots=NULL, absorb.cons=FALSE, scale.penalty=TRUE, n=nrow(data), dataX=NULL, null.space.penalty=FALSE, sparse.cons=0, diagonal.penalty=FALSE, apply.by=TRUE, modCon=0)
PredictMat(object, data, n=nrow(data))

Arguments
object is a smooth specification object or a smooth object.
data A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it’s a list then n must be supplied.
knots An optional data frame supplying any knot locations to be supplied for basis construction.
absorb.cons Set to TRUE in order to have identifiability constraints absorbed into the basis.
scale.penalty should the penalty coefficient matrix be scaled to have approximately the same ‘size’ as the inner product of the terms model matrix with itself? This can improve the performance of gamm fitting.
smoothCon

n

number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if data is a list.

dataX

Sometimes the basis should be set up using data in data, but the model matrix should be constructed with another set of data provided in dataX — n is assumed to be the same for both. Facilitates smooth id's.

null.space.penalty

Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.

apply.by

set to FALSE to have basis setup exactly as in default case, but to return add an additional matrix X0 to the return object, containing the model matrix without the by variable, if a by variable is present. Useful for bam discrete method setup.

sparse.cons

If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with bam). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint.

diagonal.penalty

If TRUE then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix diagRP in the returned object for use by PredictMat.

modCon

force modification of any smooth supplied constraints. 0 - do nothing. 1 - delete supplied constraints, replacing with automatically generated ones. 2 - set fit and predict constraint to predict constraint. 3 - set fit and predict constraint to fit constraint.

Details

These wrapper functions exist to allow smooths specified using smooth.construct and Predict.matrix method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine's also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object by done. If this does not exist then smoothCon will use the default code. Similarly if a user defined Predict.matrix method handles by variables internally then the returned matrix should have a "by .done" attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix C of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix C should have no rows. There is an option to use centering constraint that generate no, or limited infil, if the smoother has a sparse model matrix.

smoothCon returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. smoothCon modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by PredictMat.

The parameterization used by gam can be controlled via gam.control.
Value

From smoothCon a list of smooth objects returned by the appropriate smooth.construct method function. If constraints are to be absorbed then the objects will have attributes "qrc" and "nCons". "nCons" is the number of constraints. "qrc" is usually the qr decomposition of the constraint matrix (returned by qr), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

**sp.vcov**

Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit

**Description**

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated gam object, provided the fit was with a method that evaluated the required Hessian.

**Usage**

```
sp.vcov(x, edge.correct=TRUE, reg=1e-3)
```

**Arguments**

- `x`: a fitted model object of class `gam` as produced by `gam()`.
- `edge.correct`: if the model was fitted with `edge.correct=TRUE` (see `gam.control`), then the returned covariance matrix will be for the edge corrected log smoothing parameters.
- `reg`: regularizer for Hessian - default is equivalent to prior variance of 1000 on log smoothing parameters.

**Details**

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

**Value**

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise NULL. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter. If `edge.correct=TRUE` and this was used in fitting then the edge corrected smoothing parameters are in attribute `lsp` of the returned matrix.

`gam`, `gam.vcomp`
Examples

```r
require(mgcv)
n <- 100
x <- runif(n); z <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10)+s(z),knots=list(x=seq(0,1,length=10)),method="REML")
sp.vcov(mod)
```

`spasm.construct`  
**Experimental sparse smoothers**

Description

These are experimental sparse smoothing functions, and should be left well alone!

Usage

```r
spasm.construct(object, data)
spasm.sp(object, sp, w=rep(1, object$nobs), get.trH=TRUE, block=0, centre=FALSE)
spasm.smooth(object, X, residual=FALSE, block=0)
```

Arguments

- `object`: sparse smooth object
- `data`: data frame
- `sp`: smoothing parameter value
- `w`: optional weights
- `get.trH`: Should (estimated) trace of sparse smoother matrix be returned
- `block`: index of block, 0 for all blocks
- `centre`: should sparse smooth be centred?
- `X`: what to smooth
- `residual`: apply residual operation?

WARNING

It is not recommended to use these yet

Author(s)

Simon N. Wood <simon.wood@r-project.org>
Description

There is no `step.gam` in package `mgcv`. The `mgcv` default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows’ Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way, i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smooths can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see `s`).

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggliness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to `gam` causes this latter approach to be used. Unpenalized terms (e.g. `s(x,fx=TRUE)`) remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

summary.gam

Summary for a GAM fit

Description

Takes a fitted gam object produced by gam() and produces various useful summaries from it. (See sink to divert output to a file.)

Usage

## S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, re.test=TRUE, ...)

## S3 method for class 'summary.gam'
print(x,digits = max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"),...)

Arguments

object       a fitted gam object as produced by gam().
x            a summary.gam object produced by summary.gam().
dispersion   A known dispersion parameter. NULL to use estimate or default (e.g. 1 for Poisson).
freq         By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to TRUE then the frequentist covariance matrix of the parameters is used instead.
re.test       Should tests be performed for random effect terms (including any term with a zero dimensional null space)? For large models these tests can be computationally expensive.
digits controls number of digits printed in output.

signif.stars Should significance stars be printed alongside output.

other arguments.

Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix \( A \) for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let \( P_i \) be the matrix giving the parameters of the \( i \)th smooth when applied to the data (or pseudodata in the generalized case) and let \( X \) be the design matrix of the model. Then \( \text{tr}(XP_i) \) is the edf for the \( i \)th term. Clearly this definition causes the edf’s to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of \( 2A - AA \).

\text{print.summary.gam} \) tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka’s (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurvity).

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (\( \text{freq=}\text{TRUE} \)), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the \( \text{paraPen} \) argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting \( \text{freq=}\text{TRUE} \) is appropriate.

Value

\text{summary.gam} produces a list of summary information for a fitted \text{gam} object.

\text{p.coeff} is an array of estimates of the strictly parametric model coefficients.

\text{p.t} is an array of the \text{p.coeff}'s divided by their standard errors.
is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.

The number of smooth terms in the model.

An array of test statistics for assessing the significance of model smooth terms. See details.

An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.

array of standard error estimates for all parameter estimates.

The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that r.sq does not include any offset in the one parameter model.

The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so dev.expl can be substantially lower than r.sq when an offset is present.

array of estimated degrees of freedom for the model terms.

estimated residual degrees of freedom.

number of data.

number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).

apparent model rank.

The smoothing selection criterion used.

The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.

estimated (or given) scale parameter.

the family used.

the original GAM formula.

the scale parameter.

the degrees of freedom associated with each parametric term (excluding the constant).

a Wald statistic for testing the null hypothesis that the each parametric term is zero.

p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.

The estimated covariance matrix of the parameters (estimators if freq=TRUE), divided by scale parameter.

The estimated covariance matrix of the parameters (estimators if freq=TRUE).

significance table for parameters

significance table for smooths

significance table for parametric model terms
WARNING

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

### t2

*Define alternative tensor product smooths in GAM formulae*

**Description**

Alternative to `te` for defining tensor product smooths in a `gam` formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl (mgcv implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with `gamm4` from package `gamm4`.

**Usage**

```r
t2(..., k = NA, bs = "cr", m = NA, d = NA, by = NA, xt = NULL, id = NULL, sp = NULL, full = FALSE, ord = NULL, pc = NULL)
```

**Arguments**

- `...` a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `t2(log(x), z)` is fine, but `t2(I(x/sd(x)), z)` is not (see `predict.gam`).
- `k` the dimension(s) of the bases used to represent the smooth term. If not supplied then set to 5^d. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See `choose.k` for further information.
bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See smooth.terms for details and full list. User defined bases can also be used here (see smooth.construct for an example). If only one basis code is given then this is used for all bases.

m The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. p.spline and Duchon.spline), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set d=c(2,1). Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See gam.models for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see gam.models and linear.functional.terms for details).

xt Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

sp any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to gam. Ignored by gamm.

full If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.

ord an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.

pc If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See identifiability.
Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See pen.edf for some further information.

Note that there are two ways to construct the product. When full=FALSE then the null space bases are treated as a whole in each product, but when full=TRUE each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

Value

A class t2.smooth.spec object defining a tensor product smooth to be turned into a basis and penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

- margin: A list of smooth.spec objects of the type returned by s, defining the basis from which the tensor product smooth is constructed.

- term: An array of text strings giving the names of the covariates that the term is a function of.

- by: is the name of any by variable as text ("NA" for none).

- fx: logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.

- label: A suitable text label for this smooth term.
dim
The dimension of the smoother - i.e. the number of covariates that it is a function of.

mp TRUE is multiple penalties are to be used (default).

np TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).

id the id argument supplied to te.

sp the sp argument supplied to te.

Define tensor product smooths or tensor product interactions in GAM formulae

Description

Functions used for the definition of tensor product smooths and interactions within gam model formulae. te produces a full tensor product smooth, while ti produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present. The functions do not evaluate the smooth - they exist purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).
Usage

te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
  np=TRUE, xt=NULL, id=NULL, sp=NULL, pc=NULL)
ti(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
  np=TRUE, xt=NULL, id=NULL, sp=NULL, mc=NULL, pc=NULL)

Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. te(log(x), z) is fine, but te(I(x/sd(x)), z) is not (see predict.gam).

k the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See choose.k for further information.

bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See smooth.terms for details and full list. User defined bases can also be used here (see smooth.construct for an example). If only one basis code is given then this is used for all bases.

m The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. p.spline and Duchon.spline), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set d=c(2,1). Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case causes a replicate of the smooth to be produced for each factor level. See gam.models for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see gam.models and linear.functional.terms for details).

fx indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).

np TRUE to use the 'normal parameterization' for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at 'knots', spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.

xt Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id
then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

sp

any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to gam. Ignored by gamm.

mc

For ti smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or FALSE/TRUE values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that 'ti' only applies constraints to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work.

pc

If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See identifiability.

Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in tensor.prod.model.matrix and tensor.prod.penalties, to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use, and is deprecated: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

\[ f_1(x) + f_2(z) + f_3(x, z) \]

This functional ANOVA decomposition is supported by ti terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the \(~ \text{ti}(x) + \text{ti}(z) + \text{ti}(x, z)\) would produce the above main effects + interaction structure. This is much better than attempting the same thing with sor te terms representing the interactions (although mgcv does not forbid it). Technically ti terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework). See Wood (2017, section 5.6.3).

The ‘normal parameterization’ (np=TRUE) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done
for marginals of a single variable. This parameterization can reduce numerical stability when used
with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set np=FALSE.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if
any marginals would not need centering. The constructor for tensor product smooths ensures that
this happens.

The function does not evaluate the variable arguments.

Value

A class tensor.smooth.spec object defining a tensor product smooth to be turned into a basis and
penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

margin A list of smooth.spec objects of the type returned by s, defining the basis from
which the tensor product smooth is constructed.

term An array of text strings giving the names of the covariates that the term is a
function of.

by is the name of any by variable as text ("NA" for none).

fx logical array with element for each penalty of the term (tensor product smooths
have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.

label A suitable text label for this smooth term.

dim The dimension of the smoother - i.e. the number of covariates that it is a function
of.

mp TRUE is multiple penalties are to be used (default).

np TRUE to re-parameterize 1-D marginal smooths in terms of function values (de-
fault).

id the id argument supplied to te.

sp the sp argument supplied to te.

inter TRUE if the term was generated by ti, FALSE otherwise.

mc the argument mc supplied to ti.

tensor.prod.model.matrix

Row Kronecker product/ tensor product smooth construction
Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth (marginals and results can be sparse). The model matrix construction uses row Kronecker products.

Usage

tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
a%.*b

Arguments

X a list of model matrices for the marginal bases of a smooth. Items can be class "matrix" or "dgCMatrix", but not a mixture of the two.
S a list of penalties for the marginal bases of a smooth.
a a matrix with the same number of rows as A.
b a matrix with the same number of rows as B.

Details

If \(X[[1]], X[[2]] \ldots X[[m]]\) are the model matrices of the marginal bases of a tensor product smooth then the \(i\)th row of the model matrix for the whole tensor product smooth is given by \(X[[1]][i,]\%x\%X[[2]][i,]\%x\% \ldots X[[m]][i,]\), where \%x\% is the Kronecker product. Of course the routine operates column-wise, not row-wise!

A%.*B is the operator form of this ‘row Kronecker product’.

If \(S[[1]], S[[2]] \ldots S[[m]]\) are the penalty matrices for the marginal bases, and \(I[[1]], I[[2]] \ldots I[[m]]\) are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has \(m\) associate penalties of the form:

\(S[[1]]%x%I[[2]]%x% \ldots I[[m]].\)
\(I[[1]]%x%S[[2]]%x% \ldots I[[m]].\)

\(\ldots\)
\(I[[1]]%x%I[[2]]%x% \ldots S[[m]].\)

Of course it’s important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

Value

Either a single model matrix for a tensor product smooth (of the same class as the marginals), or a list of penalty terms for a tensor product smooth.

Simon N. Wood <simon.wood@r-project.org>

References

totalPenaltySpace

Obtaining (orthogonal) basis for null space and range of the penalty matrix

Description

INTERNAL function to obtain (orthogonal) basis for the null space and range space of the penalty, and obtain actual null space dimension components are roughly rescaled to avoid any dominating.

Usage

totalPenaltySpace(S, H, off, p)

Arguments

S a list of penalty matrices, in packed form.
H the coefficient matrix of an user supplied fixed quadratic penalty on the parameters of the GAM.
off a vector where the i-th element is the offset for the i-th matrix.
p total number of parameters.

Value

A list of matrix square roots such that S[[i]]=B[[i]]%*%t(B[[i]])

Author(s)

Simon N. Wood <simon.wood@r-project.org>.
**trichol**  

*Choleski decomposition of a tri-diagonal matrix*

**Description**

Computes Choleski decomposition of a (symmetric positive definite) tri-diagonal matrix stored as a leading diagonal and sub/super diagonal.

**Usage**

`trichol(ld, sd)`

**Arguments**

- `ld`  
  leading diagonal of matrix

- `sd`  
  sub-super diagonal of matrix

**Details**

Calls `dpttrf` from LAPACK. The point of this is that it has $O(n)$ computational cost, rather than the $O(n^3)$ required by dense matrix methods.

**Value**

A list with elements `ld` and `sd`. `ld` is the leading diagonal and `sd` is the super diagonal of bidiagonal matrix $B$ where $B^TB = T$ and $T$ is the original tridiagonal matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

**See Also**

`bandchol`

**Examples**

```r
require(mgcv)
## simulate some diagonals...
set.seed(19); k <- 7
ld <- runif(k)+1
sd <- runif(k-1) -.5
## get diagonals of chol factor...
trichol(ld, sd)
## compare to dense matrix result...
A <- diag(ld); for (i in 1:(k-1)) A[i,i+1] <- A[i+1,i] <- sd[i]
```
trind.generator

Generates index arrays for upper triangular storage

Description

Generates index arrays for upper triangular storage up to order four. Useful when working with higher order derivatives, which generate symmetric arrays. Mainly intended for internal use.

Usage

trind.generator(K = 2)

Arguments

K positive integer determining the size of the array.

Details

Suppose that m=1 and you fill an array using code like ```R <- chol(A) diag(R); diag(R[, -1])``` and do this because actually the same "something" would be stored for any permutation of the indices i,j,k,l. Clearly in storage we have the restriction l >= k >= j >= i, but for access we want no restriction on the indices. i4[i,j,k,1] produces the appropriate m for unrestricted indices. i3 and i2 do the same for 3d and 2d arrays.

Value

A list where the entries i1 to i4 are arrays in up to four dimensions, containing K indexes along each dimension.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

Examples

```library(mgcv) A <- trind.generator(3)
# All permutations of c(1, 2, 3) point to the same index (5)
Tweedie families, designed for use with `gam` from the `mgcv` library. Restricted to variance function powers between 1 and 2. A useful alternative to `quasi` when a full likelihood is desirable. Tweedie is for use with fixed $p$. `tw` is for use when $p$ is to be estimated during fitting. For fixed $p$ between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power $p$.

tw is only usable with `gam` and `bam` but not `gamm`. Tweedie works with all three.

**Usage**

```r
Tweedie(p=1, link = power(θ))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```

**Arguments**

- **p**
  
  the variance of an observation is proportional to its mean to the power $p$. $p$ must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.

- **link**
  
  The link function: one of "log", "identity", "inverse", "sqrt", or a power link (Tweedie only).

- **theta**
  
  Related to the Tweedie power parameter by $p = (a + b \exp(θ))/(1 + \exp(θ))$. If this is supplied as a positive value then it is taken as the fixed value for $p$. If it is a negative values then its absolute value is taken as the initial value for $p$.

- **a**
  
  lower limit on $p$ for optimization.

- **b**
  
  upper limit on $p$ for optimization.

**Details**

A Tweedie random variable with $1<p<2$ is a sum of $N$ gamma random variables where $N$ has a Poisson distribution. The $p=1$ case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For $1<p<2$ the distribution is supported on the positive reals with a point mass at zero. $p=2$ is a gamma distribution. As $p$ gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at $p=1$, and is therefore highly multimodal. See `ldTweedie` for more on this behaviour.

Tweedie is based partly on the `poisson` family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. $p$ and the scale parameter. Without restricting $p$ to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over `quasi`. If you need this case then the `tweedie` package is the place to start.
For Tweedie, an object inheriting from class family, with additional elements

dvar the function giving the first derivative of the variance function w.r.t. mu.

d2var the function giving the second derivative of the variance function w.r.t. mu.

ls A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter.

For tw, an object of class extended.family.

twlss

Tweedie location scale family

Description

Tweedie family in which the mean, power and scale parameters can all depend on smooth linear predictors. Restricted to estimation via the extended Fellner Schall method of Wood and Fasiolo (2017). Only usable with gam. Tweedie distributions are exponential family with variance given by $\phi \mu^p$ where $\phi$ is a scale parameter, $p$ a parameter (here between 1 and 2) and $\mu$ is the mean.

Usage

twlss(link=list("log", "identity", "identity"), a=1.01, b=1.99)

Arguments

- **link**
  - The link function list: currently no choice.
- **a**
  - lower limit on the power parameter relating variance to mean.
- **b**
  - upper limit on power parameter.

Details

A Tweedie random variable with $1 < p < 2$ is a sum of $N$ gamma random variables where $N$ has a Poisson distribution. The $p=1$ case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For $1 < p < 2$ the distribution is supported on the positive reals with a point mass at zero. $p=2$ is a gamma distribution. As $p$ gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at $p=1$, and is therefore highly multimodal. See ldTweedie for more on this behaviour.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. $p$ and the scale parameter. Without restricting $p$ to $(1,2)$ the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over quasi. If you need this case then the tweedie package is the place to start.

Value

An object inheriting from class general.family.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.
**uniquecombs**

**Description**

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit need not be the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

**Usage**

```r
uniquecombs(x, ordered=FALSE)
```
Arguments

**x**

is an R matrix (numeric), or data frame.

**ordered**

set to TRUE to have the rows of the returned object in the same order regardless of input ordering.

Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model.

When `x` has only one column then the routine uses `unique` and `match` to get the index. When there are multiple columns then it uses `paste0` to produce labels for each row, which should be unique if the row is unique. Then `unique` and `match` can be used as in the single column case. Obviously the pasting is inefficient, but still quicker for large n than the C based code that used to be called by this routine, which had O(nlog(n)) cost. In principle a hash table based solution in C would be only O(n) and much quicker in the multicolumn case.

`unique` and `duplicated`, can be used in place of this, if the full index is not needed. Relative performance is variable.

If `x` is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

Value

A matrix or data frame consisting of the unique rows of `x` (in arbitrary order).

The matrix or data frame has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row i of the original matrix.

WARNINGS

If a dataframe contains variables of a type other than numeric, logical, factor or character, which either have no `as.character` method, or whose `as.character` method is a many to one mapping, then the routine is likely to fail.

If the character representation of a dataframe variable (other than of class factor of character) contains `*` then in principle the method could fail (but with a warning).

`unique`, `duplicated`, `match`.

Examples

```r
require(mgcv)

## matrix example...
X <- matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
Xu <- uniquecombs(X);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]
```
## same with fixed output ordering

```r
Xu <- uniquecombs(X,TRUE); Xu
ind <- attr(Xu,"index")
```

## find the value for row 3 of the original from Xu

```r
Xu[ind[3],];X[3,]
```

## data frame example...

```r
df <- data.frame(f=factor(c("er",3,"b","er",3,3,1,2,"b")),
                 x=c(.5,1,1.4,.5,1,.6,4,3,1.7),
                 bb = c(rep(TRUE,5),rep(FALSE,4)),
                 fred = c("foo","a","b","foo","a","vf","er","r","g"),
                 stringsAsFactors=FALSE)
uniquecombs(df)
```

---

### vcov.gam

Extract parameter (estimator) covariance matrix from GAM fit

#### Description

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted `gam` object.

#### Usage

```
## S3 method for class 'gam'
vcov(object, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)
```

#### Arguments

- `object` : fitted model object of class `gam` as produced by `gam()`.
- `freq` : TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters.
- `dispersion` : a value for the dispersion parameter: not normally used.
- `unconditional` : if TRUE (and freq==FALSE) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.
- `...` : other arguments, currently ignored.

#### Details

Basically, just extracts `object$Ve` or `object$Vp` from a `gamObject`.

#### Value

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument `freq`.

#### Author(s)

Henric Nilsson. Maintained by Simon N. Wood <simon.wood@r-project.org>
vis.gam

gam

Examples

```r
require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

---

**vis.gam**  
*Visualization of GAM objects*

**Description**

Produces perspective or contour plot views of gam model predictions, fixing all but the values in `view` to the values supplied in `cond`.

**Usage**

```r
vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA, color="heat", contour.col=NULL, se=-1, type="link", plot.type="persp", zlim=NULL, nCol=50, ...)
```

**Arguments**

- **x**  
a gam object, produced by gam()

- **view**  
an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won't work as view variables, and vis.gam can not detect that this has happened when setting defaults.

- **cond**  
a named list of the values to use for the other predictor terms (not in `view`). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occuring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median.

- **n.grid**  
The number of grid nodes in each direction used for calculating the plotted surface.

- **too.far**  
plot grid nodes that are too far from the points defined by the variables given in `view` can be excluded from the plot. `too.far` determines what is too far. The grid is scaled into the unit square along with the `view` variables and then grid nodes more than `too.far` from the predictor variables are excluded.
**col**

The colours for the facets of the plot. If this is NA then if se>0 the facets are transparent, otherwise the colour scheme specified in **color** is used. If **col** is not NA then it is used as the facet colour.

**color**

the colour scheme to use for plots when se<=0. One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when se>0.

**contour.col**

sets the colour of contours when using **plot.type="contour"**. Default scheme used if NULL.

**se**

if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus se standard errors, one at the predicted values and one at the predicted values plus se standard errors.

**type**

"link" to plot on linear predictor scale and "response" to plot on the response scale.

**plot.type**

one of "contour" or "persp".

**zlim**

a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.

**nCol**

The number of colors to use in color schemes.

**...**

other options to pass on to **persp**, **image** or **contour**. In particular **ticktype="detailed"** will add proper axes labelling to the plots.

**Details**

The x and y limits are determined by the ranges of the terms named in **view**. If se<=0 then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- se standard errors. Parts of the x-y plane too far from data can be excluded by setting **too.far**

All options to the underlying graphics functions can be reset by passing them as extra arguments **...**: such supplied values will always over-ride the default values used by **vis.gam**.

**Value**

Simply produces a plot.

**WARNINGS**

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a **view** variable. When setting default **view** variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

**XWXd**

Internal functions for discretized model matrix handling

**Description**

Routines for computing with discretized model matrices as described in Wood et al. (2017) and Li and Wood (2019).
Usage

\texttt{XWXd(X,w,k,ks,ts,dt,v,qc,nthreads=1,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,lt=NULL,rt=NULL)}
\texttt{XWyd(X,y,k,ks,ts,dt,v,qc,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,lt=NULL)}
\texttt{Xbd(X,beta,k,ks,ts,dt,v,qc,drop=NULL,lt=NULL)}
\texttt{diagXVXd(X,V,k,ks,ts,dt,v,qc,drop=NULL,nthreads=1,lt=NULL,rt=NULL)}

Arguments

\textbf{X} \hspace{1cm} A list of the matrices containing the unique rows of model matrices for terms of a full model matrix, or the model matrices of the terms margins. if term subsetting arguments \texttt{lt} and \texttt{rt} are non-NULL then this requires an "lpip" attribute: see details. The elements of \texttt{X} may be sparse matrices of class "dgCMatrix", in which case the list requires attributes "r" and "off" defining reverse indices (see details).

\textbf{w} \hspace{1cm} An n-vector of weights

\textbf{y} \hspace{1cm} n-vector of data.

\textbf{beta} \hspace{1cm} coefficient vector.

\textbf{k} \hspace{1cm} A matrix whose columns are index n-vectors each selecting the rows of an \texttt{X[ii]} required to create the full matrix.

\textbf{ks} \hspace{1cm} The \texttt{i}th term has index vectors \texttt{ks[i,1]:(ks[i,2]-1)}. The corresponing full model matrices are summed over.

\textbf{ts} \hspace{1cm} The element of \texttt{X} at which each model term starts.

\textbf{dt} \hspace{1cm} How many elements of \texttt{X} contribute to each term.

\textbf{v} \hspace{1cm} \texttt{v[i]} is Householder vector for \texttt{i}th term, if \texttt{qc[i]>0}.

\textbf{qc} \hspace{1cm} if \texttt{qc[i]>0} then term has a constraint.

\textbf{nthreads} \hspace{1cm} number of threads to use

\textbf{drop} \hspace{1cm} list of columns of model matrix/parameters to drop

\textbf{ar.stop} \hspace{1cm} Negative to ignore. Otherwise sum rows \texttt{(ar.stop[i]-1)+ar.stop[i]} of the rows selected by \texttt{ar.row} and weighted by \texttt{ar.w} to get \texttt{i}th row of model matrix to use.

\textbf{ar.row} \hspace{1cm} extract these rows...

\textbf{ar.w} \hspace{1cm} weight by these weights, and sum up according to \texttt{ar.stop}. Used to implement AR models.

\textbf{lt} \hspace{1cm} use only columns of \texttt{X} corresponding to these model matrix terms (for left hand \texttt{X in XWXd}). If \texttt{NULL} set to \texttt{rt}.

\textbf{rt} \hspace{1cm} as \texttt{lt} for right hand \texttt{X}. If \texttt{NULL} set to \texttt{lt}. If \texttt{lt} and \texttt{rt} are \texttt{NULL} use all columns.

\textbf{V} \hspace{1cm} Coefficient covariance matrix.

Details

These functions are really intended to be internal, but are exported so that they can be used in the initialization code of families without problem. They are primarily used by \texttt{bam} to implement the methods given in the references. \texttt{XWXd} produces \texttt{X^T W X}, \texttt{XWy} produces \texttt{X^T W y}, \texttt{Xbd} produces \texttt{X beta} and \texttt{diagXVXd} produces the diagonal of \texttt{X V X^T}.

The "lpip" attribute of \texttt{X} is a list of the coefficient indices for each term. Required if subsetting via \texttt{lt} and \texttt{rt}.
X can be a list of sparse matrices of class "dgCMatrix", in which case reverse indices are needed, mapping stored matrix rows to rows in the full matrix (that is the reverse of k which maps full matrix rows to the stored unique matrix rows). r is the same dimension as k while off is a list with as many elements as k has columns. r and off are supplied as attributes to X. For simplicity let r and codeoff denote a single column and element corresponding to each other: then coder[off[j]:off[j+1]-1] contains the rows of the full matrix corresponding to row j of the stored matrix. The reverse indices are essential for efficient computation with sparse matrices. See the example code for how to create them efficiently from the forward index matrix, k.

**ziP**

**GAM zero-inflated (hurdle) Poisson regression family**

**Description**

Family for use with `gam` or `bam`, implementing regression for zero inflated Poisson data when the complimentary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

**Usage**

```r
ziP(theta = NULL, link = "identity", b=0)
```

**Arguments**

- `theta`  
  the 2 parameters controlling the slope and intercept of the linear transform of the mean controlling the zero inflation rate. If supplied then treated as fixed parameters ($\theta_1$ and $\theta_2$), otherwise estimated.

- `link`  
  The link function: only the "identity" is currently supported.

- `b`  
  a non-negative constant, specifying the minimum dependence of the zero inflation rate on the linear predictor.
Details

The probability of a zero count is given by \(1 - p\), whereas the probability of count \(y > 0\) is given by the truncated Poisson probability function \(p\mu^y/((\exp(\mu) - 1)y!)\). The linear predictor gives \(\log \mu\), while \(\eta = \log(-\log(1 - p))\) and \(\eta = \theta_1 + \{b + \exp(\theta_2)\} \log \mu\). The \(\theta\) parameters are estimated alongside the smoothing parameters. Increasing the \(b\) parameter from zero can greatly reduce identifiability problems, particularly when there are very few non-zero data.

The fitted values for this model are the log of the Poisson parameter. Use the \texttt{predict}\ function with \texttt{type=="response"} to get the predicted expected response. Note that the \(\theta\) parameters reported in model summaries are \(\theta_1\) and \(b + \exp(\theta_2)\).

These models should be subject to very careful checking, especially if fitting has not converged. It is quite easy to set up models with identifiability problems, particularly if the data are not really zero inflated, but simply have many zeroes because the mean is very low in some parts of the covariate space. See example for some obvious checks. Take convergence warnings seriously.

Value

An object of class \texttt{extended.family}.

WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes *given the model mean* may imply zero inflation.

b$outer.info ## check convergence!!
b
plot(b,pages=1)
plot(b,pages=1,unconditional=TRUE) ## add s.p. uncertainty
gam.check(b)
## more checking...
## 1. If the zero inflation rate becomes decoupled from the linear predictor,
## it is possible for the linear predictor to be almost unbounded in regions
## containing many zeroes. So examine if the range of predicted values
## is sane for the zero cases?
range(predict(b,type="response")[b$y==0])

## 2. Further plots...
par(mfrow=c(2,2))
plot(predict(b,type="response"),residuals(b))
plot(predict(b,type="response"),b$y);abline(0,1,col=2)
plot(b$linear.predictors,b$y)
qq.gam(b,rep=20,level=1)

## 3. Refit fixing the theta parameters at their estimated values, to check we
## get essentially the same fit...
thb <- b$family$getTheta()
b0 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=ziP(theta=thb),data=dat)
b;b0

## Example fit forcing minimum linkage of prob present and
## linear predictor. Can fix some identifiability problems.
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=ziP(b=.3),data=dat)

ziplss

Zero inflated (hurdle) Poisson location-scale model family

Description

The ziplss family implements a zero inflated (hurdle) Poisson model in which one linear predictor controls the probability of presence and the other controls the mean given presence. Useable only with gam, the linear predictors are specified via a list of formulae. Should be used with care: simply having a large number of zeroes is not an indication of zero inflation.

Requires integer count data.

Usage

ziplss(link=list("identity","identity"))
zipll(y,g,eta,deriv=0)
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>link</td>
<td>two item list specifying the link - currently only identity links are possible, as parameterization is directly in terms of log of Poisson response and logit of probability of presence.</td>
</tr>
<tr>
<td>y</td>
<td>response</td>
</tr>
<tr>
<td>g</td>
<td>gamma vector</td>
</tr>
<tr>
<td>eta</td>
<td>eta vector</td>
</tr>
<tr>
<td>deriv</td>
<td>number of derivatives to compute</td>
</tr>
</tbody>
</table>

Details

ziplss is used with gam to fit 2 stage zero inflated Poisson models. gam is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the Poisson parameter on the right hand side. The second is one sided, specifying the linear predictor for the probability of presence on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the log of the Poisson parameter, and the second column is the complimentary log log of probability of presence. Predictions using predict.gam will also produce 2 column matrices for type "link" and "response".

The null deviance computed for this model assumes that a single probability of presence and a single Poisson parameter are estimated.

For data with large areas of covariate space over which the response is zero it may be advisable to use low order penalties to avoid problems. For 1D smooths uses e.g. \( s(x, m=1) \) and for isotropic smooths use Duchon.splines in place of thin plate terms with order 1 penalties, e.g \( s(x, z, m=c(1, .5)) \) — such smooths penalize towards constants, thereby avoiding extreme estimates when the data are uninformative.

zipll is a function used by ziplss, exported only to allow external use of the ziplss family. It is not usually called directly.

Value

For ziplss An object inheriting from class general.family.

WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes *given the model mean* may imply zero inflation.

The nlme package

ACF  Autocorrelation Function

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls and lme.

Usage
ACF(object, maxLag, ...)

Arguments
object  any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted.
maxLag  maximum lag for which the autocorrelation should be calculated.
...  some methods for this generic require additional arguments.

Value
will depend on the method function used; see the appropriate documentation.

Author(s)
José Pinheiro and Douglas Bates <Bates@stat.wisc.edu>

References

ACF.gls, ACF.lme, plot.ACF
Examples

## see the method function documentation

### ACF.gls

#### Autocorrelation Function for gls Residuals

**Description**

This method function calculates the empirical autocorrelation function for the residuals from a gls fit. If a grouping variable is specified in form, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```r
## S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

**Arguments**

- `object`: an object inheriting from class "gls", representing a generalized least squares fitted model.
- `maxLag`: an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.
- `resType`: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `form`: an optional one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. The time covariate must be integer valued. When a grouping factor is present in form, the autocorrelations are calculated using residual pairs within the same group. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes ACF.gls to print an error message and terminate if there are any incomplete observations.
- `...`: some methods for this generic require additional arguments.

**Value**

A data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
References

ACF.lme, plot.ACF

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
ACF(fm1, form = ~ 1 | Mare)

# Pinheiro and Bates, p. 255-257
fm1Dial.gls <- gls(rate ~ (pressure+I(pressure^2)+I(pressure^3)+I(pressure^4))*QB, Dialyzer)
fm2Dial.gls <- update(fm1Dial.gls, weights = varPower(form = ~ pressure))
ACF(fm2Dial.gls, form = ~ 1 | Subject)
```

---

**Description**

This method function calculates the empirical autocorrelation function for the within-group residuals from an `lme` fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```r
## S3 method for class 'lme'
ACF(object, maxLag, resType, ...)
```

**Arguments**

- `object`  
an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `maxLag`  
an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.
- `resType`  
an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `...`  
some methods for this generic require additional arguments – not used.
Value

A data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

```r
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time),
           Ovary, random = ~ sin(2*pi*Time) | Mare)
ACF(fm1, maxLag = 11)
```

# Pinheiro and Bates, p240-241
```r
fm1Over.lme <- lme(follicles ~ sin(2*pi*Time) +
               cos(2*pi*Time), data=Ovary,
               random=pdDiag(~sin(2*pi*Time)) )
(ACF.fm1Over <- ACF(fm1Over.lme, maxLag=10))
plot(ACF.fm1Over, alpha=0.01)
```

### Description

The `Alfalfa` data frame has 72 rows and 4 columns.

### Format

This data frame contains the following columns:

- **Variety** a factor with levels Cossack, Ladak, and Ranger
- **Date** a factor with levels None S1 S20 07
- **Block** a factor with levels 1 2 3 4 5 6
- **Yield** a numeric vector
Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a 3x4 full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (*Cossac*, *Ladak*, and *Ranger*) were assigned randomly to the blocks and the dates of third cutting (*None*, *S1*—September 1, *S20*—September 20, and *O7*—October 7) were randomly assigned to the plots. All four dates were used on each block.

allCoef  
Extract Coefficients from a Set of Objects

Description

The extractor function is applied to each object in . . . , with the result being converted to a vector. A map attribute is included to indicate which pieces of the returned vector correspond to the original objects in dots.

Usage

allCoef(..., extract)

Arguments

...  
objects to which extract will be applied. Generally these will be model components, such as corStruct and varFunc objects.

extract  
an optional extractor function. Defaults to coef.

Value

a vector with all elements, generally coefficients, obtained by applying extract to the objects in . . .

Author(s)

José’ Pinheiro and Douglas Bates

cs1 <- corAR1(0.1)
vf1 <- varPower(0.5)
allCoef(cs1, vf1)
```
Compare Likelihoods of Fitted Objects

Description

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when `Terms` and `L` are `NULL`), a combination of model terms (when `Terms` in `NULL`), or linear combinations of the model coefficients (when `L` is not `NULL`). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned.

If `test=TRUE`, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

Usage

```r
## S3 method for class 'gls'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

Arguments

- **object**: a fitted model object inheriting from class `gls`, representing a generalized least squares fit.
- **...**: other optional fitted model objects inheriting from classes `"gls"`, `"gnls"`, `"lm"`, `"lme"`, `"lmList"`, `"nlme"`, `"nlsList"`, or `"nls"`.
- **test**: an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by `object` and the objects in `...`. Defaults to `TRUE`.
- **type**: an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".
- **adjustSigma**: an optional logical value. If `TRUE` and the estimation method used to obtain `object` was maximum likelihood, the residual standard error is multiplied by $\sqrt{\frac{\text{dfres}}{\text{dfres} - \text{npars}}}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is `TRUE`.
- **Terms**: an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is `NULL`.

L an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will
be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

verbose

an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

Value

da data frame inheriting from class "anova.lme".

Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

**anova.lme**

*Compare Likelihoods of Fitted Objects*

**Description**

When only one fitted model object is present, a data frame with the numerator degrees of freedom, denominator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms in not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic with the associated p-value is included in the returned data frame.

**Usage**

```r
## S3 method for class 'lme'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
## S3 method for class 'anova.lme'
print(x, verbose, ...)
```

**Arguments**

- `object` an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `...` other optional fitted model objects inheriting from classes "gls", "gnls", "lm", "lme", "lmList", "nlme", "nlsList", or "nls".
an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.

type
an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".

adjustSigma
an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by \( \sqrt{\frac{n_{\text{obs}}}{n_{\text{obs}} - n_{\text{par}}}} \), converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.

Terms
an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

L
an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

x
an object inheriting from class "anova.lme"

verbose
an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

Value
a data frame inheriting from class "anova.lme".

Note
Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

as.matrix.corStruct

Matrix of a corStruct Object

Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.
Usage

```r
## S3 method for class 'corStruct'
as.matrix(x, ...)
```

Arguments

- `x`: an object inheriting from class "corStruct", representing a correlation structure.
- `...`: further arguments passed from other methods.

Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with `object`.

**as.matrix.pdMat**

Matrix of a pdMat Object

Description

This method function extracts the positive-definite matrix represented by `x`.

Usage

```r
## S3 method for class 'pdMat'
as.matrix(x, ...)
```

Arguments

- `x`: an object inheriting from class "pdMat", representing a positive-definite matrix.
- `...`: further arguments passed from other methods.
as.matrix.reStruct

Value

a matrix corresponding to the positive-definite matrix represented by x.

asOneFormula

Combine Formulas of a Set of Objects

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

Usage

asOneFormula(..., omit)

Arguments

... objects, or lists of objects, from which a formula can be extracted.

omit an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(".", "pi").

Value

a one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in omit.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

formula, all.vars

Examples

asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))
Description

The Assay data frame has 60 rows and 4 columns.

Format

This data frame contains the following columns:

- **Block**: an ordered factor with levels 2 < 1 identifying the block where the wells are measured.
- **sample**: a factor with levels a to f identifying the sample corresponding to the well.
- **dilut**: a factor with levels 1 to 5 indicating the dilution applied to the well.
- **logDens**: a numeric vector of the log-optical density.

Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

Source

---

**asTable**

Convert groupedData to a matrix

Description

Create a tabular representation of the response in a balanced groupedData object.

Usage

`asTable(object)`

Arguments

- **object**: A balanced groupedData object
**Details**

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

**Value**

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`groupedData`, `isBalanced`, `balancedGrouped`

**Examples**

```r
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

---

**augPred**

**Augmented Predictions**

**Description**

Predicted values are obtained at the specified values of primary. If object has a grouping structure (i.e. `getGroups(object)` is not NULL), predicted values are obtained for each group. If level has more than one element, predictions are obtained for each level of the max(level) grouping factor. If other covariates besides primary are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```r
augPred(object, primary, minimum, maximum, length.out, ...)
```

## S3 method for class 'lme'

```r
augPred(object, primary = NULL,
        minimum = min(primary), maximum = max(primary),
        length.out = 51, level = Q, ...)
```
Arguments

object  a fitted model object from which predictions can be extracted, using a predict method.

primary an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate object (using getCovariate), it will be used as primary.

minimum an optional lower limit for the primary covariate. Defaults to min(primary).

maximum an optional upper limit for the primary covariate. Defaults to max(primary).

length.out an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.

level an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

... some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: original for the observed values and predicted (single or no grouping factor) or predict.groupVar (multiple levels of grouping), with groupVar replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class "augPred".

Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

```
balancedGrouped  Create a groupedData object from a matrix

Description
Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

Usage
balancedGrouped(form, data, labels=NULL, units=NULL)

Arguments

form
A formula of the form y ~ x | g giving the name of the response, the primary covariate, and the grouping factor.

data
A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate.

labels
an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.

units
an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.

Value
A balanced groupedData object.

labels = list(x = "Age",
y = "Distance from pituitary to pterygomaxillary fissure"),
units = list(x = "(yr)", y = "(mm)"))
Orth2[ 1:10, ]  ## check the first few entries
In this data frame:

- schoolNR: a factor denoting the school.
- pupilNR: a factor denoting the pupil.
- IQ.verb: a numeric vector of verbal IQ scores.
- IQ.perf: a numeric vector of IQ scores.
- sex: Sex of the student.
- Minority: a factor indicating if the student is a member of a minority group.
- repeatgr: an ordered factor indicating if one or more grades have been repeated.
- aritPRET: a numeric vector.
- classNR: a numeric vector.
- aritPOST: a numeric vector.
- langPRET: a numeric vector.
- langPOST: a numeric vector.
- ses: a numeric vector of socioeconomic status indicators.
- denomina: a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.
- schoolSES: a numeric vector.
- satiprin: a numeric vector.
- natittest: a factor with levels 0 and 1.
- meetings: a numeric vector.
- currmeet: a numeric vector.
- mixedgra: a factor indicating if the class is a mixed-grade class.
- percmino: a numeric vector.
- aritdiff: a numeric vector.
- homework: a numeric vector.
- classsiz: a numeric vector.
- groupsiz: a numeric vector.

BodyWeight

*Rat weight over time for different diets*

---

Description

The BodyWeight data frame has 176 rows and 4 columns.

Format

This data frame contains the following columns:

- **weight**: a numeric vector giving the body weight of the rat (grams).
- **Time**: a numeric vector giving the time at which the measurement is made (days).
- **Rat**: an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.
- **Diet**: a factor with levels 1 to 3 indicating the diet that the rat receives.

Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Source

Pharmacokinetics of Cefamandole

Description

The Cefamandole data frame has 84 rows and 3 columns.

Format

This data frame contains the following columns:

- **Subject**: a factor giving the subject from which the sample was drawn.
- **Time**: a numeric vector giving the time at which the sample was drawn (minutes post-injection).
- **conc**: a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

Details

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

Source

Examples

```r
plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)
```

Assign Values to Coefficients

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "pdMat", "corStruct" and "varFunc" classes, "reStruct", and "modelStruct".

Usage

```r
coef(object, ...) <- value
```
coef.corStruct

Arguments

- **object**: any object representing a fitted model, or, by default, any object with a coef component.
- **...**: some methods for this generic function may require additional arguments.
- **value**: a value to be assigned to the coefficients associated with object.

Value

will depend on the method function; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

c coef

Examples

## see the method function documentation

c coef.corStruct

Coefficients of a corStruct Object

Description

This method function extracts the coefficients associated with the correlation structure represented by object.

Usage

## S3 method for class 'corStruct'
c coef(object, unconstrained, ...)
## S3 replacement method for class 'corStruct'
c coef(object, ...) <- value

Arguments

- **object**: an object inheriting from class "corStruct", representing a correlation structure.
- **unconstrained**: a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
- **value**: a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef(object) and must be given in unconstrained form.
- **...**: some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using Initialize) before new values can be assigned to its coefficients.

Author(s)

José Pinheiro and Douglas Bates

References

Examples

cst1 <- corARMA(p = 1, q = 1)
coef(cst1)

---

Description

The estimated coefficients for the nonlinear model represented by object are extracted.

Usage

## S3 method for class 'gnls'
coef(object, ...)

Arguments

object an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the estimated coefficients for the nonlinear model represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
**Description**

The estimated coefficients at level \(i\) are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to \(i\). The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

**Usage**

```r
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN, 
    omitGroupingFactor, subset, ...)
```

**Arguments**

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `augFrame`: an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `level`: an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
- `which`: an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function,
defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor

an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset

an optional expression specifying a subset

... some methods for this generic require additional arguments. None are used in this method.

Value

a data frame inheriting from class "coef.lme" with the estimated coefficients at level level and, optionally, other covariates summarized over groups. The returned object also inherits from classes "ranef.lme" and "data.frame".

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

describe coef.lmList

Extract lmList Coefficients

Description

The coefficients of each lm object in the object list are extracted and organized into a data frame, with rows corresponding to the lm components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the lm components.

Usage

## S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
   omitGroupingFactor, ...)

```r

```
Arguments

object
an object inheriting from class "lmList", representing a list of lm objects with a common model.

augFrame
an optional logical value. If TRUE, the returned data frame is augmented with variables defined in the data frame used to produce object; else, if FALSE, only the coefficients are returned. Defaults to FALSE.

data
an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.

which
an optional positive integer or character vector specifying which columns of the data frame used to produce object should be used in the augmentation of the returned data frame. Defaults to all variables in the data.

FUN
an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor
an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

...some methods for this generic require additional arguments. None are used in this method.

Value

a data frame inheriting from class "coef.lmList" with the estimated coefficients for each "lm" component of object and, optionally, other covariates summarized over the groups corresponding to the "lm" components. The returned object also inherits from classes "ranef.lmList" and "data.frame".

coef(fm1, augFrame = TRUE)
```

`coef.modelStruct`  
Extract modelStruct Object Coefficients

Description

This method function extracts the coefficients associated with each component of the `modelStruct` list.

Usage

```r
## S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class "modelStruct", representing a list of model components, such as "corStruct" and "varFunc" objects.
- `unconstrained`: a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", possibly constrained, form. Defaults to `TRUE`.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

- a vector with all coefficients corresponding to the components of `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. Object must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`Initialize`
Examples

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                  corStruct = corAR1(0.3))
coef(lms1)
```

Description

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

Usage

```r
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

Arguments

- `object` an object inheriting from class "pdMat", representing a positive-definite matrix.
- `unconstrained` a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to TRUE.
- `value` a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

coef.reStruct

reStruct Object Coefficients

Description

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

Usage

## S3 method for class 'reStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'reStruct'
coef(object, ...) <- value

Arguments

object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
value a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef(object) and must be given in unconstrained form.
... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

rsl <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
    B = pdDiag(2 * diag(4), form = ~Educ)))
coef(rsl)

Description

This method function extracts the coefficients associated with the variance function structure represented by object.

Usage

## S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent'
coef(object, ...) <- value

Arguments

object an object inheriting from class "varFunc" representing a variance function structure.
unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", generally constrained form. Defaults to TRUE.
allCoef a logical value. If FALSE only the coefficients which may vary during the optimization are returned. If TRUE all coefficients are returned. Defaults to FALSE.
value a vector with the replacement values for the coefficients associated with object. It must be have the same length of coef{object} and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients.
... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value.

collapse

Collapse According to Groups

Description

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a groupedData method is available.

Usage

collapse(object, ...)

Arguments

object an object to be collapsed, usually a data frame.
...
some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

collapse.groupedData

Examples

### see the method function documentation
collapse.groupedData  

**Collapse a groupedData Object**

**Description**

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

**Usage**

```r
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel, 
    outer, inner, preserve, FUN, subset, ...)
```

**Arguments**

- `object`  
  an object inheriting from class groupedData, generally with multiple grouping factors.

- `collapseLevel`  
  an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.

- `displayLevel`  
  an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is collapseLevel.

- `outer`  
  an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.

- `inner`  
  an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor. If equal to TRUE, attr(object, "inner") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.

- `preserve`  
  an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.

- `FUN`  
  an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables.
in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

subset an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used.

Value
a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
groupedData, plot.nmGroupedData

Examples
# collapsing by Dog
collapse(Pixel, collapse = 1) # same as collapse(Pixel, collapse = "Dog")
**comparePred**

Value

a three-dimensional array, with the third dimension given by the number of unique column names in either `object1` or `object2`. To each column name there corresponds a matrix with as many rows as the rows in `object1` and two columns, corresponding to `object1` and `object2`. The returned object inherits from class `compareFits`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`plot.compareFits`, `pairs.compareFits`, `comparePred`, `coef`, `random.effects`

Examples

```r
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
(cF12 <- compareFits(coef(fm1), coef(fm2)))
```

### Description

Predicted values are obtained at the specified values of `primary` for each object. If either `object1` or `object2` have a grouping structure (i.e. `getGroups(object)` is not NULL), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides `primary` are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

```r
comparePred(object1, object2, primary, minimum, maximum,
           length.out, level, ...)
```

Arguments

- `object1`, `object2`: fitted model objects, from which predictions can be extracted using the `predict` method.
- `primary`: an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using `getCovariate`), it will be used as `primary`.
- `minimum`: an optional lower limit for the primary covariate. Defaults to `min(primary)`, after `primary` is evaluated in the data used in fitting `object1`.
- `maximum`: an optional upper limit for the primary covariate. Defaults to `max(primary)`, after `primary` is evaluated in the data used in fitting `object1`.
length.out  an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.

level  an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.

...  some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects’ names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes comparePred and augPred.

Note

This function is generic: method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

augPred, getGroups

Examples

```r
fm1 <- lme(distance ~ age * Sex, data = Orthodont, random = ~ age)
fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
```
corAR1

Arguments

value  the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).

form  a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corAR1, representing an autocorrelation structure of order 1.

**corARMA**  
**ARMA(p,q) Correlation Structure**

**Description**

This function is a constructor for the corARMA class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

corARMA(value, form, p, q, fixed)

**Arguments**

- **value**: a vector with the values of the autoregressive and moving average parameters, which must have length p + q and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.

- **form**: a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **p, q**: non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.
Value

an object of class corARMA, representing an autocorrelation-moving average correlation structure.

**corCAR1**

*Continuous AR(1) Correlation Structure*

**Description**

This function is a constructor for the corCAR1 class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate Initialize method.

**Usage**

```r
corCAR1(value, form, fixed)
```

**Arguments**

- **value**: the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.
- **form**: a one sided formula of the form \( \sim t \) or \( \sim t \mid g \), specifying a time covariate \( t \) and, optionally, a grouping factor \( g \). Covariates for this correlation structure need not be integer valued. When a grouping factor is present in \( form \), the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \( \sim 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

an object of class corCAR1, representing an autocorrelation structure of order 1, with a continuous time covariate.

corCompSymm

Compound Symmetry Correlation Structure

Description

This function is a constructor for the corCompSymm class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corCompSymm(value, form, fixed)

Arguments

value
the correlation between any two correlated observations. Defaults to 0.

form
a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corCompSymm, representing a compound symmetry correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## covariate is observation order and grouping factor is Subject
cs1 <- corCompSymm(0.5, form = ~ 1 | Subject)

# Pinheiro and Bates, pp. 222-225
fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
                 random = ~ Time)
# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())
# p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)

## Print/Summary methods for the empty case:
(cCS <- corCompSymm()) # Uninitialized correlation struc..
summary(cCS) # (ditto)
```

corExp

Exponential Correlation Structure

Description

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( \exp(-r/d) \) when no nugget effect is present and \( (1-n) \exp(-r/d) \) when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

```r
corExp(value, form, nugget, metric, fixed)
```

Arguments

- `value`: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- `form`: a one sided formula of the form \( \sim S1+\ldots+Sp \), or \( \sim S1+\ldots+Sp \ | \ g \), specifying spatial covariates \( S1 \) through \( Sp \) and, optionally, a grouping factor \( g \). When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \( \sim 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget  an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

anova(fm3BW.lme, fm4BW.lme)
```

---

**corFactor**

### Factor of a Correlation Matrix

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

**Usage**

```r
corFactor(object, ...)
```

**Arguments**

- `object`  an object from which a correlation matrix can be extracted.
- `...`  some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `corFactor.corStruct`, `recalc.corStruct`

**Examples**

```r
## see the method function documentation
```
corFactor.corStruct  

Factor of a corStruct Object Matrix

Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by `object`.

Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L^tL$. This method extracts $L^{-t}$.

Usage

```r
## S3 method for class 'corStruct'
corFactor(object, ...)
```

Arguments

- `object`: an object inheriting from class "corStruct" representing a correlation structure, which must have been initialized (using `Initialize`).
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with `object` stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

Note

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `corMatrix` method function can be used to obtain transpose inverse square-root factors in matrix form.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`corFactor`, `corMatrix.corStruct`, `recalc.corStruct`, `Initialize.corStruct`

Examples

```r
cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```
Description

This function is a constructor for the corGaus class, representing a Gaussian spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( \exp\left(-\left(\frac{r}{d}\right)^2\right) \) when no nugget effect is present and \( (1-n) \exp\left(-\left(\frac{r}{d}\right)^2\right) \) when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate 'Initialize' method.

Usage

corGaus(value, form, nugget, metric, fixed)

Arguments

- **value**: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form \(~ S1+...+Sp\) or \(~ S1+...+Sp \mid g\), specifying spatial covariates \( S1 \) through \( Sp \) and, optionally, a grouping factor \( g \). When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corGaus, also inheriting from class corSpatial, representing a Gaussian spatial correlation structure.
corLin

Description

This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r < d \) apart is \( 1 - (r/d) \) when no nugget effect is present and \( (1 - n)(1 - (r/d)) \) when a nugget effect is assumed. If \( r \geq d \) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corLin(value, form, nugget, metric, fixed)
Arguments

value

an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form

a one sided formula of the form ~ S1+...+Sp or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget

an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric

an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed

an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corLin, also inheriting from class corSpatial, representing a linear spatial correlation structure.

corMatrix

Extract Correlation Matrix

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

Usage

corMatrix(object, ...)

Arguments

object an object for which a correlation matrix can be extracted.

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

corMatrix.corStruct, corMatrix.pdMat

Examples

## see the method function documentation
corMatrix.corStruct

Matrix of a corStruct Object

Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to covariate and object. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L' L$. When $corr = FALSE$, this method extracts $L^{-1}$.

Usage

```r
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

Arguments

- **object**: an object inheriting from class "corStruct" representing a correlation structure.
- **covariate**: an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.
- **corr**: a logical value. If TRUE the function returns the correlation matrix, or list of correlation matrices, represented by object. If FALSE the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

If covariate is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the covariate is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of covariate.

corMatrix.pdMat  

**Extract Correlation Matrix from a pdMat Object**

**Description**

The correlation matrix corresponding to the positive-definite matrix represented by object is obtained.

**Usage**

```r
## S3 method for class 'pdMat'
corMatrix(object, ...)
```

**Arguments**

- `object` an object inheriting from class "pdMat", representing a positive definite matrix.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

the correlation matrix corresponding to the positive-definite matrix represented by object.

corNatural

Description

This function is a constructor for the corNatural class, representing a general correlation structure in the “natural” parameterization, which is described under pdNatural. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corNatural(value, form, fixed)

Arguments

value
an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form
a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corNatural representing a general correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Initialize.corNatural, pdNatural, summary.corNatural

Examples

## covariate is observation order and grouping factor is Subject

cs1 <- corNatural(form = ~ 1 | Subject)
**corRatio**

**Rational Quadratic Correlation Structure**

**Description**

This function is a constructor for the corRatio class, representing a rational quadratic spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( 1/(1 + (r/d)^2) \) when no nugget effect is present and \( (1 - n)/(1 + (r/d)^2) \) when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate Initialize method.

**Usage**

```
corRatio(value, form, nugget, metric, fixed)
```

**Arguments**

- **value**: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form \( ~ S_1 + \ldots + S_p \) or \( ~ S_1 + \ldots + S_p \mid g \), specifying spatial covariates \( S_1 \) through \( S_p \) and, optionally, a grouping factor \( g \). When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \( ~ 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

**Value**

an object of class corRatio, also inheriting from class corSpatial, representing a rational quadratic spatial correlation structure.
corSpatial

Spatial Correlation Structure

Description

This function is a constructor for the corSpatial class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: corExp, corGaus, corLin, corRatio, and corSpher. The returned object will inherit from one of these "real" classes, determined by the type argument, and from the "virtual" corSpatial class. Objects created using this constructor must later be initialized using the appropriate Initialize method.
corSpatial

Usage

corSpatial(value, form, nugget, type, metric, fixed)

Arguments

value an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

type an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions corSpher, corExp, corGaus, corLin, and corRatio for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class determined by the type argument and also inheriting from class corSpatial, representing a spatial correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

corSpher

Spherical Correlation Structure

Description

This function is a constructor for the corSpher class, representing a spherical spatial correlation structure. Letting \(d\) denote the range and \(n\) denote the nugget effect, the correlation between two observations a distance \(r < d\) apart is \(1 - 1.5(r/d) + 0.5(r/d)^{3}\) when no nugget effect is present and \((1 - n)(1 - 1.5(r/d) + 0.5(r/d)^{3})\) when a nugget effect is assumed. If \(r \geq d\) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corSpher(value, form, nugget, metric, fixed)

Arguments

- **value**: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form \(\sim S1+\ldots+Sp\), or \(\sim S1+\ldots+Sp \mid g\), specifying spatial covariates \(S1\) through \(Sp\) and, optionally, a grouping factor \(g\). When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(\sim 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

Examples

```r
sp1 <- corSpatial(form = ~ x + y + z, type = "g", metric = "man")
```
metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSpher, also inheriting from class corSpatial, representing a spherical spatial correlation structure.

corSymm

General Correlation Structure

Description

This function is a constructor for the corSymm class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corSymm(value, form, fixed)

Arguments

value an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSymm representing a general correlation structure.

### Covariate

<table>
<thead>
<tr>
<th>Covariate</th>
<th>Assign Covariate Values</th>
</tr>
</thead>
</table>

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all “varFunc” classes.

### Usage

```r
covariate(object) <- value
```

### Arguments

- **object**: any object with a covariate component.
- **value**: a value to be assigned to the covariate associated with object.

### Value

will depend on the method function; see the appropriate documentation.
Covariate.varFunc

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
getCovariate

Examples
## see the method function documentation

Covariate.varFunc Assign varFunc Covariate

Description
The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

Usage
## S3 replacement method for class 'varFunc'
covariate(object) <- value

Arguments
object an object inheriting from class "varFunc", representing a variance function structure.
value a value to be assigned to the covariate associated with object.

Value
a varFunc object similar to object, but with its covariate attribute replaced by value.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
getCovariate.varFunc

Examples
vf1 <- varPower(1.1, form = ~age) covariate(vf1) <- Orthodont["age"]]
Dialyzer

Description

The Dialyzer data frame has 140 rows and 5 columns.

Format

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject.
- **QB**: a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- **pressure**: a numeric vector giving the transmembrane pressure (dmHg).
- **rate**: the hemodialyzer ultrafiltration rate (mL/hr).
- **index**: index of observation within subject—1 through 7.

Details

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dL/min or 300~dL/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

Dim

Extract Dimensions from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: "corSpatial", "corStruct", "pdCompSymm", "pdDiag", "pdIdent", "pdMat", and "pdSymm".

Usage

Dim(object, ...)
Arguments

object any object for which dimensions can be extracted.

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Note

If `dim` allowed more than one argument, there would be no need for this generic function.

---

**Description**

if `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```r
## S3 method for class 'corSpatial'
Dim(object, groups, ...)
```

**Arguments**

- `object`: an object inheriting from class "corSpatial", representing a spatial correlation structure.
- `groups`: an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
- `...`: further arguments to be passed to or from methods.
Value

a list with components:

- **N** length of groups
- **M** number of groups
- **spClass** an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin
- **sumLenSq** sum of the squares of the number of observations per group
- **len** an integer vector with the number of observations per group
- **start** an integer vector with the starting position for the distance vectors in each group, beginning from zero
