ops Logical flag. Activates completion after the $ and @ operators.
ns Logical flag. Controls namespace related completions.
args Logical flag. Enables completion of function arguments.
dots Logical flag. If disabled, drops ... from list of function arguments. Relevant only if args is enabled.
func Logical flag. Enables detection of functions. If enabled, a customizable extension ("(" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.
S3 Logical flag. When args = TRUE, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).
ipck Logical flag. Enables completion of installed package names inside library and require.
data Logical flag. Enables completion of data sets (including those already visible) inside data.
**Help**

Logical flag. Enables completion of help requests starting with a question mark, by looking inside help index files.

**Argdb**

Logical flag. When `args = TRUE`, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to `args`. While this gives results that are technically correct, the use of the `...` argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting `argdb = TRUE` enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function `addFunctionInfo` (see below).

**Fuzzy**

Logical flag. Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change.

**Quotes**

Logical flag. Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by `?`), help completion is invoked. Setting this to FALSE relegates completion to the underlying completion frontend, which may do its own processing (for example, `readline` on Unix-alikes will do filename completion).

**Files**

Logical flag. Deprecated. Use quotes instead.

**Name, ...**

User-settable options. Currently valid names are

- `function.suffix`: default "(
- `funarg.suffix`: default "=
- `package.suffix`: default ":::"

Usage is similar to that of `options`.

**X**

An R object for which valid names after "$" are computed and returned.

**Pattern**

A regular expression. Only matching names are returned.

### Details

There are several types of completion, some of which can be disabled using `rc.settings`. The arguments of `rc.settings` are all logical flags, turning specific optional completion features on and off. All settings are on by default except `ipck`, `func`, and `fuzzy`. Turn more off if your CPU cycles are valuable; you will still retain basic completion.

The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

**Completion after extractors $ and @**: When the `ops` setting is turned on, completion after `$` and `@` is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `[`, `$`, etc *do not* inhibit evaluation).

Valid completions after the `$` extractor are determined by the generic function `.DollarNames`. Some basic methods are provided, and more can be written for custom classes.
Completion inside namespaces: When the ns setting is turned on, completion inside namespaces is attempted when a token is preceded by the :: or ::: operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., foopkg:: becomes a valid completion of foo if "foopkg" is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if MASS is not loaded, MAS will not complete to MASS:::. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on MASS::fr will load MASS if it is not already loaded.

Completion for help items: When the help setting is turned on, completion on help topics is attempted when a token is preceded by ?. Prefixes (such as class, method) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the args setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that ... is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an in-line function call. Our compromise is to consider arguments of all currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like print and plot), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the S3 setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete seq([TAB] and seq(from = 1, [TAB]) will both list only the arguments of seq (or any of its methods), whereas trying to complete seq(length[TAB] will list both the length.out argument and the length( function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

Special functions: For a few special functions (library, data, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The ipck setting, which controls whether library and require will complete on installed packages, is disabled by default because the first call to installed.packages is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to installed.packages is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.
Value

If `rc.settings` is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns `NULL` invisibly.

`rc.status` returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to `rc.status` itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

- `comps`: The possible completions generated by the last call to `.completeToken`, as a character vector.
- `token`: The token that was (or, is to be) completed, as set by the last call to `.assignToken` (possibly inside a call to `.guessTokenFromLine`).
- `linebuffer`: The full line, as set by the last call to `.assignLinebuffer`.
- `start`: The start position of the token in the line buffer, as set by the last call to `.assignStart`.
- `end`: The end position of the token in the line buffer, as set by the last call to `.assignEnd`.
- `fileName`: Logical, indicating whether the cursor is currently inside quotes.
- `fguess`: The name of the function the cursor is currently inside.
- `isFirstArg`: Logical. If cursor is inside a function, is it the first argument?

In addition, the components `settings` and `options` give the current values of settings and options respectively. `rc.getOption` and `rc.options` behave much like `getOption` and `options` respectively.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

- `.assignToken(text)`
- `.assignLinebuffer(line)`
- `.assignStart(start)`
- `.assignEnd(end)`
- `.completeToken()`
- `.retrieveCompletions()`
- `.getFileComp()`
- `.guessTokenFromLine()`
- `.win32consoleCompletion(linebuffer, cursorPosition, check.repeat = TRUE, minlength = -1)`
- `.addFunctionInfo(...)`
The first four functions set up a completion attempt by specifying the token to be completed (text), and indicating where (start and end, which should be integers) the token is placed within the complete line typed so far (line).

Potential completions of the token are generated by `.completeToken`, and the completions can be retrieved as an R character vector using `.retrieveCompletions`. It is possible for the user to specify a replacement for this function by setting `rc.options("custom.completer");` if not `NULL`, this function is called to compute potential completions. This facility is meant to help in situations where completing as R code is not appropriate. See source code for more details.

If the cursor is inside quotes, completion may be suppressed. The function `.getFileComp` can be used after a call to `.completeToken` to determine if this is the case (returns `TRUE`), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `.guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The `.win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the linebuffer and cursor position as arguments, and returns a list with three components, addition, possible and comps. If there is an unambiguous extension at the current position, addition contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in possible, or as a single string in comps. possible consists of lines formatted using the current width option, so that printing them on the console one line at a time will be a reasonable way to list them. comps is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The `minlength` argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If `check.repeat` is `TRUE`, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `.addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is `TRUE`, these are used as a source of valid argument names for the relevant functions.

**Note**

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i, 1:10]$ba` will evaluate `foo[i, 1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this will affect promises and lazy loaded symbols.

**Author(s)**

Deepayan Sarkar, <deepayan.sarkar@r-project.org>
**read.DIF**

**Data Input from Spreadsheet**

**Description**

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

**Usage**

```r
read.DIF(file, header = FALSE,
          dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
          row.names, col.names, as.is = !stringsAsFactors,
          na.strings = "NA", colClasses = NA, nrow = 1,
          skip = 0, check.names = TRUE, blank.lines.skip = TRUE,
          stringsAsFactors = FALSE,
          transpose = FALSE, fileEncoding = "")
```

**Arguments**

- **file**
  - the name of the file which the data are to be read from, or a `connection`, or a complete URL.
  - The name "clipboard" may also be used on Windows, in which case `read.DIF("clipboard")` will look for a DIF format entry in the Windows clipboard.

- **header**
  - a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to `TRUE` if and only if the first row contains only character values and the top left cell is empty.

- **dec**
  - the character used in the file for decimal points.

- **numerals**
  - string indicating how to convert numbers whose conversion to double precision would lose accuracy, see `type.convert`.

- **row.names**
  - a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.
  - If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if `row.names` is missing, the rows are numbered.
  - Using `row.names = NULL` forces row numbering.

- **col.names**
  - a vector of optional names for the variables. The default is to use "V" followed by the column number.

- **as.is**
  - controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by `colClasses`. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

**Note:** In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using `type.convert` as in `read.table`.

Note: to suppress all conversions including those of numeric columns, set `colClasses = "character"`

Note that `as.is` is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

`na.strings` a character vector of strings which are to be interpreted as `NA` values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

`colClasses` character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be `NA`.

Possible values are `NA` (when `type.convert` is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an `as` method (from package `methods`) for conversion from "character" to the specified formal class.

Note that `colClasses` is specified per column (not per variable) and so includes the column of row names (if any).

`nrows` the maximum number of rows to read in. Negative values are ignored.

`skip` the number of lines of the data file to skip before beginning to read data.

`check.names` logical. If `TRUE` then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.

`blank.lines.skip` logical: if `TRUE` blank lines in the input are ignored.

`stringsAsFactors` logical: should character vectors be converted to factors?

`transpose` logical, indicating if the row and column interpretation should be transposed. Microsoft’s Excel has been known to produce (non-standard conforming) DIF files which would need `transpose = TRUE` to be read correctly.

`fileEncoding` character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the ‘Encoding’ section of the help for `file`, the ‘R Data Import/Export’ manual and ‘Note’.

### Value

A data frame (`data.frame`) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame.

### Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

### Author(s)

R Core; `transpose` option by Christoph Buser, ETH Zurich
Reference

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also https://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

See Also

The R Data Import/Export manual.

scan, type.convert, read.fwf for reading fixed width formatted input; read.table, data.frame.

Examples

```r
## read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

read.fortran

Read Fixed-Format Data in a Fortran-like Style

Description

Read fixed-format data files using Fortran-style format specifications.

Usage

```r
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

Arguments

- `file` : File or connection to read from.
- `format` : Character vector or list of vectors. See ‘Details’ below.
- `...` : Other arguments for `read.fwf`.
- `as.is` : Keep characters as characters?
- `colClasses` : Variable classes to override defaults. See `read.table` for details.

Details

The format for a field is of one of the following forms: `rFl.d`, `rDl.d`, `rXl`, `rAl`, `rIl`, where `l` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `l` is required except for `X` formats when `r` is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped `X` columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.
Value
A data frame

Note
read.fortran does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying \( d > 0 \) in the \( F \) or \( D \) format will shift the decimal \( d \) places to the left, even if it is explicitly specified in the input file.

See Also
read.fwf, read.table, read.csv

Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1","F2.0","I2"))
read.fortran(ff, c("2F1.0","2X","2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1","A2"), c("3I2","2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

**read.fwf**  
**Read Fixed Width Format Files**

Description
Read a table of fixed width formatted data into a data.frame.

Usage

```r
read.fwf(file, widths, header = FALSE, sep = "\t",
  skip = 0, row.names, col.names, n = -1,
  buffersize = 2000, fileEncoding = "", ...)
```

Arguments

- **file**  
  the name of the file which the data are to be read from.  
  Alternatively, file can be a connection, which will be opened if necessary, and  
  if so closed at the end of the function call.

- **widths**  
  integer vector, giving the widths of the fixed-width fields (of one line), or list of  
  integer vectors giving widths for multiline records.

- **header**  
  a logical value indicating whether the file contains the names of the variables as  
  its first line. If present, the names must be delimited by sep.
read.fwf

sep character; the separator used internally; should be a character that does not occur in the file (except in the header).

skip number of initial lines to skip; see read.table.

row.names see read.table.

col.names see read.table.

n the maximum number of records (lines) to be read, defaulting to no limit.

buffersize Maximum number of lines to read at one time

fileEncoding character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, the ‘R Data Import/Export’ manual and ‘Note’.

... further arguments to be passed to read.table. Useful such arguments include as.is, na.strings, colClasses and strip.white.

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in file are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by read.table and so should not be included in a col.names or colClasses argument (nor in the header line, if present).

Reducing the buffersize argument may reduce memory use when reading large files with long lines. Increasing buffersize may result in faster processing when enough memory is available.

Note that read.fwf (not read.table) reads the supplied file, so the latter’s argument encoding will not be useful.

Value

A data.frame as produced by read.table which is called internally.

Author(s)

Brian Ripley for R version: originally in Perl by Kurt Hornik.

scan and read.table.

read.fortran for another style of fixed-format files.

Examples

ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3)) #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3)) #> 1 NA 23 NA \ 9 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
**read.socket**

**Read from or Write to a Socket**

**Description**

read.socket reads a string from the specified socket, write.socket writes to the specified socket. There is very little error checking done by either.

**Usage**

read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)

**Arguments**

- **socket**: a socket object.
- **maxlen**: maximum length (in bytes) of string to read.
- **loop**: wait for ever if there is nothing to read?
- **string**: string to write to socket.

**Value**

read.socket returns the string read as a length-one character vector.
write.socket returns the number of bytes written.

**Author(s)**

Thomas Lumley

**See Also**

close.socket, make.socket

**Examples**

```r
finger <- function(user, host = "localhost", port = 79, print = TRUE) {
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, "\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
```
## Not run:
finger("root")  ## only works if your site provides a finger daemon
## End(Not run)

### Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

### Usage

```r
read.table(file, header = FALSE, sep = "", quote = "\"",
    dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
    row.names, col.names, as.is = !stringsAsFactors, tryLogical = TRUE,
    na.strings = "NA", colClasses = NA, nrows = -1,
    skip = 0, check.names = TRUE, fill = !blank.linesskip,
    strip.white = FALSE, na.strings = "NA", colClasses = NA, nrows = -1,
    skip = 0, check.names = TRUE, fill = !blank.linesskip,
    comment.char = "#",
    allowEscapes = FALSE, flush = FALSE,
    stringsAsFactors = FALSE,
    fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)
```

```r
read.csv(file, header = TRUE, sep = ",", quote = "\"",
    dec = ".", fill = TRUE, comment.char = "", ...)
```

```r
read.csv2(file, header = TRUE, sep = ";", quote = "\"",
    dec = ",", fill = TRUE, comment.char = "", ...)
```

```r
read.delim(file, header = TRUE, sep = "\t",
    quote = "\"",
    dec = ".", fill = TRUE, comment.char = "", ...)
```

```r
read.delim2(file, header = TRUE, sep = "\t",
    quote = "\"",
    dec = ",", fill = TRUE, comment.char = "", ...)
```

### Arguments

- `file` the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an `absolute` path, the file name is `relative` to the current working directory, `getwd()`. Tilde-expansion is performed where supported. This can be a compressed file (see `file`). Alternatively, `file` can be a readable text-mode `connection` (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If `stdin()` is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on `stdin()` will be cleared before return.)

- `file` can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for `url`.)
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.</td>
</tr>
<tr>
<td>sep</td>
<td>the field separator character. Values on each line of the file are separated by this character. If sep = &quot;&quot; (the default for read.table) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.</td>
</tr>
<tr>
<td>quote</td>
<td>the set of quoting characters. To disable quoting altogether, use quote = &quot;&quot;. See scan for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless colClasses is specified.</td>
</tr>
<tr>
<td>dec</td>
<td>the character used in the file for decimal points.</td>
</tr>
<tr>
<td>numerals</td>
<td>string indicating how to convert numbers whose conversion to double precision would lose accuracy, see type.convert. Can be abbreviated. (Applies also to complex-number inputs.)</td>

<tr>
<td>as.is</td>
<td>controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors. Note: to suppress all conversions including those of numeric columns, set colClasses = &quot;character&quot;. Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</td>
</tr>
<tr>
<td>tryLogical</td>
<td>a logical determining if columns consisting entirely of “F”, “T”, “FALSE”, and ”TRUE” should be converted to logical; passed to type.convert, true by default.</td>
</tr>
<tr>
<td>na.strings</td>
<td>a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens after white space is stripped from the input, so na.strings values may need their own white space stripped in advance.</td>
</tr>
<tr>
<td>colClasses</td>
<td>character. A vector of classes to be assumed for the columns. If unnamed, recycled as necessary. If named, names are matched with unspecified values being taken to be NA. Possible values are NA (the default, when type.convert is used), &quot;NULL&quot; (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or “factor”, ”Date” or ”POSIXct”. Other-</td>
</tr>
</tbody>
</table>
wise there needs to be an as method (from package methods) for conversion
from "character" to the specified formal class.
Note that colClasses is specified per column (not per variable) and so includes
the column of row names (if any).

nrows integer: the maximum number of rows to read in. Negative and other invalid
values are ignored.

skip integer: the number of lines of the data file to skip before beginning to read data.

check.names logical. If TRUE then the names of the variables in the data frame are checked
to ensure that they are syntactically valid variable names. If necessary they are
adjusted (by make.names) so that they are, and also to ensure that there are no
duplicates.

fill logical. If TRUE then in case the rows have unequal length, blank fields are
implicitly added. See ‘Details’.

strip.white logical. Used only when sep has been specified, and allows the stripping of leading
and trailing white space from unquoted character fields (numeric fields are always stripped). See scan for further details (including the exact meaning of
‘white space’), remembering that the columns may include the row names.

blank.lines.skip logical: if TRUE blank lines in the input are ignored.

comment.char character: a character vector of length one containing a single character or an
empty string. Use ‘’ to turn off the interpretation of comments altogether.

allowEscapes logical. Should C-style escapes such as ‘\n’ be processed or read verbatim (the
default)? Note that if not within quotes these could be interpreted as a delimiter
(but not as a comment character). For more details see scan.

flush logical: if TRUE, scan will flush to the end of the line after reading the last of the
fields requested. This allows putting comments after the last field.

stringsAsFactors logical: should character vectors be converted to factors? Note that this is over-
ridden by as.is and colClasses, both of which allow finer control.

fileEncoding character string: if non-empty declares the encoding used on a file (not a con-
nection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, the ‘R Data Import/Export’ manual and ‘Note’.

encoding encoding to be assumed for input strings. It is used to mark character strings as
known to be in Latin-1 or UTF-8 (see Encoding): it is not used to re-encode the
input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’.

text character string: if file is not supplied and this is, then data are read from the
value of text via a text connection. Notice that a literal string can be used to
include (small) data sets within R code.

skipNul logical: should nuls be skipped?

... Further arguments to be passed to read.table.

Details
This function is the principal means of reading tabular data into R.
Unless colClasses is specified, all columns are read as character columns and then converted using
type.convert to logical, integer, numeric, complex or (depending on as.is) factor as appropriate.
Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If row.names is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If row.names is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of col.names if it is specified and is longer. This could conceivably be wrong if fill or blank.lines.skip are true, so specify col.names if necessary (as in the 'Examples').

read.csv and read.csv2 are identical to read.table except for the defaults. They are intended for reading 'comma separated value' files (’.csv’) or (read.csv2) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, read.delim and read.delim2 are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that header = TRUE and fill = TRUE in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided blank.lines.skip = TRUE; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded nulls are unsupported: skipping them (with skipNul = TRUE) may work.

Value

A data frame (data.frame) containing a representation of the data in the file.

Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame. Note that in either case the columns will be logical unless colClasses was supplied.

Character strings in the result (including factor levels) will have a declared encoding if encoding is "latin1" or "UTF-8".

CSV files

See the help on write.csv for the various conventions for .csv files. The commonest form of CSV file with row names needs to be read with read.csv(., row.names = 1) to use the names in the first column of the file as row names.

Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if colClasses is specified as one of the six atomic vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using nrows, even as a mild over-estimate, will help memory usage.

Using comment.char = "" will be appreciably faster than the read.table default.
read.table is not the right tool for reading large matrices, especially those with many columns: it is designed to read data frames which may have columns of very different classes. Use scan instead for matrices.

Note

The columns referred to in as.is and colClasses include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the encoding argument to declare that. If the input is in some other encoding, then it may be translated on input. The fileEncoding argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

References

The 'R Data Import/Export' manual.

scan, type.convert, read.fwf for reading fixed width formatted input; write.table; data.frame.

count.fields can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

https://www.rfc-editor.org/rfc/rfc4180 for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

Examples

```r
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)
read.csv(tf, fill = TRUE)  # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE, col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
c d"")
```
readRegistry

Read a Windows Registry Hive

Description

On Windows, read values of keys in the Windows Registry, and optionally whole hives.

Usage

readRegistry(key, hive = c("HLM", "HCR", "HCU", "HU", "HCC", "HPD"),
             maxdepth = 1, view = c("default", "32-bit", "64-bit"))

Arguments

key character string, the path to the key in the Windows Registry.
hive The ‘hive’ containing the key. The abbreviations are for
       HKEY_LOCAL_MACHINE, HKEY_CLASSES_ROOT, HKEY_CURRENT_USER,
       HKEY_USERS, HKEY_CURRENT_CONFIG and HKEY_PERFORMANCE_DATA
maxdepth How far to recurse into the subkeys of the key. By default only the values of the
         key and the names of subkeys are returned.
view On 64-bit Windows, the view of the Registry to be used: see ‘Details’.

Details

Registry access is done using the security settings of the current R session: this means that some
Registry keys may not be accessible even if they exist. This may result in NULL values in the object
returned, and, possibly, empty element names.

On 64-bit Windows, this will by default read the 32-bit view of the Registry when run from 32-bit R,

Value

A named list of values and subkeys (which may themselves be named lists). The default value (if
any) precedes named values which precede subkeys, and both the latter sets are sorted alphabetically.

Note

This is only available on Windows.

Examples

if(.Platform$OS.type == "windows") withAutoprint({
  ## only in HLM if set in an admin-mode install.
  try(readRegistry("SOFTWARE\R-core", maxdepth = 3))
}

gmt <- file.path("SOFTWARE", "Microsoft", "Windows NT",
                 "CurrentVersion", "Time Zones",
                 "GMT Standard Time", fsep = "\")
readRegistry(gmt, "HLM")
## Not run: ## on a 64-bit R need this to find 32-bit JAGS
readRegistry("SOFTWARE\JAGS", maxdepth = 3, view = "32")

## See if there is a 64-bit user install
readRegistry("SOFTWARE\R-core\R64", "HCU", maxdepth = 2)

## End(Not run)

---

### recover

#### Browsing after an Error

**Description**

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

**Usage**

```r
recover()
```

**Details**

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

**Value**

Nothing useful is returned. However, you can invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

**Compatibility Note**

The R `recover` function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

**References**

See the compatibility note above, however.
See Also

browser for details about the interactive computations; options for setting the error option; dump.frames to save the current environments for later debugging.

Examples

```r
## Not run:
options(error = recover) # setting the error option

### Example of interaction

> myFit <- lm(y ~ x, data = xy, weights = w)

```

```r
## End(Not run)
```

relist

Allow Re-Listing an unlist()ed Object

Description

relist() is an S3 generic function with a few methods in order to allow easy inversion of unlist(obj) when that is used with an object obj of (S3) class "relistable".

Usage

relist(flesh, skeleton)

## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))

## S3 method for class 'factor'
Arguments

- **flesh**: a vector to be relisted
- **skeleton**: a list, the structure of which determines the structure of the result
- **x**: an R object, typically a list (or vector).
- **recursive**: logical. Should unlisting be applied to list components of x?
- **use.names**: logical. Should names be preserved?

Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

\[
\text{list(}\text{mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))}.\]

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```r
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
               log = TRUE))
}

optim(unlist(initial.param), ll)
```

relist takes two parameters: skeleton and flesh. Skeleton is a sample object that has the right shape but the wrong content. Flesh is a vector with the right content but the wrong shape. Invoking
relist(flesh, skeleton)

will put the content of flesh on the skeleton. You don’t need to specify skeleton explicitly if the skeleton is stored as an attribute inside flesh. In particular, if flesh was created from some object obj with unlist(as.relistable(obj)) then the skeleton attribute is automatically set. (Note that this does not apply to the example here, as optim is creating a new vector to pass to ll and not its par argument.)

As long as skeleton has the right shape, it should be an inverse of unlist. These equalities hold:

\[
\text{relist(unlist(x), x)} == x \\
\text{unlist(relist(y, skeleton))} == y \\
x \leftarrow \text{as.relistable(x)} \\
\text{relist(unlist(x))} == x
\]

Note however that the relisted object might not be identical to the skeleton because of implicit coercions performed during the unlisting step. All elements of the relisted objects have the same type as the unlisted object. NULL values are coerced to empty vectors of that type.

Value

an object of (S3) class "relistable" (and "list").

Author(s)

R Core, based on a code proposal by Andrew Clausen.

unlist

Examples

ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))

---

**REMOVE**

Remove Add-on Packages

**Description**

Utility for removing add-on packages.

**Usage**

R CMD REMOVE [options] [-l lib] pkgs
remove.packages

**Arguments**

pkgs  
a space-separated list with the names of the packages to be removed.

lib  
the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form `--library=lib`.

options  
further options for help or version.

**Details**

If used as R CMD REMOVE pkgs without explicitly specifying lib, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree lib instead of the default one, use R CMD REMOVE -l lib pkgs.

Use R CMD REMOVE --help for more usage information.

**Note**

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

**See Also**

`INSTALL`, `remove.packages`

---

**Description**

Removes installed packages/bundles and updates index information as necessary.

**Usage**

`remove.packages(pkgs, lib)`

**Arguments**

pkgs  
a character vector with the names of the packages to be removed.

lib  
a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in `.libPaths()`.

**See Also**

On Unix-alikes, `REMOVE` for a command line version;
`install.packages` for installing packages.
Description

When `options("keep.source")` is `TRUE`, a copy of the original source code to a function is stored with it. Similarly, `parse()` may keep formatted source for an expression. Such source reference attributes are removed from the object by `removeSource()`.

Usage

`removeSource(fn)`

Arguments

`fn` a function or another language object (fulfilling `is.language`) from which to remove the source.

Details

This removes the "srcref" and related attributes, via recursive cleaning of `body(fn)` in the case of a function or the recursive language parts, otherwise.

Value

A copy of the `fn` object with the source removed.

See Also

`is.language` about language objects.

`srcref` for a description of source reference records, `deparse` for a description of how functions are deparsed.

Examples

```r
## to make this act independently of the global 'options()' setting:
op <- options(keep.source = TRUE)
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}
fn
names(attributes(fn))  # "srcref" (only)
names(attributes(body(fn)))  # "srcref" "srcfile" "wholeSrcref"
f2 <- removeSource(fn)
f2
stopifnot(length(attributes(fn)) > 0,
  is.null(attributes(f2)),
  is.null(attributes(body(f2))))

## Source attribute of parse()d expressions,
## have ("srcref", "srcfile", "wholeSrcref"):
E <- parse(text = "a <- x^y # power") ; names(attributes(E ))
E. <- removeSource(E) ; names(attributes(E.))
```
stopifnot(length(attributes(E)) > 0,
    is.null(attributes(E.)))
options(op) # reset to previous state

---

**RHOME**

*R Home Directory*

**Description**

Returns the location of the `R` home directory, which is the root of the installed `R` tree.

**Usage**

```r
R RHOME
```

---

**roman**

*Roman Numerals*

**Description**

Simple manipulation of (a small set of) integer numbers as roman numerals.

**Usage**

```r
as.roman(x)
.romans
r1 + r2
r1 <= r2
max(r1)
sum(r2)
```

**Arguments**

- `x`  
  a numeric or character vector of arabic or roman numerals.
- `r1, r2`  
  a roman number vector, i.e., of class "roman".

**Details**

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, coercion, etc, see `methods(class = "roman")`.

Arithmetic ("Arith"), Comparison ("Compare") and ("Logic"), i.e., all "Ops" group operations work as for regular numbers via R’s integer functionality.

Only numbers between 1 and 3899 have a unique representation as roman numbers, and hence others result in `as.roman(NA)`.  
`.romans` is the basic dictionary, a named character vector.
References

Examples

```r
## First five roman 'numbers'.
(y <- as.roman(1:5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## Today, and 10, 20, 30, and 100 years ago ...
y - 10*c(0:3,10)

## mixture of arabic and roman numbers :
as.roman(c(NA, 1:3, "", strrep("I", 1:6))) # + NA with a warning for "IIIIII"
cc <- c(NA, 1:3, strrep("I", 0:5))
(rc <- as.roman(cc)) # two NAs: 0 is not "roman"
(ic <- as.integer(rc)) # works automatically [without an explicit method]
rNA <- as.roman(NA)

## simple consistency checks -- arithmetic when result is in {1,2,...,3899} :
stopifnot(identical(rc, as.roman(rc)), # as.roman(.) is "idempotent"
identical(rc + rc + (3*rc), rc*5),
identical(ic, c(NA, 1:3, NA, 1:5)),
identical(as.integer(5*rc), 5L*ic),
identical(as.numeric(rc), as.numeric(ic)),
identical(rc[1], rNA),
identical(as.roman(NA), rNA),
identical(as.integer(NA), rNA),
identical(as.list(rc), as.list(ic)))

## Non-Arithmetic 'Ops':
stopifnot(exprs = {
  # Comparisons :
  identical(ic < 1:5, rc < 1:5)
  identical(ic < 1:5, rc < as.roman(1:5))
  # Logic [inters |-> logical] :
  identical(rc & TRUE, rc & TRUE)
  identical(rc & FALSE, ic & FALSE)
  identical(rc | FALSE, ic | FALSE)
  identical(rc | NA, ic | NA)
})

## 'Summary' group functions (and comparison):
(rc. <- rc[!is.na(rc)])
stopifnot(exprs = {
  identical(min(rc), as.roman(NA))
  identical(min(rc, na.rm=TRUE),
    as.roman(min(ic, na.rm=TRUE)))
  identical(range(rc.),
    as.roman(range(as.integer(rc.)))))
  identical(sum (rc, na.rm=TRUE), as.roman("XXI"))
  identical(format(prod(rc, na.rm=TRUE)), "DCCXX")
  format(prod(rc.)) == "DCCXX"
})
```
Enable Profiling of R's Execution

Description

Enable or disable profiling of the execution of R expressions.

Usage

Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
memory.profiling = FALSE, gc.profiling = FALSE,
line.profiling = FALSE, filter.callframes = FALSE,
umfiles = 100L, bufsize = 10000L)

Arguments

filename The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
append logical: should the file be over-written or appended to?
interval real: time interval between samples.
memory.profiling logical: write memory use information to the file?
gc.profiling logical: record whether GC is running?
line.profiling logical: write line locations to the file?
filter.callframes logical: filter out intervening call frames of the call tree. See the filtering out call frames section.
numfiles, bufsize integers: line profiling memory allocation

Details

Enabling profiling automatically disables any existing profiling to another or the same file.
Profiling works by writing out the call stack every interval seconds, to the file specified. Either the summaryRprof function or the wrapper script R CMD Rprof can be used to process the output file to produce a summary of the usage; use R CMD Rprof --help for usage information.

How time is measured varies by platform:

On Windows: Exactly what the time interval measures is subtle: it is time that the R process is running and executing an R command. It is not however just CPU time, for if readline() is waiting for input, that counts (on Windows, but not on a Unix-alike).
Note that the timing interval cannot be too small, for the time spent in each profiling step is added to the interval. What is feasible is machine-dependent, but 10ms seemed as small as advisable on a 1GHz machine.

On Unix-alikes it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by system to return.
Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10 ms).
On Linux, the interval needs to be at least 10ms, on all other platforms at least 1ms. Shorter intervals will be rounded up with a warning.

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some primitive functions do not do so: specifically those which are of type “special” (see the ‘R Internals’ manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is TRUE, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

**Filtering Out Call Frames**

Lazy evaluation makes the call stack more complex because intervening call frames are created between the time arguments are applied to a function, and the time they are effectively evaluated. When the call stack is represented as a tree, these intervening frames appear as sibling nodes. For instance, evaluating `try(EXPR)` produces the following call tree, at the time `EXPR` gets evaluated:

1. `+-base::try(EXPR)
2. | \-base::tryCatch(...)
3. | \-base::tryCatchList(expr, classes, parentenv, handlers)
4. | \-base:::tryCatchOne(expr, names, parentenv, handlers[[1L]])
5. | \-base:::doTryCatch(return(expr), name, parentenv, handler)
6. \-EXPR

Lines 2 to 5 are intervening call frames, the last of which finally triggered evaluation of `EXPR`. Setting `filter.callframes` to TRUE simplifies the profiler output by removing all sibling nodes of intervening frames.

The same kind of call frame filtering is applied with `eval()` frames. When you call `eval()`, two frames are pushed on the stack to ensure a continuity between frames. Say we have these definitions:

```r
calling <- function() evaluator(quote(called()), environment())
evaluator <- function(expr, env) eval(expr, env)
called <- function() EXPR()
```

calling() calls called() in its own environment, via `eval()`. The latter is called indirectly through `evaluator()`. The net effect of this code is identical to just calling `called()` directly, without the intermediaries. However, the full call stack looks like this:

1. `calling()
2. \-evaluator(quote(called()), environment())
3. \-base::eval(expr, env)
4. \-base::eval(expr, env)
5. \-called()
6. \-EXPR()

When call frame filtering is turned on, the true calling environment of `called()` is looked up, and the filtered call stack looks like this:

1. `calling()
5. \-called()
6. \-EXPR()`
If the calling environment is not on the stack, the function called by `eval()` becomes a root node. Say we have:

calling <- function() evaluator(quote(called()), new.env())

With call frame filtering we then get the following filtered call stack:

5. called()
6. \-EXPR()

Note

On Unix-alikes: Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with `--disable-R-profiling` to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for C-level profiling.

On Windows: `filename` can be a UTF-8-encoded filepath that cannot be translated to the current locale.

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

See Also

The chapter on “Tidying and profiling R code” in ‘Writing R Extensions’ (see the ‘doc/manual’ subdirectory of the R source tree).

`summaryRprof` to analyse the output file.

`tracemem, Rprofmem` for other ways to track memory use.

Examples

```r
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
## ...
## Now post-process the output as described in Details

## End(Not run)
```
Rprofmem

Enable Profiling of R's Memory Use

Description

Enable or disable reporting of memory allocation in R.

Usage

Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)

Arguments

filename
The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.

append
logical: should the file be over-written or appended to?

threshold
numeric: allocations on R’s "large vector" heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. (It is enabled in a standard Windows build of R.)

The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.

tracemem traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"
Examples

```r
## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
```

Rscript  

### Description

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

### Usage

```
Rscript [options] file [args]
Rscript [options] -e expr [-e expr2 ...] [args]
```

### Arguments

- **options**: a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details.
- **expr**, **expr2**: R expression(s), properly quoted.
- **file**: the name of a file containing R commands. ‘-’ indicates ‘stdin’.
- **args**: arguments to be passed to the script in `file` or expressions supplied via ‘-e’.

### Details

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--no-echo --no-restore’ are always supplied. these imply ‘--no-save’. Arguments that contain spaces cannot be specified directly on the ‘#!’ line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the ‘#!’ line. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.

The prescribed order of arguments is important: e.g. ‘--verbose’ specified after ‘-e’ will be part of args and passed to the expression; the same will happen to ‘-e’ specified after file.

Additional options accepted as part of options (before file or ‘-e’) are

- ‘--verbose’ gives details of what Rscript is doing.
- ‘--default-packages=list’ where list is a comma-separated list of package names or NULL.
  
  Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup.
Spaces are allowed in `expr` and `file` (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If `--default-packages` is not used, then `Rscript` checks the environment variable `R_SCRIPT_DEFAULT_PACKAGES`. If this is set, then it takes precedence over `R_DEFAULT_PACKAGES`.

Normally the version of `R` is determined at installation, but this can be overridden by setting the environment variable `RHOME`.

`stdin()` refers to the input file, and `file("stdin")` to the stdin file stream of the process.

**Note**

`Rscript` is only supported on systems with the `execv` system call.

**Examples**

```r
## Not run:
Rscript --date() -e 'format(Sys.time(), "%a %b %d %X %Y")'

# Get the same initial packages in the same order as default R:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()'

## example #! script for a Unix-alike
## (arguments given on the #! line end up as [options] to Rscript, while
## arguments passed to the #! script end up as [args], so available to
## commandArgs())
#!/path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

---

**RShowDoc** 2089

**Description**

Utility function to find and display R documentation.

**Usage**

```r
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

**Arguments**

- `what`: a character string: see 'Details'.
- `type`: an optional character string giving the preferred format. Can be abbreviated.
- `package`: an optional character string specifying the name of a package within which to look for documentation.
**Details**

what can specify one of several different sources of documentation, including the \texttt{R} manuals (\texttt{R-admin}, \texttt{R-data}, \texttt{R-exts}, \texttt{R-intro}, \texttt{R-ints}, \texttt{R-lang}), \texttt{NEWS}, \texttt{COPYING} (the GPL licence), any of the licenses in `share/licenses`, \texttt{FAQ} (also available as \texttt{R-FAQ}), and the files in ‘\texttt{R_HOME/doc}’.

Only on Windows, the \texttt{R} for Windows FAQ is specified by \texttt{rw-FAQ}.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).

**Value**

A invisible character string given the path to the file found.

**See Also**

For displaying regular help files, \texttt{help} (or \texttt{?}) and \texttt{help.start}.

For type = "txt", \texttt{file.show} is used. \texttt{vignettes} are nicely viewed via \texttt{RShowDoc(*, package=.)}.

**Examples**

\begin{verbatim}
RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")
\end{verbatim}

---

**RSiteSearch**  
*Search for Key Words or Phrases in Documentation*

**Description**

Search for key words or phrases in various documentation, such as \texttt{R} manuals, help pages of base and CRAN packages, vignettes, task views and others, using the search engine at \url{https://search.r-project.org} and view them in a web browser.

**Usage**

\begin{verbatim}
RSiteSearch(string,  
  restrict = c("functions", "descriptions", "news", "Rfunctions",  
    "Rmanuals", "READMEs", "views", "vignettes"),  
  format,  
  sortby = c("score", "date:late", "date:early", "subject",  
    "subject:descending", "size", "size:descending"),  
  matchesPerPage = 20,  
  words = c("all", "any"))
\end{verbatim}
Arguments

string  A character string specifying word(s) or phrase(s) to search. If the words are to
be searched as one entity, enclose them either in (escaped) quotes or in braces.

restrict  A character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: functions for help pages of CRAN packages, descriptions for extended descriptions of CRAN packages, news for package NEWS, Rfunctions for help pages of R base packages, Rmanuals for R manuals, READMEs for README files of CRAN packages, views for task views, vignettes for package vignettes.

format  deprecated.

sortby  character string (can be abbreviated) indicating how to sort the search results:
(score, date:late for sorting by date with latest results first, date:early for earliest first, subject for captions in alphabetical order, subject:descending for reverse alphabetical order, size or size:descending for size.)

matchesPerPage  How many items to show per page.

words  Show results matching all words/phrases (default) or any of them.

Details

This function is designed to work with the search site at https://search.r-project.org. Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron and Gennadiy Starostin

See Also

help.search, help.start for local searches.
browseURL for how the help file is displayed.

Examples

# need Internet connection
## for phrase searching you may use (escaped) double quotes or brackets
RSiteSearch("(logistic regression) \"glm object\"")
RSiteSearch("logistic regression")

## Search in vignettes and help files of R base packages
## store the query string:
fullquery <- RSiteSearch("lattice", restrict = c("vignettes","Rfunctions"))
fullquery # a string of 112 characters
**rtags**  
*An Etags-like Tagging Utility for R*

### Description

**rtags** provides etags-like indexing capabilities for R code, using R's own parser.

### Usage

```r
tags(path = ".", pattern = "\.[RrSs]$", recursive = FALSE,  
src = list.files(path = path, pattern = pattern,  
full.names = TRUE, recursive = recursive),  
keep.re = NULL,  
ofile = "", append = FALSE,  
verbose = getOption("verbose"),  
type = c("etags", "ctags"))
```

### Arguments

- **path, pattern, recursive**  
  Arguments passed on to `list.files` to determine the files to be tagged. By default, these are all files with extension `.R`, `.r`, `.S`, and `.s` in the current directory. These arguments are ignored if `src` is specified.

- **src**  
  A vector of file names to be indexed.

- **keep.re**  
  A regular expression further restricting `src` (the files to be indexed). For example, specifying `keep.re = "/R/[\^/]*\.R$"` will only retain files with extension `.R` inside a directory named `R`.

- **ofile**  
  Passed on to `cat` as the file argument; typically the output file where the tags will be written ("TAGS" or "tags" by convention). By default, the output is written to the R console (unless redirected).

- **append**  
  Logical, indicating whether the output should overwrite an existing file, or append to it.

- **verbose**  
  Logical. If TRUE, file names are echoed to the R console as they are processed.

- **type**  
  Character string specifying whether emacs style ("etags") or vi style ("ctags") tags are to be generated.

### Details

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style ctags format and the emacs-style etags format. Tag files in these formats are usually generated by the `ctags` and `etags` utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R's parser) and produces tags in both etags and ctags formats. The support for vi-style ctags is rudimentary, and was adapted from a patch by Neal Fultz; see PR#17214.
It may be more convenient to use the command-line wrapper script `R CMD rtags`.

Examples

```r
## Not run:
rtags("/path/to/src/repository",
    pattern = ".\.*\.[RrSs]$",
    keep.re = "/R/",
    verbose = TRUE,
    ofile = "TAGS",
    append = FALSE,
    recursive = TRUE)

## End(Not run)
```

Rtangle

R Driver for Stangle

Description

A driver for Stangle that extracts R code chunks. Notably all RtangleSetup() arguments may be used as arguments in the Stangle() call.

Usage

```r
Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
    split = FALSE, quiet = FALSE, drop.evalFALSE = FALSE, ...)
```

Arguments

- **file**: name of Sweave source file. See the description of the corresponding argument of Sweave.
- **syntax**: an object of class SweaveSyntax.
- **output**: name of output file used unless split = TRUE: see ‘Details’.
- **annotate**: a logical or function. When true, as by default, code chunks are separated by comment lines specifying the names and line numbers of the code chunks. If FALSE the decorating comments are omitted. Alternatively, annotate may be a function, see section ‘Chunk annotation’.
split
quiet

drop.evalFALSE

... additional named arguments setting defaults for further options listed in ‘Supported Options’.

Details

Unless split = TRUE, the default name of the output file is basename(file) with an extension corresponding to the Sweave syntax (e.g., ‘Rnw’, ‘Stex’) replaced by ‘R’. File names “stdout” and “stderr” are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘.R’).

Note that this driver does more than simply extract the code chunks verbatim, because chunks may re-use earlier chunks.

Chunk annotation (annotate)

By default annotate = TRUE, the annotation is of one of the forms

```
# code chunk number 3: viewport
```

```
# code chunk number 18: grid.Rnw:647-648
```

```
# code chunk number 19: trellisdata (eval = FALSE)
```

using either the chunk label (if present, i.e., when specified in the source) or the file name and line numbers.

annotate may be a function with formal arguments (options, chunk, output), e.g. to produce less dominant chunk annotations; see Rtangle()$runcode how it is called instead of the default.

Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

- **engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **keep.source**: logical (TRUE). If keep. source == TRUE the original source is copied to the file. Otherwise, deparsed source is output.
- **eval**: logical (TRUE). If FALSE, the code chunk is copied across but commented out.
- **prefix** Used if split = TRUE. See prefix.string.
prefix.string: a character string, default is the name of the source file (without extension). Used if split = TRUE as the prefix for the filename if the chunk has no label, or if it has a label and prefix = TRUE. Note that this is used as part of filenames, so needs to be portable.

show.line.nos logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

Author(s)
Friedrich Leisch and R-core.

'Sweave User Manual', a vignette in the utils package.
Sweave, RweaveLatex

Examples

```
nmRnw <- "example-1.Rnw"
exfile <- system.file("Sweave", nmRnw, package = "utils")
## Create R source file
Stangle(exfile)
nmR <- sub("Rnw$", "R", nmRnw) # the (default) R output file name
if(interactive()) file.show("example-1.R")

## Smaller R source file with custom annotation:
my.Ann <- function(options, chunk, output) {
  cat("### chunk #", options$chunknr, ": ",
  if(!is.null(ol <- options$label)) ol else .RtangleCodeLabel(chunk),
  if(!options$eval) " (eval = FALSE)"
  "\n",
  file = output, sep = "\"
}
Stangle(exfile, annotate = my.Ann)
if(interactive()) file.show("example-1.R")

Stangle(exfile, annotate = my.Ann, drop.evalFALSE=TRUE)
if(interactive()) file.show("example-1.R")
```

---

RweaveLatex

R/LaTeX Driver for Sweave

Description
A driver for Sweave that translates R code chunks in \LaTeX files by “running them”, i.e., parse() and eval() each.

Usage

RweaveLatex()

RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE, debug = FALSE, stylepath, ...)
Arguments

file  Name of Sweave source file. See the description of the corresponding argument of Sweave.
syntax An object of class SweaveSyntax.
output Name of output file. The default is to remove extension ‘.nw’, ‘.Rnw’ or ‘.Snw’ and to add extension ‘.tex’. Any directory paths in file are also removed such that the output is created in the current working directory.
quiet If TRUE all progress messages are suppressed.
debug If TRUE, input and output of all code chunks is copied to the console.
stylistepath See ‘Details’.

... named values for the options listed in ‘Supported Options’.

Details

The \LaTeX file generated needs to contain the line ‘\usepackage{Sweave}’, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the \texttt{RweaveLatex} driver as last line before the ‘\begin{document}’ statement. If \texttt{stylepath = TRUE}, a hard-coded path to the file ‘Sweave.sty’ in the R installation is set in place of Sweave. The hard-coded path makes the \LaTeX file less portable, but avoids the problem of installing the current version of ‘Sweave.sty’ to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for \texttt{stylepath} is now taken from the environment variable \texttt{SWEAVE\_STYLEPATH\_DEFAULT}, or is \texttt{FALSE} it that is unset or empty. If set, it should be exactly \texttt{TRUE} or \texttt{FALSE}: any other values are taken as \texttt{FALSE}.

The simplest way for frequent Sweave users to ensure that ‘Sweave.sty’ is in the TeX input path is to add ‘\texttt{R\_HOME/share/texmf}’ as a ‘texmf tree’ (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, ‘Sweave.sty’ loads the ‘graphicx’ \LaTeX package and sets the width of all included graphics to:

\texttt{\setkeys{Gin}{width=0.8\textwidth}}.

This setting (defined in the ‘graphicx’ package) affects the width size option passed to the ‘\includegraphics{}’ directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.

Thus, for example, you may set width=3 in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to ‘0.8\textwidth’ and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the ‘\setkeys{Gin}{width=...}’ directive in your ‘.Rnw’ file after the ‘\begin{document}’ directive and changing the width option value as you prefer, using standard \LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a ‘\usepackage[nogin]{Sweave}’ directive in your preamble. In this case, no size/scaling options will be passed to the ‘\includegraphics{}’ directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

‘Sweave.sty’ also supports the ‘[nofontenc]’ option, which skips the default inclusion of ‘\usepackage[T1]{fontenc}’ for pdfTeX processing.
It also supports the ‘[inconsolata]’ option, to render monospaced text in \texttt{inconsolata}, the font used by default for \texttt{R} help pages.

The use of fancy quotes (see \texttt{sQuote}) can cause problems when setting \texttt{R} output in non-UTF-8 locales (note that pdf\TeX{} assumes UTF-8 by default since 2018). Either set \texttt{options(useFancyQuotes = FALSE)} or arrange that \texttt{\LaTeX} is aware of the encoding used and ensure that typewriter fonts containing directional quotes are used.

Some \texttt{\LaTeX} graphics drivers do not include ‘.png’ or ‘.jpg’ in the list of known extensions. To enable them, add something like ‘\texttt{\DeclareGraphicsExtensions{.png,.pdf,.jpg}}’ to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are \texttt{TRUE} both files will be produced by \texttt{Sweave}, and their order in the ‘\texttt{\DeclareGraphicsExtensions}’ list determines which will be used by pdf\LaTeX.

**Supported Options**

\texttt{RweaveLatex} supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from \texttt{Sweave} through \ldots but not when used in the header of a code chunk.

- **engine**: character string (“R”). Only chunks with \texttt{engine} equal to “R” or “S” are processed.
- **echo**: logical (\texttt{TRUE}). Include \texttt{R} code in the output file?
- **keep.source**: logical (\texttt{TRUE}). When echoing, if \texttt{TRUE} the original source is copied to the file. Otherwise, deparsed source is echoed.
- **eval**: logical (\texttt{TRUE}). If \texttt{FALSE}, the code chunk is not evaluated, and hence no text nor graphical output produced.
- **results**: character string (“verbatim”). If “verbatim”, the output of \texttt{R} commands is included in the verbatim-like ‘\texttt{Soutput}’ environment. If “tex”, the output is taken to be already proper \texttt{\LaTeX} markup and included as is. If “hide” then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.
- **print**: logical (\texttt{FALSE}). If \texttt{TRUE}, this forces auto-printing of all expressions.
- **term**: logical (\texttt{TRUE}). If \texttt{TRUE}, visibility of values emulates an interactive \texttt{R} session: values of assignments are not printed, values of single objects are printed. If \texttt{FALSE}, output comes only from explicit \texttt{print} or similar statements.
- **split**: logical (\texttt{FALSE}). If \texttt{TRUE}, text output is written to separate files for each code chunk.
- **strip.white**: character string (“true”). If “true”, blank lines at the beginning and end of output are removed. If “all”, then all blank lines are removed from the output. If “false” then blank lines are retained.
  A ‘blank line’ is one that is empty or includes only whitespace (spaces and tabs).
  Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.
- **prefix**: logical (\texttt{TRUE}). If \texttt{TRUE} generated filenames of figures and output all have the common prefix given by the \texttt{prefix.string} option: otherwise only unlabelled chunks use the prefix.
- **prefix.string**: a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.
- **include**: logical (\texttt{TRUE}), indicating whether input statements for text output (if \texttt{split = TRUE}) and ‘\texttt{\includegraphics}’ statements for figures should be auto-generated. Use \texttt{include = FALSE} if the output should appear in a different place than the code chunk (by placing the input line manually).
\texttt{fig}: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

\texttt{eps}: logical (FALSE), indicating whether EPS figures should be generated. Ignored if \texttt{fig} = FALSE.

\texttt{pdf}: logical (TRUE), indicating whether PDF figures should be generated. Ignored if \texttt{fig} = FALSE.

\texttt{pdf.version, pdf.encoding, pdf.compress}: passed to \texttt{pdf} to set the version, encoding and compression (or not). Defaults taken from \texttt{pdf.options()}.

\texttt{png}: logical (FALSE), indicating whether PNG figures should be generated. Ignored if \texttt{fig} = FALSE. Only available in R $\geq 2.13.0$.

\texttt{jpeg}: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if \texttt{fig} = FALSE. Only available in R $\geq 2.13.0$.

\texttt{grdevice}: character (NULL): see section ‘Custom Graphics Devices’. Ignored if \texttt{fig} = FALSE. Only available in R $\geq 2.13.0$.

\texttt{width}: numeric (6), width of figures in inches. See ‘Details’.

\texttt{height}: numeric (6), height of figures in inches. See ‘Details’.

\texttt{resolution}: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

\texttt{concordance}: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers.

\texttt{figs.only}: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a ‘\SweaveOpts{}’ line in the document. For unknown options, their type is set at first use.

\textbf{Custom Graphics Devices}

If option \texttt{grdevice} is supplied for a code chunk with both \texttt{fig} and \texttt{eval} true, the following call is made

\begin{verbatim}
get(options$grdevice, envir = .GlobalEnv)(name=, width=, height=, options)
\end{verbatim}

which should open a graphics device. The chunk’s code is then evaluated and \texttt{dev.off} is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

\begin{verbatim}
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
grDevices::png(filename = paste(name, "png", sep = ","),
               width = width, height = height, res = 100,
               units = "in", type = "quartz", bg = "transparent")
@
\end{verbatim}

Alternatively for R $\geq 3.4.0$, if the function exists in a package (rather than the \texttt{.GlobalEnv}) it can be used by setting \texttt{grdevice = "pkg::my.Swd"} (or with ‘::’ instead of ‘:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\\
Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for `dev.off` can be provided as a function with suffix `.off`, e.g. `my.Swd.off()` or `pkg::my.Swd.off()`, respectively.

**Hook Functions**

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each *logical* option of a code chunk (echo, print, ...) a hook can be specified, which is executed if and only if the respective option is `TRUE`. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called `clean` that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.

---

**Rwin configuration**

The file ‘Rconsole’ configures the R GUI (`Rgui`) console under MS Windows and `loadRconsole(*)` loads a new configuration.

The file ‘Rdevga’ configures the graphics devices `windows`, `win.graph`, `win.metafile` and `win.print`, as well as the bitmap devices `bmp`, `jpeg`, `png` and `tiff` (which use for `type = "windows"` use `windows` internally).

**Usage**

`loadRconsole(file)`

**Arguments**

`file` The file from which to load a new ‘Rconsole’ configuration. By default a file dialog is used to select a file.
Details

There are system copies of these files in `R_HOME\etc`. Users can have personal copies of the files: these are looked for in the location given by the environment variable `R_USER`. The system files are read only if a corresponding personal file is not found.

If the environment variable `R_USER` is not set, the R system sets it to `HOME` if that is set (stripping any trailing slash), otherwise to the Windows ‘personal’ directory, otherwise to `{HOMEDRIVE}\{HOMEPATH}` if `HOMEDRIVE` and `HOMEPATH` are both set otherwise to the working directory. This is as described in the file ‘rw-FAQ’.

Value

Each of the files contains details in its comments of how to set the values.

At the time of writing ‘Rdevga’ configured the mapping of font numbers to fonts, and ‘Rconsole’ configured the appearance (single or multiple document interface, toolbar, statusbar on MDI), size, font and colours of the GUI console, and whether resizing the console sets `options("width")`. The file ‘Rconsole’ also configures the internal pager. This shares the font and colours of the console, but can be sized separately.

‘Rconsole’ can also set the initial positions of the console and the graphics device, as well as the size and position of the MDI workspace in MDI mode.

`loadRconsole` is called for its side effect of loading new defaults. It returns no useful value.

Chinese/Japanese/Korean

Users of these languages will need to select a suitable font for the console (perhaps `MS Mincho`) and for the graphics device (although the default `Arial` has many East Asian characters). It is essential that the font selected for the console has double-width East Asian characters – many monospaced fonts do not.

Note

The GUI preferences item on the Edit menu brings up an dialog box which can be used to edit the console settings, and to save them to a file.

This is only available on Windows.

`windows`

Examples

```r
if(.Platform$OS.type == "windows") withAutoprint(
  ruser <- Sys.getenv("R_USER")
  cat("\n\nLocation for personal configuration files is\n  R_USER = ",
    ruser, "\n\n", sep = "")
  ## see if there are personal configuration files
  file.exists(file.path(ruser, c("Rconsole", "Rdevga")))
  ## show the configuration files used
```
showConfig <- function(file)
{
  ruser <- Sys.getenv("R_USER")
  path <- file.path(ruser, file)
  if(!file.exists(path)) path <- file.path(R.home(), "etc", file)
  file.show(path, header = path)
}

showConfig("Rconsole")

savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
  prefix = "##------ ", suffix = " ------##",
  quiet = FALSE)

Arguments

file The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.

max.show The maximum number of lines to show. Inf will give all of the currently available history.

reverse logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.

pattern A character string to be matched against the lines of the history. When supplied, only unique matching lines are shown.

... Arguments to be passed to grep when doing the matching.

stamp A value or vector of values to be written into the history.

prefix A prefix to apply to each line.

suffix A suffix to apply to each line.

quiet If TRUE, suppress printing timestamp to the console.
Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Notably, there are different implementations for Unix and Windows.

**Windows:** The functions described here work in Rgui and interactive Rterm but not in batch use of Rterm nor in embedded/DCOM versions.

**Unix-alikes:** The functions described here work under the readline command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without readline.

R.app, the console on macOS, has a separate and largely incompatible history mechanism, which by default uses a file `.Rapp.history` and saves up to 250 entries. These functions are not currently implemented there.

The (readline on Unix-alikes) history mechanism is controlled by two environment variables: R_HISTSIZE controls the number of lines that are saved (default 512), and R_HISTFILE (default `.Rhistory`) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for loadhistory/savehistory). There is no limit on the number of lines of history retained during a session, so setting R_HISTSIZE to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of `Sys.setenv`.

On Unix-alikes: Note that readline history library saves files with permission 0600, that is with read/write permission for the user and not even read permission for any other account.

The timestamp function writes a timestamp (or other message) into the history and echoes it to the console. On platforms that do not support a history mechanism only the console message is printed.

**Note**

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

**Examples**

```r
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
.Last <- function()
  if(interactive()) try(savehistory("~/Rhistory"))

## End(Not run)
```

---

select.list  
Select Items from a List

**Description**

Select item(s) from a character vector.

**Usage**

```r
select.list(choices, preselect = NULL, multiple = FALSE,
            title = NULL, graphics =getOption("menu.graphics"))
```
Arguments

- choices: a character vector of items.
- preselect: a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- multiple: logical: can more than one item be selected?
- title: optional character string for window title, or NULL for no title.
- graphics: logical: should a graphical widget be used?

Details

The normal default is graphics = TRUE.

On Windows, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. If multiple is true, further items can be selected or deselected by holding the control key down whilst selecting, and shift-clicking can be used to select ranges.

Normal termination is via the ‘OK’ button or by hitting Enter or double-clicking an item. Selection can be aborted via the ‘Cancel’ button or pressing Escape.

Under the macOS GUI, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If graphics is FALSE or no graphical widget is available it displays a text list from which the user can choose by number(s). The multiple = FALSE case uses menu. Preselection is only supported for multiple = TRUE, where it is indicated by a “+” preceding the item.

It is an error to use select.list in a non-interactive session.

Value

A character vector of selected items. If multiple is false and no item was selected (or Cancel was used), ”” is returned. If multiple is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

menu, tk_select.list for a graphical version using Tcl/Tk.

Examples

```r
## Not run:
select.list(sort(.packages(all.available = TRUE)))
## End(Not run)
```
sessionInfo

Collect Information About the Current R Session

Description

Get and report version information about R, the OS and attached or loaded packages.

The print() and toLatex() methods (for a "sessionInfo" object) show the locale and timezone information by default, when locale or tzone are true. The system.codepage is only shown when it is not empty, i.e., only on Windows, and if it differs from code.page, see below or l10n_info().

Usage

sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE, tzone = locale,
    RNG = !identical(x$RNGkind, .RNGdefaults), ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, tzone = locale,
    RNG = !identical(object$RNGkind, .RNGdefaults), ...)

osVersion

Arguments

package a character vector naming installed packages, or NULL (the default) meaning all attached packages.
x an object of class "sessionInfo".
object an object of class "sessionInfo".
locale show locale, by default tzone, and (on Windows) code page information?
tzone show time zone information?
RNG show information on RNGkind()? Defaults to true iff it differs from the R version’s default, i.e., RNGversion(*).
... currently not used.

Value

sessionInfo() returns an object of class "sessionInfo" which has print and toLatex methods. This is a list with components

R.version a list, the result of calling R.Version().
platform a character string describing the platform R was built under. Where sub-architectures are in use this is of the form 'platform/sub-arch (nn-bit)'.
running a character string (or possibly NULL), the same as osVersion, see below.
RNGkind a character vector, the result of calling RNGkind().
matprod a character string, the result of calling getOption("matprod").
BLAS a character string, the result of calling extSoftVersion()["BLAS"].
LAPACK a character string, the result of calling La_library().
LA_version a character string, the result of calling La_version().
locale    a character string, the result of calling `Sys.getlocale()`.
tzone     a character string, the result of calling `Sys.timezone()`.
tzcode_type a character string indicating source (system/internal) of the date-time conversion and printing functions.
basePkgs   a character vector of base packages which are attached.
otherPkgs  (not always present): a character vector of other attached packages.
loadedOnly (not always present): a named list of the results of calling `packageDescription` on packages whose namespaces are loaded but are not attached.

osVersion

osVersion is a character string (or possibly NULL on bizarre platforms) describing the OS and version which it is running under (as distinct from built under). This attempts to name a Linux distribution and give the OS name on an Apple Mac.

It is the same as `sessionInfo()$running` and created when loading the `utils` package.

Windows may report unexpected versions: see the help for `win.version`.

How OSEs identify themselves and their versions can be arcane: where possible `osVersion` (and hence `sessionInfo()$running`) uses a human-readable form.

Where R was compiled under macOS 10.x (as the CRAN Intel distributions have been) but running under ‘Big Sur’ or later, macOS reports itself as ‘10.16’ (which R recognizes as ‘Big Sur...’) and not ‘11’, ‘12’, ‘13’ or later.

Note

The information on ‘loaded’ packages and namespaces is the current version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

See Also

`R.version`, `R_compiled_by`

Examples

```r
sI <- sessionInfo()
sI
# The same, showing the RNGkind, but not the locale :
print(sI, RNG = TRUE, locale = FALSE)
toLatex(sI, locale = FALSE) # shortest; possibly desirable at end of report
```

Description

Interact with the user to choose the package repositories to be used.
setRepositories

Usage

```r
setRepositories(graphics = getOption("menu.graphics"),
    ind = NULL, addURLs = character())
```

Arguments

**graphics**
Logical. If true, use a graphical list: on Windows or macOS GUI use a list box, and on a Unix-alike if `tcltk` and an X server are available, use Tk widget. Otherwise use a text menu.

**ind**
NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for `graphics = FALSE`.

**addURLs**
A character vector of additional URLs: it is often helpful to use a named vector.

Details

The default list of known repositories is stored in the file `R_HOME/etc/repositories`. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable `R_REPOSITORIES`, or if this is unset or does not exist, in `HOME/.R/repositories`, which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`, e.g. via `chooseBioCmirror` — the default value is “https://bioconductor.org”. This version of R chooses Bioconductor version 3.16 by default, but that can be changed via the environment variable `R_BIOC_VERSION`.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g., only source packages or not macOS binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type “both” is equivalent to “source”.)

Repository 'CRAN' is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a list with component `repos`) or NULL if no changes were applied.

Note

This does not set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic Startup).

See Also

`chooseCRANmirror, chooseBioCmirror, install.packages`
Examples

## Not run:
setRepositories(addURLs =
c(CRANxtras = "https://www.stats.ox.ac.uk/pub/RWin"))

## End(Not run)

setWindowTitle

Set the Window Title or the Statusbar of the RGui in Windows

Description

Set or get the title of the R (i.e. RGui) window which will appear in the task bar, or set the statusbar (if in use).

Usage

setWindowTitle(suffix, title = paste(getIdentification(), suffix))

getWindowTitle()

getIdentification()

setStatusBar(text)

Arguments

suffix a character string to form part of the title
title a character string forming the complete new title
text a character string of up to 255 characters, to be displayed in the status bar.

Details

setWindowTitle appends suffix to the normal window identification (RGui, R Console or Rterm). Use suffix ="" to reset the title.
getWindowTitle gets the current title.
This sets the title of the frame in MDI mode, the title of the console for RGui --sdi, and the title of the window from which it was launched for Rterm. It has no effect in embedded uses of R.
getIdentification returns the normal window identification.
setStatusBar sets the text in the statusbar of an MDI frame: if this is not currently shown it is selected and shown.

Value

The first three functions return a length 1 character vector.
setWindowTitle returns the previous window title (invisibly).
getWindowTitle and getIdentification return the current window title and the normal window identification, respectively.
Note

These functions are only available on Windows and only make sense when using the \texttt{Rgui}. E.g., in \texttt{Rterm} (and hence in ESS) the title is not visible (but can be set and gotten), and in a version of \texttt{RStudio} it has been "", invariably.

Examples

\begin{verbatim}
if(.Platform$OS.type == "windows") withAutoprint({
  ## show the current working directory in the title, saving the old one
  oldtitle <- setWindowTitle(getwd())
  Sys.sleep(0.5)
  ## reset the title
  setWindowTitle(""")
  Sys.sleep(0.5)
  ## restore the original title
  setWindowTitle(title = oldtitle)
})
\end{verbatim}

---

\textbf{SHLIB}

\textit{Build Shared Object/DLL for Dynamic Loading}

\textbf{Description}

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into \texttt{R} using \texttt{dyn.load} or \texttt{library.dynam}.

\textbf{Usage}

\begin{verbatim}
R CMD SHLIB [options] [-o dllname] files
\end{verbatim}

\textbf{Arguments}

\begin{description}
\item[files] a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.
\item[dllname] the full name of the shared object/DLL to be built, including the extension (typically `.so` on Unix systems, and `.dll` on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file.
\item[options] Further options to control the processing. Use \texttt{R CMD SHLIB --help} for a current list.
\end{description}

\textbf{Details}

\texttt{R CMD SHLIB} is the mechanism used by \texttt{INSTALL} to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add \texttt{cpp} flags and to add libraries to the link step) and for details of some of its quirks.
Items in files with extensions '.c', '.cpp', '.cc', '.C', '.f', '.f90', '.f95', '.m' (ObjC), '.M' and '.mm' (ObjC++) are regarded as source files, and those with extension '.o' as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on macOS.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option `--n` (also known as `--dry-run`) will show the commands that would be run without actually executing them.

Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also

COMPILE, dyn.load, library.dynam.

The 'R Installation and Administration' and 'Writing R Extensions' manuals, including the section on 'Customizing compilation' in the former.

Examples

```r
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml
## End(Not run)
```

---

## shortPathName

Express File Paths in Short Form on Windows

### Description

Convert file paths to the short form. This is an interface to the Windows API call GetShortPathNameW.

### Usage

`shortPathName(path)`

### Arguments

- `path`: character vector of file paths.

### Details

For most file systems, the short form is the ‘DOS’ form with 8+3 path components and no spaces, and this used to be guaranteed. But some file systems on recent versions of Windows do not have short path names when the long-name path will be returned instead.
Value

A character vector. The path separator will be \\.
If a file path does not exist, the supplied path will be returned with slashes replaced by backslashes.

Note

This is only available on Windows.

See Also

normalizePath.

Examples

if(.Platform$OS.type == "windows") withAutoprint({
  cat(shortPathName(c(R.home(), tempdir())), sep = "\n")
})

sourceutils Source Reference Utilities

Description

These functions extract information from source references.

Usage

getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
gsrcref(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
  first = TRUE)

Arguments

x
full.names
unique
which
first

An object (typically a function) containing source references.
Whether to include the full path in the filename result.
Whether to list only unique filenames/directories.
Which part of a source reference to extract. Can be abbreviated.
Whether to show the first (or last) location of the object.

Details

Each statement of a function will have its own source reference if the "keep.source" option is TRUE. These functions retrieve all of them.

The components are as follows:

line  The line number where the object starts or ends.
column The column number where the object starts or ends. Horizontal tabs are converted to spaces.

byte As for "column", but counting bytes, which may differ in case of multibyte characters (and horizontal tabs).

parse As for "line", but this ignores #line directives.

Value

getSrcFilename and getSrcDirectory return character vectors holding the filename/directory.
getSrcRef returns a list of "srcRef" objects or NULL if there are none.
getSrcLocation returns an integer vector of the requested type of locations.

See Also

crcRef, getParseData

Examples

fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved

getSrcDirectory(fn)
getSrcLocation(fn, "line")

stack Stack or Unstack Vectors from a Data Frame or List

Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

Usage

stack(x, ...)

## Default S3 method:
stack(x, drop=FALSE, ...)

## S3 method for class 'data.frame'
stack(x, select, drop=FALSE, ...)

unstack(x, ...)

## Default S3 method:
unstack(x, form, ...)

## S3 method for class 'data.frame'
unstack(x, form, ...)
Arguments

x a list or data frame to be stacked or unstacked.
select an expression, indicating which variable(s) to select from a data frame.
form a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to \texttt{formula(x)} in the data frame method for \texttt{unstack}.
drop Whether to drop the unused levels from the “ind” column of the return value.
... further arguments passed to or from other methods.

Details

The \texttt{stack} function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The \texttt{unstack} function reverses this operation.

Note that \texttt{stack} applies to vectors (as determined by \texttt{is.vector}): non-vector columns (e.g., factors) will be ignored with a warning. Where vectors of different types are selected they are concatenated by \texttt{unlist} whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by \texttt{as.list}.

Value

\texttt{unstack} produces a list of columns according to the formula \texttt{form}. If all the columns have the same length, the resulting list is coerced to a data frame.

\texttt{stack} produces a data frame with two columns:

values the result of concatenating the selected vectors in \texttt{x}.
ind a factor indicating from which vector in \texttt{x} the observation originated.

Author(s)

Douglas Bates

See Also

\texttt{lm}, \texttt{reshape}

Examples

\begin{verbatim}
require(stats)
formula(PlantGrowth) # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg) # now put it back together
stack(pg, select = -ctrl) # omitting one vector
\end{verbatim}
Compactly Display the Structure of an Arbitrary R Object

Description

Compactly display the internal structure of an R object, a diagnostic function and an alternative to summary (and to some extent, dput). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls args for (non-primitive) function objects.

strOptions() is a convenience function for setting options(str = .), see the examples.

Usage

str(object, ...)

## S3 method for class 'data.frame'

str(object, ...)

## Default S3 method:
str(object, max.level = NA,
   vec.len = strO$vec.len, digits.d = strO$digits.d,
   nchar.max = 128, give.attr = TRUE,
   drop.deparse.attr = strO$drop.deparse.attr,
   give.head = TRUE, give.length = give.head,
   width = getOption("width"), nest.lev = 0,
   indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
                      collapse = "..")
   comp.str = ",", no.list = FALSE, envir = baseenv(),
   strict.width = strO$strict.width,
   formatNum = strO$formatNum, list.len = strO$list.len,
   deparse.lines = strO$deparse.lines, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
         list.len = 99, deparse.lines = NULL,
         drop.deparse.attr = TRUE,
         formatNum = function(x, ...)
         format(x, trim = TRUE, drop0trailing = TRUE, ...))

Arguments

object any R object about which you want to have some information.
max.level maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default NA: Display all nesting levels.
vec.len numeric (>= 0) indicating how many ‘first few’ elements are displayed of each vector. The number is multiplied by different factors (from .5 to 3) depending on the kind of vector. Defaults to the vec.len component of option "str" (see options) which defaults to 4.
digits.d number of digits for numerical components (as for print). Defaults to the digits.d component of option "str" which defaults to 3.
str

nchar.max maximal number of characters to show for character strings. Longer strings are truncated, see length example below.
give.attr logical; if TRUE (default), show attributes as sub structures.
drop.deparse.attr logical; if TRUE (default), deparse(control = <S>) will not have "showAttributes" in <S>. Used to be hard coded to FALSE and hence can be set via strOptions() for back compatibility.
give.length logical; if TRUE (default), indicate length (as [1:...]).
give.head logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as <type>[1:...]).
width the page width to be used. The default is the currently active options("width"); note that this has only a weak effect, unless strict.width is not "no".
nest.lev current nesting level in the recursive calls to str.
indent.str the indentation string to use.
comp.str string to be used for separating list components.
no.list logical; if true, no 'list of ...' nor the class are printed.
envir the environment to be used for promise (see delayedAssign) objects only.
strict.width string indicating if the width argument’s specification should be followed strictly, one of the values c("no", "cut", "wrap"), which can be abbreviated. Defaults to the strict.width component of option "str" (see options) which defaults to "no" for back compatibility reasons; "wrap" uses strwrap(*, width = width) whereas "cut" cuts directly to width. Note that a small vec.length may be better than setting strict.width = "wrap".
formatNum a function such as format for formatting numeric vectors. It defaults to the formatNum component of option "str", see Usage of strOptions() above, which is almost back compatible to R <= 2.7.x, however, using formatC may be slightly better.
list.len numeric; maximum number of list elements to display within a level.
deparse.lines numeric or NULL as by default, determining the nlines argument to deparse() when object is a call. When NULL, the nchar.max and width arguments are used to determine a smart default.
...
potential further arguments (required for Method/Generic reasons).

Value

str does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Note

See the extensive annotated ‘Examples’ below.

The default method tries to “work always”, but needs to make some assumptions for the case when object has a class but no own str() method which is the typical case: There it relies on "[" and "[[" subsetting methods to be compatible with length(). When this is not the case, or when is.list(object) is TRUE, but length(object) differs from length(unclass(object))) it treats it as “irregular” and reports the contents of unclass(object) as “hidden list”.

strcapture

Capture String Tokens into a data.frame

Description

Given a character vector and a regular expression containing capture expressions, strcapture will extract the captured tokens into a tabular data structure, such as a data.frame, the type and structure of which is specified by a prototype object. The assumption is that the same number of tokens are captured from every input string.

Usage

strcapture(pattern, x, proto, perl = FALSE, useBytes = FALSE)

Arguments

pattern The regular expression with the capture expressions.
x A character vector in which to capture the tokens.
proto A data.frame or S4 object that behaves like one. See details.
perl,useBytes Arguments passed to regexec.

Details

The proto argument is typically a data.frame, with a column corresponding to each capture expression, in order. The captured character vector is coerced to the type of the column, and the column names are carried over to the return value. Any data in the prototype are ignored. See the examples.
Value

A tabular data structure of the same type as proto, so typically a data.frame, containing a column for each capture expression. The column types and names are inherited from proto. Cases in x that do not match pattern have NA in every column.

See Also

regexec and regmatches for related low-level utilities.

Examples

x <- "chr1:1-1000"
pattern <- "(.*?):([^:]+)?-([^:]+)?"
proto <- data.frame(chr=character(), start=integer(), end=integer())
strcapture(pattern, x, proto)

summaryRprof

Summarise Output of R Sampling Profiler

Description

Summarise the output of the Rprof function to show the amount of time used by different R functions.

Usage

summaryRprof(filename = "Rprof.out", chunksize = 5000,
memory = c("none", "both", "tseries", "stats"),
lines = c("hide", "show", "both"),
index = 2, diff = TRUE, exclude = NULL,
basenames = 1)

Arguments

filename Name of a file produced by Rprof().
chunksize Number of lines to read at a time.
memory Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated.
lines Summaries for line information. See ‘Line profiling’ below. Can be abbreviated.
index How to summarize the stack trace for memory information. See ‘Details’ below.
diff If TRUE memory summaries use change in memory rather than current memory.
exclude Functions to exclude when summarizing the stack trace for memory summaries.
basenames Number of components of the path to filenames to display.

Details

This function provides the analysis code for Rprof files used by R CMD Rprof.

As the profiling output file could be larger than available memory, it is read in blocks of chunksize lines. Increasing chunksize will make the function run faster if sufficient memory is available.
Value

If \texttt{memory = "none"} and \texttt{lines = "hide"}, a list with components

by.self \hspace{1cm} A data frame of timings sorted by 'self' time.
by.total \hspace{1cm} A data frame of timings sorted by 'total' time.
sample.interval \hspace{1cm} The sampling interval.
sampling.time \hspace{1cm} Total time of profiling run.

The first two components have columns 'self.time', 'self.pct', 'total.time' and 'total.pct', the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If \texttt{lines = "show"}, an additional component is added to the list:

by.line \hspace{1cm} A data frame of timings sorted by source location.

If \texttt{memory = "both"} the same list but with memory consumption in Mb in addition to the timings.
If \texttt{memory = "tseries"} a data frame giving memory statistics over time. Memory usage is in bytes.
If \texttt{memory = "stats"} a \texttt{by} object giving memory statistics by function. Memory usage is in bytes.
If no events were recorded, a zero-row data frame is returned.

Memory profiling

Options other than \texttt{memory = "none"} apply only to files produced by \texttt{Rprof(memory.profiling = TRUE)}.

When called with \texttt{memory.profiling = TRUE}, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from \texttt{malloc}), memory in nodes on the R heap. It also records the number of calls to the internal function \texttt{duplicate} in the time interval. \texttt{duplicate} is called by C code when arguments need to be copied.

Note that the profiler does not track which function actually allocated the memory.

With \texttt{memory = "both"} the change in total memory (truncated at zero) is reported in addition to timing data.

With \texttt{memory = "tseries"} or \texttt{memory = "stats"} the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With \texttt{memory = "tseries"} the index is used to construct labels and may be a vector to give multiple sets of labels. With \texttt{memory = "stats"} the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both \texttt{memory = "tseries"} and \texttt{memory = "stats"} the argument \texttt{diff = TRUE} asks for summaries of the increase in memory use over the sampling interval and \texttt{diff = FALSE} asks for the memory use at the end of the interval.

Line profiling

If the code being run has source reference information retained (via \texttt{keep.source = TRUE} in \texttt{source} or \texttt{KeepSource = TRUE} in a package 'DESCRIPTION' file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the \texttt{lines} parameter can enable the display.

If \texttt{lines = "show"}, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If \texttt{lines = "both"}, line locations will be mixed with function names in a combined display.

Examples

## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)

## End(Not run)

---

Sweave Automatic Generation of Reports

Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.

Usage

Sweave(file, driver = RweaveLatex(),
       syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rtangle(),
        syntax = getOption("SweaveSyntax"), encoding = "", ...)

Arguments

file Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches file.

driver the actual workhorse, (a function returning) a named list of five functions; for details, see Section 5 of the ‘Sweave User Manual’ available as vignette("Sweave").

syntax NULL or an object of class "SweaveSyntax" or a character string with its name. See the section ‘Syntax Definition’.

encoding The default encoding to assume for file.

... further arguments passed to the driver’s setup function. See RweaveLatexSetup and RtangleSetup, respectively, for the arguments of the default drivers.
Details

An Sweave source file contains both text in a markup language (like \LaTeX) and R (or S) code. The code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an R source file that can be run using source. (Code inside \Sexpr{} statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used and are provided by various contributed packages.

Environment variable SWEAVE_OPTIONS can be used to override the initial options set by the driver: it should be a comma-separated set of key=value items, as would be used in a `\SweaveOpts` statement in a document.

If the encoding is unspecified (the default), non-ASCII source files must contain a line of the form

\usepackage[foo]{inputenc}

(where `foo` is typically `latin1`, `latin2`, `utf8` or `cp1252` or `cp1250`) or a comment line

```latex
\%\SweaveUTF8
```

to declare UTF-8 input (the default encoding assumed by pdfTeX since 2018), or they will give an error. Re-encoding can be turned off completely with argument encoding = "bytes".

Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a \LaTeX-style syntax can be used. (See the user manual for further details.)

If syntax = NULL (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects SweaveSyntaxNoweb (with extension = "[.][rsRS]nw$") and SweaveSyntaxLatex (with extension = "[.][rsRS]tex$") are supplied, but users or packages can supply others with names matching the pattern SweaveSyntax.*.

Author(s)

Friedrich Leisch and R-core.

tools::buildVignette to process source files using Sweave or alternative vignette processing engines.
Examples

```r
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")
## enforce par(ask = FALSE)
options(device.ask.default = FALSE)
## create a LaTeX file - in the current working directory, getwd():
Sweave(testfile)
## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")
## or outside R by
##
## R CMD texi2pdf Sweave-test-1.tex
## on Unix-alikes which sets the appropriate TEXINPUTS path.
##
## On Windows,
## Rcmd texify --pdf Sweave-test-1.tex
## if MiKTeX is available.
## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")
```

SweaveSyntConv

Convert Sweave Syntax

Description

This function converts the syntax of files in Sweave format to another Sweave syntax definition.

Usage

```r
SweaveSyntConv(file, syntax, output = NULL)
```

Arguments

- **file**: Name of Sweave source file.
- **syntax**: An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted.
- **output**: Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory.

Examples

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")

---

**tar**

Create a Tar Archive

Description

Create a tar archive.

Usage

```r
tar(tarfile, files = NULL, compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"), extra_flags ="")
```

Arguments

- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary writes.
- **files**: A character vector of filepaths to be archived: the default is to archive all files under the current directory.
- **compression**: character string giving the type of compression to be used (default none). Can be abbreviated.
- **compression_level**: integer: the level of compression. Only used for the internal method.
- **tar**: character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by `shQuote`) – but argument `tar` may also contain flags separated from the command by spaces.
- **extra_flags**: Any extra flags for an external tar.
Details

This is either a wrapper for a tar command or uses an internal implementation in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (the ‘factory-fresh’ default). Note that whereas Unix-alike versions of R set the environment variable TAR, its value is not the default for this function.

Argument extra_flags is passed to an external tar and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acls’, ‘--exclude-backups’, ‘--exclude-vcs’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths). Rtools 4 and earlier included a tar which used ‘--force-local’, but Rtools 4.2 includes original GNU tar, which does not use it by default.

A convenient and robust way to set options for GNU tar is via environment variable TAR_OPTIONS. Appending ‘--force-local’ to TAR does not work with GNU tar due to restrictions on how some options can be mixed. The tar available on Windows 10 (libarchive’s bsdtar) supports drive letters by default. It does not support the ‘--force-local’, but ignores TAR_OPTIONS.

For GNU tar, ‘--format=ustar’ forces a more portable format. (The default is set at compilation and will be shown at the end of the output from tar --help: for version 1.30 ‘out-of-the-box’ it is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=posix’ which is the same as pax – it was never part of the POSIX standard for tar and should not be used.) For libarchive’s bsdtar, ‘--format=ustar’ is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU tar or libarchive tar (aka bsdtar).

Note that files = '.' will usually not work with an external tar as that would expand the list of files after tarfile is created. (It does work with the default internal method.)

Value

The return code from system or 0 for the internal version, invisibly.

Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of pax, and in any case many common implementations diverged from the former standard.

Many R platforms use a version of GNU tar, but the behaviour seems to be changed with each version. macOS >= 10.6, FreeBSD and Windows 10 use bsdtar from the libarchive project (but for macOS a version from 2017 or earlier, 2010 for High Sierra), and commercial Unixes will have their own versions. bsdtar is available for many other platforms: macOS up to at least 10.9 had GNU tar as gnutar and other platforms, e.g. Solaris, have it as gtar: on a Unix-alike configure will try gnutar and gtar before tar.

Known problems arise from

• The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recent tar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by untar).

Most formats do not record the encoding of file paths.
• (File) links. `tar` was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdtar` ignores it. The internal method uses the GNU extension, with a warning.

• Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.

• File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU `tar` which by default pads with ‘null’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with higher resolution it is conventional to discard fractional seconds.

**Compression**

When an external `tar` command is used, compressing the tar archive requires that `tar` supports the ‘-z’, ‘-j’ or ‘-J’ flag, and may require the appropriate command (gzip, bzip2 or xz) to be available. For GNU `tar`, further compression programs can be specified by e.g. `extra_flags = "-I lz4"`. Some versions of `bsdtar` accept options such as ‘--lz4’, ‘--lzop’ and ‘--lrzip’ or an external compressor via `--use-compress-program lz4`: these could be supplied in `extra_flags`. NetBSD prior to 8.0 used flag ‘--xz’ rather than ‘-J’, so this should be used via `extra_flags = "--xz"` rather than `compression = "xz"`. The commands from OpenBSD and the Heirloom Toolchest are not documented to support xz.

The `tar` programs in commercial Unixen such as AIX and Solaris do not support compression.

**Note**

For users of macOS. Apple’s file systems have a legacy concept of ‘resource forks’ dating from classic Mac OS and rarely used nowadays. Apple’s version of `tar` stores these as separate files in the tarball with names prefixed by ‘.’_, and unpacks such files into resource forks (if possible): other ways of unpacking (including `untar` in R) unpack them as separate files.

When argument `tar` is set to the command `tar` on macOS, environment variable `COPYFILE_DISABLE=1` is set, which for the system version of `tar` prevents these separate files being included in the tarball.

toLatex

Converting R Objects to BibTeX or LaTeX

Description
These methods convert R objects to character vectors with BibTeX or LaTeX markup.
Usage
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex'
print(x, prefix = "", ...)
## S3 method for class 'Latex'
print(x, prefix = "", ...)
Arguments
object
x
prefix
...

object of a class for which a toBibtex or toLatex method exists.
object of class "Bibtex" or "Latex".
a character string which is printed at the beginning of each line, mostly used to
insert whitespace for indentation.
in the print methods, passed to writeLines.

Details
Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one
line of the corresponding BibTeX or LaTeX file.

citEntry and sessionInfo for examples

txtProgressBar

Text Progress Bar

Description
Text progress bar in the R console.
Usage
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
width = NA, title, label, style = 1, file = "")
getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)


Arguments

min, max  (finite) numeric values for the extremes of the progress bar. Must have min < max.
initial, value initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.
char the character (or character string) to form the progress bar. Must have non-zero display width.
width the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into getOption("width").
style the ‘style’ of the bar – see ‘Details’.
file an open connection object or "" which indicates the console: stderr() might be useful here.
pb, con an object of class "txtProgressBar".
title, label ignored, for compatibility with other progress bars.
... for consistency with the generic.

Details

txtProgressBar will display a progress bar on the R console (or a connection) via a text representation.

setTxtProgressBar will update the value. Missing (NA) and out-of-range values of value will be (silently) ignored. (Such values of initial cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

style = 1 and style = 2 just shows a line of char. They differ in that style = 2 redraws the line each time, which is useful if other code might be writing to the R console. style = 3 marks the end of the range by | and gives a percentage to the right of the bar.

Value

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

Note

Using style 2 or 3 or reducing the value with style = 1 uses ‘\r’ to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when stdout() is redirected to a file.

See Also

winProgressBar (Windows only), tkProgressBar (Unix-alike platforms).
Examples

# slow
testit <- function(x = sort(runif(20)), ...){
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
testit(char= '➤')

---

**Examples**

```r
# slow
testit <- function(x = sort(runif(20)), ...){
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
testit(char= '\u27a4')
```

**Description**

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

**Usage**

```r
type.convert(x, ...)
## Default S3 method:
type.convert(x, na.strings = "NA", as.is, dec = ".",
  numerals = c("allow.loss", "warn.loss", "no.loss"),
  tryLogical = TRUE, ...)
## S3 method for class 'data.frame'
type.convert(x, ...)
## S3 method for class 'list'
type.convert(x, ...)
```

**Arguments**

- **x**: a vector, matrix, array, data frame, or list.
- **na.strings**: a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- **as.is**: whether to store strings as plain character. When false, convert character vectors to factors. See ‘Details’.
- **dec**: the character to be assumed for decimal points.
- **numerals**: string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when x has more digits than can be stored in a double. Can be abbreviated. Possible values are numerals = "allow.loss", **default**: the conversion happens with some accuracy loss.
  numerals = "warn.loss": a warning about accuracy loss is signalled and the conversion happens as with numerals = "allow.loss".
  numerals = "no.loss": x is not converted to a number, but to a factor or character, depending on as.is.

---

**type.convert**  
**Convert Data to Appropriate Type**

**Description**

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

**Usage**

```r
type.convert(x, ...)
## Default S3 method:
type.convert(x, na.strings = "NA", as.is, dec = ".",
  numerals = c("allow.loss", "warn.loss", "no.loss"),
  tryLogical = TRUE, ...)
## S3 method for class 'data.frame'
type.convert(x, ...)
## S3 method for class 'list'
type.convert(x, ...)
```

**Arguments**

- **x**: a vector, matrix, array, data frame, or list.
- **na.strings**: a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- **as.is**: whether to store strings as plain character. When false, convert character vectors to factors. See ‘Details’.
- **dec**: the character to be assumed for decimal points.
- **numerals**: string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when x has more digits than can be stored in a double. Can be abbreviated. Possible values are numerals = "allow.loss", **default**: the conversion happens with some accuracy loss.
  numerals = "warn.loss": a warning about accuracy loss is signalled and the conversion happens as with numerals = "allow.loss".
  numerals = "no.loss": x is not converted to a number, but to a factor or character, depending on as.is.
tryLogical  a logical determining if vectors consisting entirely of F, T, FALSE, TRUE and na.strings should be converted to logical; true, by default.

... arguments to be passed to or from methods.

Details

This helper function is used by read.table. When the data object x is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and when additionally as.is = FALSE (no longer the default!), converts a character vector to factor. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

If tryLogical is true as by default, vectors containing just F, T, FALSE, TRUE and values from na.strings are converted to logical. This may be surprising in a context where you have many character columns with e.g., 1-letter strings and you happen to get one with only "F". In such cases tryLogical = FALSE is recommended.

Vectors containing optional whitespace followed by decimal constants representable as R integers or values from na.strings are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see NumericConstants), or NaN, Inf or infinity (ignoring case) or values from na.strings are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings or (for as.is = FALSE) factors.

Since this is a helper function, the caller should always pass an appropriate value of as.is.

Value

An object like x but using another storage mode when appropriate.

Author(s)

R Core, with a contribution by Arni Magnusson

See Also

read.table, class, storage.mode.

Examples

```r
## Numeric to integer
class(rivers)
x <- type.convert(rivers, as.is = TRUE)
class(x)

## Convert many columns
auto <- type.convert(mtcars, as.is = TRUE)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones, as.is = TRUE)
storage.mode(WorldPhones)
storage.mode(phones)
```
## Factor or character

```r
chr <- c("A", "B", "B", "A")
ch2 <- c("F", "F", "NA", "F")
(fac <- factor(chr))
type.convert(chr, as.is = FALSE) # -> factor
type.convert(fac, as.is = FALSE) # -> factor
type.convert(chr, as.is = TRUE) # -> character
type.convert(fac, as.is = TRUE) # -> character
type.convert(ch2, as.is = TRUE) # -> logical
(type.convert(ch2, as.is = TRUE, tryLogical=FALSE) #-> character
```

---

**untar**

**Extract or List Tar Archives**

**Description**

Extract files from or list the contents of a tar archive.

**Usage**

```r
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
compressed = NA, extras = NULL, verbose = FALSE,
restore_times = TRUE,
support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE),
tar = Sys.getenv("TAR")
)
```

**Arguments**

- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary reads. For a compressed tarfile, and if a connection is to be used, that should be created by `gzfile(.)` (or `gzcon(.)` which currently only works for "gzip", whereas `gzfile()` works for all compressions available in `tar()`).
- **files**: A character vector of recorded filepaths to be extracted: the default is to extract all files.
- **list**: If `TRUE`, list the files (the equivalent of `tar -tf`). Otherwise extract the files (the equivalent of `tar -xf`).
- **exdir**: The directory to extract files to (the equivalent of `tar -C`). It will be created if necessary.
- **compressed**: (Deprecated in favour of auto-detection, used only for an external `tar` command.) Logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). `TRUE` indicates gzip compression, `FALSE` no known compression, and `NA` (the default) indicates that the type is to be inferred from the file header. The external command may ignore the selected compression type but detect a type automagically.
- **extras**: NULL or a character string: further command-line flags such as `"-p` to be passed to an external `tar` program.
- **verbose**: logical: if true echo the command used for an external `tar` program.
untar

**restore_times**
logical. If true (default) restore file modification times. If false, the equivalent of the `'-m'` flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.

Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).

**support_old_tars**
logical. If false (the default), the external tar command is assumed to be able handle compressed tarfiles and if compressed does not specify it, to automatically detect the type of compression. (The major implementations have done so since 2009; for GNU tar since version 1.22.)

If true, the R code calls an appropriate decompressor and pipes the output to tar, for compressed = NA examining the tarfile header to determine the type of compression.

**tar**
character string: the path to the command to be used or "internal". If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces.

**Details**

This is either a wrapper for a tar command or for an internal implementation written in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (except on Windows, when tar.exe is tried first).

Unless otherwise stated three types of compression of the tar file are supported: gzip, bzip2 and xz.

What options are supported will depend on the tar implementation used: the "internal" one is intended to provide support for most in a platform-independent way.

**GNU tar:** Modern GNU tar versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for xz compression.

On a Unix-alike, configure will set environment variable TAR, preferring GNU tar if found.

**bsdtar:** macOS 10.6 and later (and FreeBSD and some other OSes) have a tar from the libarchive project which detects all three forms of compression automagically (even if undocumented in macOS).

**NetBSD:** It is undocumented if NetBSD’s tar can detect compression automatically: for versions before 8 the flag for xz compression was ‘--xz’ not ‘-J’. So support_old_tars = TRUE is recommended (or use bsdtar if installed).

**OpenBSD:** OpenBSD’s tar does not detect compression automatically. It has no support for xz beyond reporting that the file is xz-compressed. So support_old_tars = TRUE is recommended.

**Heirloom Toolchest:** This tar does automatically detect gzip and bzip2 compression (undocumented) but has no support for xz compression.

**Older support:** Environment variable R_GZIPCMD gives the command to decompress gzip files, and R_BZIPCMD for bzip2 files. (On Unix-alikes these are set at installation if found.) xz is used if available: if not decompression is expected to fail.

Arguments compressed, extras and verbose are only used when an external tar is used.

Some external tar commands will detect some of lrzip, lzma, lz4, lzop and zstd compression in addition to gzip, bzip2 and xz. (For some external tar commands, compressed
unzip

Extract or List Zip Archives

Description

Extract files from or list a zip archive.

Usage

unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE, junkpaths = FALSE, exdir = ".", unzip = "internal", setTimes = FALSE)
Arguments

zipfile  The pathname of the zip file: tilde expansion (see path.expand) will be performed.

dest    A character vector of recorded filepaths to be extracted: the default is to extract all files.

list    If TRUE, list the files and extract none. The equivalent of unzip -l.

overwrite

If TRUE, overwrite existing files (the equivalent of unzip -o), otherwise ignore such files (the equivalent of unzip -n).

junkpaths

If TRUE, use only the basename of the stored filepath when extracting. The equivalent of unzip -j.

exdir  The directory to extract files to (the equivalent of unzip -d). It will be created if necessary.

unzip  The method to be used. An alternative is to use getOption("unzip"), which on a Unix-alike may be set to the path to a unzip program.

setTimes  logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.)

Value

If list = TRUE, a data frame with columns Name (character), Length (the size of the uncompressed file, numeric) and Date (of class "POSIXct").

Otherwise for the "internal" method, a character vector of the filepaths extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows’ users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use unzip = "unzip" with unzip 6.00 or later. It does have some support for bzip2 compression and > 2GB zip files (but not >= 4GB files pre-compression contained in a zip file: like many builds of unzip it may truncate these, in R’s case with a warning if possible).

If unzip specifies a program, the format of the dates listed with list = TRUE is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from unzip 6.00).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses zlib and is in particular based on the contributed ‘minizip’ application in the zlib sources (from https://zlib.net/) by Gilles Vollant.

unz to read a single component from a zip file.
zip for packing, i.e., the “inverse” of unzip(); further untar and tar, the corresponding pair for (un)packing tar archives (“tarballs”) such as R source packages.
Description

old.packages indicates packages which have a (suitable) later version on the repositories whereas update.packages offers to download and install such packages.

new.packages looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
                 contriburl = contrib.url(repos, type),
                 method, instlib = NULL,
                 ask = TRUE, available = NULL,
                 oldPkgs = NULL, ..., checkBuilt = FALSE,
                 type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
              contriburl = contrib.url(repos, type),
              instPkgs = installed.packages(lib.loc = lib.loc, ...),
              method, available = NULL, checkBuilt = FALSE, ...,
              type = getOption("pkgType"))

ew.packages(lib.loc = NULL, repos = getOption("repos"),
              contriburl = contrib.url(repos, type),
              instPkgs = installed.packages(lib.loc = lib.loc, ...),
              method, available = NULL, ask = FALSE, ...,
              type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos. Incompatible with type = "both".
method Download method, see download.file. Unused if a non-NULL available is supplied.
instlib character string giving the library directory where to install the packages.
ask logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. The latter value only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE. ask does not control questions asked before installing packages from source via type = "both" (see option "install.packages.compile.from.source").
available

an object as returned by `available.packages` listing packages available at the repositories, or `NULL` which makes an internal call to `available.packages`. Incompatible with `type = "both"`. 

checkBuilt

If `TRUE`, a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be ‘old’.

oldPkgs

if specified as non-NULL, `update.packages()` only considers these packages for updating. This may be a character vector of package names or a matrix as returned by `old.packages`.

instPkgs

by default all installed packages, `installed.packages(lib.loc = lib.loc)`. A subset can be specified; currently this must be in the same (character matrix) format as returned by `installed.packages()`.

... Arguments such as `destdir` and dependencies to be passed to `install.packages` and `ignore_repo_cache`, `max_repo_cache_age` and `noCache` to `available.packages` or `installed.packages`.

type

character, indicating the type of package to download and install. See `install.packages`.

Details

old.packages compares the information from `available.packages` with that from instPkgs (computed by `installed.packages` by default) and reports installed packages that have newer versions on the repositories or, if checkBuilt = `TRUE`, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

new.packages does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `instlib` if specified).

For how the list of suitable available packages is determined see `available.packages`. `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

Value

`update.packages` returns `NULL` invisibly.

For `old.packages`, `NULL` or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, after any selected via `ask` have been installed.

Warning

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

---

url.show Display a Text URL

Description

Extension of file.show to display text files from a remote server.

Usage

url.show(url, title = url, file = tempfile(), delete.file = TRUE, method, ...)

Arguments

url The URL to read from.
title Title for the browser.
file File to copy to.
delete.file Delete the file afterwards?
method File transfer method: see download.file
...

Arguments to pass to file.show.

Note

Since this is for text files, it will convert to CRLF line endings on Windows.

See Also

url, file.show, download.file

Examples

## Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")
URLencode  

Encode or Decode (partial) URLs

Description

Functions to percent-encode or decode characters in URLs.

Usage

URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)

Arguments

<table>
<thead>
<tr>
<th>URL</th>
<th>a character vector.</th>
</tr>
</thead>
<tbody>
<tr>
<td>reserved</td>
<td>logical: should 'reserved' characters be encoded? See 'Details'.</td>
</tr>
<tr>
<td>repeated</td>
<td>logical: should apparently already-encoded URLs be encoded again?</td>
</tr>
</tbody>
</table>

Details

Characters in a URL other than the English alphanumeric characters and '- _ . ~' should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as 'percent-encoding'.

In addition, '!' '$' '(' ')' '*' '+' ',' '=' ':' '?' '@' '[' ']' are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLencode is to leave them alone, which is appropriate for 'file:///' URLs, but probably not for 'http:///' ones.

An 'apparently already-encoded URL' is one containing %xx for two hexadecimal digits.

Value

A character vector.

References

Internet STD 66 (formerly RFC 3986), [https://www.rfc-editor.org/info/std66](https://www.rfc-editor.org/info/std66)

Examples

```r
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted

## both functions support character vectors of length > 1
y <- URLdecode(URLencode(c("url with space", "another one")))
```
**utils-deprecated**

*Deprecated Functions in Package utils*

**Description**

(Currently none)

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

**See Also**

Deprecated, Defunct

---

**View**

*Invoke a Data Viewer*

**Description**

Invoke a spreadsheet-style data viewer on a matrix-like R object.

**Usage**

View(x, title)

**Arguments**

- **x**
  
an R object which can be coerced to a data frame with non-zero numbers of rows and columns.

- **title**
  
title for viewer window. Defaults to name of x prefixed by Data::.

**Details**

Object x is coerced (if possible) to a data frame, then columns are converted to character using `format.data.frame`. The object is then viewed in a spreadsheet-like data viewer, a read-only version of `data.entry`.

If there are row names on the data frame that are not 1:nrow, they are displayed in a separate first column called row.names.

Objects with zero columns or zero rows are not accepted.

**On Unix-alikes**, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

**On Windows**, the array of cells can be navigated via the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see Rconsole), but adjusted downwards to show a whole number of rows and columns.
vignette

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

edit.data.frame, data.entry.

vignette View, List or Get R Source of Package Vignettes

Description

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

Usage

vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)

## S3 method for class 'vignette'
edit(name, ...)

Arguments

topic a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

package a character vector with the names of packages to search through, or NULL in which ‘all’ packages (as defined by argument all) are searched.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.

all logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.

x, name object of class vignette.

... ignored by the print method, passed on to file.edit by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it.

On Unix-alikes, the program specified by the pdfviewer option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class “packageIQR”.
See Also

browseVignettes for an HTML-based vignette browser; RShowDoc(<basename>, package = "<pkg>") displays a "rendered" vignette (pdf or html).

Examples

## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## The grid intro vignette -- open it
## Not run: vignette("grid") # calling print()
## The same (conditional on existence of the vignette).
## Not run: !is.null(v1 <- vignette("grid", package="grid"))
## Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
## Not run: v1 # calling print(.)
str(v1)
## Now let us have a closer look at the code

## Not run: edit(v1) # e.g., to send lines ...
## if( has vignette "installed")
## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
## vignette("rotated")
## The same, but without searching for it:
  vignette("rotated", package = "grid")
}

warnErrList Collect and Summarize Errors From List

Description

Collect errors (class "error", typically from tryCatch) from a list x into a “summary warning”, by default produce a warning and keep that message as "warningMsg" attribute.

Usage

warnErrList(x, warn = TRUE, errValue = NULL)

Arguments

x a list, typically from applying models to a list of data (sub)sets, e.g., using tryCatch(*, error = identity).
warn logical indicating if warning() should be called.
errValue the value with which errors should be replaced.
Value

a list of the same length and names as the x argument, with the error components replaced by errValue, NULL by default, and summarized in the "warningMsg" attribute.

See Also

The warnErrList() utility has been used in lmList() and nlsList() in recommended package nlme forever.

Examples

## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[, "Chick"])
sapply(ChWtgrps, nrow)# typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
        lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL

nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
        lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all

nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
        lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
        , identical(nl3[-1], nlis3[-1])
        , is.null(nl3[[1]])
)

## With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
data(Soybean, package="nlme")
attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
L <- lapply(split(Soybean, Soybean[, "Plot"]),
    function(DD) tryCatch(error = identity,
        nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
Lw <- warnErrList(L)
} # if <nlme>

winDialog

Dialog Boxes under Windows

Description

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

Usage

winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
    message)

winDialogString(message, default)
Arguments

- **type**: character. The type of dialog box. It will have the buttons implied by its name.
- **message**: character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R).
- **default**: character. The default string.

Value

For `winDialog` a character string giving the name of the button pressed (in capitals) or NULL (invisibly) if the user had no choice.

For `winDialogString` a string giving the contents of the text box when Ok was pressed, or NULL if Cancel was pressed.

Note

The standard keyboard accelerators work with these dialog boxes: where appropriate Return accepts the default action, Esc cancels and the underlined initial letter (Y or N) can be used.

These functions are only available on Windows.

See Also

- `winMenuAdd`
- `file.choose` to select a file
- package `windlgs` in the package source distribution for ways to program dialogs in C in the GraphApp toolkit.

Examples

```r
## Not run: winDialog("yesno", "Is it OK to delete file blah")
```

---

### Description

Get the self-reported Microsoft Windows version number.

#### Usage

```r
win.version()
```

#### Details

`win.version` is an auxiliary function for `sessionInfo` and `bug.report`.

#### Value

A character string describing the version of Windows reported to be in use.
Note
This function is only available on Microsoft Windows.

The result is based on the Windows GetVersionEx API function. It is not known how to detect
a version of Windows before it is released, and hence the textual information returned by R may
identify an older version than installed. The build number is more reliable. When running R in
compatibility mode, the reported version including the build number is the compatibility version,
ot the installed version.

Examples
if(.Platform$OS.type == "windows")
  print(win.version())

winMenus

User Menus under MS Windows (Rgui)

Description
Enables users to add, delete and program menus for the Rgui in MS Windows.

Usage

  winMenuAdd(menuname)
  winMenuAddItem(menuname, itemname, action)
  winMenuDel(menuname)
  winMenuDelItem(menuname, itemname)
  winMenuNames()
  winMenuItems(menuname)

Arguments

  menuname  a character string naming a menu.
  itemname  a character string naming a menu item on an existing menu.
  action    a character string describing the action when that menu is selected, or "enable"
or "disable".

Details

User menus are added to the right of existing menus, and items are added at the bottom of the menu.

By default the action character string is treated as R input, being echoed on the command line and
parsed and executed as usual.

If the menuname parameter of winMenuAddItem does not already exist, it will be created automati-
cally.

Normally new submenus and menu items are added to the main console menu. They may be added
elsewhere using the following special names:

$ConsoleMain  The console menu (the default)
$ConsolePopup  The console popup menu
$Graph<n>Main  The menu for graphics window <n>
$Graph<\text{n}>Popup  The popup menu for graphics window $\langle n \rangle$

Specifying an existing item in \texttt{winMenuAddItem} enables the action to be changed.
Submenus can be specified by separating the elements in \texttt{menuname} by slashes: as a consequence
menu names may not contain slashes.
If the action is specified as "none" no action is taken: this can be useful to reserve items for future expansion.

The function \texttt{winMenuNames} can be used to find out what menus have been created by the user and
returns a vector of the existing menu names.

The \texttt{winMenuItems} function will take the name of a menu and return the items that exist in that
menu. The return value is a named vector where the names correspond to the names of the items
and the values of the vector are the corresponding actions.

The \texttt{winMenuDel} function will delete a menu and all of its items and submenus. \texttt{winMenuDelItem}
just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu
string cannot exceed 500 bytes.

\section*{Value}

NULL, invisibly. If an error occurs, an informative error message will be given.

\section*{Note}

These functions are only available on Windows and only when using the \texttt{Rgui}, hence not in \texttt{ESS}
or \texttt{RStudio}.

\section*{See Also}

\texttt{winDialog}

\section*{Examples}

\begin{verbatim}
## Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit/extras")
winMenuAddItem("Testit", ",-", """)
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit/extras", "one more", "ddd")
winMenuAddItem("Testit/extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")
\end{verbatim}

## End(Not run)
Description

Put up a Windows progress bar widget, update and access it.

Usage

winProgressBar(title = "R progress bar", label = "", min = 0, max = 1, initial = 0, width = 300)

getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'winProgressBar'
close(con, ...)

Arguments

title, label character strings, giving the window title and the label on the dialog box respectively.
min, max (finite) numeric values for the extremes of the progress bar.
initial, value initial or new value for the progress bar.
width the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
pb, con an object of class "winProgressBar".
... for consistency with the generic.

Details

winProgressBar will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.
setWinProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with, but it will be garbage-collected once no R object refers to it.

Value

For winProgressBar an object of class "winProgressBar".
For getWinProgressBar and setWinProgressBar, a length-one numeric vector giving the previous value (invisibly for setWinProgressBar).

Note

These functions are only available on Windows.

On all platforms, txtProgressBar, tkProgressBar
write.table

Data Output

Description

write.table prints its required argument x (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

Usage

```r
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,
            col.names = TRUE, qmethod = c("escape", "double"),
            fileEncoding = "")
```

write.csv(...)  
write.csv2(...)  

Arguments

- **x**: the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce x to a data frame.
- **file**: either a character string naming a file or a connection open for writing. "" indicates output to the console.
- **append**: logical. Only relevant if file is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
- **quote**: a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.
- **sep**: the field separator string. Values within each row of x are separated by this string.
- **eol**: the character(s) to print at the end of each line (row). For example, eol = "\r\n" will produce Windows’ line endings on a Unix-alike OS, and eol = "\r" will produce files as expected by Excel:mac 2004.
- **na**: the string to use for missing values in the data.
- **dec**: the string to use for decimal points in numeric or complex columns: must be a single character.
- **row.names**: either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.
- **col.names**: either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on 'CSV files' for the meaning of col.names = NA.
- **qmethod**: a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for write.table), in which case the quote character is escaped in C style by a backslash, or "double" (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter.
fileEncoding character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file.

... arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered.

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via as.matrix) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use options("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see options), but with the internal equivalent of digits = 15. For finer control, use format to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename", "wb").

CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

read.csv(file = "<filename>", row.names = 1)

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "." for the decimal point and a comma for the separator.

write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism)
correctly if they are ASCII or UTF-16 (use `fileEncoding = "UTF-16LE"`) or perhaps in the current Windows codepage (e.g., "CP1252"), but the ‘Text Import Wizard’ (from the ‘Data’ tab) allows far more choice of encodings. Excel:mac 2004/8 can import only ‘Macintosh’ (which seems to mean Mac Roman), ‘Windows’ (perhaps Latin-1) and ‘PC-8’ files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (https://www.rfc-editor.org/rfc/rfc4180) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.

**Note**

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

**See Also**

The ‘R Data Import/Export’ manual.

`read.table, write, write.matrix` in package `MASS`.

**Examples**

```r
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = " ", col.names = NA, qmethod = "double")
## and to read this file back into R one needs
do.call(read.table, list(file = "foo.csv", header = TRUE, sep = ",", row.names = 1))
## NB: you do need to specify a separator if qmethod = "double".

## Alternatively
write.table(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.table(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")
## End(Not run)
```

**zip**

Create Zip Archives

**Description**

A wrapper for an external `zip` command to create zip archives.
Usage

zip(zipfile, files, flags = "-r9X", extras = "",
    zip = Sys.getenv("R_ZIPCMD", "zip"))

Arguments

zipfile The pathname of the zip file: tilde expansion (see \texttt{path.expand}) will be performed.
files A character vector of recorded filepaths to be included.
flags A character string of flags to be passed to the command: see ‘Details’.
extras An optional character vector: see ‘Details’.
zip A character string specifying the external command to be used.

Details

On a Unix-alike, the default for \texttt{zip} will use the value of \texttt{R_ZIPCMD}, whose default is set in ‘\texttt{etc/Renviron}’ to the \texttt{zip} command found during configuration. On Windows, the default relies on a \texttt{zip} program (for example that from Rtools) being in the path.

The default for \texttt{flags} is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the \texttt{zip} command for other possibilities.

Argument \texttt{extras} can be used to specify \texttt{-x} or \texttt{-i} followed by a list of filepaths to exclude or include. Since \texttt{extras} will be treated as if passed to \texttt{system}, if the filepaths contain spaces they must be quoted e.g. by \texttt{shQuote}.

Value

The status value returned by the external command, invisibly.

See Also

\texttt{unzip}, \texttt{unz}; further, \texttt{tar} and \texttt{untar} for (un)packing tar archives.
Part II
Chapter 15

The KernSmooth package

bkde \hspace{1cm} Compute a Binned Kernel Density Estimate

Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

Usage

bkde(x, kernel = "normal", canonical = FALSE, bandwidth, gridsize = 401L, range.x, truncate = TRUE)

Arguments

x \hspace{1cm} numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.

bandwidth \hspace{1cm} the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the ‘oversmoothed bandwidth selector’ of Wand and Jones (1995, page 61).

kernel \hspace{1cm} character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.

canonical \hspace{1cm} length-one logical vector: if TRUE, canonically scaled kernels are used.

gridsize \hspace{1cm} the number of equally spaced points at which to estimate the density.

range.x \hspace{1cm} vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.

truncate \hspace{1cm} logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each \( x \) value in the sample, the kernel is centered on that \( x \) and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding \( y \) value in the output.

Value

- A list containing the following components:
  - \( x \): vector of sorted \( x \) values at which the estimate was computed.
  - \( y \): vector of density estimates at the corresponding \( x \).

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

bkde2D

Compute a 2D Binned Kernel Density Estimate

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

\texttt{bkde2D(x, bandwidth, gridsize = \texttt{c(51L, 51L)}, range.x, truncate = \texttt{TRUE})}
Arguments

x  a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.

bandwidth  numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.

gridsize  vector containing the number of equally spaced points in each direction over which the density is to be estimated.

range.x  a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.

truncate  logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

a list containing the following components:

x1  vector of values of the grid points in the first coordinate direction at which the estimate was computed.

x2  vector of values of the grid points in the second coordinate direction at which the estimate was computed.

fhat  matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1,x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

persp(est$fhat)
**Compute a Binned Kernel Functional Estimate**

**Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```r
bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

- `x`: numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- `drv`: order of derivative in the density functional. Must be a non-negative even integer.
- `bandwidth`: the kernel bandwidth smoothing parameter. Must be supplied.
- `gridsize`: the number of equally-spaced points over which binning is performed.
- `range.x`: vector containing the minimum and maximum values of `x` at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- `binned`: logical flag: if TRUE, then `x` and `y` are taken to be grid counts rather than raw data.
- `truncate`: logical flag: if TRUE, data with `x` values outside the range specified by `range.x` are ignored.

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)

Arguments

- x: numeric vector containing the sample on which the histogram is to be constructed.
- scalest: estimate of scale.
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- level: number of levels of functional estimation used in the plug-in rule.
- gridsize: number of grid points used in the binned approximations to functional estimates.
- range.x: range over which functional estimates are obtained. The default is the minimum and maximum data values.
- truncate: if truncate is TRUE then observations outside of the interval specified by range.x are omitted. Otherwise, they are used to weight the extreme grid points.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bin width.

Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

dpik
Select a Bandwidth for Kernel Density Estimation

Description
Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage
dpik(x, scalest = "minim", level = 2L, kernel = "normal",
canonical = FALSE, gridsize = 401L, range.x = range(x),
truncate = TRUE)

Arguments
x numeric vector containing the sample on which the kernel density estimate is to be constructed.
scalest estimate of scale.
"stdev" - standard deviation is used.
"iqr" - inter-quartile range divided by 1.349 is used.
"minim" - minimum of "stdev" and "iqr" is used.
level number of levels of functional estimation used in the plug-in rule.
kernel character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
canonical logical flag: if TRUE, canonically scaled kernels are used
gridsize the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
range.x  vector containing the minimum and maximum values of \( x \) at which to compute the estimate. The default is the minimum and maximum data values.

truncate  logical flag: if \( \text{TRUE} \), data with \( x \) values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

References

dpill  Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05, gridsize = 401L, range.x, truncate = \text{TRUE})
Arguments

x  numeric vector of x data. Missing values are not accepted.
y  numeric vector of y data. This must be same length as x, and missing values are not accepted.
blockmax the maximum number of blocks of the data for construction of an initial parametric estimate.
divisor the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
trim the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
proptrun the proportion of the range of x at each end truncated in the functional estimates.
gridsize number of equally-spaced grid points over which the function is to be estimated.
range.x vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow's $C_p$ is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)
```

**locpoly**

*Estimate Functions Using Local Polynomials*

**Description**

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

**Usage**

```r
locpoly(x, y, drv = 0L, degree, kernel = "normal",
bandwidth, gridsize = 401L, bwdisc = 25,
range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

- `x`: numeric vector of x data. Missing values are not accepted.
- `bandwidth`: the kernel bandwidth smoothing parameter. It may be a single number or an array having length `gridsize`, representing a bandwidth that varies according to the location of estimation.
- `y`: vector of y data. This must be same length as x, and missing values are not accepted.
- `drv`: order of derivative to be estimated.
- `degree`: degree of local polynomial used. Its value must be greater than or equal to the value of `drv`. The default value is of degree is `drv + 1`.
- `kernel`: "normal" - the Gaussian density function. Currently ignored.
- `gridsize`: number of equally-spaced grid points over which the function is to be estimated.
- `bwdisc`: number of logarithmically-equally-spaced bandwidths on which `bandwidth` is discretised, to speed up computation.
- `range.x`: vector containing the minimum and maximum values of x at which to compute the estimate.
- `binned`: logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
- `truncate`: logical flag: if TRUE, data with x values outside the range specified by `range.x` are ignored.
Value

If \( y \) is specified, a local polynomial regression estimate of \( E[Y|X] \) (or its derivative) is computed. If \( y \) is missing, a local polynomial estimate of the density of \( x \) (or its derivative) is computed.

A list containing the following components:

- \( x \): vector of sorted \( x \) values at which the estimate was computed.
- \( y \): vector of smoothed estimates for either the density or the regression at the corresponding \( x \).

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length \( \text{gridsize} \).

- **Usage**
  
  accdeaths

- **Details**
  
  The values for first six months of 1979 (p. 326) were 7798 7406 8363 8460 9217 9316.
addterm

Try All One-Term Additions to a Model

Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes \texttt{lm} and \texttt{glm} and the default method will work for many other classes.

Usage

\begin{verbatim}
addterm(object, ...) \\
## Default S3 method: 
addterm(object, scope, scale = 0, test = c("none", "Chisq"), 
      k = 2, sorted = FALSE, trace = FALSE, ...) \\
## S3 method for class 'lm' 
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"), 
      k = 2, sorted = FALSE, ...) \\
## S3 method for class 'glm' 
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"), 
      k = 2, sorted = FALSE, trace = FALSE, ...) 
\end{verbatim}

Arguments

\begin{itemize}
  \item \textbf{object} An object fitted by some model-fitting function.
  \item \textbf{scope} a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
  \item \textbf{scale} used in the definition of the AIC statistic for selecting the models, currently only for \texttt{lm}, \texttt{aov} and \texttt{glm} models. Specifying \texttt{scale} asserts that the residual standard error or dispersion is known.
  \item \textbf{test} should the results include a test statistic relative to the original model? The F test is only appropriate for \texttt{lm} and \texttt{aov} models, and perhaps for some over-dispersed \texttt{glm} models. The Chisq test can be an exact test (\texttt{lm} models with known scale) or a likelihood-ratio test depending on the method.
  \item \textbf{k} the multiple of the number of degrees of freedom used for the penalty. Only \(k = 2\) gives the genuine AIC: \(k = \log(n)\) is sometimes referred to as BIC or SBC.
  \item \textbf{sorted} should the results be sorted on the value of AIC?
  \item \textbf{trace} if \texttt{TRUE} additional information may be given on the fits as they are tried.
  \item \ldots{} arguments passed to or from other methods.
\end{itemize}
The definition of AIC is only up to an additive constant: when appropriate (\texttt{lm} models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

addterm(quine.lo, quine.hi, test="F")

house.glm0 <- glm(Freq ~ Infl*Type*Cont + Sat, family=poisson,
data=housing)
addterm(house.glm0, \(~ . + Sat:(Infl+Type+Cont)), test="Chisq")
house.glm1 <- update(house.glm0, \(~ . + Sat:(Infl+Type+Cont))
addterm(house.glm1, \(~ . + Sat:(Infl+Type+Cont)^2, test = "Chisq")
```

Description

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

Usage

Aids2

Format

This data frame contains 2843 rows and the following columns:

\texttt{state} Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.
\texttt{sex} Sex of patient.
\texttt{diag} (Julian) date of diagnosis.
\texttt{death} (Julian) date of death or end of observation.
\texttt{status} "A" (alive) or "D" (dead) at end of observation.
\texttt{T.categ} Reported transmission category.
\texttt{age} Age (years) at diagnosis.
Animals

Note
This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

**anova.negbin**

*Likelihood Ratio Tests for Negative Binomial GLMs*

**Description**

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

**Usage**

```r
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```
Arguments

object  Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of \texttt{glm.nb()}.

...  Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.

test  Argument to match the test argument of \texttt{anova.glm}. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function \texttt{anova()} for class "negbin". It can be invoked by calling \texttt{anova(x)} for an object \texttt{x} of the appropriate class, or directly by calling \texttt{anova.negbin(x)} regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The theta parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case theta is assumed to have been re-estimated for each model.

References

See Also

\texttt{glm.nb}, \texttt{negative.binomial}, \texttt{summary.negbin}

Examples

\begin{verbatim}
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
\end{verbatim}

area  Adaptive Numerical Integration

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

\begin{verbatim}
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
\end{verbatim}
Arguments

- **f**: The integrand as an S function object. The variable of integration must be the first argument.
- **a**: Lower limit of integration.
- **b**: Upper limit of integration.
- **...**: Additional arguments needed by the integrand.
- **fa**: Function value at the lower limit.
- **fb**: Function value at the upper limit.
- **limit**: Limit on the depth to which recursion is allowed to go.
- **eps**: Error tolerance to control the process.

Details

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

Value

The integral from \(a\) to \(b\) of \(f(x)\).

References

Examples

```r
area(sin, 0, pi) # integrate the sin function from 0 to pi.
```

bacteria

*Presence of Bacteria after Drug Treatments*

Description

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

Usage

bacteria

Format

This data frame has 220 rows and the following columns:

- **y**: presence or absence: a factor with levels \(n\) and \(y\).
- **ap**: active/placebo: a factor with levels \(a\) and \(p\).
- **hilo**: hi/low compliance: a factor with levels \(hi\) and \(lo\).
- **week**: numeric: week of test.
- **ID**: subject ID: a factor.
- **trt**: a factor with levels \(placebo\), \(drug\) and \(drug+\), a re-coding of \(ap\) and \(hilo\).
Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of \textit{H. influenzae} was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

    family = binomial, data = bacteria))
```

bandwidth.nrd

\textit{Bandwidth for density()} via Normal Reference Distribution

Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

Usage

\texttt{bandwidth.nrd(x)}
bcv

Arguments

x A data vector.

Value

A bandwidth on a scale suitable for the width argument of density.

References

Examples

# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}

bcv Biased Cross-Validation for Bandwidth Selection

Description

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

bcv(x, nb = 1000, lower, upper)

Arguments

x a numeric vector

nb number of bins to use.

lower, upper Range over which to minimize. The default is almost always satisfactory.

Value

a bandwidth

birhtwt  Risk Factors Associated with Low Infant Birth Weight

Description

The birthwt data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

Usage

birthwt

Format

This data frame contains the following columns:

- low: indicator of birth weight less than 2.5 kg.
- age: mother's age in years.
- lwt: mother's weight in pounds at last menstrual period.
- race: mother's race (1 = white, 2 = black, 3 = other).
- smoke: smoking status during pregnancy.
- ptl: number of previous premature labours.
- ht: history of hypertension.
- ui: presence of uterine irritability.
- ftv: number of physician visits during the first trimester.
- bwt: birth weight in grams.

Source

References

Examples

bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))

  ftv <- factor(ftv)
  levels(ftv)[-(1:2)] <- "2+
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
    ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
**Boston Housing Values in Suburbs of Boston**

**Description**

The Boston data frame has 506 rows and 14 columns.

**Usage**

Boston

**Format**

This data frame contains the following columns:

- **crim** per capita crime rate by town.
- **zn** proportion of residential land zoned for lots over 25,000 sq.ft.
- **indus** proportion of non-retail business acres per town.
- **chas** Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).
- **nox** nitrogen oxides concentration (parts per 10 million).
- **rm** average number of rooms per dwelling.
- **age** proportion of owner-occupied units built prior to 1940.
- **dis** weighted mean of distances to five Boston employment centres.
- **rad** index of accessibility to radial highways.
- **tax** full-value property-tax rate per $10,000.
- **ptratio** pupil-teacher ratio by town.
- **black** \(1000(Bk - 0.63)^2\) where \(Bk\) is the proportion of blacks by town.
- **lstat** lower status of the population (percent).
- **medv** median value of owner-occupied homes in $1000s.

**Source**

**Box-Cox Transformations for Linear Models**

**Description**

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```r
boxcox(object, ...)  
## Default S3 method:  
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
interp, eps = 1/50, xlab = expression(lambda),  
ylab = "log-Likelihood", ...)  
## S3 method for class 'formula'  
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
interp, eps = 1/50, xlab = expression(lambda),  
ylab = "log-Likelihood", ...)  
## S3 method for class 'lm'  
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
interp, eps = 1/50, xlab = expression(lambda),  
ylab = "log-Likelihood", ...)  
```

**Arguments**

- `object` a formula or fitted model object. Currently only `lm` and `aov` objects are handled.
- `lambda` vector of values of `lambda` – default (−2, 2) in steps of 0.1.
- `plotit` logical which controls whether the result should be plotted.
- `interp` logical which controls whether spline interpolation is used. Default to `TRUE` if plotting with `lambda` of length less than 100.
- `eps` Tolerance for `lambda = 0`; defaults to 0.02.
- `xlab` defaults to "lambda".
- `ylab` defaults to "log-Likelihood".
- `...` additional parameters to be used in the model fitting.

**Value**

A list of the `lambda` vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Side Effects**

If `plotit = TRUE` plots log-likelihood vs `lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.
cabbages

References

Examples

boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))

cabbages

Data from a cabbage field trial

Description

The cabbages data set has 60 observations and 4 variables

Usage

cabbages

Format

This data frame contains the following columns:

Cult  Factor giving the cultivar of the cabbage, two levels: c39 and c52.
Date  Factor specifying one of three planting dates: d16, d20 or d21.
HeadWt  Weight of the cabbage head, presumably in kg.
VitC  Ascorbic acid content, in undefined units.

par(mfrow=c(1,1))
```

Cars93  

Data from 93 Cars on Sale in the USA in 1993

Description

The Cars93 data frame has 93 rows and 27 columns.

Usage

Cars93
Format

This data frame contains the following columns:

- Manufacturer
- Model
- Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".
- Min.Price Minimum Price (in $1,000): price for a basic version.
- Price Midrange Price (in $1,000): average of Min.Price and Max.Price.
- Max.Price Maximum Price (in $1,000): price for “a premium version”.
- MPG.city City MPG (miles per US gallon by EPA rating).
- MPG.highway Highway MPG.
- AirBags Air Bags standard. Factor: none, driver only, or driver & passenger.
- DriveTrain Drive train type: rear wheel, front wheel or 4WD; (factor).
- Cylinders Number of cylinders (missing for Mazda RX-7, which has a rotary engine).
- EngineSize Engine size (litres).
- Horsepower Horsepower (maximum).
- RPM RPM (revs per minute at maximum horsepower).
- Rev.per.mile Engine revolutions per mile (in highest gear).
- Man.trans.avail Is a manual transmission version available? (yes or no, Factor).
- Fuel.tank.capacity Fuel tank capacity (US gallons).
- Passengers Passenger capacity (persons)
- Length Length (inches).
- Wheelbase Wheelbase (inches).
- Width Width (inches).
- Turn.circle U-turn space (feet).
- Rear.seat.room Rear seat room (inches) (missing for 2-seater vehicles).
- Luggage.room Luggage capacity (cubic feet) (missing for vans).
- Weight Weight (pounds).
- Origin Of non-USA or USA company origins? (factor).
- Make Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the Consumer Reports issue and the PACE Buying Guide. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the Consumer Reports source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once. Further description can be found in Lock (1993).

**con2tr**

*Convert Lists to Data Frames for use by lattice*

Description

Convert lists to data frames for use by lattice.

Usage

con2tr(obj)

Arguments

obj A list of components x, y and z as passed to contour.

Details

con2tr repeats the x and y components suitably to match the vector z.
Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage

## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)

Arguments

- object: a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
- parm: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- level: the confidence level required.
- trace: logical. Should profiling be traced?
- ...: additional argument(s) for methods.

Details

confint is a generic function in package stats.

These confint methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1 - level)/2 and 1 - (1 - level)/2 in % (by default 2.5% and 97.5%).

confint(budworm.lg0, "ldose")

contr.sdif

Successive Differences Contrast Coding

Description

A coding for factors based on successive differences.

Usage

contr.sdif(n, contrasts = TRUE, sparse = FALSE)

Arguments

n
   The number of levels required.

contrasts
   logical: Should there be n - 1 columns orthogonal to the mean (the default) or n
   columns spanning the space?
sparse logical. If true and the result would be sparse (only true for contrasts = FALSE), return a sparse matrix.

Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

Value

If contrasts is TRUE, a matrix with n rows and n - 1 columns, and the n by n identity matrix if contrasts is FALSE.

corresp  Simple Correspondence Analysis

Description

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

Usage

corresp(x, ...)  
## S3 method for class 'matrix'
corresp(x, nf = 1, ...)
## S3 method for class 'factor'
corresp(x, y, ...)
## S3 method for class 'data.frame'
corresp(x, ...)
## S3 method for class 'xtabs'
corresp(x, ...)
## S3 method for class 'formula'
corresp(formula, data, ...)

Arguments

x, formula  The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulae of the form ~ F1 + F2, where F1 and F2 are factors.

nf  The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.

y  a second factor for a cross-classification.

data  an optional data frame, list or environment against which to preferentially resolve variables in the formula.

...  If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.
Details

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the *areas* of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices \( A = Dr^{(-1/2)} U L \) and \( B = Dc^{(-1/2)} V L \) where the singular value decomposition is \( U L V \). Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does *not* have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class "correspondence" for which `print`, `plot` and `biplot` methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

Examples

```r
## IGNORE_RDIFF_BEGIN
## The signs can vary by platform
(ct <- corresp(~ Age + Eth, data = quine))
plot(ct)

corresp(caith)
biplot(corresp(caith, nf = 2))
## IGNORE_RDIFF_END
```

---

**cov.rob**

*Resistant Estimation of Multivariate Location and Scatter*

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. `cov.mve` and `cov.mcd` are compatibility wrappers.

Usage

```r
cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
        method = c("mve", "mcd", "classical"),
        nsamp = "best", seed)
```

`cov.mve(...)`

`cov.mcd(...)`
**Arguments**

- **x**: a matrix or data frame.
- **cor**: should the returned result include a correlation matrix?
- **quantile.used**: the minimum number of the data points regarded as good points.
- **method**: the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using `cov.mve` or `cov.mcd` forces `mve` or `mcd` respectively.
- **nsamp**: the number of samples or "best" or "exact" or "sample". The limit If "sample" the number chosen is min(5*p, 3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted.
- **seed**: the seed to be used for random sampling: see `RNGkind`. The current value of `.Random.seed` will be preserved if it is set.
- **...**: arguments to `cov.rob` other than method.

**Details**

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an ad hoc finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of p of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

There is a hard limit on the allowed number of samples, $2^{31} - 1$. However, practical limits are likely to be much lower and one might check the number of samples used for exhaustive enumeration, `combn(NROW(x), NCOL(x) + 1)`, before attempting it.

**Value**

A list with components

- **center**: the final estimate of location.
- **cov**: the final estimate of scatter.
- **cor**: (only is cor = TRUE) the estimate of the correlation matrix.
- **sing**: message giving number of singular samples out of total
- **crit**: the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
- **best**: the subset used. For MVE the best sample, for MCD the best set of size `quantile.used`.
- **n.obs**: total number of observations.

cov.trob

Covariance Estimation for Multivariate t Distribution

Description

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

Usage

cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
maxit = 25, tol = 0.01)

Arguments

x data matrix. Missing values (NAs) are not allowed.
wt A vector of weights for each case: these are treated as if the case i actually occurred wt[i] times.
cor Flag to choose between returning the correlation (cor = TRUE) or covariance (cor = FALSE) matrix.
center a logical value or a numeric vector providing the location about which the covariance is to be taken. If center = FALSE, no centering is done; if center = TRUE the MLE of the location vector is used.
nu ‘degrees of freedom’ for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
maxit Maximum number of iterations in fitting.
tol Convergence tolerance for fitting.
Value
A list with the following components

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cov</td>
<td>the fitted covariance matrix.</td>
</tr>
<tr>
<td>center</td>
<td>the estimated or specified location vector.</td>
</tr>
<tr>
<td>wt</td>
<td>the specified weights: only returned if the wt argument was given.</td>
</tr>
<tr>
<td>n.obs</td>
<td>the number of cases used in the fitting.</td>
</tr>
<tr>
<td>cor</td>
<td>the fitted correlation matrix: only returned if cor = TRUE.</td>
</tr>
<tr>
<td>call</td>
<td>The matched call.</td>
</tr>
<tr>
<td>iter</td>
<td>The number of iterations used.</td>
</tr>
</tbody>
</table>

### cpus

**Performance of Computer CPUs**

**Description**
A relative performance measure and characteristics of 209 CPUs.

**Usage**

```r
 cpus
```

**Format**
The components are:

- **name**: manufacturer and model.
- **syct**: cycle time in nanoseconds.
- **mmin**: minimum main memory in kilobytes.
- **mmax**: maximum main memory in kilobytes.
- **cach**: cache size in kilobytes.
- **chmin**: minimum number of channels.
- **chmax**: maximum number of channels.
- **perf**: published performance on a benchmark mix relative to an IBM 370/158-3.
- **estperf**: estimated performance (by Ein-Dor & Feldmesser).

**crabs**  
*Morphological Measurements on Leptograpsus Crabs*

**Description**

The *crabs* data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

**Usage**

*crabs*

**Format**

This data frame contains the following columns:

- `sp` species: "B" or "O" for blue or orange.
- `sex` as it says.
- `index` index 1:50 within each of the four groups.
- `FL` frontal lobe size (mm).
- `RW` rear width (mm).
- `CL` carapace length (mm).
- `CW` carapace width (mm).
- `BD` body depth (mm).

Cushings

Diagnostic Tests on Patients with Cushing’s Syndrome

Description

Cushing’s syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

Usage

Cushings

Format

The Cushings data frame has 27 rows and 3 columns:

- Tetrahydrocortisone: urinary excretion rate (mg/24hr) of Tetrahydrocortisone.
- Pregnanetriol: urinary excretion rate (mg/24hr) of Pregnanetriol.
- Type: underlying type of syndrome, coded a (adenoma), b (bilateral hyperplasia), c (carcinoma) or u for unknown.

denumeraten Transform an Allowable Formula for 'loglm' into one for 'terms'

Description
loglm allows dimension numbers to be used in place of names in the formula. denumerate modifies such a formula into one that terms can process.

Usage
denumerate(x)

Arguments
x A formula conforming to the conventions of loglm, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

Details
The model fitting function loglm fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ... margins in a similar way to variable names. As the model formula has to be parsed by terms, which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. denumerate replaces these numbers with names of a special form, namely n is replaced by .vn. This allows terms to parse the formula in the usual way.
Value

A linear model formula like that presented, except that where dimension numbers, say \( n \), have been used to specify fixed margins these are replaced by names of the form \(.vn\) which may be processed by terms.

dose.p
Predict Doses for Binomial Assay model

Description
Calibrate binomial assays, generalizing the calculation of LD50.

Usage
dose.p(obj, cf = 1:2, p = 0.5)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obj</td>
<td>A fitted model object of class inheriting from &quot;glm&quot;.</td>
</tr>
<tr>
<td>cf</td>
<td>The terms in the coefficient vector giving the intercept and coefficient of (log-)dose</td>
</tr>
<tr>
<td>p</td>
<td>Probabilities at which to predict the dose needed.</td>
</tr>
</tbody>
</table>

Value
An object of class "glm.dose" giving the prediction (attribute "p") and standard error (attribute "SE") at each response probability.

References

Examples

dose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)

dropterm

Try All One-Term Deletions from a Model

Description

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

Usage

dropterm (object, ...)  

## Default S3 method:  
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),  
          k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'  
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
          k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'glm'  
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
          k = 2, sorted = FALSE, trace = FALSE, ...)
Arguments

object  A object fitted by some model-fitting function.
scope   a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
scale   used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
test    should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known scale) or a likelihood-ratio test depending on the method.
k      the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.
sorted  should the results be sorted on the value of AIC?
trace   if TRUE additional information may be given on the fits as they are tried.
...  arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (`lm` models with specified `scale`) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

pairs(prof)
Description

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

Usage

dataset

Format

This data frame has 236 rows and the following 9 columns:

- **y**: the count for the 2-week period.
- **trt**: treatment, "placebo" or "progabide".
- **base**: the counts in the baseline 8-week period.
- **age**: subject's age, in years.
- **V4**: 0/1 indicator variable of period 4.
- **subject**: subject number, 1 to 59.
- **period**: period, 1 to 4.
- **lbase**: log-counts for the baseline period, centred to have zero mean.
- **lage**: log-ages, centred to have zero mean.

eqscplot

Plots with Geometrically Equal Scales

Description

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

Usage

eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)

Arguments

- x: vector of x values, or a 2-column matrix, or a list with components x and y
- y: vector of y values
- ratio: desired ratio of units on the axes. Units on the y axis are drawn at ratio times the size of units on the x axis. Ignored if uin is specified and of length 2.
- tol: proportion of white space at the margins of plot
- uin: desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
- ...: further arguments for plot and graphical parameters. Note that par(xaxs="i", yaxs="i") is enforced, and xlim and ylim will be adjusted accordingly.

Details

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by ratio. Finally both are stretched by \(1 + \text{tol}\) to move points away from the axes, and the points plotted.

Value

invisibly, the values of uin used for the plot.
Side Effects

performs the plot.

Note

Arguments ratio and uin were suggested by Bill Dunlap.

fgl Measurements of Forensic Glass Fragments

Description

The fgl data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

Usage

fgl

Format

This data frame contains the following columns:

- **RI**: refractive index; more precisely the refractive index is 1.518xxxx. The next 8 measurements are percentages by weight of oxides.
  - **Na**: sodium.
  - **Mg**: manganese.
  - **Al**: aluminium.
  - **Si**: silicon.
  - **K**: potassium.
  - **Ca**: calcium.
  - **Ba**: barium.
  - **Fe**: iron.

- **type**: The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (WinF: 70), window non-float glass (WinNF: 76), vehicle window glass (Veh: 17), containers (Con: 13), tableware (Tabl: 9) and vehicle headlamps (Head: 29).

References

**fitdistr**

*Maximum-likelihood Fitting of Univariate Distributions*

**Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

```r
fitdistr(x, densfun, start, ...)
```

**Arguments**

- `x` A numeric vector of length at least one containing only finite values.
- `densfun` Either a character string or a function returning a density evaluated at its first argument.
  Distributions "beta", "cauchy", "chi-squared", "exponential", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.
- `start` A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).
- `...` Additional parameters, either for `densfun` or for `optim`. In particular, it can be used to specify bounds via `lower` or `upper` or both. If arguments of `densfun` (or the density function corresponding to a character-string specification) are included they will be held fixed.

**Details**

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using `optim`. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied (when L-BFGS-B is used) or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location \(m\) and scale \(s\).

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by \(mu\) and \(size\)), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are `print`, `coef`, `vcov` and `logLik` methods for class "fitdistr".

---

**Example**

```r
library(MASS)
fit <- fitdistr(x, densfun = "normal")
```
forbes

Value

An object of class "fitdistr", a list with four components,

- `estimate`: the parameter estimates,
- `sd`: the estimated standard errors,
- `vcov`: the estimated variance-covariance matrix, and
- `loglik`: the log-likelihood.

Note

Numerical optimization cannot work miracles: please note the comments in `optim` on scaling data.
If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

References

Examples

```r
## avoid spurious accuracy
op <- options(digits = 3)

Forbes’ Data on Boiling Points in the Alps

Description

A data frame with 17 observations on boiling point of water and barometric pressure in inches of mercury.
fractions

Usage

forbes

Format

bp  boiling point (degrees Fahrenheit).
pres  barometric pressure in inches of mercury.

Source

<table>
<thead>
<tr>
<th>fractions</th>
<th>Rational Approximation</th>
</tr>
</thead>
</table>

Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

fractions(x, cycles = 10, max.denominator = 2000, ...)
as.fractions(x)
is.fractions(f)

Arguments

x  Any object of mode numeric. Missing values are now allowed.
cycles  The maximum number of steps to be used in the continued fraction approximation process.
max.denominator  An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
...  arguments passed to or from other methods.
f  an R object.

Details

Each component is first expanded in a continued fraction of the form

\[
x = \text{floor}(x) + \frac{1}{p_1 + \frac{1}{p_2 + \cdots}}
\]

where \(p_1, p_2, \ldots\) are positive integers, terminating either at cycles terms or when a \(p_j >\) max.denominator. The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.
Value

An object of class "fractions". A structure with .Data component the same as the input numeric x, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

References

See Also

GAGurine               Level of GAG in Urine of Children

Description

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child’s GAG concentration is ‘normal’.

Usage

GAGurine

Format

This data frame contains the following columns:

Age  age of child in years.
GAG  concentration of GAG (the units have been lost).

Source

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

References

**galaxies**

*Velocities for 82 Galaxies*

**Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

**Usage**

```r
galaxies
```

**Note**

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

**Source**

**References**

**Examples**

```r
gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)
```

---

**gamma.dispersion**

*Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit*

**Description**

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

**Usage**

```r
gamma.dispersion(object, ...)
```
gamma.shape

Arguments

object  Fitted model object giving the gamma fit.
...     Additional arguments passed on to gamma.shape.

Value

The MLE of the dispersion parameter of the gamma distribution.

References

See Also

gamma.shape.glm, including the example on its help page.

gamma.shape

Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

gamma.shape(object, ...)

## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
           eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)

Arguments

object  Fitted model object from a Gamma family or quasi family with variance = "mu^2".
it.lim Upper limit on the number of iterations.
eps.max Maximum discrepancy between approximations for the iteration process to continue.
verbose If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
...     further arguments passed to or from other methods.

Details

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.
Value

List of two components

- alpha: the maximum likelihood estimate
- SE: the approximate standard error, the square-root of the reciprocal of the observed information.

gehan  
Remission Times of Leukaemia Patients

Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug 6-mercaptopurine and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

Usage

gehan

Format

This data frame contains the following columns:

- pair: label for pair.
- time: remission time in weeks.
- cens: censoring, 0/1.
- treat: treatment, control or 6-MP.
Source

References

Examples

```r
library(survival)
gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan,
                       conf.type = "log-log")
summary(gehan.surv)
survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exponential")
summary(survreg(Surv(time, cens) ~ treat, gehan, dist = "exponential"))
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

---

**Description**

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

**Usage**

```r
genotype
```

**Format**

The data frame has the following components:

- **Litter** genotype of the litter.
- **Mother** genotype of the foster mother.
- **Wt** Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

**Source**

Old Faithful Geyser Data

Description

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

Usage

geyser

Format

A data frame with 299 observations on 2 variables.

| duration | numeric | Eruption time in mins |
| waiting  | numeric | Waiting time for this eruption |

Note

The waiting time was incorrectly described as the time to the next eruption in the original files, and corrected for MASS version 7.3-30.

CRAN package sm.
gilgais

*Line Transect of Soil in Gilgai Territory*

**Description**

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

**Usage**

gilgais

**Format**

This data frame contains the following columns:

- pH00 pH at depth 0–10 cm.
- pH30 pH at depth 30–40 cm.
- pH80 pH at depth 80–90 cm.
- e00 electrical conductivity in mS/cm (0–10 cm).
- e30 electrical conductivity in mS/cm (30–40 cm).
- e80 electrical conductivity in mS/cm (80–90 cm).
- c00 chloride content in ppm (0–10 cm).
- c30 chloride content in ppm (30–40 cm).
- c80 chloride content in ppm (80–90 cm).

ginv

Generalized Inverse of a Matrix

Description
Calculates the Moore-Penrose generalized inverse of a matrix $X$.

Usage
```r
ginv(X, tol = sqrt(.Machine$double.eps))
```

Arguments
- `X` Matrix for which the Moore-Penrose inverse is required.
- `tol` A relative tolerance to detect zero singular values.

Value
A MP generalized inverse matrix for $X$.

References

See Also
- `solve`, `svd`, `eigen`

glm.convert

Change a Negative Binomial fit to a GLM fit

Description
This function modifies an output object from `glm.nb()` to one that looks like the output from `glm()` with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage
```r
glm.convert(object)
```

Arguments
- `object` An object of class "negbin", typically the output from `glm.nb()`.

Details
Convenience function needed to effect some low level changes to the structure of the fitted model object.
glm.nb

Value
An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

See Also
glm.nb, negative.binomial, glm

Examples

quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)

Description
A modification of the system function glm() to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

Usage

glm.nb(formula, data, weights, subset, na.action,
       start = NULL, etastart, mustart,
       control = glm.control(...), method = "glm.fit",
       model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
       init.theta, link = log)

Arguments

formula, data, weights, subset, na.action, start, etastart, mustart, control, method, model, x, y, contrasts arguments for the glm() function. Note that these exclude family and offset (but offset() can be used).

init.theta Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

link The link function. Currently must be one of log, sqrt or identity.

Details
An alternating iteration process is used. For given theta the GLM is fitted using the same process as used by glm(). For fixed means the theta parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating theta are controlled by the maxit parameter of glm.control.)

Setting trace > 0 traces the alternating iteration process. Setting trace > 1 traces the glm fit, and setting trace > 2 traces the estimation of theta.
Value

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of theta, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

References

See Also

glm, negative.binomial, anova.negbin, summary.negbin, theta.md

There is a `simulate` method.

Examples

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

---

**glmmPQL**

*Fit Generalized Linear Mixed Models via PQL*

### Description

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

### Usage

```r
glmmPQL(fixed, random, family, data, correlation, weights, 
control, niter = 10, verbose = TRUE, ...)
```

### Arguments

- `fixed`: a two-sided linear formula giving fixed-effects part of the model.
- `random`: a formula or list of formulae describing the random effects.
- `family`: a GLM family.
- `data`: an optional data frame, list or environment used as the first place to find variables in the formulae, weights and if present in `...`, subset.
- `correlation`: an optional correlation structure.
- `weights`: optional case weights as in `glm`.
- `control`: an optional argument to be passed to `lme`.
- `niter`: maximum number of iterations.
- `verbose`: logical: print out record of iterations?
- `...`: Further arguments for `lme`.
Details
glmmPQL works by repeated calls to \texttt{lme}, so namespace \texttt{nlme} will be loaded at first use. (Before 2015 it used to attach \texttt{nlme} but nowadays only loads the namespace.)

Unlike \texttt{lme}, \texttt{offset} terms are allowed in \texttt{fixed} – this is done by pre- and post-processing the calls to \texttt{lme}.

Note that the returned object inherits from class \texttt{"lme"} and that most generics will use the method for that class. As from version 3.1-158, the fitted values have any offset included, as do the results of calling \texttt{predict}.

Value

A object of class \texttt{c("glmmPQL", "lme")}: see \texttt{lmeObject}.

References

\texttt{lme}

Examples

\begin{verbatim}
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID, family = binomial, data = bacteria))

## an example of an offset: the coefficient of ’week’ changes by one.
summary(glmmPQL(y ~ trt + week, random = ~ 1 | ID, family = binomial, data = bacteria))
summary(glmmPQL(y ~ trt + week + offset(week), random = ~ 1 | ID, family = binomial, data = bacteria))
\end{verbatim}

hills

\textit{Record Times in Scottish Hill Races}

Description

The record times in 1984 for 35 Scottish hill races.

Usage

\texttt{hills}
Format

The components are:

dist  distance in miles (on the map).
climb total height gained during the route, in feet.
time record time in minutes.

Source

[A.C. Atkinson (1988) Transformations unmasked. *Technometrics* 30, 311–318 “corrects” the time for Knock Hill from 78.65 to 18.65. It is unclear if this based on the original records.]

References

**hist.scott**

*Plot a Histogram with Automatic Bin Width Selection*

**Description**

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

**Usage**

```
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

**Arguments**

- `x` A data vector
- `prob` Should the plot have unit area, so be a density estimate?
- `xlab, ...` Further arguments to `hist`.

**Value**

For the `nclass.*` functions, the suggested number of classes.

**Side Effects**

Plot a histogram.

**References**

**See Also**

`hist`
Frequency Table from a Copenhagen Housing Conditions Survey

Description

The housing data frame has 72 rows and 5 variables.

Usage

housing

Format

Sat  Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).
Infl Perceived degree of influence householders have on the management of the property (High, Medium, Low).
Type Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).
Cont Contact residents are afforded with other residents, (Low, High).
Freq Frequencies: the numbers of residents in each class.

```

### Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

### Usage

`Insurance`

### Format

This data frame contains the following columns:

- **District**: factor: district of residence of policyholder (1 to 4): 4 is major cities.
- **Group**: an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
- **Age**: an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.
- **Holders**: numbers of policyholders.
- **Claims**: numbers of claims

### Source

### References

### Examples

```r
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
    data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```
**isoMDS**

**Kruskal’s Non-metric Multidimensional Scaling**

**Description**

One form of non-metric multidimensional scaling

**Usage**

\[
\text{isoMDS}(d, y = \text{cmdscale}(d, k), k = 2, \text{maxit} = 50, \text{trace} = \text{TRUE}, \\
\text{tol} = \text{1e}-3, p = 2)
\]

\[
\text{Shepard}(d, x, p = 2)
\]

**Arguments**

- **d**: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.
- **y**: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution, unless there are missing or infinite dissimilarities.
- **k**: The desired dimension for the solution, passed to `cmdscale`.
- **maxit**: The maximum number of iterations.
- **trace**: Logical for tracing optimization. Default `TRUE`.
- **tol**: Convergence tolerance.
- **p**: Power for Minkowski distance in the configuration space.
- **x**: A final configuration.

**Details**

This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an \(O(n^2)\) calculation, it is slow for large datasets. Further, since for the default \(p = 2\) the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**

Two components:

- **points**: A k-column vector of the fitted configuration.
- **stress**: The final stress achieved (in percent).

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

kde2d

Two-Dimensional Kernel Density Estimation

Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated
on a square grid.

Usage

kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))

Arguments

x x coordinate of data
y y coordinate of data
h vector of bandwidths for x and y directions. Defaults to normal reference band-
width (see bandwidth.nrd). A scalar value will be taken to apply to both direc-
tions.
n Number of grid points in each direction. Can be scalar or a length-2 integer
vector.
lims The limits of the rectangle covered by the grid as c(xl, xu, y1, yu).

Value

A list of three components.

x, y The x and y coordinates of the grid points, vectors of length n.
z An n[1] by n[2] matrix of the estimated density: rows correspond to the value
of x, columns to the value of y.
References

Examples

contour(f1, xlab = "previous duration",
 ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
detach("geyser")

lda

Linear Discriminant Analysis

Description

Linear discriminant analysis.

Usage

lda(x, ...)

## S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

## Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
lda(x, ...)

## S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
Arguments

- **formula**: A formula of the form `groups ~ x1 + x2 + ...` That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.

- **data**: An optional data frame, list or environment from which variables specified in `formula` are preferentially to be taken.

- **x** (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.

- **grouping** (required if no formula principal argument is given.) a factor specifying the class for each observation.

- **prior**: the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.

- **tol**: A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than `tol^2`.

- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)

- **method**: "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a $t$ distribution.

- **CV**: If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.

- **nu**: degrees of freedom for `method = "t"`.

- **...**: arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

- **prior**: the prior probabilities used.
ldahist

means       the group means.
scaling     a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
svd         the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.
N           The number of observations used.
call        The (matched) function call.

Note

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but subset= and na.action=, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using update() in the usual way.

ldahist  Histograms or Density Plots of Multiple Groups

Description

Plot histograms or density plots of data on a single Fisher linear discriminant.
ldahist(data, g, nbins = 25, h, x0 = -h/1000, breaks, 
xlim = range(breaks), ymax = 0, width, 
type = c("histogram", "density", "both"), 
sep = (type != "density"), 
col = 5, xlab = deparse(substitute(data)), bty = "n", ...)  

Arguments  
data vector of data. Missing values (NAs) are allowed and omitted. 
g factor or vector giving groups, of the same length as data. 
nbins Suggested number of bins to cover the whole range of the data. 
h The bin width (takes precedence over nbins). 
x0 Shift for the bins - the breaks are at x0 + h * (... , -1, 0, 1, ...) 
breaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins). 
xlim The limits for the x-axis. 
ymax The upper limit for the y-axis. 
width Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately. 
type Type of plot. 
sep Whether there is a separate plot for each group, or one combined plot. 
col The colour number for the bar fill. 
xlab label for the plot x-axis. By default, this will be the name of data. 
bty The box type for the plot - defaults to none. 
... additional arguments to polygon. 

Side Effects  
Histogram and/or density plots are plotted on the current device.

Survival Times and White Blood Counts for Leukaemia Patients

Description
A data frame of data from 33 leukaemia patients.

Usage
leuk

Format
A data frame with columns:
wbc white blood count.
ag a test result, "present" or "absent".
time survival time in weeks.

Details
Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
**lm.gls**

*Fit Linear Models by Generalized Least Squares*

**Description**

Fit linear models by Generalized Least Squares

**Usage**

```r
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
       method = "qr", model = FALSE, x = FALSE, y = FALSE,
       contrasts = NULL, ...)
```

**Arguments**

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `data`: an optional data frame, list or environment in which to interpret the variables occurring in `formula`.
- `W`: a weight matrix.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `inverse`: logical: if true `W` specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
- `method`: method to be used by `lm.fit`.
- `model`: should the model frame be returned?
- `x`: should the design matrix be returned?
- `y`: should the response be returned?
- `contrasts`: a list of contrasts to be used for some or all of
- `...`: additional arguments to `lm.fit`.

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

**See Also**

`gls`, `lm`, `lm.ridge`
lm.ridge

Ridge Regression

Description
Fit a linear model by ridge regression.

Usage

lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE, x = FALSE, y = FALSE, contrasts = NULL, ...)

Arguments

formula a formula expression as for regression models, of the form response ~ predictors. See the documentation of formula for other details. offset terms are allowed.
data an optional data frame, list or environment in which to interpret the variables occurring in formula.
subset expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action a function to filter missing data.
lambda A scalar or vector of ridge constants.
model should the model frame be returned? Not implemented.
x should the design matrix be returned? Not implemented.
y should the response be returned? Not implemented.
contrasts a list of contrasts to be used for some or all of factor terms in the formula. See the contrasts.arg of model.matrix.default.
... additional arguments to lm.fit.
obj an R object, such as an "lm.ridge" fit.

Details
If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

Value
A list with components

coeff matrix of coefficients, one row for each value of lambda. Note that these are not on the original scale and are for use by the coef method.
scales scalings used on the X matrix.
Inter was intercept included?
lambda vector of lambda values
ym mean of y
loglm

xm column means of x matrix
GCV vector of GCV values
kHKB HKB estimate of the ridge constant.
kLW L-W estimate of the ridge constant.

loglm

Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, loglin, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as glm.

Usage

loglm(formula, data, subset, na.action, ...)

Arguments

formula A linear model formula specifying the log-linear model.
    If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the dimnames attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.

data Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to xtabs.
loglm

subset Specifies a subset of the rows in the data frame to be used. The default is to take all rows.

na.action Specifies a method for handling missing observations. The default is to fail if missing values are present.

... May supply other arguments to the function loglm1.

Details

If the left-hand side of the formula is empty the data argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by loglin. Structural zeros may be specified by giving a start argument with those entries set to zero, as described in the help information for loglin.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by loglin. Hence terms such as a:b, a*b and a/b are all equivalent.

Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions print, summary, deviance, fitted, coef, resid, anova and update, which perform the expected tasks. Only log-likelihood ratio tests are allowed using anova.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. loglin itself takes no action to allow for structural zeros. loglm deduces one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

# The loglm residual degrees of freedom is wrong because of
# a non-detectable redundancy in the model matrix.
```

### logtrans

Estimate log Transformation Parameter

**Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form \( \log(y + \alpha) \sim x_1 + x_2 + \ldots \).

**Usage**

```r
logtrans(object, ...)
```

# Default S3 method:
```r
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
plotit = TRUE, interp =, xlab = "alpha",
ylab = "log Likelihood")
```

# S3 method for class 'formula'
```r
logtrans(object, data, ...)
```

# S3 method for class 'lm'
```r
logtrans(object, ...)
```
Arguments

object  Fitted linear model object, or formula defining the untransformed model that is \( y \sim x_1 + x_2 + \ldots \). The function is generic.

...  If object is a formula, this argument may specify a data frame as for `lm`.

alpha  Set of values for the transformation parameter, alpha.

plotit  Should plotting be done?

interp  Should the marginal log-likelihood be interpolated with a spline approximation? (Default is `TRUE` if plotting is to be done and the number of real points is less than 100.)

xlab  as for `plot`.

ylab  as for `plot`.

data  optional data argument for `lm` fit.

Value

List with components `x` (for alpha) and `y` (for the marginal log-likelihood values).

Side Effects

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

References

        alpha = seq(0.75, 6.5, len=20))
```

---

`lqs`  

*Resistant Regression*

Description

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.
Usage

lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ...,
    method = c("lts", "lqs", "lms", "S", "model.frame"),
    subset, na.action, model = TRUE,
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
    quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)

Arguments

formula    a formula of the form y ~ x1 + x2 + ....
data        an optional data frame, list or environment from which variables specified in
            formula are preferentially to be taken.
subset      an index vector specifying the cases to be used in fitting. (NOTE: If given, this
            argument must be named exactly.)
na.action   function to specify the action to be taken if NAs are found. The default action is
            for the procedure to fail. Alternatives include na.omit and na.exclude, which
            lead to omission of cases with missing values on any required variable. (NOTE:
            If given, this argument must be named exactly.)
model, x.ret, y.ret
            logical. If TRUE the model frame, the model matrix and the response are re-
            turned, respectively.
contrasts   an optional list. See the contrasts.arg of model.matrix.default.
x           a matrix or data frame containing the explanatory variables.
y           the response: a vector of length the number of rows of x.
intercept   should the model include an intercept?
method      the method to be used. model.frame returns the model frame: for the others
            see the Details section. Using lmsreg or ltsreg forces "lms" and "lts" respectively.
quantile    the quantile to be used: see Details. This is over-ridden if method = "lms".
control     additional control items: see Details.
k0          the cutoff / tuning constant used for \( \chi() \) and \( \psi() \) functions when method = "S",
            currently corresponding to Tukey’s ‘biweight’.
seed        the seed to be used for random sampling: see .Random.seed. The current value of
            .Random.seed will be preserved if it is set.
...         arguments to be passed to lqs.default or lqs.control, see control above
            and Details.
Details

Suppose there are \( n \) data points and \( p \) regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are floor\((\frac{n+p+1}{2})\) and floor\((\frac{n+1}{2})\) respectively. For "lts" the default is floor\((\frac{n}{2}) + \frac{1}{2}\).

The "S" estimation method solves for the scale \( s \) such that the average of a function chi of the residuals divided by \( s \) is equal to a given constant.

The control argument is a list with components

- **psamp**: the size of each sample. Defaults to \( p \).
- **nsamp**: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is min\((5p, 3000)\), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.
- **adjust**: should the intercept be optimized for each sample? Defaults to TRUE.

Value

An object of class "lqs". This is a list with components

- **crit**: the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.
- **sing**: character. A message about the number of samples which resulted in singular fits.
- **coefficients**: of the fitted linear model
- **bestone**: the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
- **fitted.values**: the fitted values.
- **residuals**: the residuals.
- **scale**: estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

Note

There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate \( n^{-1/3} \)) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of \( (\frac{\text{floor}(n-p)+1}{n}) \) attained if floor\((\frac{n+p}{2})\) <= quantile <= floor\((\frac{n+p+1}{2})\). The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if \( n \) is large and \( p \) small.

Opinions differ over the choice of psamp. Rousseeuw and Hubert (1997) only consider \( p \); Marazzi (1993) recommends \( p+1 \) and suggests that more samples are better than adjustment for a given computational limit.
The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

mammalsBrain and Body Weights for 62 Species of Land Mammals

Description

A data frame with average brain and body weights for 62 species of land mammals.

Usage

mammals

Format

- **body**: body weight in kg.
- **brain**: brain weight in g.
- **name**: Common name of species. (Rock hyrax-a = *Heterohyrax brucci*, Rock hyrax-b = *Procavia habessinica*...)

Source

References

**mca**

*Multiple Correspondence Analysis*

**Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```r
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

- `df`: A data frame containing only factors
- `nf`: The number of dimensions for the MCA. Rarely 3 might be useful.
- `abbrev`: Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if `abbrev = TRUE` they are just ‘level’ which will suffice if the factors have distinct levels.

**Value**

An object of class "mca", with components

- `rs`: The coordinates of the rows, in `nf` dimensions.
- `cs`: The coordinates of the column vertices, one for each level of each factor.
- `fs`: Weights for each row, used to interpolate additional factors in `predict.mca`.
- `p`: The number of factors
- `d`: The singular values for the `nf` dimensions.
- `call`: The matched call.

Minnesota High School Graduates of 1938

Description

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The minn38 data frame has 168 rows and 5 columns.

Usage

minn38

Format

This data frame contains the following columns:
- hs  high school rank: "L", "M" and "U" for lower, middle and upper third.
- phs post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").
- fol father’s occupational level, (seven levels, "F1", "F2", . . . , "F7").
- sex  sex: factor with levels "F" or "M".
- f frequency.
motors

Source

Description

The motors data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

Usage

motors

Format

This data frame contains the following columns:

- **temp** the temperature (degrees C) of the test.
- **time** the time in hours to failure or censoring at 8064 hours (= 336 days).
- **cens** an indicator variable for death.

Source

References

Examples

```r
library(survival)

# fit Weibull model
motor.wei <- survreg(Surv(time, cens) ~ temp, motors)
summary(motor.wei)
# and predict at 130C
unlist(predict(motor.wei, data.frame(temp=130), se.fit = TRUE))

motor.cox <- coxph(Surv(time, cens) ~ temp, motors)
summary(motor.cox)
# predict at temperature 200
```
plot(survfit(motor.cox, newdata = data.frame(temp=200),
conf.type = "log-log"))
summary( survfit(motor.cox, newdata = data.frame(temp=130)) )

### muscle

**Effect of Calcium Chloride on Muscle Contraction in Rat Hearts**

**Description**

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

**Usage**

`muscle`

**Format**

This data frame contains the following columns:

- Strip: which heart muscle strip was used?
- Conc: concentration of calcium chloride solution, in multiples of 2.2 mM.
- Length: the change in length (shortening) of the strip, (allegedly) in mm.

**Source**

**References**

**Examples**

```r
## IGNORE_RDIFF_BEGIN
A <- model.matrix(~ Strip - 1, data=muscle)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),

                })

\textbf{mvrnorm} \hspace{1cm} \textit{Simulate from a Multivariate Normal Distribution}

\textbf{Description}

Produces one or more samples from the specified multivariate normal distribution.

\textbf{Usage}

\texttt{mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)}

\textbf{Arguments}

- \texttt{n} \hspace{1cm} the number of samples required.
- \texttt{mu} \hspace{1cm} a vector giving the means of the variables.
- \texttt{Sigma} \hspace{1cm} a positive-definite symmetric matrix specifying the covariance matrix of the variables.
- \texttt{tol} \hspace{1cm} tolerance (relative to largest variance) for numerical lack of positive-definiteness in \texttt{Sigma}.
- \texttt{empirical} \hspace{1cm} logical. If true, \texttt{mu} and \texttt{Sigma} specify the empirical not population mean and covariance matrix.
- \texttt{EISPACK} \hspace{1cm} logical: values other than \texttt{FALSE} are an error.

\textbf{Details}

The matrix decomposition is done via \texttt{eigen}; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

\textbf{Value}

If \texttt{n} = 1 a vector of the same length as \texttt{mu}, otherwise an \texttt{n} by \texttt{length(mu)} matrix with one sample in each row.

\textbf{Side Effects}

Causes creation of the dataset \texttt{.Random.seed} if it does not already exist, otherwise its value is updated.
negative.binomial

Family function for Negative Binomial GLMs

Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known theta parameter, using glm().

Usage

negative.binomial(theta = stop("'theta' must be specified"), link = "log")

Arguments

theta

The known value of the additional parameter, theta.

link

The link function, as a character string, name or one-element character vector specifying one of log, sqrt or identity, or an object of class "link-glm".

Value

An object of class "family", a list of functions and expressions needed by glm() to fit a Negative Binomial generalized linear model.

References

See Also

glm.nb, anova.negbin, summary.negbin

Examples

# Fitting a Negative Binomial model to the quine data
# with theta = 2 assumed known.
#
# glm(Days ~ .^4, family = negative.binomial(2), data = quine)
newcomb

**Description**

A numeric vector giving the ‘Third Series’ of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The 'true' value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

```
28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
36 23 27 27 28 27 31 27 26 33 26 32 24 39 28 24 25 32 25
29 27 28 29 16 23
```

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

**Usage**

```
newcomb
```

**Source**

nlschools

**Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

**Usage**

```
nlschools
```
**npk**

**Classical N, P, K Factorial Experiment**

**Description**

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

**Usage**

npk
**Format**

The npk data frame has 24 rows and 5 columns:

- **block** which block (label 1 to 6).
- **N** indicator (0/1) for the application of nitrogen.
- **P** indicator (0/1) for the application of phosphate.
- **K** indicator (0/1) for the application of potassium.
- **yield** Yield of peas, in pounds/plot (the plots were (1/70) acre).

**Note**

This dataset is also contained in R 3.0.2 and later.

**Source**

**References**

**Examples**

```r
options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
## IGNORE_RDIFF_BEGIN

model.tables(npk.aov1, type = "means", se = TRUE)
## IGNORE_RDIFF_END
```

**npr1**

**US Naval Petroleum Reserve No. 1 data**

**Description**

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

**Usage**

npr1
Format

This data frame contains the following columns:

- x  x coordinates, in miles (origin unspecified).
- y  y coordinates, in miles.
- perm permeability in milli-Darcies.
- por porosity (%).

References

---

Null

**Null Spaces of Matrices**

Description

Given a matrix, \( M \), find a matrix \( N \) giving a basis for the (left) null space. That is \( \text{crossprod}(N, M) = t(N) \%\% M \) is an all-zero matrix and \( N \) has the maximum number of linearly independent columns.

Usage

\[ \text{Null}(M) \]

Arguments

- \( M \)  
  Input matrix. A vector is coerced to a 1-column matrix.

Details

For a basis for the (right) null space \( \{ x : Mx = 0 \} \), use \( \text{Null}(t(M)) \).

Value

The matrix \( N \) with the basis for the (left) null space, or a matrix with zero columns if the matrix \( M \) is square and of maximal rank.

References

See Also

- \( \text{qr}, \text{qr.Q} \).
Examples

```r
# The function is currently defined as
function(M)
{
  tmp <- qr(M)
  set <- if(tmp$rank == 0L) seq_len(ncol(M)) else -seq_len(tmp$rank)
  qr.Q(tmp, complete = TRUE)[, set, drop = FALSE]
}
```

oats

Data from an Oats Field Trial

Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

Usage

`oats`

Format

This data frame contains the following columns:

- `B` Blocks, levels I, II, III, IV, V and VI.
- `V` Varieties, 3 levels.
- `N` Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.
- `Y` Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

Source

References

Examples

```r
oats$Nf <- ordered(oats$N, levels = sort(levels(oats$N)))
oats.aov <- aov(Y ~ Nf*V + Error(B/V), data = oats, qr = TRUE)
## IGNORE_RDIFF_BEGIN
summary(oats.aov)

plot(fitted(oats.aov[[4]]), studres(oats.aov[[4]]))
```
abline(h = 0, lty = 2)
oats.pr <- proj(oats.aov)
qqnorm(oats.pr[[4]][, "Residuals"], ylab = "Stratum 4 residuals")
qqline(oats.pr[[4]][, "Residuals"])

par(mfrow = c(1,1), pty = "m")
oats.aov2 <- aov(Y ~ N + V + Error(B/V), data = oats, qr = TRUE)
model.tables(oats.aov2, type = "means", se = TRUE)

OME

Tests of Auditory Perception in Children with OME

Description

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

Usage

OME

Format

The OME data frame has 1129 rows and 7 columns:

- ID: Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- OME: "low" or "high" or "N/A" (at ages other than 30 and 60 months).
- Age: Age of the subject (months).
- Loud: Loudness of stimulus, in decibels.
- Noise: Whether the signal in the stimulus was "coherent" or "incoherent".
- Correct: Number of correct responses from Trials trials.
- Trials: Number of trials performed.

Background

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of
severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

## End(Not run)
Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

Usage

```
painters
```

Format

- **Composition**: Composition score.
- **Drawing**: Drawing score.
- **Colour**: Colour score.
- **Expression**: Expression score.
- **School**: The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

```
pairs.lda
```

**Produce Pairwise Scatterplots from an 'lda' Fit**

Description

Pairwise scatterplot of the data on the linear discriminants.

Usage

```r
## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
     dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```
Arguments

- **x**: Object of class "lda".
- **labels**: vector of character strings for labelling the variables.
- **panel**: panel function to plot the data in each panel.
- **dimen**: The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
- **abbrev**: whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
- **...**: additional arguments for pairs.default.
- **cex**: graphics parameter cex for labels on plots.
- **type**: type of plot. The default is in the style of pairs.default; the style "trellis" uses the Trellis function splom.

Details

This function is a method for the generic function pairs() for class "lda". It can be invoked by calling pairs(x) for an object x of the appropriate class, or directly by calling pairs.lda(x) regardless of the class of the object.

parcoord: Parallel Coordinates Plot

Description

Parallel coordinates plot

Usage

parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)

Arguments

- **x**: a matrix or data frame who columns represent variables. Missing values are allowed.
- **col**: A vector of colours, recycled as necessary for each observation.
- **lty**: A vector of line types, recycled as necessary for each observation.
- **var.label**: If TRUE, each variable’s axis is labelled with maximum and minimum values.
- **...**: Further graphics parameters which are passed to matplot.
Side Effects

a parallel coordinates plots is drawn.

Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples

```r
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])
ir <- rbind(iris3[,,1], iris3[,,2], iris3[,,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

petrol

*N. L. Prater’s Petrol Refinery Data*

Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

Usage

`petrol`

Format

The variables are as follows

- **No** crude oil sample identification label. (Factor.)
- **SG** specific gravity, degrees API. (Constant within sample.)
- **VP** vapour pressure in pounds per square inch. (Constant within sample.)
- **V10** volatility of crude; ASTM 10% point. (Constant within sample.)
- **EP** desired volatility of gasoline. (The end point. Varies within sample.)
- **Y** yield as a percentage of crude.

Source

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.
References

Examples

```r
library(nlme)
Petrol <- petrol
Petrol[, 2:5] <- scale(as.matrix(Petrol[, 2:5]), scale = FALSE)
pet3.lme <- lme(Y ~ SG + VP + V10 + EP,
    random = - 1 | No, data = Petrol)
pet3.lme <- update(pet3.lme, method = "ML")
pet4.lme <- update(pet3.lme, fixed = Y ~ V10 + EP)
anova(pet4.lme, pet3.lme)
```

### Pima.tr

**Diabetes in Pima Indian Women**

Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

- `Pima.tr`
- `Pima.tr2`
- `Pima.te`

Format

These data frames contain the following columns:

- `npreg` number of pregnancies.
- `glu` plasma glucose concentration in an oral glucose tolerance test.
- `bp` diastolic blood pressure (mm Hg).
- `skin` triceps skin fold thickness (mm).
- `bmi` body mass index (weight in kg/(height in m)^2).
- `ped` diabetes pedigree function.
- `age` age in years.
- `type` Yes or No, for diabetic according to WHO criteria.

Details

The training set `Pima.tr` contains a randomly selected set of 200 subjects, and `Pima.te` contains the remaining 332 subjects. `Pima.tr2` contains `Pima.tr` plus 100 subjects with missing values in the explanatory variables.
plot.lda

Description

Plots a set of data on one, two or more linear discriminants.

Usage

```R
## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
    abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

Arguments

- `x`: An object of class "lda".
- `panel`: the panel function used to plot the data.
- `...`: additional arguments to `pairs.lda`, `ldahist` or `eqscplot`.
- `cex`: graphics parameter `cex` for labels on plots.
- `dimen`: The number of linear discriminants to be used for the plot; if this exceeds the number determined by `x` the smaller value is used.
- `abbrev`: whether the group labels are abbreviated on the plots. If `abbrev > 0` this gives `minlength` in the call to `abbreviate`.
- `xlab`: label for the x axis
- `ylab`: label for the y axis

Details

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object `x` of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a pairs plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

plot.mca

Plot Method for Objects of Class ‘mca’

Description
Plot a multiple correspondence analysis.

Usage
## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)

Arguments
x An object of class "mca".
rows Should the coordinates for the rows be plotted, or just the vertices for the levels?
col, cex The colours and cex to be used for the row points and level vertices respectively.
... Additional parameters to plot.

References

See Also
mca, predict.mca

Examples
plot(mca(farms, abbrev = TRUE))

plot.profile

Plotting Functions for ‘profile’ Objects

Description
plot and pairs methods for objects of class "profile".

Usage
## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)

Arguments
x an object inheriting from class "profile".
colours Colours to be used for the mean curves conditional on x and y respectively.
... arguments passed to or from other methods.
Details

This is the main plot method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters x and y, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of y|x and x|y, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also

`profile.glm`, `profile.nls`.

Examples

```r
## see ?profile.glm for an example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

---

**polr**

**Ordered Logistic or Probit Regression**

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

Usage

```r
polr(formula, data, weights, start, ..., subset, na.action,
    contrasts = NULL, Hess = FALSE, model = TRUE,
    method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```
Arguments

- **formula**: a formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of `formula` for other details.

- **data**: an optional data frame, list or environment in which to interpret the variables occurring in `formula`.

- **weights**: optional case weights in fitting. Default to 1.

- **start**: initial values for the parameters. This is in the format `c(coefficients, zeta)`: see the Values section.

- **...**: additional arguments to be passed to `optim`, most often a control argument.

- **subset**: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

- **na.action**: a function to filter missing data.

- **contrasts**: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

- **Hess**: logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call `summary` or `vcov` on the fit.

- **model**: logical for whether the model matrix should be returned.

- **method**: logistic or probit or (complementary) log-log or cauchit (corresponding to a Cauchy latent variable).

Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable $Y_i$ which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin $Y_i$ falls into with breakpoints $\zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty$.

This leads to the model

$$\text{logit}P(Y \leq k | x) = \zeta_k - \eta$$

with `logit` replaced by `probit` for a normal latent variable, and $\eta$ being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for $\eta$ (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category $k$ or less, and since these are log odds which differ only by a constant for different $k$, the odds are proportional. Hence the term *proportional odds logistic regression*.

The log-log and complementary log-log links are the increasing functions $F^{-1}(p) = -\log(-\log(p))$ and $F^{-1}(p) = \log(-\log(1 - p))$; some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A *proportional hazards* model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

`predict`, `summary`, `vcov`, `anova`, `model.frame` and an `extractAIC` method for use with `stepAIC` (and `step`). There are also `profile` and `confint` methods.
Value

A object of class "polr". This has components

- **coefficients**: the coefficients of the linear predictor, which has no intercept.
- **zeta**: the intercepts for the class boundaries.
- **deviance**: the residual deviance.
- **fitted.values**: a matrix, with a column for each level of the response.
- **lev**: the names of the response levels.
- **terms**: the terms structure describing the model.
- **df.residual**: the number of residual degrees of freedoms, calculated using the weights.
- **edf**: the (effective) number of degrees of freedom used by the model.
- **n, nobs**: the (effective) number of observations, calculated using the weights. (nobs is for use by `stepAIC`.
- **call**: the matched call.
- **method**: the matched method used.
- **convergence**: the convergence code returned by `optim`.
- **niter**: the number of function and gradient evaluations used by `optim`.
- **lp**: the linear predictor (including any offset).
- **Hessian**: (if Hess is true). Note that this is a numerical approximation derived from the optimization proces.
- **model**: (if model is true).

Note

The `vcov` method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, `method = "cloglog"` confusingly gave the log-log link, implicitly assuming the first response level was the ‘best’.

predict.glmmPQL  Predict Method for glmmPQL Fits

Description
Obtains predictions from a fitted generalized linear model with random effects.

Usage
## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
level, na.action = na.pass, ...)

Arguments

object  a fitted object of class inheriting from "glmmPQL".
newdata optionally, a data frame in which to look for variables with which to predict.
type the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
level an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
na.action function determining what should be done with missing values in newdata. The default is to predict NA.

Value
If level is a single integer, a vector otherwise a data frame.

See Also

`glmmPQL`, `predict.lme`. 
Example

```r
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
    family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

Classify Multivariate Observations by Linear Discrimination

Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

Usage

```r
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
    method = c("plug-in", "predictive", "debiased"), ...)
```

Arguments

- `object`: object of class "lda"
- `newdata`: data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lda` object.
- `prior`: The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to `lda`.
- `dimen`: the dimension of the space to be used. If this is less than `min(p, ng-1)`, only the first `dimen` discriminant components are used (except for `method="predictive"`), and only those dimensions are returned in `x`.
- `method`: This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
- `...`: arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.
Value

- a list with components
  - `class`: The MAP classification (a factor)
  - `posterior`: posterior probabilities for the classes
  - `x`: the scores of test cases on up to dimen discriminant variables

References

`lda`, `qda`, `predict.qda`

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[,1], iris3[,2], iris3[,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- lda(train, cl)
predict(z, test)$class
```

---

**predict.lqs**

*Predict from an lqs Fit*

Description

Predict from an resistant regression fitted by lqs.

Usage

```r
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

Arguments

- `object`: object inheriting from class "lqs"
- `newdata`: matrix or data frame of cases to be predicted or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the lqs object.
- `na.action`: function determining what should be done with missing values in `newdata`. The default is to predict NA.
- `...`: arguments to be passed from or to other methods.
This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

A vector of predictions.

B.D. Ripley

**Examples**

```r
set.seed(123)
fm <- lqs(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)
```

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```r
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

- `object` An object of class "mca", usually the result of a call to `mca`.
- `newdata` A data frame containing either additional rows of the factors used to fit `object` or additional factors for the cases used in the original fit.
- `type` Are predictions required for further rows or for new factors?
- `...` Additional arguments from `predict`: unused.

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.
References

mca, plot.mca

predict.qda

Classify from Quadratic Discriminant Analysis

Description

Classify multivariate observations in conjunction with qda

Usage

## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
       method = c("plug-in", "predictive", "debiased", "looCV"), ...)

Arguments

object          object of class "qda"
newdata        data frame of cases to be classified or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the qda object.
prior          The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to qda.
method         This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned.
...

...        arguments based from or to other methods

Details

This function is a method for the generic function predict() for class "qda". It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.qda(x) regardless of the class of the object.

Missing values in newdata are handled by returning NA if the quadratic discriminants cannot be evaluated. If newdata is omitted and the na.action of the fit omitted cases, these will be omitted on the prediction.
profile.glm

Method for Profiling glm Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```r
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, ...)
```

Arguments

- `fitted` the original fitted model object.
- `which` the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- `alpha` highest significance level allowed for the profile t-statistics.
- `maxsteps` maximum number of points to be used for profiling each parameter.
- `del` suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `trace` logical: should the progress of profiling be reported?
- `...` further arguments passed to or from other methods.
Details
The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value
A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables
par.vals a matrix of parameter values for each fitted model.
tau the profile t-statistics.

Author(s)
Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also
glm, profile, plot.profile

Examples
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)

qda

Quadratic Discriminant Analysis

Description
Quadratic discriminant analysis.

Usage
qda(x, ...)

## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)

## S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)

### Arguments

- **formula**: A formula of the form `groups ~ x1 + x2 + ...`. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- **data**: An optional data frame, list or environment from which variables specified in `formula` are preferentially to be taken.
- **x**: (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
- **grouping**: (required if no formula principal argument is given.) a factor specifying the class for each observation.
- **prior**: the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.
- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- **method**: "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a t distribution.
- **CV**: If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
- **nu**: degrees of freedom for `method = "t"`.
- **...**: arguments passed to or from other methods.

### Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

### Value

An object of class "qda" containing the following components:

- **prior**: the prior probabilities used.
- **means**: the group means.
- **scaling**: for each group `i`, `scaling[,i]` is an array which transforms observations so that within-groups covariance matrix is spherical.
- **ldet**: a vector of half log determinants of the dispersion matrix.
- **lev**: the levels of the grouping factor.
- **terms**: (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

```

---

### Description

The *quine* data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

### Usage

`quine`

### Format

This data frame contains the following columns:

- **Eth** ethnic background: Aboriginal or Not, ("A" or "N").
- **Sex** sex: factor with levels ("F" or "M").
- **Age** age group: Primary ("F0"), or forms "F1," "F2" or "F3".
- **Lrn** learner status: factor with levels Average or Slow learner, ("AL" or "SL").
- **Days** days absent from school in the year.

### Source

Blood Pressure in Rabbits

Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the $5 - HT_3$ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of $5 - HT_3$ receptors.

Usage

Rabbit

Format

This data frame contains 60 rows and the following variables:

- **BPchange**: change in blood pressure relative to the start of the experiment.
- **Dose**: dose of Phenylbiguanide in micrograms.
- **Run**: label of run ("C1" to "C5", then "M1" to "M5").
- **Treatment**: placebo or the $5 - HT_3$ antagonist MDL 72222.
- **Animal**: label of animal used ("R1" to "R5").

Source

[The numerical data are not in the paper but were supplied by Professor Ludbrook]

References

rational

Rational Approximation

Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

rational(x, cycles = 10, max.denominator = 2000, ...)

Arguments

x
Any object of mode numeric. Missing values are now allowed.

cycles
The maximum number of steps to be used in the continued fraction approximation process.

max.denominator
An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.

...
Arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

\[ x = \text{floor}(x) + 1/(p_1 + 1/(p_2 + ...)) \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

Value

A numeric object with the same attributes as x but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

See Also

fractions

Examples

X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
renumerate

Convert a Formula Transformed by 'denumerate'

Description

denumerate converts a formula written using the conventions of loglm into one that terms is able to process. renumerate converts it back again to a form like the original.

Usage

renumerate(x)

Arguments

x A formula, normally as modified by denumerate.

Details

This is an inverse function to denumerate. It is only needed since terms returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

Value

A formula where all variables with names of the form .vn, where n is an integer, converted to numbers, n, as allowed by the formula conventions of loglm.

See Also
denumerate

Examples

denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b

r1m

Robust Fitting of Linear Models

Description

Fit a linear model by robust regression using an M estimator.
Usage

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
    method = c("M", "MM", "model.frame"),
    wt.method = c("inv.var", "case"),
    model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
    init = "ls", psi = psi.huber,
    scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
    method = c("M", "MM"), wt.method = c("inv.var", "case"),
    maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

Arguments

formula a formula of the form y ~ x1 + x2 + ....
data an optional data frame, list or environment from which variables specified in
   formula are preferentially to be taken.
weights a vector of prior weights for each case.
subset An index vector specifying the cases to be used in fitting.
na.action A function to specify the action to be taken if NAs are found. The ‘factory-fresh’
   default action in R is na.omit, and can be changed by options(na.action=).
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
method currently either M-estimation or MM-estimation or (for the formula method
   only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-
   weight initialized by a specific S-estimator. See the ‘Details’ section.
wt.method are the weights case weights (giving the relative importance of case, so a weight
   of 2 means there are two of these) or the inverse of the variances, so a weight of
   two means this error is half as variable?
model should the model frame be returned in the object?
x.ret should the model matrix be returned in the object?
y.ret should the response be returned in the object?
contrasts optional contrast specifications: see lm.
w (optional) initial down-weighting for each case.
init (optional) initial values for the coefficients OR a method to find initial values
   OR the result of a fit with a coef component. Known methods are "ls" (the
default) for an initial least-squares fit using weights w*weights, and "lts" for
an unweighted least-trimmed squares fit with 200 samples.
psi the psi function is specified by this argument. It must give (possibly by name)
a function g(x, ..., deriv) that for deriv=0 returns psi(x)/x and for deriv=1
returns psi’(x). Tuning constants will be passed in via ....
scale.est  method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2").
k2  tuning constant used for Huber proposal 2 scale estimation.
maxit  the limit on the number of IWLS iterations.
acc  the accuracy for the stopping criterion.
test.vec  the stopping criterion is based on changes in this vector.
...  additional arguments to be passed to rlm.default or to the psi function.
lqs.control  An optional list of control values for lqs.
u  numeric vector of evaluation points.
k, a, b, c  tuning constants.
deriv  0 or 1: compute values of the psi function or of its first derivative.

Details
Fitting is done by iterated re-weighted least squares (IWLS).
Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as psi.huber, psi.hampel and psi.bisquare. Huber’s corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.
Selecting method = "MM" selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with k0 = 1.548; this gives (for n ≫ p) breakdown point 0.5. The final estimator is an M-estimator with Tukey’s biweight and fixed scale that will inherit this breakdown point provided c > k0; this is true for the default value of c that corresponds to 95% relative efficiency at the normal. Case weights are not supported for method = "MM".

Value
An object of class "rlm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.
The additional components not in an lm object are
s  the robust scale estimate used
w  the weights used in the IWLS process
psi  the psi function with parameters substituted
conv  the convergence criteria at each iteration
converged  did the IWLS converge?
wresid  a working residual, weighted for "inv.var" weights only.

Note
Prior to version 7.3-52, offset terms in formula were omitted from fitted and predicted values.
rms.curv

**References**

**See Also**

`lm`, `lqs`.

**Examples**

```r
summary(rlm(stack.loss ~ ., stackloss))
rlm(stack.loss ~ ., stackloss, psi = psi.hampel, init = "lts")
rlm(stack.loss ~ ., stackloss, psi = psi.bisquare)
```

---

**rms.curv**  
*Relative Curvature Measures for Non-Linear Regression*

**Description**

Calculates the root mean square parameter effects and intrinsic relative curvatures, $c_\theta$ and $c_\iota$, for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

**Usage**

```r
rms.curv(obj)
```

**Arguments**

- `obj`  
  Fitted model object of class "nls". The model must be fitted using the default algorithm.

**Details**

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the pc and ic components only, suitably annotated.

If either pc or ic exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

**Value**

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by `sqrt(F)`, `ct` and `ci` for $c_\theta$ and $c_\iota$ (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.
rnegbin

Simulate Negative Binomial Variates

Description

Function to generate random outcomes from a Negative Binomial distribution, with mean \( \mu \) and variance \( \mu + \mu^2/\theta \).

Usage

\[ \text{rnegbin}(n, \mu = n, \theta = \text{stop}("'theta' must be specified")) \]

Arguments

- \( n \): If a scalar, the number of sample values required. If a vector, length(\( n \)) is the number required and \( n \) is used as the mean vector if \( \mu \) is not specified.
- \( \mu \): The vector of means. Short vectors are recycled.
- \( \theta \): Vector of values of the \( \theta \) parameter. Short vectors are recycled.

Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike \texttt{rbinom} the index can be arbitrary.

Value

Vector of random Negative Binomial variate values.

Side Effects

Changes \texttt{.Random.seed} in the usual way.
Examples

```
# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)

road

Road Accident Deaths in US States

Description

A data frame with the annual deaths in road accidents for half the US states.

Usage

road

Format

Columns are:

- state name.
- deaths number of deaths.
- drivers number of drivers (in 10,000s).
- popden population density in people per square mile.
- rural length of rural roads, in 1000s of miles.
- temp average daily maximum temperature in January.
- fuel fuel consumption in 10,000,000 US gallons per year.

rotifer

Numbers of Rotifers by Fluid Density

Description

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, *Polyarthra major* and *Keratella cochlearis* and for each species the number falling out and the total number are given.

Usage

rotifer
Rubber

Format

density specific density of fluid.

dm.y number falling out for P. major.

dm.total total number of P. major.

kc.y number falling out for K. cochlearis.

kc.tot total number of K. cochlearis.

Source

Samson’s Non-Linear Mapping

Description

One form of non-metric multidimensional scaling.

Usage

```r
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
magic = 0.2, tol = 1e-4)
```

Arguments

- `d`: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.
- `y`: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution. (If there are missing values in `d`, an initial configuration must be provided.) This must not have duplicates.
- `k`: The dimension of the configuration.
- `niter`: The maximum number of iterations.
- `trace`: Logical for tracing optimization. Default `TRUE`.
- `magic`: initial value of the step size constant in diagonal Newton method.
- `tol`: Tolerance for stopping, in units of stress.

Details

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

Value

Two components:

- `points`: A two-column vector of the fitted configuration.
- `stress`: The final stress achieved.

Side Effects

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

**snails**  
**Snail Mortality Data**

**Description**

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

**Usage**

`snails`

**Format**

The data frame contains the following components:

- **Species**  snail species A (1) or B (2).
- **Exposure**  exposure in weeks.
- **Rel.Hum**  relative humidity (4 levels).
- **Temp**  temperature, in degrees Celsius (3 levels).
- **Deaths**  number of deaths.
- **N**  number of snails exposed.

**stepAIC**  
*Choose a model by AIC in a Stepwise Algorithm*

**Description**  
Performs stepwise model selection by AIC.

**Usage**  
stepAIC(object, scope, scale = 0,  
direction = c("both", "backward", "forward"),  
trace = 1, keep = NULL, steps = 1000, use.start = FALSE,  
k = 2, ...)

**Arguments**  
- **object** an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.
- **scope** defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.
- **scale** used in the definition of the AIC statistic for selecting the models, currently only for *lm* and *aov* models (see *extractAIC* for details).
stepAIC

direction the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".

trace if positive, information is printed during the running of stepAIC. Larger values may give more information on the fitting process.

keep a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.

steps the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

use.start if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for glm (and other fits), but it can also slow them down. Not used in R.

k the multiple of the number of degrees of freedom used for the penalty. Only k = 2 gives the genuine AIC: k = log(n) is sometimes referred to as BIC or SBC.

... any additional arguments to extractAIC. (None are currently used.)

Details

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by update.formula.

There is a potential problem in using glm fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The glm method for extractAIC makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

Where a conventional deviance exists (e.g. for lm, aov and glm fits) this is quoted in the analysis of variance table: it is the unscaled deviance.

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the keep= argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding lm, aov and survreg fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an na.action other than na.fail is used (as is the default in R). We suggest you remove the missing values first.

stormer

The Stormer Viscometer Data

Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form Time = (B1*Viscosity)/(Weight - B2) + E where B1 and B2 are unknown parameters to be estimated, and E is error.

Usage

stormer
Format

The data frame contains the following components:

Viscosity  viscosity of fluid.
Wt  actuating weight.
Time  time taken.

Summary Method Function for Objects of Class 'loglm'

Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using `loglm`.

Usage

```r
## S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)
```

Arguments

- `object`: a fitted `loglm` model object.
- `fitted`: if `TRUE` return observed and expected frequencies in the result. Using `fitted = TRUE` may necessitate re-fitting the object.
- `...`: arguments to be passed to or from other methods.

Details

This function is a method for the generic function `summary()` for class "loglm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

Value

A list is returned for use by `print.summary.loglm`. This has components

- `formula`: the formula used to produce `object`.
- `tests`: the table of test statistics (likelihood ratio, Pearson) for the fit.
- `oe`: if `fitted = TRUE`, an array of the observed and expected frequencies, otherwise NULL.

References

See Also

`loglm`, `summary`
Summary Method Function for Objects of Class 'negbin'

Description

Identical to summary.glm, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

Usage

```r
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

Arguments

- `object`: fitted model object of class `negbin` inheriting from `glm` and `lm`. Typically the output of `glm.nb`.
- `dispersion`: as for `summary.glm`, with a default of 1.
- `correlation`: as for `summary.glm`.
- `...`: arguments passed to or from other methods.

Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class "negbin". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

References

See Also

`summary, glm.nb, negative.binomial, anova.negbin`

Examples

```r
summary(glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log))
```
summary.rlm

Summary Method for Robust Linear Models

Description

summary method for objects of class "rlm"

Usage

## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)

Arguments

object the fitted model. This is assumed to be the result of some fit that produces an
object inheriting from the class rlm, in the sense that the components returned
by the rlm function will be available.

method Should the weighted (by the IWLS weights) or unweighted cross-products ma-
trix be used?

correlation logical. Should correlations be computed (and printed)?

... arguments passed to or from other methods.

Details

This function is a method for the generic function summary() for class "rlm". It can be invoked by
calling summary(x) for an object x of the appropriate class, or directly by calling summary.rlm(x)
regardless of the class of the object.

Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following
components. Printing always takes place if this function is invoked automatically as a method for
the summary function.

correlation The computed correlation coefficient matrix for the coefficients in the model.
cov.unscaled The unscaled covariance matrix; i.e, a matrix such that multiplying it by an
estimate of the error variance produces an estimated covariance matrix for the
coefficients.
sigma The scale estimate.
stddev A scale estimate used for the standard errors.
df The number of degrees of freedom for the model and for residuals.
coefficients A matrix with three columns, containing the coefficients, their standard errors
and the corresponding t statistic.
terms The terms object used in fitting this model.

survey  Student Survey Data

Description

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

Usage

survey

Format

The components of the data frame are:

Sex  The sex of the student. (Factor with levels "Male" and "Female".)
Wt.Hnd  span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.
NW.Hnd  span of non-writing hand.
W.Hnd  writing hand of student. (Factor, with levels "Left" and "Right".)
Fold  "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)
Pulse  pulse rate of student (beats per minute).
Clap  'Clap your hands! Which hand is on top?' (Factor, with levels "Right", "Left", "Neither".)
Exer  how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)
Smoke  how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)
Height  height of the student in centimetres.
M.I  whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)
Age  age of the student in years.

**Synthetic Classification Problem**

**Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used for training and `synth.te` for testing.

**Usage**

- `synth.tr`
- `synth.te`

**Format**

These data frames contain the following columns:

- `xs` x-coordinate
- `ys` y-coordinate
- `yc` class, coded as 0 or 1.

**Source**

---

**Estimate theta of the Negative Binomial**

**Description**

Given the estimated mean vector, estimate theta of the Negative Binomial Distribution.

**Usage**

- `theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)`
- `theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25, trace = FALSE)`
- `theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)`
### Arguments

- **y**: Vector of observed values from the Negative Binomial.
- **mu**: Estimated mean vector.
- **n**: Number of data points (defaults to the sum of weights).
- **dfr**: Residual degrees of freedom (assuming theta known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
- **weights**: Case weights. If missing, taken as 1.
- **limit**: Limit on the number of iterations.
- **eps**: Tolerance to determine convergence.
- **trace**: logical: should iteration progress be printed?

### Details

**theta.md** estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

**theta.ml** uses maximum likelihood.

**theta.mm** calculates the moment estimator of theta by equating the Pearson chi-square $\sum(y - \mu)^2/(\mu + \mu^2/\theta)$ to the residual degrees of freedom.

### Value

The required estimate of theta, as a scalar. For **theta.ml**, the standard error is given as attribute "SE".

### See Also

**glm.nb**

### Examples

```r
quine.nb <- glm.nb(Days ~ .^2, data = quine)
theta.md(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
theta.ml(quine$Days, fitted(quine.nb))
theta.mm(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))

## weighted example
yeast <- data.frame(cbind(numbers = 0:5, fr = c(213, 128, 37, 18, 3, 1)))
fit <- glm.nb(numbers ~ 1, weights = fr, data = yeast)
summary(fit)
mu <- fitted(fit)
theta.md(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
theta.ml(yeast$numbers, mu, limit = 15, weights = yeast$fr)
theta.mm(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
```
topo

*Spatial Topographic Data*

**Description**

The topo data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

**Usage**

`topo`

**Format**

This data frame contains the following columns:

- `x` x coordinates (units of 50 feet)
- `y` y coordinates (units of 50 feet)
- `z` heights (feet)

Traffic

*Effect of Swedish Speed Limits on Accidents*

**Description**

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day \( j \) in 1962 was comparable to day \( j \) in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

`Traffic`

**Format**

This data frame contains the following columns:

- `year` 1961 or 1962.
- `day` of year.
- `limit` was there a speed limit?
- `y` traffic accident count for that day.
truehist

Source

References

truehist

*Plot a Histogram*

Description

Creates a histogram on the current graphics device.

Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
   breaks, prob = TRUE, xlim = range(breaks),
   ymax = max(est), col = "cyan",
   xlab = deparse(substitute(data)), bty = "n", 
   ...)
```

Arguments

data numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.

nbins The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)

h The bin width, a strictly positive number (takes precedence over nbins).

x0 Shift for the bins - the breaks are at x0 + h * (...,-1,0,1,...)

breaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).

prob If true (the default) plot a true histogram. The vertical axis has a relative frequency density scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.

xlim The limits for the x-axis.

ymax The upper limit for the y-axis.

col The colour for the bar fill: the default is colour 5 in the default R palette.

xlab label for the plot x-axis. By default, this will be the name of data.

bty The box type for the plot - defaults to none.

... additional arguments to `rect` or `plot`. 

Details

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

Side Effects

A histogram is plotted on the current device.

**Description**

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

**Usage**

UScereal

**Format**

This data frame contains the following columns:

- **mfr** Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.
- **calories** number of calories in one portion.
- **protein** grams of protein in one portion.
- **fat** grams of fat in one portion.
- **sodium** milligrams of sodium in one portion.
- **fibre** grams of dietary fibre in one portion.
- **carbo** grams of complex carbohydrates in one portion.
- **sugars** grams of sugars in one portion.
- **shelf** display shelf (1, 2, or 3, counting from the floor).
- **potassium** grams of potassium.
- **vitamins** vitamins and minerals (none, enriched, or 100%).

**Source**

**References**

Description

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

Usage

UScrime

Format

This data frame contains the following columns:

- So: indicator variable for a Southern state.
- Ed: mean years of schooling.
- Po1: police expenditure in 1960.
- Po2: police expenditure in 1959.
- LF: labour force participation rate.
- M/F: number of males per 1000 females.
- Pop: state population.
- NW: number of non-whites per 1000 people.
- U1: unemployment rate of urban males 14–24.
- U2: unemployment rate of urban males 35–39.
- GDP: gross domestic product per head.
- Ineq: income inequality.
- Prob: probability of imprisonment.
- Time: average time served in state prisons.
- y: rate of crimes in a particular category per head of population.

Veteran’s Administration Lung Cancer Trial

**Description**

Veteran’s Administration lung cancer trial from Kalbfleisch & Prentice.

**Usage**

**Format**

A data frame with columns:

- **stime**: survival or follow-up time in days.
- **status**: dead or censored.
- **treat**: treatment: standard or test.
- **age**: patient’s age in years.
- **Karn**: Karnofsky score of patient’s performance on a scale of 0 to 100.
- **diag.time**: times since diagnosis in months at entry to trial.
- **cell**: one of four cell types.
- **prior**: prior therapy?

Counts of Waders at 15 Sites in South Africa

**Description**

The wader’s data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

**Usage**

**waders**
Format

This data frame contains the following columns (species)

- S1 Oystercatcher
- S2 White-fronted Plover
- S3 Kitt Lutz’s Plover
- S4 Three-banded Plover
- S5 Grey Plover
- S6 Ringed Plover
- S7 Bar-tailed Godwit
- S8 Whimbrel
- S9 Marsh Sandpiper
- S10 Greenshank
- S11 Common Sandpiper
- S12 Turnstone
- S13 Knot
- S14 Sanderling
- S15 Little Stint
- S16 Curlew Sandpiper
- S17 Ruff
- S18 Avocet
- S19 Black-winged Stilt

The rows are the sites:

- A = Namibia North coast
- B = Namibia North wetland
- C = Namibia South coast
- D = Namibia South wetland
- E = Cape North coast
- F = Cape North wetland
- G = Cape West coast
- H = Cape West wetland
- I = Cape South coast
- J = Cape South wetland
- K = Cape East coast
- L = Cape East wetland
- M = Transkei coast
- N = Natal coast
- O = Natal wetland

House Insulation: Whiteside’s Data

Description

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

Usage

whiteside

Format

The whiteside data frame has 56 rows and 3 columns:

- Insul  A factor, before or after insulation.
- Temp  Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)
- Gas  The weekly gas consumption in 1000s of cubic feet.

Source

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

References

Examples

```r
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  }, xlab = "Average external temperature (deg. C)",
  ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))

width.SJ  

Bandwidth Selection by Pilot Estimation of Derivatives

Description

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))

Arguments

x        a numeric vector
nb       number of bins to use.
upper, lower range over which to search for solution if method = "ste".
method   Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

a bandwidth.

Note

A faster version for large n (thousands) is available in R ≥ 3.4.0 as part of bw.SJ: quadruple its value for comparability with this version.

write.matrix  Write a Matrix or Data Frame

Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

write.matrix(x, file = "", sep = " ", blocksize)

Arguments

x  matrix or data frame.
file  name of output file. The default (""") is the console.
sep  The separator between columns.
blocksize  If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available.

Details

If x is a matrix, supplying blocksize is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If x is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects

A formatted file is produced, with column headings (if x has them) and columns of data.

## IGNORE_RDIFF_END
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```
Chapter 17

The Matrix package

abIndex-class

Class “abIndex” of Abstract Index Vectors

Description

The "abIndex" class, short for “Abstract Index Vector”, is used for dealing with large index vectors more efficiently, than using integer (or numeric) vectors of the kind 2:1000000 or c(0:1e5, 1000:1e6).

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (packageDescription("Matrix")$Maintainer).

Objects from the Class

Objects can be created by calls of the form new("abIndex", ...), but more easily and typically either by as(x, "abIndex") where x is an integer (valued) vector, or directly by abIseq() and combination c(...) of such.

Slots

kind: a character string, one of ("int32", "double", "rleDiff"), denoting the internal structure of the abindex object.

x: Object of class "numLike"; is used (i.e., not of length 0) only iff the object is not compressed, i.e., currently exactly when kind != "rleDiff".

rle0: object of class "rleDiff", used for compression via rle.

Methods

as.numeric, as.integer, as.vector signature(x = "abIndex"): ... [ signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...

coerce signature(from = "numeric", to = "abIndex"): ...

coerce signature(from = "abIndex", to = "numeric"): ...

coerce signature(from = "abIndex", to = "integer"): ...

length signature(x = "abIndex"): ...
**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**: see **Ops** for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"): ...

**Ops** signature(e1 = "abIndex", e2 = "numeric"): ...

**Summary** signature(x = "abIndex"): ...

**show** ("abIndex"): simple **show** method, building on **show(<rleDiff>)**.

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite, is.infinite** ("abIndex"): ditto.

**Note**

This is currently experimental and not yet used for our own code. Please contact us (packageDescription("Matrix")$Maintainer), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package **ff**.

**See Also**

**rle** (**base**) which is used here; **numeric**

**Examples**

```r
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(-3:20,
                  as(abIseq1(-3,20), "vector")))
```

---

**abIseq**

*Sequence Generation of "abIndex", Abstract Index Vectors*

**Description**

Generation of abstract index vectors, i.e., objects of class "abIndex".

abIseq() is designed to work entirely like **seq**, but producing "abIndex" vectors.

abIseq1() is its basic building block, where abIseq1(n,m) corresponds to n:m.

c(x, ...) will return an "abIndex" vector, when x is one.

**Usage**

```r
abIseq1(from = 1, to = 1)
abIseq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
       length.out = NULL, along.with = NULL)

## S3 method for class 'abIndex'
c(...)
```
Arguments

from, to the starting and (maximal) end value of the sequence.
by number: increment of the sequence.
length.out desired length of the sequence. A non-negative number, which for seq and
seq.int will be rounded up if fractional.
along.with take the length from the length of this argument.
... in general an arbitrary number of R objects; here, when the first is an "abIndex"
vector, these arguments will be concatenated to a new "abIndex" object.

Value

An abstract index vector, i.e., object of class "abIndex".

See Also

the class abIndex documentation; rep2abI() for another constructor; rle (base).

Examples

stopifnot(identical(-3:20,
as(abIseq(-3,20), "vector")))

try( ## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)

all-methods "Matrix" Methods for Functions all() and any()

Description

The basic R functions all and any now have methods for Matrix objects and should behave as for
matrix ones.

Methods

all signature(x = "Matrix", ..., na.rm = FALSE): ...
any signature(x = "Matrix", ..., na.rm = FALSE): ...
all signature(x = "ldenseMatrix", ..., na.rm = FALSE): ...
all signature(x = "lsparseMatrix", ..., na.rm = FALSE): ...

Examples

M <- Matrix(1:12 +0, 3,4)
all(M >= 1) # TRUE
any(M < 0 ) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0 ) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
all.equal-methods  Matrix Package Methods for Function all.equal()

Description

Methods for function `all.equal()` (from R package `base`) are defined for all `Matrix` classes.

Methods

target = "Matrix", current = "Matrix" \n
`target = "ANY", current = "Matrix"` \n
`target = "Matrix", current = "ANY"` these three methods are simply using `all.equal.numeric` directly and work via `as.vector()`.

There are more methods, notably also for "sparseVector"'s, see `showMethods("all.equal")`.

Examples

```r
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
                     lu.@L %*% lu.@U),
          with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
                           L %*% U)),
          with(ex, all.equal(as(A, "CsparseMatrix"),
                           t(P) %*% L %*% U %*% t(Q))))
```

atomicVector-class  Virtual Class "atomicVector" of Atomic Vectors

Description

The class "atomicVector" is a virtual class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

Objects from the Class

A virtual Class: No objects may be created from it.

Methods

In the `Matrix` package, the "atomicVector" is used in signatures where typically "old-style" "matrix" objects can be used and can be substituted by simple vectors.

Extends

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".
**band**

**Author(s)**

Martin Maechler

**See Also**

`is.atomic`, `integer`, `numeric`, `complex`, etc.

**Examples**

```r
showClass("atomicVector")
```

---

### band

**Extract bands of a matrix**

**Description**

Return the matrix obtained by setting to zero elements below a diagonal (`triu`), above a diagonal (`tril`), or outside of a general band (`band`).

**Usage**

```r
band(x, k1, k2, ...)
triu(x, k = 0, ...)
tril(x, k = 0, ...)
```

**Arguments**

- `x` : a matrix-like object
- `k, k1, k2` : integers specifying the diagonals that are not set to zero. These are interpreted relative to the main diagonal, which is `k=0`. Positive and negative values of `k` indicate diagonals above and below the main diagonal, respectively.
- `...` : optional arguments passed methods (currently unused by package `Matrix`)

**Details**

`triu(x, k)` is equivalent to `band(x, k, dim(x)[2])`. Similarly, `tril(x, k)` is equivalent to `band(x, -dim(x)[1], k).

**Value**

An object of a suitable matrix class, inheriting from `triangularMatrix` where appropriate. It inherits from `sparseMatrix` if and only if `x` does.

**Methods**

- `x = "CsparseMatrix"` : method for compressed, sparse, column-oriented matrices.
- `x = "RsparseMatrix"` : method for compressed, sparse, row-oriented matrices.
- `x = "TsparseMatrix"` : method for sparse matrices in triplet format.
- `x = "diagonalMatrix"` : method for diagonal matrices.
- `x = "denseMatrix"` : method for dense matrices in packed or unpacked format.
- `x = "matrix"` : method for traditional matrices of implicit class `matrix`.
See Also

\texttt{bandSparse} for the \textit{construction} of a banded sparse matrix directly from its non-zero diagonals.

Examples

```r
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)  # lower triangle
tril(mm, -1)  # strict lower triangle
triu(mm, 1)  # strict upper triangle
band(mm, -1, 2)  # general band

## Generically banded matrices

(m5 <- Matrix(rnorm(25), ncol = 5))
tril(m5)  # lower triangle
tril(m5, -1)  # strict lower triangle
triu(m5, 1)  # strict upper triangle
band(m5, -1, 2)  # general band

(m65 <- Matrix(rnorm(30), ncol = 5))  # not square
triu(m65)  # result not "dtrMatrix" unless square

## Covariance matrix

(sm5 <- crossprod(m5))  # symmetric
band(sm5, -1, 1)  # "dsyMatrix": symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix")  # often preferable

(sm <- round(crossprod(triu(mm/2))))  # sparse symmetric ("dsC*")
band(sm, -1, 1)  # remains "dsC", *however*
band(sm, -2, 1)  # -> "dgC"
```

\texttt{bandSparse}  

**Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals**

\texttt{Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals}

**Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

\texttt{bandSparse(n, m = n, k, diagonals, symmetric = FALSE, repr = "C", giveCsparse = (repr == "C"))}

**Arguments**

- \texttt{n, m}  
  the matrix dimension \((n, m) = (nrow, ncol)\).
- \texttt{k}  
  integer vector of "diagonal numbers", with identical meaning as in \texttt{band(*, k)}, i.e., relative to the main diagonal, which is \texttt{k=0}. 
bandSparse

| diagonals | optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class \texttt{nMatrix}. diagonals can also be $n' \times d$ matrix, where $d \leq \text{length(k)}$ and $n' \geq \min(n, m)$. In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals. |
| symmetric | logical; if true the result will be symmetric (inheriting from class \texttt{symmetricMatrix}) and only the upper or lower triangle must be specified (via \texttt{k} and \texttt{diagonals}). |
| repr | character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes \texttt{CsparseMatrix}, \texttt{TsparseMatrix}, or \texttt{RsparseMatrix}. |
| giveCsparse | (deprecated, replaced with \texttt{repr}): logical indicating if the result should be a \texttt{CsparseMatrix} or a \texttt{TsparseMatrix}, where the default was \texttt{TRUE}, and now is determined from \texttt{repr}; very often Csparse matrices are more efficient subsequently, but not always. |

Value

a sparse matrix (of class \texttt{CsparseMatrix}) of dimension $n \times m$ with diagonal “bands” as specified.

See Also

\texttt{band}, for extraction of matrix bands; \texttt{bdiag}, \texttt{diag}, \texttt{sparseMatrix}, \texttt{Matrix}.

Examples

Bs[1:15, 1:30]

## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),

Value

a sparse matrix (of class \texttt{CsparseMatrix}) of dimension $n \times m$ with diagonal “bands” as specified.
bdiag

Construct a Block Diagonal Matrix

Description
Build a block diagonal matrix given several building block matrices.

Usage
bdiag(...) .bdiag(lst)

Arguments
... individual matrices or a list of matrices.
lst non-empty list of matrices.

Details
For non-trivial argument list, bdiag() calls .bdiag(). The latter maybe useful to programmers.

Value
A sparse matrix obtained by combining the arguments into a block diagonal matrix.
The value of bdiag() inherits from class CsparseMatrix, whereas .bdiag() returns a TsparseMatrix.

Note
This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.
It is currently inefficient for the case of many small dense block matrices. For the case of many dense \( k \times k \) matrices, the bdiag_m() function in the 'Examples' is an order of magnitude faster.

Author(s)
Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on TsparseMatrix objects.

See Also
Diagonal for constructing matrices of class diagonalMatrix, or kronecker which also works for "Matrix" inheriting matrices.
bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals.
Note that other CRAN R packages have own versions of bdiag() which return traditional matrices.
Examples

```r
bdiag(matrix(1:4, 2), diag(3))
## combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)

dim(T12 <- bdiag_m(l12)) 48 x 48
T12[1:20, 1:20]
```
Description

The Bunch-Kaufman Decomposition of a square symmetric matrix $A$ is $A = PLDL'P'$ where $P$ is a permutation matrix, $L$ is unit-lower triangular and $D$ is block-diagonal with blocks of dimension $1 \times 1$ or $2 \times 2$.

This is a generalization of a pivoting $LDL'$ Cholesky decomposition.

Usage

```r
## S4 method for signature 'dsyMatrix'
BunchKaufman(x, ...)
## S4 method for signature 'dspMatrix'
BunchKaufman(x, ...)
## S4 method for signature 'matrix'
BunchKaufman(x, uplo = NULL, ...)
```

Arguments

- `x`: a symmetric square matrix.
- `uplo`: optional string, "U" or "L" indicating which “triangle” half of `x` should determine the result. The default is "U" unless `x` has a `uplo` slot which is the case for those inheriting from class `symmetricMatrix`, where `x@uplo` will be used.
- `...`: potentially further arguments passed to methods.

Details

FIXME: We really need an `expand()` method in order to work with the result!

Value

an object of class `BunchKaufman`, which can also be used as a (triangular) matrix directly. Somewhat amazingly, it inherits its `uplo` slot from `x`.

Methods

Currently, only methods for `dense` numeric symmetric matrices are implemented. To compute the Bunch-Kaufman decomposition, the methods use either one of two Lapack routines:

- `x = "dspMatrix"` routine `dsptrf()`; whereas
- `x = "dsyMatrix"`, and
- `x = "matrix"` use `dsytrf()`.

References

The original LAPACK source code, including documentation; [https://netlib.org/lapack/double/dsytrf.f](https://netlib.org/lapack/double/dsytrf.f) and [https://netlib.org/lapack/double/dsptrf.f](https://netlib.org/lapack/double/dsptrf.f)

See Also

The resulting class, `BunchKaufman`. Related decompositions are the LU, `lu`, and the Cholesky, `chol` (and for `sparse` matrices, `Cholesky`).
Examples

```r
data(CAex)
dim(CAex)
isSymmetric(CAex)# TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
  bk. <- BunchKaufman(CAs)
## does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA
pkCA <- pack(bkCA)
stopifnot(is(bkCA, "triangularMatrix"),
is(pkCA, "triangularMatrix"),
is(pkCA, "packedMatrix"))

image(bkCA)# shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
## an upper triangular 72x72 matrix with only 144 non-zero entries
stopifnot(is(R.CA, "triangularMatrix"), is(R.CA, "CsparseMatrix"))
```

Description

An example of a sparse matrix for which `eigen()` seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help ([https://stat.ethz.ch/mailman/listinfo/r-help](https://stat.ethz.ch/mailman/listinfo/r-help)), by Casper J Albers, Open University, UK.

Usage

```r
data(CAex)
```

Format

This is a 72 × 72 symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

Details

Historical note (2006-03-30): In earlier versions of R, `eigen(CAex)` fell into an infinite loop whereas `eigen(CAex, EISPACK=TRUE)` had been okay.

Examples

```r
data(CAex)
str(CAex) # of class "dgCMatrix"

image(CAex)# -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
```
```r
## and
stopifnot(class(sCA) == "dsCMatrix",
     as(sCA, "matrix") == as(CAex, "matrix"))
```

---

cBind

### Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `...`. Now, when S4 objects are found among the arguments, base `cbind()` and `rbind()` internally “dispatch” recursively, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

`cbind2()` and `rbind2()` are from the `methods` package, i.e., standard R, and have been provided for binding together two matrices, where in Matrix, we have defined methods for these and the 'Matrix' matrices.

### Usage

```r
## cbind(..., deparse.level = 1)
## rbind(..., deparse.level = 1)
```

### Arguments

- `..., x, y` matrix-like R objects to be bound together, see `cbind` and `rbind`.
- `sparse` option `logical` indicating if the result should be sparse, i.e., formally inheriting from "sparseMatrix". The default, `NA`, decides from the "sparsity" of `x` and `y`, see e.g., the R code in `selectMethod(cbind2, c("sparseMatrix","denseMatrix"))`.
- `deparse.level` integer determining under which circumstances column and row names are built from the actual arguments’ ‘expression’, see `cbind`.

### Value

typically a ‘matrix-like’ object of a similar `class` as the first argument in `...`.

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries is than non-zero ones (as the default `sparse` in `Matrix()`).
Historical Remark

Before R version 3.2.0 (April 2015), we have needed a substitute for S4-enabled versions of \texttt{cbind} and \texttt{rbind}, and provided \texttt{cBind} and \texttt{rBind} with identical syntax and semantic in order to bind together multiple matrices ("matrix" or "Matrix" and vectors. With R version 3.2.0 and newer, \texttt{cbind} and \texttt{rbind} are deprecated and produce a deprecation warning (via \texttt{.Deprecated}), and your code should start using \texttt{cbind()} and \texttt{rbind()} instead.

Our class definition help pages mentioning \texttt{cbind2()} and \texttt{rbind2()} methods: "denseMatrix", "diagonalMatrix", "indMatrix".

Examples

(a <- matrix(c(2:1,1:2), 2,2))

(M1 <- cbind(0, rbind(a, 7))) # a traditional matrix

D <- Diagonal(2)
(M2 <- cbind(4, a, D, -1, D, 0)) # a sparse Matrix

stopifnot(validObject(M2), inherits(M2, "sparseMatrix"), dim(M2) == c(2,9))

CHMfactor-class  

\textit{CHOLMOD-based Cholesky Factorizations}

Description

The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "CHMsimpl") or supernodal (virtual class "CHMsuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMsimpl" and "dCHMsuper") or symbolic factorizations (classes "nCHMsimpl" and "nCHMsuper").

Usage

\texttt{isLDL(x)}

\texttt{update(object, parent, mult = 0, ...)}

\texttt{.updateCHMfactor(object, parent, mult)}

\texttt{solve(a, b, system = c("A","LDLt","LD","DLt","L","Lt","D","P","Pt"), ...)}

\texttt{-----} see below
Arguments

- **x, object, a**
  - `x` is a "CHMfactor" object (almost always the result of `Cholesky()`).
  - `object` is a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated object. If `parent` is symmetric, of class "dsCMatrix", then `object` should be a decomposition of a matrix with the same nonzero pattern as `parent`. If `parent` is not symmetric then `object` should be the decomposition of a matrix with the same nonzero pattern as `tcrossprod(parent)`.
  - `parent` is a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated `object`. If `parent` is symmetric, of class "dsCMatrix", then `object` should be a decomposition of a matrix with the same nonzero pattern as `parent`. If `parent` is not symmetric then `object` should be the decomposition of a matrix with the same nonzero pattern as `tcrossprod(parent)`.
  - Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to `dsparseMatrix` and `CsparseMatrix` if needed.

- **mult**
  - A numeric scalar (default 0). `mult` times the identity matrix is (implicitly) added to `parent` or `tcrossprod(parent)` before updating the decomposition object.

- **...**
  - Potentially further arguments to the methods.

Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper", ...)` but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

Slots

- "CHMfactor" and all classes inheriting from it:
  - **perm**: An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.
  - **colcount**: Object of class "integer" ....
  - **type**: Object of class "integer" ....

- Slots of the non virtual classes "[dl]CHM(super|simpl)":
  - **p**: Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".
  - **i**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".
  - **x**: For the "d*" classes: "numeric" - the non-zero elements of the matrix.

Methods

- **isLDL** (`x`) returns a logical indicating if `x` is an LDL' decomposition or (when FALSE) an LL' one.
- **coerce** signature(`from = "CHMfactor", to = "sparseMatrix"`) (or equivalently, `to = "Matrix"` or `to = "triangularMatrix"`)
  - `as(*, "sparseMatrix")` returns the lower triangular factor `L` from the LL' form of the Cholesky factorization. Note that (currently) the factor from the LL' form is always returned, even if the "CHMfactor" object represents an LDL' decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the expand method for obtaining both the permutation matrix, `P`, and the lower Cholesky factor, `L`.
- **coerce** signature(`from = "CHMfactor", to = "pMatrix"`) returns the permutation matrix `P`, representing the fill-reducing permutation used in the decomposition.
**CHMfactor-class**

expand signature(x = "CHMfactor") returns a list with components \(P\), the matrix representing the fill-reducing permutation, and \(L\), the lower triangular Cholesky factor. The original positive-definite matrix \(A\) corresponds to the product \(A = P'LL'P\). Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying drop0 to it. However, the extra 'non-zeros' should be very small in magnitude.

image signature(x = "CHMfactor"): Plot the image of the lower triangular factor, \(L\), from the decomposition. This method is equivalent to image(as(x, "sparseMatrix")) so the comments in the above description of the coerce method apply here too.

solve signature(a = "CHMfactor", b = "ddenseMatrix"), system= *:
The solve methods for a "CHMfactor" object take an optional third argument system whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", or "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve \(Ax = b\) for \(x\) where \(A\) is the sparse, positive-definite matrix that was factored to produce \(a\). Analogously, system = "L" returns the solution \(x\), of \(Lx = b\). Similarly, for all system codes but "P" and "Pt" where, e.g., \(x < - solve(a, b, system= "P")\) is equivalent to \(x < - P' x\) %*% b. See also solve-methods.

determinant signature(x = "CHMfactor", logarithm = "logical") returns the determinant (or the logarithm of the determinant, if logarithm = TRUE, the default) of the factor \(L\) from the \(LL'\) decomposition (even if the decomposition represented by \(x\) is of the \(LDL'\) form (!)). This is the square root of the determinant (half the logarithm of the determinant when logarithm = TRUE) of the positive-definite matrix that was decomposed.

update signature(object = "CHMfactor"), parent. The update method requires an additional argument parent, which is either a "dsCMatrix" object, say \(A\), (with the same structure of nonzeros as the matrix that was decomposed to produce object) or a general "dgCMatrix", say \(M\), where \(A := MM'\) (== tcrossprod(parent)) is used for \(A\). Further it provides an optional argument mult, a numeric scalar. This method updates the numeric values in object to the decomposition of \(A + mI\) where \(A\) is the matrix above (either the parent or \(MM'\)) and \(m\) is the scalar mult. Because only the numeric values are updated this method should be faster than creating and decomposing \(A + mI\). It is not uncommon to want, say, the determinant of \(A + mI\) for many different values of \(m\). This method would be the preferred approach in such cases.

See Also

Cholesky, also for examples; class dgCMatrix.

Examples

```r
## An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
    i = sample(n, nnz, replace = TRUE),
    j = sample(m, nnz, replace = TRUE),
    x = round(rnorm(nnz),1))
XX <- crossprod(M1) ## = M1 ' M1 = M M'  where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
str(CX) ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P)) ## == L' P
PLL.P <- crossprod(L.P) ## == (L' P)' L' P == P' L' L' P = XX = M M'
```

b <- sample(m)
stopifnot(all.equal(PLLP, XX,
  all(as.vector(solve(CX, b, system="P")) == r%*%b),
  all(as.vector(solve(CX, b, system="Pt")) == t(r%*%b)) )

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M1), mult=pi) # with the original M, where XX = M M
stopifnot(all.equal(u1,u2, tol=1e-14))

## [ See help(Cholesky) for more examples ]

chol

The Cholesky Decomposition - 'Matrix' S4 Generic and Methods

Description

Compute the Cholesky factorization of a real symmetric positive definite square matrix.

Usage

chol(x, ...)
## S4 method for signature 'dsyMatrix'
chol(x, ...)
## S4 method for signature 'dspMatrix'
chol(x, ...)
## S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
## S4 method for signature 'dsRMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)
## S4 method for signature 'dsTMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)

Arguments

x a (sparse or dense) square matrix, here inheriting from class Matrix; if x is not symmetric positive definite, then an error is signalled.
pivot logical indicating if pivoting is to be used. Currently, this is not made use of for dense matrices.
cache logical indicating if the result should be cached in x@factors; note that this argument is experimental and only available for certain classes inheriting from compMatrix.
... potentially further arguments passed to methods.

Details

Note that these Cholesky factorizations are typically cached with x currently, and these caches are available in x@factors, which may be useful for the sparse case when pivot = TRUE, where the permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider Cholesky() in such situations, since chol(x, pivot=TRUE) uses the same algorithm (but not the same return value!) as Cholesky(x, LDL=FALSE) and chol(x) corresponds to Cholesky(x, perm=FALSE, LDL=FALSE).
Value

A matrix of class Cholesky, i.e., upper triangular: \( R \) such that \( R' R = x \) (if pivot=FALSE) or \( P' R' R P = x \) (if pivot=TRUE and \( P \) is the corresponding permutation matrix).

Methods

Use `showMethods(chol)` to see all; some are worth mentioning here:

- `chol` signature \((x = \text{"dpoMatrix"})\): Returns (and stores) the Cholesky decomposition of \( x \), via LAPACK routines `dlacpy` and `dpotrF`.
- `chol` signature \((x = \text{"dppMatrix"})\): Returns (and stores) the Cholesky decomposition of \( x \), via LAPACK routine `dpptrf`.
- `chol` signature \((x = \text{"dsyMatrix"})\): works via "dpoMatrix", see class `dpoMatrix`.
- `chol` signature \((x = \text{"dspMatrix"})\): works via "dppMatrix", see class `dppMatrix`.
- `chol` signature \((x = \text{"dsCMatrix"})\): Returns (and stores) the Cholesky decomposition of \( x \). If pivot is TRUE, then the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of \( x \) so as to reduce fill-in.
- `chol` signature \((x = \text{"dsRMatrix"})\): works via "dsCMatrix", see class `dsCMatrix`.
- `chol` signature \((x = \text{"dsTMatrix"})\): works via "dsCMatrix", see class `dsCMatrix`.

References

See Also

The default from base, chol; for more flexibility (but not returning a matrix!) Cholesky.

Examples

```r
showMethods(chol, inherited = FALSE) # show different methods

sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA,32,77))
(c2 <- chol(sy2))#-> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)

## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector"))) # 5 x 5
(R <- chol(mm)) ## default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot( identical(R, R2), all.equal(crossprod(R), mm) )
(R. <- chol(mm, pivot=TRUE))# nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),

```

all.equal(prod(diag(R)), det(R)),
all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
(M2 <- toeplitz(as(c(1,.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
## For the experts, check the caching of the factorizations:
ff <- M2@factors["spdCholesky"]
FF <- M2@factors["sPdCholesky"]
L1 <- as(ff, "Matrix")# pivot=FALSE: no perm.
L2 <- as(FF, "Matrix"); P2 <- as(FF, "pMatrix")
stopifnot(identical(t(L1), c2),
    all.equal(t(L2), C2, tolerance=0),##-- why not identical()? 
    all.equal(M2, tcrossprod(L1)),  # M = LL'
    all.equal(M2, crossprod(crossprod(L2, P2)))## M = P'L L'P 
)

chol2inv-methods

Inverse from Choleski or QR Decomposition – Matrix Methods

Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute \((X'X)^{-1}\) from the \((R)\) part of the QR decomposition of \(X\).
Even more generally, given an upper triangular matrix \(R\), compute \((R'R)^{-1}\).

Methods

- \(x = "ANY"\) the default method from base, see chol2inv, for traditional matrices.
- \(x = "dtrMatrix"\) method for the numeric triangular matrices, built on the same LAPACK DPOTRI function as the base method.
- \(x = "denseMatrix"\) if \(x\) is coercable to a triangularMatrix, call the "dtrMatrix" method above.
- \(x = "sparseMatrix"\) if \(x\) is coercable to a triangularMatrix, use solve() currently.

See Also

chol (for Matrix objects); further, chol2inv (from the base package), solve.

Examples

(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cm <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cm) %*% cm # the identity
stopifnot(all(chol2inv(cm) %*% M - Diagonal(nrow(M))) < 1e-10)
Description

Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically `chol()` should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

Usage

```r
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)
```

Arguments

- **A**: sparse symmetric matrix. No missing values or IEEE special values are allowed.
- **perm**: logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of `A`. Default is `TRUE`.
- **LDL**: logical scalar indicating if the decomposition should be computed as LDL' where `L` is a unit lower triangular matrix. The alternative is LL' where `L` is lower triangular with arbitrary diagonal elements. Default is `TRUE`. Setting it to `NA` leaves the choice to a CHOLMOD-internal heuristic.
- **super**: logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is `FALSE`. Setting it to `NA` leaves the choice to a CHOLMOD-internal heuristic.
- **Imult**: numeric scalar which defaults to zero. The matrix that is decomposed is `A+m*I` where `m` is the value of `Imult` and `I` is the identity matrix of order `ncol(A)`.
- **...**: further arguments passed to or from other methods.

Details

This is a generic function with special methods for different types of matrices. Use `showMethods("Cholesky")` to list all the methods for the `Cholesky` generic.

The method for class `dsCMatrix` of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use `chol(.)`.

Note that if `perm=TRUE` (default), the decomposition is

\[ A = P'LDP' = P'LL'P, \]

where `L` can be extracted by `as(*, "Matrix"), \ P` by `as(*, "pMatrix")` and both by `expand(*), see the class CHMfactor documentation.

Note that consequently, you cannot easily get the “traditional” cholesky factor \( \tilde{R} \), from this decomposition, as

\[ R'R = A = P'LL'P = P'R\tilde{R}P = (\tilde{R}P)'(\tilde{R}P), \]

but \( \tilde{R}P \) is not triangular even though \( \tilde{R} \) is.
an object inheriting from either "CHMsuper", or "CHMsimpl", depending on the super argument; both classes extend "CHMfactor" which extends "MatrixFactorization".

In other words, the result of Cholesky() is not a matrix, and if you want one, you should probably rather use chol(), see Details.

**References**

**See Also**

Class definitions CHMfactor and dsCMatrix and function expand. Note the extra solve(*, system = .) options in CHMfactor.

Note that chol() returns matrices (inheriting from "Matrix") whereas Cholesky() returns a "CHMfactor" object, and hence a typical user will rather use chol(A).

**Examples**

data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'sPDCholesky' (simpl)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'sPDCholesky' *and* 'SPdCholesky'
str(cm1 <- as(C1, "sparseMatrix"))
 estr(cm <- as(Cm, "sparseMatrix"))# hmm: super is *less* sparse here

```
cm1[1:20, 1:20]
```

b <- matrix(c(rep(0, 711), 1), ncol = 1)
## solve(Cm, b) by default solves Ax = b, where A = Cm*Cm (= mtm)!
## hence, the identical() check *should* work, but fails on some GOTOblas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b)),
          all.equal(x, solve(mtm, b)))

```
Cn <- Cholesky(mtm, perm = FALSE)# no permutation -- much worse:
 sizes <- c(simple = object.size(C1),
           super = object.size(Cm),
           noPerm = object.size(Cn))
## simple is 100, super= 137, noPerm= 812 :
oquote(cbind(format(100 * sizes / sizes[1], digits=4)))
```

```
## Visualize the sparseness:
dq <- function(ch) paste("",ch,"", sep="") # dQuote(<UTF-B>) gives bad plots

### Cholesky-class

**Cholesky and Bunch-Kaufman Decompositions**

#### Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "BunchKaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their packed storage versions.

#### Objects from the Class

Objects can be created by calls of the form `new("Cholesky", ...)` or `new("BunchKaufman", ...), etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "dpoMatrix" or "dsyMatrix" class or as a side-effect of other functions applied to "dpoMatrix" objects (see `dpoMatrix`).

#### Slots

A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "dtrMatrix" class.

- `uplo`: inherited from the "dtrMatrix" class.
- `diag`: inherited from the "dtrMatrix" class.
- `x`: inherited from the "dtrMatrix" class.
- `Dim`: inherited from the "dtrMatrix" class.
Dimnames: inherited from the "dtrMatrix" class.

A Bunch-Kaufman decomposition also extends the "dtrMatrix" class and has a perm slot representing a permutation matrix. The packed versions extend the "dtpMatrix" class.

**Extends**

Class "MatrixFactorization" and "dtrMatrix", directly. Class "dgeMatrix", by class "dtrMatrix". Class "Matrix", by class "dtrMatrix".

**Methods**

Both these factorizations can directly be treated as (triangular) matrices, as they extend "dtrMatrix", see above. There are currently no further explicit methods defined with class "Cholesky" or "BunchKaufman" in the signature.

**Note**

1. Objects of class "Cholesky" typically stem from chol(D), applied to a dense matrix D.
   
   On the other hand, the function Cholesky(S) applies to a sparse matrix S, and results in objects inheriting from class `CHMfactor`.

2. For traditional matrices m, chol(m) is a traditional matrix as well, triangular, but simply an $n \times n$ numeric matrix. Hence, for compatibility, the "Cholesky" and "BunchKaufman" classes (and their "p*" packed versions) also extend triangular Matrix classes (such as "dtrMatrix"). Consequently, determinant(R) for R <- chol(A) returns the determinant of R, not of A. This is in contrast to class `CHMfactor` objects C, where determinant(C) gives the determinant of the original matrix A, for C <- Cholesky(A), see also the determinant method documentation on the class `CHMfactor` page.

**See Also**

Classes `dtrMatrix`, `dpoMatrix`; function `chol`.

Function `Cholesky` resulting in class `CHMfactor` objects, not class "Cholesky" ones, see the section 'Note'.

**Examples**

(sm <- pack(Matrix(diag(5) + 1))) # dspMatrix

signif(csm <- chol(sm), 4)

(pm <- crossprod(Matrix(rnorm(18), nrow = 6, ncol = 3)))

(ch <- chol(pm))

if (toupper(ch@uplo) == "U") # which is TRUE
crossprod(ch)

stopifnot(all.equal(as(crossprod(ch), "matrix"),
                     as(pm, "matrix"), tolerance=1e-14))
colSums

Form Row and Column Sums and Means

Description

Form row and column sums and means for objects, for \texttt{sparseMatrix} the result may optionally be sparse (\texttt{sparseVector}), too. Row or column names are kept respectively as for \texttt{base} matrices and \texttt{colSums} methods, when the result is \texttt{numeric} vector.

Usage

\begin{verbatim}
colSums(x, na.rm = FALSE, dims = 1L, ...)
rowSums(x, na.rm = FALSE, dims = 1L, ...)
colMeans(x, na.rm = FALSE, dims = 1L, ...)
rowMeans(x, na.rm = FALSE, dims = 1L, ...)

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE,
         dims = 1L, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE,
         dims = 1L, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE,
         dims = 1L, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE,
         dims = 1L, sparseResult = FALSE)
\end{verbatim}

Arguments

- \texttt{x} a Matrix, i.e., inheriting from \texttt{Matrix}.
- \texttt{na.rm} logical. Should missing values (including NaN) be omitted from the calculations?
- \texttt{dims} completely ignored by the \texttt{Matrix} methods.
- \texttt{...} potentially further arguments, for method \texttt{<-} generic compatibility.
- \texttt{sparseResult} logical indicating if the result should be sparse, i.e., inheriting from class \texttt{sparseVector}. Only applicable when \texttt{x} is inheriting from a \texttt{sparseMatrix} class.

Value

returns a numeric vector if \texttt{sparseResult} is \texttt{FALSE} as per default. Otherwise, returns a \texttt{sparseVector}.

\texttt{dimnames(x)} are only kept (as \texttt{names(v)}) when the resulting \texttt{v} is \texttt{numeric}, since \texttt{sparseVectors} do not have names.

See Also

- \texttt{colSums} and the \texttt{sparseVector} classes.
Examples

```r
(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0'; drop those:
MM <- drop0(MM)
length(MM@x) # 32

cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
  identical(cm, as.numeric(scm)))
rowSums (MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero

## Since we have no 'NA's, these two are equivalent:
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
  rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
  rowMeans(Diagonal(16)) == 1/16,
  colSums(Diagonal(7)) == 1)

## dimnames(x) --> names( <value> ) :
dimnames(M) <- list(paste0("r", 1:7), paste0("V",1:8))
M
colSums(M)
rowMeans(M)

## Assertions :
stopifnot(all.equal(colSums(M),
  setNames(c(1,1,6,6,6,6,2), colnames(M))),
  all.equal(rowMeans(M), structure(c(1,1,4,8,12,3,2) / 8,
  .Names = paste0("r", 1:7)))
```

compMatrix-class

Class "compMatrix" of Composite (Factorizable) Matrices

Description

Virtual class of composite matrices; i.e., matrices that can be factorized, typically as a product of simpler matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

- factors: Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e., list(), initially and is updated automagically whenever a matrix factorization is computed.

- Dim, Dimnames: inherited from the Matrix class, see there.

Extends

Class "Matrix", directly.
Methods

`dimnames<-` signature(x = "compMatrix", value = "list"): set the dimnames to a list of length 2, see `dimnames<-`. The factors slot is currently reset to empty, as the factorization dimnames would have to be adapted, too.

See Also

The matrix factorization classes "MatrixFactorization" and their generators, `lu()`, `qr()`, `chol()` and `Cholesky()`, `BunchKaufman()`, `Schur()`.

condest

`Compute Approximate CONDition number and 1-Norm of (Large) Matrices`

Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix A. It works by apply a fast randomized approximation of the 1-norm, `norm(A, "1")`, through `onenormest(.)`.

Usage

```r
condest(A, t = min(n, 5), normA = norm(A, "1"),
   silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n,
   silent = FALSE, quiet = silent,
   iter.max = 10, eps = 4 * .Machine$double.eps)
```

Arguments

- **A**: a square matrix, optional for `onenormest()`, where instead of A, A.x and At.x can be specified, see there.
- **t**: number of columns to use in the iterations.
- **normA**: number; (an estimate of) the 1-norm of A, by default `norm(A, "1")`; may be replaced by an estimate.
- **silent**: logical indicating if warning and (by default) convergence messages should be displayed.
- **quiet**: logical indicating if convergence messages should be displayed.
- **A.x, At.x**: when A is missing, these two must be given as functions which compute A %*% x, or t(A) %*% x, respectively.
- **n**: `nrow(A)`, only needed when A is not specified.
- **iter.max**: maximal number of iterations for the 1-norm estimator.
- **eps**: the relative change that is deemed irrelevant.
condest

Details

condest() calls lu(A), and subsequently onenormest(A x = , At x = ) to compute an approximate norm of the inverse of A, A$^{-1}$, in a way which keeps using sparse matrices efficiently when A is sparse.

Note that onenormest() uses random vectors and hence both functions’ results are random, i.e., depend on the random seed, see, e.g., set.seed().

Value

Both functions return a list; condest() with components,

- `est` a number > 0, the estimated (1-norm) condition number $\tilde{\kappa}$; when $r := rcond(A), 1/\tilde{\kappa} \approx r$.
- `v` the maximal $Ax$ column, scaled to norm(v) = 1. Consequently, norm(Av) = norm(A)/est; when est is large, v is an approximate null vector.

The function onenormest() returns a list with components,

- `est` a number > 0, the estimated norm(A, "1").
- `v` 0-1 integer vector length n, with an 1 at the index $j$ with maximal column $A[,j]$ in A.
- `w` numeric vector, the largest $Ax$ found.
- `iter` the number of iterations used.

Author(s)

This is based on octave’s condest() and onenormest() implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

References

See Also

norm, rcond.

Examples

data(KNex)
mtm <- with(KNex, crossprod(mm))
system.time(ce <- condest(mtm))
sum(abs(ce$v)) ## || v ||_1 == 1
## Proof that || A v || = || A || / est (as ||v|| = 1):
stopifnot(all.equal(norm(mtm %*% ce$v),
                  norm(mtm) / ce$est))

## reciprocal
1 / ce$est
system.time(rc <- rcond(mtm)) # takes ca 3 x longer
rc
all.equal(rc, 1/ce$est) # TRUE -- the approximation was good

one <- onenormest(mtm)
str(one) ## est = 12.3
## the maximal column:
which(one$v == 1) # mostly 4, rarely 1, depending on random seed

---

CsparsesMatrix-class

Class "CsparsesMatrix" of Sparse Matrices in Column-compressed Form

Description

The "CsparsesMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("CsparsesMatrix") for its subclasses.

Slots

i: Object of class "integer" of length nnzero (number of non-zero elements). These are the 0-based row numbers for each non-zero element in the matrix, i.e., i must be in 0:(nrow(.)-1).

p: integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. @p is of length ncol(.) + 1, with p[1] == 0 and p[length(p)] == nnzero, such that in fact, diff(.@p) are the number of non-zero elements for each column.

In other words, m@p[1:ncol(m)] contains the indices of those elements in m@x that are the first elements in the respective column of m.

Dim, Dimnames: inherited from the superclass, see the sparseMatrix class.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

matrix products %*%, crossprod() and tcrossprod(), several solve methods, and other matrix methods available:

signature(e1 = "CsparsesMatrix", e2 = "numeric"): ...

Arith signature(e1 = "numeric", e2 = "CsparsesMatrix"): ...

Math signature(x = "CsparsesMatrix"): ...

band signature(x = "CsparsesMatrix"): ...

- signature(e1 = "CsparsesMatrix", e2 = "numeric"): ...

+ signature(e1 = "CsparsesMatrix", e2 = "numeric"): ...

+ signature(e1 = "numeric", e2 = "CsparsesMatrix"): ...

coerce signature(from = "CsparsesMatrix", to = "TsparseMatrix"): ...

coerce signature(from = "CsparsesMatrix", to = "denseMatrix"): ...

coerce signature(from = "CsparsesMatrix", to = "matrix"): ...

coerce signature(from = "CsparsesMatrix", to = "lsparseMatrix"): ...
coerce signature(from = "CsparseMatrix", to = "nsparseMatrix"): ...
coerce signature(from = "TsparseMatrix", to = "CsparseMatrix"): ...
coerce signature(from = "denseMatrix", to = "CsparseMatrix"): ...
diag signature(x = "CsparseMatrix"): ...
gamma signature(x = "CsparseMatrix"): ...
lgamma signature(x = "CsparseMatrix"): ...
log signature(x = "CsparseMatrix"): ...
t signature(x = "CsparseMatrix"): ...
tril signature(x = "CsparseMatrix"): ...
triu signature(x = "CsparseMatrix"): ...

Note
All classes extending CsparseMatrix have a common validity (see validObject) check function. That function additionally checks the i slot for each column to contain increasing row numbers. In earlier versions of Matrix (<= 0.999375-16), validObject automatically re-sorted the entries when necessary, and hence new() calls with somewhat permuted i and x slots worked, as new(...) (with slot arguments) automatically checks the validity. Now, you have to use sparseMatrix to achieve the same functionality or know how to use .validateCsparse() to do so.

See Also
colSums, kronecker, and other such methods with own help pages.

Further, the super class of CsparseMatrix, sparseMatrix, and, e.g., class dgCMatrix for the links to other classes.

Examples
getClass("CsparseMatrix")

## The common validity check function (based on C code):
getValidity(getClass("CsparseMatrix"))
Methods

Most methods are implemented via as(*, "generalMatrix") and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method. Use showMethods(class = "ddenseMatrix", where = "package:Matrix") for an overview.

See Also

The virtual classes Matrix, dMatrix, and dsparseMatrix.

Examples

showClass("ddenseMatrix")
showMethods(class = "ddenseMatrix", where = "package:Matrix")

**ddiMatrix-class**

Class "ddiMatrix" of Diagonal Numeric Matrices

Description

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend sparseMatrix, whereas they did extend dense matrices earlier.

Objects from the Class

Objects can be created by calls of the form new("ddiMatrix", ...) but typically rather via Diagonal.

Slots

x: numeric vector. For an \( n \times n \) matrix, the x slot is of length \( n \) or 0, depending on the diag slot:

diag: "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

Dim, Dimnames: matrix dimension and dimnames, see the Matrix class description.

Extends

Class "diagonalMatrix", directly. Class "dMatrix", directly. Class "sparseMatrix", indirectly, see showClass("ddiMatrix").

Methods

\%\*\% signature(x = "ddiMatrix", y = "ddiMatrix"): ...

See Also

Class diagonalMatrix and function Diagonal.
Examples

```r
(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> 'fast' multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
  all.equal(cd2@x, c(sqrt(10),1)))
```

denseMatrix-class

Virtual Class "denseMatrix" of All Dense Matrices

Description

This is the virtual class of all dense (S4) matrices. It partitions into two subclasses `packedMatrix` and `unpackedMatrix`. Alternatively into the (currently) three subclasses `ddenseMatrix`, `ldenseMatrix`, and `ndenseMatrix`.

denseMatrix is (hence) the direct superclass of these \((2 + 3 = 5)\) classes.

Extends

class "Matrix" directly.

Slots

exactly those of its superclass "Matrix", i.e., "Dim" and "Dimnames".

Methods

Use `showMethods(class = "denseMatrix", where = "package:Matrix")` for an overview of methods.

Extraction ("[" methods, see \[-methods\].

See Also

`colSums`, `kronecker`, and other such methods with own help pages.

Its superclass `Matrix`, and main subclasses, `ddenseMatrix` and `sparseMatrix`.

Examples

`showClass("denseMatrix")`
Description

The dgCMatrix class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. dgCMatrix is the “standard” class for sparse numeric matrices in the Matrix package.

Objects from the Class

Objects can be created by calls of the form new("dgCMatrix", ...), more typically via as(*, "CsparseMatrix") or similar. Often however, more easily via Matrix(*, sparse = TRUE), or most efficiently via sparseMatrix().

Slots

x: Object of class “numeric” - the non-zero elements of the matrix.

... all other slots are inherited from the superclass "CsparseMatrix".

Methods

Matrix products (e.g., crossprod-methods), and (among other)

coerce signature(from = "matrix", to = "dgCMatrix")

coerce signature(from = "dgCMatrix", to = "matrix")

diag signature(x = "dgCMatrix"): returns the diagonal of x

dim signature(x = "dgCMatrix"): returns the dimensions of x

image signature(x = "dgCMatrix"): plots an image of x using the levelplot function

solve signature(a = "dgCMatrix", b = "."): see solve-methods, notably the extra argument sparse.

lu signature(x = "dgCMatrix"): computes the LU decomposition of a square dgCMatrix object

See Also

Classes dsCMatrix, dtCMatrix, lu

Examples

(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
dgeMatrix-class

Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices

Description

A general numeric dense matrix in the S4 Matrix representation. dgeMatrix is the "standard" class for dense numeric matrices in the Matrix package.

Objects from the Class

Objects can be created by calls of the form new("dgeMatrix", ...) or, more commonly, by coercion from the Matrix class (see Matrix) or by Matrix(...).

Slots

- x: Object of class "numeric" - the numeric values contained in the matrix, in column-major order.
- Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- Dimnames: a list of length two - inherited from class Matrix.
- factors: Object of class "list" - a list of factorizations of the matrix.

Methods

The are group methods (see, e.g., Arith)

Arith signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...
Arith signature(e1 = "dgeMatrix", e2 = "numeric"): ...
Arith signature(e1 = "numeric", e2 = "dgeMatrix"): ...
Math signature(x = "dgeMatrix"): ...
Math2 signature(x = "dgeMatrix", digits = "numeric"): ...

Matrix products %*%, crossprod() and tcrossprod(), several solve methods, and other matrix methods available:

Schur signature(x = "dgeMatrix", vectors = "logical"): ...
Schur signature(x = "dgeMatrix", vectors = "missing"): ...
chol signature(x = "dgeMatrix"): see chol.
coerce signature(from = "dgeMatrix", to = "lgeMatrix"): ...
coerce signature(from = "dgeMatrix", to = "matrix"): ...
coerce signature(from = "matrix", to = "dgeMatrix"): ...
colMeans signature(x = "dgeMatrix"): columnwise means (averages)
colSums signature(x = "dgeMatrix"): columnwise sums
diag signature(x = "dgeMatrix"): ...
dim signature(x = "dgeMatrix"): ...
dimnames signature(x = "dgeMatrix"): ...
eigen signature(x = "dgeMatrix", only.values = "logical"): ...
The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., `dgCMatrix`, are preferred and better supported in the `Matrix` package.

**Objects from the Class**

Objects can be created by calls of the form `new("dgRMatrix", ...)`.  

**Slots**

- `j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.
- `p`: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- `Dim`: Object of class "integer" - the dimensions of the matrix.

**Methods**

- `coerce` signature(from = "matrix", to = "dgRMatrix")
- `coerce` signature(from = "dgRMatrix", to = "matrix")
- `coerce` signature(from = "dgRMatrix", to = "dgTMatrix")
- `diag` signature(x = "dgRMatrix"): returns the diagonal of x
- `dim` signature(x = "dgRMatrix"): returns the dimensions of x
- `image` signature(x = "dgRMatrix"): plots an image of x using the `levelplot` function

**See Also**

- the `RsparseMatrix` class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The `dgCMatrix` class (column compressed sparse) is really preferred.
The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class dgCMatrix.

Objects from the Class

Objects can be created by calls of the form new("dgTMatrix", ...), but more typically via spMatrix() or sparseMatrix(*, repr = "T").

Slots

i: integer row indices of non-zero entries in 0-base, i.e., must be in \(0: (\text{rown}.)-1\).

j: integer column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in \(0: (\text{ncol}.)-1\).

x: numeric vector - the (non-zero) entry at position \((i,j)\). Must be the same length as slot i. If an index pair occurs more than once, the corresponding values of slot x are added to form the element of the matrix.

Dim: Object of class "integer" of length 2 - the dimensions of the matrix.

Methods

+ signature(e1 = "dgTMatrix", e2 = "dgTMatrix")

coerce signature(from = "dgTMatrix", to = "dgCMatrix")

coerce signature(from = "dgTMatrix", to = "dgeMatrix")

coerce signature(from = "dgTMatrix", to = "matrix"), and typically coercion methods for more specific signatures, we are not mentioning here.

Note that these are not guaranteed to continue to exist, but rather you should use calls like as(x,"CsparseMatrix"), as(x, "generalMatrix"), as(x, "dMatrix"), i.e. coercion to higher level virtual classes.

coerce signature(from = "matrix", to = "dgTMatrix"), (direct coercion from tradition matrix).

image signature(x = "dgTMatrix"): plots an image of x using the levelplot function

t signature(x = "dgTMatrix"): returns the transpose of x

Note

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to dgCMatrix objects.

Note that both new(.) and spMatrix constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add \(x_k\)'s that belong to identical \((i_k, j_k)\) pairs.

However this means that a matrix typically can be stored in more than one possible "TsparseMatrix" representations. Use uniqTsparse() in order to ensure uniqueness of the internal representation of such a matrix.
Diagonal

Construct a Diagonal Matrix

Description

Construct a formally diagonal \texttt{Matrix}, i.e., an object inheriting from virtual class \texttt{diagonalMatrix} (or, if desired, a mathematically diagonal \texttt{CsparseMatrix}).

Usage

\begin{verbatim}
Diagonal(n, x = NULL, names = FALSE)
.sparseDiagonal(n, x = NULL, uplo = "U", shape = "t", unitri = TRUE, kind, cols)
.trDiagonal(n, x = NULL, uplo = "U", unitri = TRUE, kind)
.symDiagonal(n, x = NULL, uplo = "U", kind)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{n} integer indicating the dimension of the (square) matrix. If missing, then \texttt{length(x)} is used.
  \item \texttt{x} numeric or logical vector listing values for the diagonal entries, to be recycled as necessary. If \texttt{NULL} (the default), then the result is a unit diagonal matrix. \texttt{.sparseDiagonal()} and friends ignore non-\texttt{NULL} \texttt{x} when \texttt{kind} = "n".
  \item \texttt{names} either \texttt{logical} \texttt{TRUE} or \texttt{FALSE} or then a \texttt{character} vector of \texttt{length} \texttt{n}. If true and \texttt{names}(x) is not \texttt{NULL}, use that as both row and column names for the resulting matrix. When a character vector, use it for both dimnames.
\end{itemize}
uplo  one of c("U", "L"), specifying the uplo slot of the result if the result is formally triangular of symmetric.

shape  one of c("t", "s", "g"), indicating if the result should be formally triangular, symmetric, or “general”. The result will inherit from virtual class triangularMatrix, symmetricMatrix, or generalMatrix, respectively.

unitri logical indicating if a formally triangular result with ones on the diagonal should be formally unit triangular, i.e., with diag slot equal to "U" rather than "N".

diag one of c("d", "l", "n"), indicating the “mode” of the result: numeric, logical, or pattern. The result will inherit from virtual class dsparseMatrix, lsparseMatrix, or nsparseMatrix, respectively. Values other than "n" are ignored when x is non-NULL; in that case the mode is determined by typeof(x).

cols optional integer vector with values in 0:(n-1), indexing columns of the specified diagonal matrix. If specified, then the result is (mathematically) D[, cols+1] rather than D, where D = Diagonal(n, x), and it is always “general” (i.e., shape is ignored).

Value
Diagonal() returns an object inheriting from virtual class diagonalMatrix.

.sparseDiagonal() returns a CsparseMatrix representation of Diagonal(n, x) or, if cols is given, of Diagonal(n, x)[, cols+1]. The precise class of the result depends on shape and kind.

.trDiagonal() and .symDiagonal() are simple wrappers, for .sparseDiagonal(shape = "t") and .sparseDiagonal(shape = "s"), respectively.

.sparseDiagonal() exists primarily to leverage efficient C-level methods available for CsparseMatrix.

Author(s)
Martin Maechler

See Also
the generic function diag for extraction of the diagonal from a matrix works for all “Matrices”.

bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals. band(A) returns a band matrix containing some sub-/super - diagonals of A.

Matrix for general matrix construction; further, class diagonalMatrix.

Examples
Diagonal(3)
Diagonal(x = 10^((3:1)))
Diagonal(x = (1:4) >= 2)##-> "ldiMatrix"

## Use Diagonal() + kronecker() for “repeated-block” matrices:
M1 <- Matrix(0+0:5, 2,3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t"))## now (2012-10) unitriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))
diagonalMatrix-class

Class "diagonalMatrix" of Diagonal Matrices

Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

diag: code"character" string, either "U" or "N", where "U" means 'unit-diagonal'.
Dim: matrix dimension, and
Dimnames: the dimnames, a list, see the Matrix class description. Typically list(NULL,NULL)

Extends

Class "sparseMatrix", directly.

Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

coece signature(from = "matrix", to = "diagonalMatrix"): ...
coece signature(from = "Matrix", to = "diagonalMatrix"): ...
coece signature(from = "diagonalMatrix", to = "generalMatrix"): ...
coece signature(from = "diagonalMatrix", to = "triangularMatrix"): ...
coece signature(from = "diagonalMatrix", to = "nMatrix"): ...
coece signature(from = "diagonalMatrix", to = "matrix"): ...
coece signature(from = "diagonalMatrix", to = "sparseVector"): ...
t signature(x = "diagonalMatrix"): ...
   and many more methods
solve signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also solve-methods.
which signature(x = "nMatrix"), semantically equivalent to base function which(x, arr.ind).
"Math" signature(x = "diagonalMatrix"): all these group methods return a "diagonalMatrix", apart from cumsum() etc which return a vector also for base matrix.
* signature(e1 = "ddiMatrix", e2="denseMatrix"): arithmetic and other operators from the Ops group have a few dozen explicit method definitions, in order to keep the results diagonal in many cases, including the following:
signature(e1 = "ddiMatrix", e2="denseMatrix"): the result is from class ddiMatrix which is typically very desirable. Note that when e2 contains off-diagonal zeros or NAs, we implicitly use \(0/x = 0\), hence differing from traditional R arithmetic (where \(0/0 \to \NaN\)), in order to preserve sparsity.

**summary** (object = "diagonalMatrix"): Returns an object of S3 class "diagSummary" which is the summary of the vector object@x plus a simple heading, and an appropriate `print` method.

See Also

Diagonal() as constructor of these matrices, and isDiagonal. ddiMatrix and ldiMatrix are “actual” classes extending "diagonalMatrix".

Examples

I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
identical(tcrossprod(I5), I5),
identical(crossprod(I5, D5), D5),
identical(tcrossprod(D5, I5), D5),
identical(solve(D5), solve(D5, I5)),
all.equal(D5, solve(solve(D5)), tolerance = 1e-12) )
solve(D5)# efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
      cbind2(D5, I5))

---

**diagU2N**  
Transform Triangular Matrices from Unit Triangular to General Triangular and Back

Description

Transform a triangular matrix \(x\), i.e., of class *triangularMatrix*, from (internally!) unit triangular (“unitriangular”) to “general” triangular (diagU2N(x)) or back (diagN2U(x)). Note that the latter, diagN2U(x), also sets the diagonal to one in cases where `diag(x)` was not all one.

.diagU2N(x) and .diagN2U(x) assume without checking that `x` is a *triangularMatrix* with suitable diag slot (“U” and “N”, respectively), hence they should be used with care.

Usage

diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)
**Arguments**

- **x**: a `triangularMatrix`, often sparse.
- **cl**: (optional, for speedup only:) class (definition) of `x`.
- **checkDense**: logical indicating if dense (see `denseMatrix`) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when `x` is dense.

**Details**

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

**Value**

A triangular matrix of the same `class` but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

**Note**

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

**See Also**

"triangularMatrix", "dtCMatrix".

**Examples**

```r
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unitriangular"
(t.u <- diagN2U(10*T))# changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
          identical(T, diagU2N(uT)))

T[upper.tri(T)] <- 5 # still "dtC"
T <- diagN2U(as(T,"triangularMatrix"))
dT <- as(T, "denseMatrix") # (unitriangular)
dT.n <- diagU2N(dT, checkDense = TRUE)
sT.n <- diagU2N(dT)
stopifnot(is(dT.n, "denseMatrix"), is(sT.n, "sparseMatrix"),
          dT@diag == "U", dT.n@diag == "N", sT.n@diag == "N",
          all(dT == dT.n), all(dT == sT.n))
```

---

**dimScale**

Scale the Rows and Columns of a Matrix

**Description**

`dimScale`, `rowScale`, and `colScale` implement $D_1 \times x \times D_2$, $D \times x$, and $x \times D$ for diagonal matrices $D_1$, $D_2$, and $D$ with diagonal entries $d_1$, $d_2$, and $d$, respectively. Unlike the explicit products, these functions preserve dimnames(`x`) and symmetry where appropriate.
Usage

dimScale(x, d1 = sqrt(1/diag(x, names = FALSE)), d2 = d1)
rowScale(x, d)
colScale(x, d)

Arguments

x          a matrix, possibly inheriting from virtual class Matrix.
d1,d2,d    numeric vectors giving factors by which to scale the rows or columns of x; they
           are recycled as necessary.

Details

dimScale(x) (with d1 and d2 unset) is only roughly equivalent to cov2cor(x). cov2cor
sets the diagonal entries of the result to 1 (exactly); dimScale does not.

Value

The result of scaling x, currently always inheriting from virtual class dMatrix.
It inherits from triangularMatrix if and only if x does. In the special case of dimScale(x, d1,
d2) with identical d1 and d2, it inherits from symmetricMatrix if and only if x does.

Author(s)

Mikael Jagan

cov2cor

Examples

n <- 6L
(x <- forceSymmetric(matrix(1, n, n)))
dimnames(x) <- rep.int(list(letters[seq_len(n)]), 2L)
d <- seq_len(n)
(D <- Diagonal(x = d))

(scx <- dimScale(x, d)) # symmetry and 'dimnames' kept
(mmx <- D %*% x %*% D) # symmetry and 'dimnames' lost
stopifnot(identical(unname(as(scx, "generalMatrix")), mmx))

rowScale(x, d)
colScale(x, d)
The \texttt{dMatrix} class is a virtual class contained by all actual classes of numeric matrices in the \texttt{Matrix} package. Similarly, all the actual classes of logical matrices inherit from the \texttt{lMatrix} class.

### Slots

Common to all matrix object in the package:

- \texttt{Dim}: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- \texttt{Dimnames}: list of length two; each component containing NULL or a \texttt{character} vector length equal the corresponding \texttt{Dim} element.

### Methods

There are (relatively simple) group methods (see, e.g., \texttt{Arith})

- \texttt{Arith} signature\(\text{e1 = "dMatrix", e2 = "dMatrix"}\): ...
- \texttt{Arith} signature\(\text{e1 = "dMatrix", e2 = "numeric"}\): ...
- \texttt{Arith} signature\(\text{e1 = "numeric", e2 = "dMatrix"}\): ...
- \texttt{Math} signature\(\text{x = "dMatrix"}\): ...
- \texttt{Math2} signature\(\text{x = "dMatrix", digits = "numeric"}\): this group contains \texttt{round()} and \texttt{signif()}.
- \texttt{Compare} signature\(\text{e1 = "numeric", e2 = "dMatrix"}\): ...
- \texttt{Compare} signature\(\text{e1 = "dMatrix", e2 = "numeric"}\): ...
- \texttt{Compare} signature\(\text{e1 = "dMatrix", e2 = "dMatrix"}\): ...
- \texttt{Summary} signature\(\text{x = "dMatrix"}\): The “Summary” group contains the seven functions \texttt{max()}, \texttt{min()}, \texttt{range()}, \texttt{prod()}, \texttt{sum()}, \texttt{any()}, and \texttt{all()}.

The following methods are also defined for all double matrices:

- \texttt{coerce} signature\(\text{from = "dMatrix", to = "matrix"}\): ...
- \texttt{expm} signature\(\text{x = "dMatrix"}\): computes the “Matrix Exponential”, see \texttt{expm}.
- \texttt{zapsmall} signature\(\text{x = "dMatrix"}\): ...

The following methods are defined for all logical matrices:

- \texttt{which} signature\(\text{x = "lsparseMatrix"}\) and many other subclasses of "\texttt{lMatrix}" as the \texttt{base} function \texttt{which(x, arr.ind)} returns the indices of the \texttt{TRUE} entries in \texttt{x}; if \texttt{arr.ind} is true, as a 2-column matrix of row and column indices. Since \texttt{Matrix} version 1.2-9, if \texttt{useNames} is true, as by default, with \texttt{dimnames}, the same as base::\texttt{which}.
See Also

The nonzero-pattern matrix class `nMatrix`, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes `dgeMatrix`, `dgCMatrix`, and `Matrix`.

`drop0(x, tol=1e-10)` is sometimes preferable to (and more efficient than) `zapsmall(x, digits=10).

Examples

```r
showClass("dMatrix")
set.seed(101)
round(Matrix(rnorm(28), 4,7), 2)
M <- Matrix(rlnorm(56, sd=10), 4,14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

### dmperm

**Dulmage-Mendelsohn Permutation / Decomposition**

#### Description

For any \( n \times m \) (typically) sparse matrix \( x \) compute the Dulmage-Mendelsohn row and columns permutations which at first splits the \( n \) rows and \( m \) columns into coarse partitions each; and then a finer one, reordering rows and columns such that the permutated matrix is “as upper triangular” as possible.

#### Usage

```r
dmperm(x, nAns = 6L, seed = 0L)
```

#### Arguments

- **x**: a typically sparse matrix; internally coerced to either "dgCMatrix" or "dtCMatrix".
- **nAns**: an integer specifying the length of the resulting list. Must be 2, 4, or 6.
- **seed**: an integer code in -1,0,1; determining the (initial) permutation; by default, seed = 0, no (or the identity) permutation; seed = -1 uses the “reverse” permutation \( k:1 \); for seed = 1, it is a random permutation (using R’s RNG, seed, etc).

#### Details

See the book section by Tim Davis; page 122–127, in the References.
Value

A named list with (by default) 6 components,

- **p**: integer vector with the permutation p, of length `nrow(x)`.
- **q**: integer vector with the permutation q, of length `ncol(x)`.
- **r**: integer vector of length rb+1, where block k is rows r[k] to r[k+1]-1 in A[p,q].
- **s**: integer vector of length rb+1, where block k is cols s[k] to s[k+1]-1 in A[p,q].
- **rr5**: integer vector of length 5, defining the coarse row decomposition.
- **cc5**: integer vector of length 5, defining the coarse column decomposition.

Author(s)

Martin Maechler, with a lot of “encouragement” by Mauricio Vargas.

References

Schur, the class of permutation matrices; "pMatrix".

Examples

```r
set.seed(17)
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
str(dm9 <- dmperm(S9))
(S9p <- with(dm9, S9[p, q]))
## looks good, but *not* quite upper triangular; these, too:
str(dm9.0 <- dmperm(S9, seed=-1)) # non-random too.
str(dm9.1 <- dmperm(S9, seed= 1)) # a random one
## The last two permutations differ, but have the same effect!
(S9p0 <- with(dm9.0, S9[p, q])) # .. hmmm ..
stopifnot(all.equal(S9p0, S9p)) # same as as default, but different from the random one

set.seed(11)
(M <- triu(rsparsematrix(9,11, 1/4)))
dM <- dmperm(M); with(dM, M[p, q])
(Mp <- M[sample.int(nrow(M)), sample.int(ncol(M))])
dMp <- dmperm(Mp); with(dMp, Mp[p, q])

set.seed(7)
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))
str(dm.7 <- dmperm(n7))
stopifnot(exprs = {
  lengths(dm.7[1:2]) == dim(n7)
  identical(dm.7, dmperm(as(n7, "dMatrix")))
  identical(dm.7[1:4], dmperm(n7, nAns=4))
  identical(dm.7[1:2], dmperm(n7, nAns=2))
})
```
**dpoMatrix-class**

Positive Semi-definite Dense (Packed \ Non-packed) Numeric Matrices

### Description

- The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked storage.
- The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.
- The "corMatrix" class of correlation matrices extends "dpoMatrix" with a slot `sd`, which allows to restore the original covariance matrix.

### Objects from the Class

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

### Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- `Dim`: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.
- `Dimnames`: inherited from class "Matrix"
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.
- `sd`: (for "corMatrix") a numeric vector of length `n` containing the (original) $\sqrt{\text{var}(\cdot)}$ entries which allow reconstruction of a covariance matrix from the correlation matrix.

### Extends

Class "dsyMatrix", directly.
Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

### Methods

- `chol` signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of `x`, see `chol`.
- `determinant` signature(x = "dpoMatrix"): Returns the determinant of `x`, via `chol(x)`, see above.
- `rcond` signature(x = "dpoMatrix", norm = "character"): Returns (and stores) the reciprocal of the condition number of `x`. The `norm` can be "0" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.
- `solve` signature(a = "dpoMatrix", b = "...."), and `solve` signature(a = "dppMatrix", b = "....") work via the Cholesky composition, see also the Matrix `solve-methods`.
Arith signature(e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically not positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with positive length(.) == 1 numbers (or `logicals`).

**Note**

Currently the validity methods for these classes such as `getValidity(getClass("dpoMatrix"))` for efficiency reasons only check the diagonal entries of the matrix – they may not be negative. This is only necessary but not sufficient for a symmetric matrix to be positive semi-definite.

A more reliable (but often more expensive) check for positive semi-definiteness would look at the signs of `diag(BunchKaufman(.))` (with some tolerance for very small negative values), and for (strict) positive definiteness at something like `!inherits(tryCatch(chol(.), error=identity), "error")`. Indeed, when coercing to these classes, a version of `Cholesky()` or `chol()` is typically used, e.g., see `selectMethod("coerce", c(from="dsyMatrix", to="dpoMatrix"))`.

**See Also**

Classes `dsyMatrix` and `dgeMatrix`; further, `Matrix`, `rcond`, `chol`, `solve`, `crossprod`.

**Examples**

```r
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is `integer`
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))
```

```r
### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
  all.equal(ch6@sd^(-2), 2*(1:6)-1, tolerance = 1e-12))
chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors$Cholesky),
  all(abs(crossprod(chch) - ch6) < 1e-10))
```

---

**drop0**

*Drop "Explicit Zeroes" from a Sparse Matrix*

**Description**

Returns a sparse matrix with no "explicit zeroes", i.e., all zero or `FALSE` entries are dropped from the explicitly indexed matrix entries.

**Usage**

`drop0(x, tol = 0, is.Csparse = NA)`
Arguments

- **x**: a Matrix, typically sparse, i.e., inheriting from `sparseMatrix`.
- **tol**: non-negative number to be used as tolerance for checking if an entry \(x_{i,j}\) should be considered to be zero.
- **is.Csparse**: logical indicating prior knowledge about the “Csparseness” of x. This exists for possible speedup reasons only.

Value

a Matrix like x but with no explicit zeros, i.e., \(!any(x@x == 0)\), always inheriting from `CsparseMatrix`.

Note

When a sparse matrix is the result of matrix multiplications, you may want to consider combining `drop0()` with `zapsmall()`, see the example.

See Also

- `spMatrix`, `class sparseMatrix; nnzero`

Examples

```r
m <- spMatrix(10, 20, i = 1:8, j = 2:9, x = c(0:2, 3:-1))
m
drop0(m)

## A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
  x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
  i = c(0L, 2L, 4L, 1L, 3L, 2L, 4L, 3L, 4L),
  p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5, t5), t5))
IT <- solve(TT)
I. <- TT %x% IT; nnzero(I.) # 697 (= 625 + 72)
I.0 <- drop0(zapsmall(I.))

## which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)),
  nnzero(I..) == 625)
```

---

### dsCMatric-class

**Numeric Symmetric Sparse (column compressed) Matrices**

**Description**

The `dsCMatrix` class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The `dsTMatrix` class is the class of symmetric, sparse numeric matrices in triplet format.
Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix", ...)` or `new("dsTMatrix", ...)`, or automatically via e.g., `as(*, "symmetricMatrix"),` or (for `dsCMatrix`) also from `Matrix(.)`. Creation “from scratch” most efficiently happens via `sparseMatrix(*, symmetric=TRUE).

Slots

uplo: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.

i: Object of class "integer" of length nnZ (half number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.

p: (only in class "dsCMatrix"): an integer vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

j: (only in class "dsTMatrix"): Object of class "integer" of length nnZ (as i). These are the column numbers for each non-zero element in the lower triangle of the matrix.

x: Object of class "numeric" of length nnZ – the non-zero elements of the matrix (to be duplicated for full matrix).

factors: Object of class "list" - a list of factorizations of the matrix.

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Extends

Both classes extend classes and `symmetricMatrix dsparseMatrix` directly; `dsCMatrix` further directly extends `CsparseMatrix`, where `dsTMatrix` does `TsparseMatrix`.

Methods

solve signature(a = "dsCMatrix", b = "..."): x <- solve(a,b) solves $Ax = b$ for $x$; see `solve-methods`.

chol signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x, see `chol`.

Cholesky signature(A = "dsCMatrix",...): Computes more flexibly Cholesky decompositions, see `Cholesky`.

determinant signature(x = "dsCMatrix", logarithm = "missing"): Evaluate the determinant of x on the logarithm scale. This creates and stores the Cholesky factorization.

determinant signature(x = "dsCMatrix", logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.

t signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the uplo slot is swapped, and the row and column indices are interchanged.

t signature(x = "dsTMatrix"): Transpose. The uplo slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

coerce signature(from = "dsCMatrix", to = "dgTMatrix")

coerce signature(from = "dsCMatrix", to = "dgeMatrix")

coerce signature(from = "dsCMatrix", to = "matrix")

coerce signature(from = "dsTMatrix", to = "dgeMatrix")
```
coerce signature(from = "dsTMatrix", to = "dsCMatrix")
coerce signature(from = "dsTMatrix", to = "dsyMatrix")
coerce signature(from = "dsTMatrix", to = "matrix")
```

See Also

Classes `dgCMatrix`, `dgTMatrix`, `dgeMatrix` and those mentioned above.

Examples

```r
mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
# automatically dsCMatrix
str(mm)
mT <- as(as(mm, "generalMatrix"), "TsparseMatrix")
## Either
(symM <- as(mT, "symmetricMatrix")) # dsT
(symC <- as(symM, "CsparseMatrix")) # dsC
## or
sT <- Matrix(mT, sparse=TRUE, forceCheck=TRUE) # dsT
sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"
```

dsparseMatrix-class  Virtual Class "dsparseMatrix" of Numeric Sparse Matrices

Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

Slots

- **Dim**: the matrix dimension, see class "Matrix".
- **Dimnames**: see the "Matrix" class.
- **x**: a numeric vector containing the (non-zero) matrix entries.

Extends

Class "dMatrix" and "sparseMatrix", directly.
Class "Matrix", by the above classes.

See Also

the documentation of the (non virtual) sub classes, see `showClass("dsparseMatrix")`; in particular, `dgTMatrix`, `dgCMatrix`, and `dgRMatrix`.

Examples

```r
showClass("dsparseMatrix")
```
dsRMMatrix-class

Symmetric Sparse Compressed Row Matrices

Description

The dsRMMatrix class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Objects from the Class

These ".RMatrix" classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMMatrix", ...).`

Slots

- **uplo**: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.
- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- **p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- **factors**: Object of class "list" - a list of factorizations of the matrix.
- **x**: Object of class "numeric" - the non-zero elements of the matrix.
- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- **Dimnames**: List of length two, see `Matrix`.

Extends

Classes RsparseMatrix, dsparseMatrix and symmetricMatrix, directly.

Class "dMatrix", by class "dsparseMatrix", class "sparseMatrix", by class "dsparseMatrix" or "RsparseMatrix"; class "compMatrix" by class "symmetricMatrix" and of course, class "Matrix".

Methods

- **forceSymmetric** signature(x = "dsRMMatrix", uplo = "missing"): a trivial method just returning x
- **forceSymmetric** signature(x = "dsRMMatrix", uplo = "character"): if uplo == x@uplo, this trivially returns x; otherwise t(x).
- **coerce** signature(from = "dsCMMatrix", to = "dsRMMatrix")

See Also

the classes dgCMMatrix, dgTMatrix, and dgeMatrix.
dsyMatrix-class

Symmetric Dense (Packed or Unpacked) Numeric Matrices

Description

• The "dsyMatrix" class is the class of symmetric, dense matrices in non-packed storage and
• "dspMatrix" is the class of symmetric dense matrices in packed storage, see pack(). Only
  the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form new("dsyMatrix", ...) or new("dspMatrix", ...),
respectively.

Slots

  uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower
  triangular.

  x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-
     major order.

  Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the
     Matrix.

  factors: Object of class "list". A named list of factorizations that have been computed for the
     matrix.

Extends

"dsyMatrix" extends class "dgeMatrix", directly, whereas
"dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use
showClass("dsyMatrix"), e.g., for details.

Methods

coerce signature(from = "ddenseMatrix", to = "dgeMatrix")
coerce signature(from = "dspMatrix", to = "matrix")
coerce signature(from = "dsyMatrix", to = "matrix")
coerce signature(from = "dsyMatrix", to = "dspMatrix"
dtCMatrix-class

Triangular, (compressed) sparse column matrices

Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

coerce signature(from = "dspMatrix", to = "dsyMatrix")

norm signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the matrix norm of the desired type, see, norm.

rcond signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the reciprocal condition number, rcond().
solve signature(a = "dspMatrix", b = "...."), and solve signature(a = "dsyMatrix", b = "...."): x <- solve(a,b) solves Ax = b for x; see solve-methods.
t signature(x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

See Also

The positive (Semi-)definite dense (packed or non-packed numeric matrix classes dpoMatrix, dppMatrix and corMatrix,

Classes dgeMatrix and Matrix; solve, norm, rcond, t

Examples

## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA,32,77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite

## 4x4 example
m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
(sym <- m%*%t(m)+diag(11:14, 4))
(S1 <- pack(sym))
(S2 <- t(S1))
stopifnot(all(S1 == S2)) # equal "seen as matrix", but differ internally :
str(S1)
S2@x
Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via `Matrix()` or coercions such as `as(x, "triangularMatrix")`.

Slots

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.

- **p**: (only present in "dtCMatrix"): an `integer` vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

- **i**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the `dtTMatrix` class.)

- **x**: Object of class "numeric" - the non-zero elements of the matrix.

- **Dim,Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

Methods

- `coerce` signature(from = "dtCMatrix", to = "dgTMatrix")
- `coerce` signature(from = "dtCMatrix", to = "dgeMatrix")
- `coerce` signature(from = "dtTMatrix", to = "dgeMatrix")
- `coerce` signature(from = "dtTMatrix", to = "dtrMatrix")
- `coerce` signature(from = "dtTMatrix", to = "matrix")

- `solve` signature(a = "dtCMatrix", b = ". . ."): sparse triangular solve (aka “backsolve” or “forwardsolve”), see `solve-methods`.

- `t` signature(x = "dtCMatrix"): returns the transpose of x

- `t` signature(x = "dtTMatrix"): returns the transpose of x

See Also

Classes `dgCMatrix`, `dgTMatrix`, `dgeMatrix`, and `dtrMatrix`.
Examples

```r
showClass("dtCMatrix")

showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
## from 0-diagonal to unit-diagonal (low-level step):
tu <- t1 ; tu@diag <- "U"
tu
(cu <- as(tu, "CsparseMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu$i == 1:0,
          all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu)))
t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)
```

## 2nd example
```r
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
          x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5)) # contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions
I5 <- iu %*% U5 # should equal the identity matrix
i5 <- iu2 %*% U5
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(          
          all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
          all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
          identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)))
)
```

dtpMatrix-class

Packed Triangular Dense Matrices - "dtpMatrix"

Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.
dtpMatrix-class

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension $d \times d$, $\text{length}(x)$ is of length $d(d+1)/2$ (also when diag == "U"!).

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

Methods

%*% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see showMethods("%*%", class = "dtpMatrix").

do coercion signature(from = "dtpMatrix", to = "dtrMatrix")

do coercion signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the determinant(x) trivially is $\prod(\text{diag}(x))$, but computed on log scale to prevent over- and underflow.

diag signature(x = "dtpMatrix"): ...

norm signature(x = "dtpMatrix", type = "character"): ...

rcond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forward-solve, see solve-methods.

t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x is upper triangular, and vice versa.

See Also

Class dtrMatrix

Examples

showClass("dtrMatrix")

demo("dtrMatrix-class", echo=FALSE)

(p1 <- pack(T2))
str(p1)
(pp <- pack(T))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
identical(t(pp), p1), identical(t(p1), pp),
all((l.d <- p1 - T2) == 0), is(l.d, "dtpMatrix"),
all((u.d <- pp - T ) == 0), is(u.d, "dtpMatrix"),
dtRMatrix-class

Triangular Sparse Compressed Row Matrices

Description

The dtRMatrix class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.
diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
j: Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
p: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the dsRMatrix class.)
x: Object of class "numeric" - the non-zero elements of the matrix.
Dim: The dimension (a length-2 "integer")
Dimnames: corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

Methods

No methods currently with class "dsRMatrix" in the signature.

See Also

Classes `dgCMatrix`, `dgTMatrix`, `dgeMatrix`
Examples

```r
(m0 <- new("dtrMatrix"))
(m2 <- new("dtrMatrix", Dim = c(2L,2L),
    x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix
```

dtrMatrix-class

Triangular, dense, numeric matrices

Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage, see `pack()`.

Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix", ...)`.  

Slots

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- **x**: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- **Dim**: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

Methods

Among others (such as matrix products, e.g. `?crossprod-methods`),

- **coerce** signature(from = "dgeMatrix", to = "dtrMatrix")
- **coerce** signature(from = "dtrMatrix", to = "matrix")
- **coerce** signature(from = "dtrMatrix", to = "ltrMatrix")
- **coerce** signature(from = "dtrMatrix", to = "matrix")
- **coerce** signature(from = "matrix", to = "dtrMatrix")
- **norm** signature(x = "dtrMatrix", type = "character")
- **rcond** signature(x = "dtrMatrix", norm = "character")
- **solve** signature(a = "dtrMatrix", b = "...")efficiently use a “forwardsolve” or backsolve for a lower or upper triangular matrix, respectively, see also `solve-methods`.
- +, -, *, ..., ==, >=,... all the Ops group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.
**expand**

**Expand a (Matrix) Decomposition into Factors**

**Description**

Expands decompositions stored in compact form into factors.

**Usage**

```
expand(x, ...)  
```

**Arguments**

- `x` a matrix decomposition.
- `...` further arguments passed to or from other methods.

**Details**

This is a generic function with special methods for different types of decompositions, see `showMethods(expand)` to list them all.

**Value**

The expanded decomposition, typically a list of matrix factors.

**Note**

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `expand` allows all factors to be fully expanded.
See Also

The LU lu, and the Cholesky decompositions which have expand methods; facmul.

Examples

```r
(x <- Matrix(round(rnorm(9),2), 3, 3))
(ex <- expand(lux <- lu(x)))
```

expm

Matrix Exponential

Description

Compute the exponential of a matrix.

Usage

```r
expm(x)
```

Arguments

- `x` a matrix, typically inheriting from the dMatrix class.

Details

The exponential of a matrix is defined as the infinite Taylor series
\[ \expm(A) = I + A + A^2/2! + A^3/3! + \ldots \]
(although this is definitely not the way to compute it). The method for the dgeMatrix class uses Ward's diagonal Pade' approximation with three step preconditioning.

Value

The matrix exponential of `x`.

Note

The `expm` package contains newer (partly faster and more accurate) algorithms for `expm()` and includes `logm` and `sqrtm`.

Author(s)

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

References

https://en.wikipedia.org/wiki/Matrix_exponential

### Description
Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

### Usage
- `readHB(file)`
- `readMM(file)`
- `writeMM(obj, file, ...)`

### Arguments
- **obj**: a real sparse matrix
- **file**: for `writeMM` - the name of the file to be written. For `readHB` and `readMM` the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in ".rua" or ".rsa". Those storing matrices in the MatrixMarket format usually end in ".mtx".
  Alternatively, `readHB` and `readMM` accept connection objects.
- **...**: optional additional arguments. Currently none are used in any methods.

### Value
The `readHB` and `readMM` functions return an object that inherits from the "Matrix" class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to file in the MatrixMarket format (writeMM).

### Note
The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

Note that these formats do not know anything about `dimnames`, hence these are dropped by `writeMM()`.

A very simple way to export small sparse matrices `S` is to use `summary(S)` which returns a data.frame with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

str(utm <- readHB(system/file("external/utm300.rua", package = "Matrix")))
str(lundA <- readMM(system/file("external/lund_a.mtx", package = "Matrix")))
str(lundA <- readHB(system/file("external/lund_a.rsa", package = "Matrix")))
str(jgl009 <- readMM(system/file("external/jgl009.mtx", package = "Matrix")))
str(sm <- readHB(gzcon(url("https://www.cise.ufl.edu/research/sparse/RB/Boeing/msc00726.tar.gz"))))

C

## Not run:
## NOTE: The following examples take quite some time
## ---- even on a fast internet connection:
if(FALSE) # the URL has been corrected, but we need an un-tar step!
str(sm -

## End(Not run)
data(KNex)
## Store as MatrixMarket (.mtx) file, here inside temporary dir/folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)
file.info(MMfile)[,c("size", "ctime")]

## very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)

## and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))

## has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))

facmul

Multiplication by Decomposition Factors

Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

Usage

facmul(x, factor, y, transpose, left, ...)
forceSymmetric

forceSymmetric

Arguments

x a matrix decomposition. No missing values or IEEE special values are allowed.
factor an indicator for selecting a particular factor for multiplication.
y a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.
transpose a logical value. When FALSE (the default) the factor is applied. When TRUE the transpose of the factor is applied.
left a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right.
...
the method for "qr.Matrix" has additional arguments.

Value

the product of the selected factor (or its transpose) and y

NOTE

Factors for decompositions such as lu and qr can be stored in a compact form. The function facmul allows multiplication without explicit formation of the factors, saving both storage and operations.

References

Examples

library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qrx <- qr(x)  # QR factorization of x
y <- rnorm(3)
facmul( qr(x), factor = "Q", y)  # form Q y
## End(Not run)

---

forceSymmetric

Force a Matrix to `symmetricMatrix` Without Symmetry Checks

Description

Force a square matrix x to a symmetricMatrix, without a symmetry check as it would be applied for as(x, "symmetricMatrix").

Usage

forceSymmetric(x, uplo)
Arguments

- **x**: any square matrix (of numbers), either “"traditional"" (**matrix**) or inheriting from **Matrix**.
- **uplo**: optional string, "U" or "L" indicating which “triangle” half of x should determine the result. The default is "U" unless x already has a uplo slot (i.e., when it is **symmetricMatrix**, or **triangularMatrix**), where the default will be x@uplo.

Value

A square matrix inheriting from class **symmetricMatrix**.

See Also

- **symmpart** for the symmetric part of a matrix, or the coercions as(x, <symmetricMatrix class>).

Examples

```r
## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try( as(hh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the **format** and print methods for sparse matrices and can be applied as well to standard **R** matrices. Note that all arguments but the first are optional.

**formatSparseM()** is the main “workhorse” of **formatSpMatrix**, the format method for sparse matrices.

**.formatSparseSimple()** is a simple helper function, also dealing with (short/empty) column names construction.

Usage

```r
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
               m = as(x,"matrix"), asLogical=NULL, uniDiag=NULL,
               digits=NULL, cx, iN0, dn = dimnames(m))
```
formatSparseM

.formatSparseSimple(m, asLogical=FALSE, digits=NULL, 
   col.names, note.dropping.colnames = TRUE, 
   dn=dimnames(m))

Arguments

x an R object inheriting from class sparseMatrix.

zero.print character which should be used for structural zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like print()ing of non-sparse matrices.

align a string specifying how the zero.print codes should be aligned, see formatSpMatrix.

m (optional) a (standard R) matrix version of x.

asLogical should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for formatSparseM().

uniDiag logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").

digits significant digits to use for printing, see print.default.

cx (optional) character matrix; a formatted version of x, still with strings such as "0.00" for the zeros.

iN0 (optional) integer vector, specifying the location of the non-zeroes of x.

col.names, note.dropping.colnames see formatSpMatrix.

dn dimnames to be used; a list (of length two) with row and column names (or NULL).

Value

a character matrix like cx, where the zeros have been replaced with (padded versions of) zero.print. As this is a dense matrix, do not use these functions for really large (really) sparse matrices!

Author(s)

Martin Maechler

See Also

formatSpMatrix which calls formatSparseM() and is the format method for sparse matrices.

printSpMatrix which is used by the (typically implicitly called) show and print methods for sparse matrices.

Examples

m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11, 0, 0, 0, 0, -7, 0), 4, 9))
m <- formatSparseM(m)
noquote(fm)
## nice, but this is nicer (with "units" vertically aligned):
print(fm, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m, align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
          (f2 == ".") == (m == 0))

generalMatrix-class  

Class "generalMatrix" of General Matrices

Description

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

defactors,
Dim,
Dimnames: all slots inherited from compMatrix; see its description.

Extends

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

See Also

Classes compMatrix, and the non-general virtual classes: symmetricMatrix, triangularMatrix, diagonalMatrix.

graph-sparseMatrix  

Conversions "graph" <-> (sparse) Matrix

Description

The Matrix package has supported conversion from and to "graph" objects from (Bioconductor) package graph since summer 2005, via the usual as(., "<class>") coercion,

as(from, Class)

Since 2013, this functionality is further exposed as the graph2T() and T2graph() functions (with further arguments than just from), which convert graphs to and from the triplet form of sparse matrices (of class "TsparseMatrix").
Usage

\texttt{graph2T(from, use.weights = )}
\texttt{T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)}

Arguments

\texttt{from} for \texttt{graph2T()}, an \texttt{R} object of class "\texttt{graph}"

\texttt{use.weights} logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class \texttt{dgTMatrix}; otherwise the result will be \texttt{ngTMatrix} or \texttt{nstMatrix}, the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used.

\texttt{need.uniq} a logical indicating if \texttt{from} may need to be internally "uniqified"; do not set this and hence rather use the default, unless you know what you are doing!

\texttt{edgemode} one of \texttt{NULL}, "\texttt{directed}", or "\texttt{undirected}". The default \texttt{NULL} looks if the matrix is symmetric and assumes "\texttt{undirected}" in that case.

Value

For \texttt{graph2T()}, a sparse matrix inheriting from "\texttt{TsparseMatrix}".

For \texttt{T2graph()} an \texttt{R} object of class "\texttt{graph}".

See Also

Note that the CRAN package \texttt{igraph} also provides conversions from and to sparse matrices (of package \texttt{Matrix}) via its \texttt{graph.adjacency()} and \texttt{get.adjacency()}.

Examples

\begin{verbatim}
if(isTRUE(try(require(graph)))) { ## super careful .. for "checking reasons"
   n4 <- LETTERS[1:4]; dns <- list(n4,n4)
   show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
   show(g1 <- as(a1, "graph")) # directed
   unlist(edgeWeights(g1)) # all '2'
   show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
   show(g2 <- as(a2, "graph")) # directed
   # now if you want it undirected:
   show(g3 <- T2graph(as(a2,"TsparseMatrix"), edgemode="undirected"))
   show(m3 <- as(g3,"Matrix"))
   show( graph2T(g3) ) # a "pattern Matrix" (\texttt{nsTMatrix})

   a. <- sparseMatrix(i= 4:1, j=1:4, dimnames=list(n4,n4), giveC=FALSE) # no 'x'
   show(a.) # "ngTMatrix"
   show(g. <- as(a., "graph"))

   }
\end{verbatim}
Hilbert

Generate a Hilbert matrix

Description

Generate the n by n symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large n, they are often used for testing numerical linear algebra code.

Usage

Hilbert(n)

Arguments

n

a non-negative integer.

Value

the n by n symmetric Hilbert matrix as a "dpoMatrix" object.

Methods for function image in package Matrix

Methods for function image in package Matrix. An image of a matrix simply color codes all matrix entries and draws the n × m matrix using an n × m grid of (colored) rectangles.

The Matrix package image methods are based on levelplot() from package lattice; hence these methods return an “object” of class "trellis", producing a graphic when (auto-) print()ed.

Usage

## S4 method for signature 'dgTMatrix'
image(x,
   xlim = c(1, di[2]),
   ylim = c(di[1], 1), aspect = "iso",
   sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
   xlab = "Column", ylab = "Row", cuts = 15,
   useRaster = FALSE,
   useAbs = NULL, colorkey = !useAbs,
   col.regions = NULL,
   lwd = NULL, border.col = NULL, ...)
Arguments

- **x**: a Matrix object, i.e., fulfilling `is(x, "Matrix")`.
- **xlim, ylim**: x- and y-axis limits; may be used to “zoom into” matrix. Note that x, y “feel reversed”: ylim is for the rows (= 1st index) and xlim for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, ylim is always used decreasingly.
- **aspect**: aspect ratio specified as number (y/x) or string; see `levelplot`.
- **sub, xlab, ylab**: axis annotation with sensible defaults; see `plot.default`.
- **cuts**: number of levels the range of matrix values would be divided into.
- **useRaster**: logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, `panel.levelplot.raster` (from `lattice` package) is used, and the colorkey is also done via rasters, see also `levelplot` and possibly `grid.raster`.
  - Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions).
- **useAbs**: logical indicating if `abs(x)` should be shown; if TRUE, the former (implicit) default, the default col.regions will be grey colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.
- **colorkey**: logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless useAbs is true. You can also specify a list, see `levelplot`, such as `list(raster=TRUE)` in the case of rastering.
- **col.regions**: vector of gradually varying colors; see `levelplot`.
- **lwd**: (only used when useRaster is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by `grid.rect`). The default depends on the matrix dimension and the device size.
- **border.col**: color for the border of each rectangle. NA means no border is drawn. When NULL as by default, `border.col <- if(lwd < .01) NA else NULL` is used. Consider using an opaque color instead of NULL which corresponds to `grid::get.gpar("col")`.

... further arguments passed to methods and `levelplot`, notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseding cuts above).

Value

as all `lattice` graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

Methods

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

See Also

`levelplot`, and `print.trellis` from package `lattice`. 
Examples

showMethods(image)
## If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)") -> imgC; imgC
stopifnot(!is.null(leg <- imgC$legend), is.list(leg$right)) # failed for 2 days ..
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)"

cCA <- Cholesky(crossprod(CAex), Imult = .01)
## See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)")
, split=c(x=1,y=1, nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE)
, split=c(x=2, y=1, nx=2, ny=1))

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
# how the result looks, may depend heavily on
# the device, screen resolution, antialiasing etc
# e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
# again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=1)
image(USCounties, c(1,100), c(1,200), lwd=5)
image(USCounties, c(1,100), c(1,200), lwd=.01)
## These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2, check.environment=FALSE)
, all.equal(I2, I3, check.environment=FALSE))
## using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyblue", 1/2))

if(interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))) {
## Using raster graphics: For PDF this would give a 77 MB file,
## however, for such a large matrix, this is typically considerably
## *slower* (than vector graphics rectangles) in most cases:
if(doPNG <- !dev.interactive())
  png("image-UCOUNTIES-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
if(doPNG)
  dev.off()
  ## and now look at the *.png image in a viewer you can easily zoom in and out
}

---

**index-class**

Virtual Class "index" - Simple Class for Matrix Indices
Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of Matrix matrices.

In fact, it is currently implemented as a simple class union (setClassUnion) of "numeric", "logical" and "character".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

[-methods, and

Subassign-methods, also for examples.

Examples

showClass("index")

indMatrix-class

Index Matrices

Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or "sampling rows with replacement", and is implemented that way in the Matrix package, see the 'Details' below.

Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting columns.) The crossproduct of an index matrix M with itself is a diagonal matrix with the number of entries in each column of M on the diagonal, i.e., $M'M = \text{Diagonal}(x=\text{table}(M@\text{perm}))$.

Permutation matrices (of class pMatrix) are special cases of index matrices: They are square, of dimension, say, $n \times n$, and their index vectors contain exactly all of 1:n.

While "row-indexing" (of more than one row or using drop=FALSE) stays within the "indMatrix" class, all other subsetting/indexing operations ("column-indexing", including, diag) on "indMatrix" objects treats them as nonzero-pattern matrices ("ngTMatrix" specifically), such that non-matrix subsetting results in logical vectors. Sub-assignment (M[i,j] <- v) is not sensible and hence an error for these matrices.

Objects from the Class

Objects can be created by calls of the form new("indMatrix", ...) or by coercion from an integer index vector, see below.
Slots

perm: An integer, 1-based index vector, i.e. an integer vector of length Dim[1] whose elements are taken from 1:Dim[2].

Dim: integer vector of length two. In some applications, the matrix will be skinny, i.e., with at least as many rows as columns.

Dimnames: a list of length two where each component is either NULL or a character vector of length equal to the corresponding Dim element.

Extends

Class "sparseMatrix" and "generalMatrix", directly.

Methods

%*% signature(x = "matrix", y = "indMatrix") and other signatures (use showMethods("%*%", class="indMatrix")): ...

coerce signature(from = "integer", to = "indMatrix"): This enables typical “indMatrix” construction, given an index vector from elements in 1:Dim[2], see the first example.

coerce signature(from = "numeric", to = "indMatrix"): a user convenience, to allow as(perm, "indMatrix") for numeric perm with integer values.

coerce signature(from = "list", to = "indMatrix"): The list must have two (integer-valued) entries: the first giving the index vector with elements in 1:Dim[2], the second giving Dim[2]. This allows "indMatrix" construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values Dim[2], Dim[2]-1, Dim[2]-2, ...

coerce signature(from = "indMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE matrix of mode logical.

coerce signature(from = "indMatrix", to = "ngTMatrix"): coercion to sparse logical matrix of class ngTMatrix.

t signature(x = "indMatrix"): return the transpose of the index matrix (which is no longer an indMatrix, but of class ngTMatrix).

colSums, colMeans, rowSums, rowMeans signature(x = "indMatrix"): return the column or row sums or means.

rbind2 signature(x = "indMatrix", y = "indMatrix"): a fast method for rowwise catenation of two index matrices (with the same number of columns).

kronecker signature(X = "indMatrix", Y = "indMatrix"): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

Author(s)

Fabian Scheipl, Uni Muenchen, building on existing "pMatrix", after a nice hike’s conversation with Martin Maechler; diverse tweaks by the latter. The crossprod(x,y) and kronecker(x,y) methods when both arguments are "indMatrix" have been made considerably faster thanks to a suggestion by Boris Vaillant.

See Also

The permutation matrices pMatrix are special index matrices. The “pattern” matrices, nMatrix and its subclasses.
Examples

```r
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
## random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

## Sample rows of a numeric matrix :
(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
## same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

# 3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")

# 3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sm1, "nMatrix")
s10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4, ] # preserves "indMatrix"-class

I1 <- as(c(5:1,6:4,7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- rbind(I1, I2))
stopifnot(is(I12, "indMatrix"),
  identical(I12, rbind(I1, I2)),
  colSums(I12) == c(2L,2:4,4:2))
```

invPerm

**Inverse Permutation Vector**

Description

From a permutation vector p, compute its inverse permutation vector.

Usage

```r
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

Arguments

- **p**: an integer vector of length, say, n.
zero.p  logical indicating if p contains values 0:(n-1) or rather (by default, zero.p = FALSE) 1:n.

zero.res logical indicating if the result should contain values 0:(n-1) or rather (by default, zero.res = FALSE) 1:n.

Value

an integer vector of the same length (n) as p. By default, (zero.p = FALSE, zero.res = FALSE), invPerm(p) is the same as order(p) or sort.list(p) and for that case, the function is equivalent to invPerm. <- function(p) { p[p] <- seq_along(p); p }.

Author(s)

Martin Maechler

See Also

the class of permutation matrices, pMatrix.

Examples

p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
## they are indeed inverse of each other:
stopifnot(
  identical(p[ip], 1:10),
  identical(ip[p], 1:10),
  identical(invPerm(ip), p)
)

is.na-methods

is.na(), is.finite() Methods for 'Matrix' Objects

Description

Methods for generic functions is.na(), is.nan(), is.finite(), is.infinite(), and anyNA(), for objects inheriting from virtual class Matrix or sparseVector.

Usage

## S4 method for signature 'dsparseMatrix'
is.na(x)
## S4 method for signature 'dsparseMatrix'
is.nan(x)
## S4 method for signature 'dsparseMatrix'
is.finite(x)
## S4 method for signature 'dsparseMatrix'
is.infinite(x)
## S4 method for signature 'dsparseMatrix'
anyNA(x)
## ...
## and for other classes
is.null.DN

Arguments

x

an R object, here a sparse or dense matrix or vector.

Value

For is.(), an nMatrix or nSparseVector matching the dimensions of x and specifying the positions in x of (some subset of) NA, NaN, Inf, and -Inf. For anyNA(), TRUE if x contains NA or NaN and FALSE otherwise.

See Also

NA, NaN, Inf

Examples

(M <- Matrix(1:6, nrow = 4, ncol = 3, dimnames = list(letters[1:4], LETTERS[1:3])))
stopifnot(!anyNA(M), !any(is.na(M)))
M[2:3, 2] <- NA
(inM <- is.na(M))
stopifnot(anyNA(M), sum(inM) == 2)

(A <- spMatrix(nrow = 10, ncol = 20, i = c(1, 3:8), j = c(2, 9, 6:10), x = 7 * (1:7)))
stopifnot(!anyNA(A), !any(is.na(A)))
(inA <- is.na(A))
stopifnot(anyNA(A), sum(inA) == 1 + 1 + 5)

is.null.DN

Are the Dimnames dn NULL-like?

Description

Are the dimnames dn NULL-like?

is.null.DN(dn) is less strict than is.null(dn), because it is also true (TRUE) when the dimnames dn are “like” NULL, or list(NULL, NULL), as they can easily be for the traditional R matrices (matrix) which have no formal class definition, and hence much freedom in how their dimnames look like.

Usage

is.null.DN(dn)

Arguments

dn

dimnames() of a matrix-like R object.

Value

logical TRUE or FALSE.
Note

This function is really to be used on “traditional” matrices rather than those inheriting from Matrix, as the latter will always have dimnames list(NULL, NULL) exactly, in such a case.

Author(s)

Martin Maechler

See Also

is.null, dimnames, matrix.

Examples

m <- matrix(round(100 * rnorm(6)), 2, 3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()), 2)

m4 ## prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
  identical(capture.output(m) -> cm,
  capture.output(m1)),
  identical(cm, capture.output(m2)),
  identical(cm, capture.output(m3)),
  identical(cm, capture.output(m4)))

hasNoDimnames <- function(.) is.null.DN(dimnames(.)

stopifnot(exprs = {
  hasNoDimnames(m)
  hasNoDimnames(m1); hasNoDimnames(m2)
  hasNoDimnames(m3); hasNoDimnames(m4)
  hasNoDimnames(Matrix(m) -> M)
  hasNoDimnames(as(M, "sparseMatrix")
})

Description

isSymmetric tests whether its argument is a symmetric square matrix, by default tolerating some numerical fuzz and requiring symmetric [dD]imnames in addition to symmetry in the mathematical sense. isSymmetric is a generic function in base, which has a method for traditional matrices of implicit class "matrix". Methods are defined here for various proper and virtual classes in Matrix, so that isSymmetric works for all objects inheriting from virtual class "Matrix".
isSymmetric-methods

Usage

## S4 method for signature 'symmetricMatrix'
isSymmetric(object, ...)
## S4 method for signature 'triangularMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'diagonalMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'indMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'dgeMatrix'
isSymmetric(object, tol = 100 * .Machine$double.eps, tol1 = 8 * tol, checkDN = TRUE, ...)
## S4 method for signature 'lgeMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'ngeMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'dgCMatrix'
isSymmetric(object, tol = 100 * .Machine$double.eps, checkDN = TRUE, ...)
## S4 method for signature 'lgCMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'ngCMatrix'
isSymmetric(object, checkDN = TRUE, ...)

Arguments

object      a "Matrix".
tol, tol1   numerical tolerances allowing approximate symmetry of numeric (rather than logical) matrices. See also isSymmetric.matrix.
checkDN     a logical indicating whether symmetry of the Dimnames slot of object should be checked.
...         further arguments passed to methods (typically methods for all.equal).

Details

The Dimnames slot of object, say dn, is considered to be symmetric if and only if

- dn[[1]] and dn[[2]] are identical or one is NULL; and
- ndn <- names(dn) is NULL or ndn[1] and ndn[2] are identical or one is the empty string "".

Hence list(a=nms, a=nms) is considered to be symmetric, and so too are list(a=nms, NULL) and list(NULL, a=nms).

Note that this definition is looser than that employed by isSymmetric.matrix, which requires dn[1] and dn[2] to be identical, where dn is the dimnames attribute of a traditional matrix.

Value

A logical, either TRUE or FALSE (never NA).

See Also

forceSymmetric; symmpart and skewpart; virtual class "symmetricMatrix" and its subclasses.
Examples

```r
isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "generalMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE
```

## Look at implementations:
showMethods("isSymmetric", includeDefs = TRUE) # includes S3 generic from base

---

**isTriangular**

Test whether a Matrix is Triangular or Diagonal

Description

`isTriangular` and `isDiagonal` test whether their argument is a triangular or diagonal matrix, respectively. Unlike the analogous `isSymmetric`, these two functions are generically from `Matrix` rather than base. Hence `Matrix` defines methods for traditional matrices of implicit class "matrix" in addition to matrices inheriting from virtual class "Matrix".

By our definition, triangular and diagonal matrices are *square*, i.e., they have the same number of rows and columns.

Usage

```r
isTriangular(object, upper = NA, ...)
isDiagonal(object)
```

Arguments

- **object**: an R object, typically a matrix.
- **upper**: a logical, either TRUE or FALSE, in which case TRUE is returned only for upper or lower triangular object; or otherwise NA (the default), in which case TRUE is returned for any triangular object.

... further arguments passed to methods (currently unused by Matrix).

Value

A logical, either TRUE or FALSE (never NA).

If `object` is triangular and `upper` is NA, then `isTriangular` returns TRUE with an attribute `kind`, either "U" or "L", indicating that `object` is upper or lower triangular, respectively. Users should not rely on how `kind` is determined for diagonal matrices, which are both upper and lower triangular.

See Also

`isSymmetric`; virtual classes "triangularMatrix" and "diagonalMatrix" and their subclasses.
Examples

isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "generalMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE

## Look at implementations:
showMethods("isTriangular", includeDefs = TRUE)
showMethods("isDiagonal", includeDefs = TRUE)

Description

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

Usage

KhatriRao(X, Y, FUN = "+", sparseY = TRUE, make.dimnames = FALSE)

Arguments

- **X, Y**: matrices of with the same number of columns.
- **FUN**: the (name of the) function to be used for the column-wise Kronecker products, see `kronecker`, defaulting to the usual multiplication.
- **sparseY**: logical specifying if Y should be coerced and treated as sparseMatrix. Set this to FALSE, e.g., to distinguish structural zeros from zero entries.
- **make.dimnames**: logical indicating if the result should inherit dimnames from X and Y in a simple way.

Value

a "CsparseMatrix", say R, the Khatri-Rao product of X \( (n \times k) \) and Y \( (m \times k) \), is of dimension \( (n \cdot m) \times k \), where the j-th column, R[ , j ] is the kronecker product kronecker(X[ , j ], Y[ , j ]).

Note

The current implementation is efficient for large sparse matrices.

Author(s)

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

  identical(K6d, K6Dd)
})

\textbf{Knex}

\textit{Koenker-Ng Example Sparse Model Matrix and Response Vector}

\section*{Description}
A model matrix \( \mathbf{mm} \) and corresponding response vector \( \mathbf{y} \) used in an example by Koenker and Ng. The matrix \( \mathbf{mm} \) is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "\texttt{dgCMatrix}" object. The vector \( \mathbf{y} \) is just \texttt{numeric} of length 1850.

\section*{Usage}
data(KNex)

\section*{References}

\section*{Examples}
data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time( # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y)))
)

head(round(sparse.sol,3))

## Compare with QR-based solution ("more accurate, but slightly slower"): system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y) ))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE
Description

Computes Kronecker products for objects inheriting from "Matrix".

In order to preserve sparseness, we treat 0 * NA as 0, not as NA as usually in R (and as used for the base function `kronecker`).

Methods

- **kronecker** signature(X = "Matrix", Y = "ANY")
- **kronecker** signature(X = "ANY", Y = "Matrix")
- **kronecker** signature(X = "diagonalMatrix", Y = "ANY")
- **kronecker** signature(X = "sparseMatrix", Y = "ANY")
- **kronecker** signature(X = "TsparseMatrix", Y = "TsparseMatrix")

Examples

```r
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12
## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix") # (lost "t"riangularity)
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dTMatrix" i.e. did keep
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
is(NN2, "sparseMatrix"), all(NN2 == NN),
is(NN, "triangularMatrix"))
```

ldenseMatrix-class

Virtual Class "ldenseMatrix" of Dense Logical Matrices

Description

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

- x: logical vector containing the entries of the matrix.
- Dim, Dimnames: see Matrix.
ldiMatrix-class

Extends

Class "ldMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "ldMatrix". Class "Matrix", by class "denseMatrix".

Methods

coerce signature(from = "matrix", to = "ldenseMatrix"): ...
coerce signature(from = "ldenseMatrix", to = "matrix"): ...

as.vector signature(x = "ldenseMatrix", mode = "missing"): ...
which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x, arr.ind): for details, see the lMatrix class documentation.

See Also

Class lgeMatrix and the other subclasses.

Examples

showClass("ldenseMatrix")

as(diag(3) > 0, "ldenseMatrix")
Examples

(lM <- Diagonal(x = c(TRUE, FALSE, FALSE)))
str(lM)#> gory details (slots)
crossprod(lM) # numeric
(nM <- as(lM, "nMatrix"))# -> sparse (not formally ```diagonal``')
crossprod(nM) # logical sparse

lgeMatrix-class

Class “lgeMatrix” of General Dense Logical Matrices

Description

This is the class of general dense logical matrices.

Slots

x: Object of class “logical”. The logical values that constitute the matrix, stored in column-major order.

Dim, Dimnames: The dimension (a length-2 “integer”) and corresponding names (or NULL), see the Matrix class.

factors: Object of class “list”. A named list of factorizations that have been computed for the matrix.

Extends

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="lgeMatrix") for details.

See Also

Non-general logical dense matrix classes such as ltrMatrix, or lsyMatrix; sparse logical classes such as lgCMatrix.

Examples

showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4, 7) > 0))# a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4, 7) > 0))# a simple random lgCMatrix
as(lM, "CsparseMatrix")
lsparseMatrix-classes

Sparse logical matrices

Description

The \texttt{lsparseMatrix} class is a virtual class of sparse matrices with \texttt{TRUE}/\texttt{FALSE} or \texttt{NA} entries. Only the positions of the elements that are \texttt{TRUE} are stored. These can be stored in the “triplet” form (class \texttt{TsparseMatrix}, subclasses \texttt{lgTMatrix}, \texttt{lsTMatrix}, and \texttt{ltTMatrix}) or in compressed column-oriented form (class \texttt{CsparseMatrix}, subclasses \texttt{lgCMatrix}, \texttt{lsCMatrix}, and \texttt{ltCMatrix}) or – rarely – in compressed row-oriented form (class \texttt{RsparseMatrix}, subclasses \texttt{lgRMatrix}, \texttt{lsRMatrix}, and \texttt{ltRMatrix}). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

Details

Note that triplet stored (\texttt{TsparseMatrix}) matrices such as \texttt{lgTMatrix} may contain duplicated pairs of indices \((i, j)\) as for the corresponding numeric class \texttt{dgTMatrix} where for such pairs, the corresponding \texttt{x} slot entries are added. For logical matrices, the \texttt{x} entries corresponding to duplicated index pairs \((i, j)\) are “added” as well if the addition is defined as logical or, i.e., “\texttt{TRUE + TRUE} |-> \texttt{TRUE}” and “\texttt{TRUE + FALSE} |-> \texttt{TRUE}”. Note the use of \texttt{uniqTsparse()} for getting an internally unique representation without duplicated \((i, j)\) entries.

Objects from the Class

Objects can be created by calls of the form \texttt{new("lgCMatrix", ...)} and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression \texttt{x != 0}.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

Slots

- \texttt{x}: Object of class "\texttt{logical}". i.e., either \texttt{TRUE}, \texttt{NA}, or \texttt{FALSE}.
- \texttt{uplo}: Object of class "\texttt{character}". Must be either "\texttt{U}" for upper triangular, and "\texttt{L}" for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- \texttt{diag}: Object of class "\texttt{character}". Must be either "\texttt{U}" for unit triangular (diagonal is all ones), or "\texttt{N}" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "\texttt{U}". Present in the triangular classes only.
- \texttt{p}: Object of class "\texttt{integer}" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- \texttt{i}: Object of class "\texttt{integer}" of length \texttt{nnzero} (number of non-zero elements). These are the row numbers for each \texttt{TRUE} element in the matrix. All other elements are \texttt{FALSE}. Present in triplet and compressed column-oriented forms only.
- \texttt{j}: Object of class "\texttt{integer}" of length \texttt{nnzero} (number of non-zero elements). These are the column numbers for each \texttt{TRUE} element in the matrix. All other elements are \texttt{FALSE}. Present in triplet and compressed row-oriented forms only.
lsyMatrix-class

**Dim:** Object of class "integer" - the dimensions of the matrix.

**Methods**

- **coerce** signature(from = "dgCMatrix", to = "lgCMatrix")
- **t** signature(x = "lgCMatrix"): returns the transpose of x
- **which** signature(x = "lsparseMatrix"), semantically equivalent to base function `which(x, arr.ind)`: for details, see the `lMatrix` class documentation.

**See Also**

the class `dgCMatrix` and `dgTMatrix`

**Examples**

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
          identical(!lm, m <= 1))
```

```r
data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1)# "lgC..."
```
**ltrMatrix-class**

**Objects from the Class**

Objects can be created by calls of the form `new("lsyMatrix", ...)`.

**Slots**

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "ldenseMatrix" and "symmetricMatrix", directly; further, class "Matrix" and others, indirectly. Use `showClass("lsyMatrix")`, e.g., for details.

**Methods**

Currently, mainly `t()` and coercion methods (for `as()`); use, e.g., `showMethods(class="dsyMatrix")` for details.

**See Also**

`lgeMatrix`, `Matrix`, `t` 

**Examples**

```r
(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
str(M2)
# can
(sM <- M2 | t(M2)) # "lge"
as(sM, "symmetricMatrix")
str(sM <- as(sM, "packedMatrix")) # packed symmetric
```

---

**ltrMatrix-class**  *Triangular Dense Logical Matrices*

**Description**

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltpMatrix" class is the same except in packed storage.
Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Both extend classes "ldenseMatrix" and "triangularMatrix", directly; further, class "Matrix", "lMatrix" and others, indirectly. Use showClass("ltrMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.); use, e.g., showMethods(class="ltpMatrix") for details.

See Also

Classes lgeMatrix, Matrix; function t

Examples

showClass("ltrMatrix")

str(new("ltpMatrix"))

(lutr <- as(upper.tri(matrix(, 4, 4)), "ldenseMatrix"))

str(lutr <- pack(lutr)) # packed matrix: only 10 = 4*(4+1)/2 entries

!lutr # the logical negation (is *not* logical triangular !)

## but this one is:

stopifnot(all.equal(lutr, pack(!lutr)))

lu (Generalized) Triangular Decomposition of a Matrix

Description

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.
Usage

lu(x, ...)
## S4 method for signature 'matrix'
lu(x, ...)
## S4 method for signature 'dgeMatrix'
u(x, warnSing = TRUE, ...)
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1,
    keep.dimnames = TRUE, ...)
## S4 method for signature 'dsyMatrix'
lu(x, cache = TRUE, ...)
## S4 method for signature 'dsCMatrix'
lu(x, cache = TRUE, ...)

Arguments

x a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.
warnSing (when x is a "denseMatrix") logical specifying if a warning should be signalled when x is singular.
errSing (when x is a "sparseMatrix") logical specifying if an error (see stop) should be signalled when x is singular. When x is singular, lu(x, errSing=FALSE) returns NA instead of an LU decomposition. No warning is signalled and the useR should be careful in that case.
order logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.
tol positive number indicating the pivoting tolerance used in cs_lu. Do only change with much care.
keep.dimnames logical indicating that dimnames should be propagated to the result, i.e., “kept”. This was hardcoded to FALSE in upto Matrix version 1.2-0. Setting to FALSE may gain some performance.
cache logical indicating if the result should be cached in x@factors; note that this argument is experimental and only available for certain classes inheriting from compMatrix.
...
... further arguments passed to or from other methods.

Details

lu() is a generic function with special methods for different types of matrices. Use showMethods("lu") to list all the methods for the lu generic.
The method for class dgeMatrix (and all dense, non-triangular matrices) is based on LAPACK’s "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.
The method for class dgCMatrix (and all sparse, non-triangular matrices) is based on functions from the CSparse library. It signals an error (or returns NA, when errSing = FALSE; see above) when the decomposition algorithm fails, as when x is (too close to) singular.

Value

An object of class "LU", i.e., "denseLU" (see its separate help page), or "sparseLU", see sparseLU; this is a representation of a triangular decomposition of x.
Because the underlying algorithm differ entirely, in the dense case (class `denseLU`), the decomposition is

\[ A = PLU, \]

where as in the sparse case (class `sparseLU`), it is

\[ A = P'L'UQ. \]
Details

The decomposition is of the form

\[ A = PLU \]

where typically all matrices are of size \( n \times n \), and the matrix \( P \) is a permutation matrix, \( L \) is lower triangular and \( U \) is upper triangular (both of class \( \text{dtrMatrix} \)).

Note that the dense decomposition is also implemented for a \( m \times n \) matrix \( A \), when \( m \neq n \).

If \( m < n \) ("wide case"), \( U \) is \( m \times n \), and hence not triangular.

If \( m > n \) ("long case"), \( L \) is \( m \times n \), and hence not triangular.

Objects from the Class

Objects can be created by calls of the form \( \text{new} \("\text{denseLU}\", \ldots) \). More commonly the objects are created explicitly from calls of the form \( \text{lu} \( \text{mm} \) \) where \( \text{mm} \) is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

Extends

"LU" directly extends the virtual class "MatrixFactorization".

"denseLU" directly extends "LU".

Slots

\( x \): object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can retrieved by the \( \text{expand}() \) method, see below.

\( \text{perm} \): Object of class "integer" - a vector of length \( \min(\text{Dim}) \) that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.

\( \text{Dim} \): the dimension of the original matrix; inherited from class \( \text{MatrixFactorization} \).

Methods

\( \text{expand} \) signature(\( x = \"\text{denseLU}\" \)): Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

\( \text{solve} \) signature(\( a = \"\text{denseLU}\", b = \"missing\" \)): Compute the inverse of \( A \), \( A^{-1} \), \( \text{solve}(A) \) using the LU decomposition, see also \( \text{solve-methods} \).

See Also

class \( \text{sparseLU} \) for LU decompositions of \( \text{sparse} \) matrices; further, class \( \text{dgeMatrix} \) and functions \( \text{lu}, \text{expand} \).

Examples

\[
\begin{align*}
\text{set.seed}(1) \\
\text{mm} &\leftarrow \text{Matrix}(\text{round}(\text{rnorm}(9), 2), \text{nrow} = 3) \\
\text{mm} &\text{str(lum} \leftarrow \text{lu}(\text{mm}) \\
\text{elu} &\leftarrow \text{expand(lum)} \\
\text{elu} &\# \text{ three components: } \text{"L"}, \text{"U"}, \text{and } \text{"P"}, \text{the permutation} \\
\text{elu} &\text{L \%\% elu}\$L \\
\text{m2} &\leftarrow \text{with(elu, P \%\% L \%\% U)) \# the same as 'mm'}
\end{align*}
\]
stopifnot(all.equal(as(mm, "matrix"),
                   as(m2, "matrix")))

---

**Description**

From an R object coercible to "TsparseMatrix", typically a (sparse) matrix, produce its triplet representation which may collapse to a "Duplet" in the case of binary aka pattern, such as "nMatrix" objects.

**Usage**

```r
mat2triplet(x, uniqT = FALSE)
```

**Arguments**

- `x` any R object for which `as(x, "TsparseMatrix")` works; typically a matrix of one of the Matrix package matrices.
- `uniqT` logical indicating if the triplet representation should be ‘unique’ in the sense of `uniqTsparse()`.

**Value**

A list, typically with three components,

- `i` vector of row indices for all non-zero entries of `x`
- `j` vector of columns indices for all non-zero entries of `x`
- `x` vector of all non-zero entries of `x`; exists only when `as(x, "TsparseMatrix")` is not a "TsparseMatrix".

Note that the order of the entries is determined by the coercion to "TsparseMatrix" and hence typically with increasing `j` (and increasing `i` within ties of `j`).

**Note**

The `mat2triplet()` utility was created to be a more efficient and more predictable substitute for `summary(<sparseMatrix>)`. UseRs have wrongly expected the latter to return a data frame with columns `i` and `j` which however is wrong for a "diagonalMatrix".

**See Also**

The `summary()` method for "sparseMatrix", `summary`, `sparseMatrix-method`. `mat2triplet()` is conceptually the inverse function of `spMatrix` and (one case of) `sparseMatrix`.
Matrix

Examples

if(FALSE) ## The function is defined (don’t redefine here!), simply as
mat2triplet <- function(x, uniqT = FALSE) {
  T <- as(x, "TsparseMatrix")
  if(uniqT && anyDuplicatedT(T)) T <- .uniqTsparse(T)
  if(is(T, "nsparseMatrix"))
    list(i = T@i + 1L, j = T@j + 1L)
  else list(i = T@i + 1L, j = T@j + 1L, x = T@x)
}

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(Ax <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
str(trA <- mat2triplet(Ax))
stopifnot(i == sort(trA$i), sort(j) == trA$j, x == sort(trA$x))

D <- Diagonal(x=4:2)
summary(D)
str(mat2triplet(D))

Matrix

Construct a Classed Matrix

Description

Construct a Matrix of a class that inherits from Matrix.

Usage

Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
       sparse = NULL, doDiag = TRUE, forceCheck = FALSE)

Arguments

data an optional numeric data vector or matrix.
nrow when data is not a matrix, the desired number of rows
ncol when data is not a matrix, the desired number of columns
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
dimnames a dimnames attribute for the matrix: a list of two character components. They are set if not NULL (as per default).
sparse logical or NULL, specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0.
doDiag logical indicating if a diagonalMatrix object should be returned when the resulting matrix is diagonal (mathematically). As class diagonalMatrix extends sparseMatrix, this is a natural default for all values of sparse.
Otherwise, if doDiag is false, a dense or sparse (depending on sparse) symmetric matrix will be returned.
forceCheck logical indicating if the checks for structure should even happen when data is already a "Matrix" object.
Details

If either of \texttt{nrow} or \texttt{ncol} is not given, an attempt is made to infer it from the length of \texttt{data} and the other parameter. Further, \texttt{Matrix()} makes efforts to keep \texttt{logical} matrices logical, i.e., inheriting from class \texttt{lMatrix}, and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a \texttt{symmetric} matrix also needs symmetric \texttt{dimnames}, e.g., by specifying \texttt{dimnames = list(NULL,NULL)}, see the examples.

Most of the time, the function works via a traditional (\texttt{full}) \texttt{matrix}. However, \texttt{Matrix(0, nrow,ncol)} directly constructs an “empty” \texttt{sparseMatrix}, as does \texttt{Matrix(FALSE, *)}.

Although it is sometime possible to mix unclassed matrices (created with \texttt{matrix}) with ones of class “Matrix”, it is much safer to always use carefully constructed ones of class “Matrix”.

Value

Returns matrix of a class that inherits from “Matrix”. Only if \texttt{data} is not a \texttt{matrix} and does not already inherit from class \texttt{Matrix} are the arguments \texttt{nrow}, \texttt{ncol} and \texttt{byrow} made use of.

See Also

The classes \texttt{Matrix}, \texttt{symmetricMatrix}, \texttt{triangularMatrix}, and \texttt{diagonalMatrix}; further, \texttt{matrix}.

Special matrices can be constructed, e.g., via \texttt{sparseMatrix} (sparse), \texttt{bdiag} (block-diagonal), \texttt{bandSparse} (banded sparse), or \texttt{Diagonal}.

Examples

\begin{verbatim}
Matrix(0, 3, 2) # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE)# -> 'dense'

## 4 cases - 3 different results :
Matrix(0, 2, 2) # diagonal !
Matrix(0, 2, 2, sparse=FALSE)# (ditto)
Matrix(0, 2, 2, doDiag=FALSE)# -> sparse symm. "dsCMatrix"
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE)# -> dense symm. "dsyMatrix"

Matrix(1:6, 3, 2) # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # (ditto)
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')

## triangular
l3 <- upper.tri(matrix(,3,3))
(M <- Matrix(l3)) # -> "ltCMatrix"
Matrix(! l3) # -> "ltrMatrix"
as(l3, "CsparseMatrix")# "lgCMatrix"

Matrix(1:9, nrow=3,
    dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3)))# identity, i.e., unit "diagonalMatrix"
str(I3) # note 'diag = "U"' and the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2))# symmetric *apart* from dimnames
Matrix(A) # hence 'dgeMatrix'
\end{verbatim}
Matrix-class

Virtual Class "Matrix" Class of Matrices

Description

The Matrix class is a class contained by all actual classes in the Matrix package. It is a “virtual” class.

Slots

Common to all matrix objects in the package:

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

Methods

determinant signature(x = "Matrix", logarithm = "missing"):

determinant signature(x = "Matrix", logarithm = "logical"):
 compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that det also works for all our matrices, calling the appropriate determinant() method. The Matrix::det is an exact copy of base::det, but in the correct namespace, and hence calling the S4-aware version of determinant().

diff signature(x = "Matrix"): As diff() for traditional matrices, i.e., applying diff() to each column.

dim signature(x = "Matrix"): extract matrix dimensions dim.

dim< signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to reshape Matrix objects, but only when prod(value) == prod(dim(x)).

dimnames signature(x = "Matrix"): extract dimnames.

dimnames<- signature(x = "Matrix", value = "list"): set the dimnames to a list of length 2, see dimnames<-.

length signature(x = "Matrix"): simply defined as prod(dim(x)) (and hence of mode "double").

show signature(object = "Matrix"): show method for printing. For printing sparse matrices, see printSpMatrix.

image signature(object = "Matrix"): draws an image of the matrix entries, using levelplot() from package lattice.

head signature(object = "Matrix"): return only the “head”, i.e., the first few rows.

tail signature(object = "Matrix"): return only the “tail”, i.e., the last few rows of the respective matrix.
as.matrix, as.array  signature(x = "Matrix"): the same as as(x, "matrix"); see also the note below.

as.vector  signature(x = "Matrix", mode = "missing"): as.vector(m) should be identical to as.vector(as(m,"matrix")), implemented more efficiently for some subclasses.

as(x, "vector"), as(x, "numeric") etc, similarly.

coerce  signature(from = "ANY", to = "Matrix"): This relies on a correct as.matrix() method for from.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., colSums, rowMeans. Even base functions may work automagically (if they first call as.matrix() on their principal argument), e.g., apply, eigen, svd or kappa all do work via coercion to a “traditional” (dense) matrix.

Note

Loading the Matrix namespace “overloads” as.matrix and as.array in the base namespace by the equivalent of function(x) as(x, "matrix"). Consequently, as.matrix(m) or as.array(m) will properly work when m inherits from the "Matrix" class — also for functions in package base and other packages. E.g., apply or outer can therefore be applied to "Matrix" matrices.

Author(s)

diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
## can reshape it even:
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
           all.equal(det(cm),
            determinant(as(cm,"matrix"), log=FALSE)$modulus,
            check.attributes=FALSE))
Matrix (Cross) Products (of Transpose)

Description

The basic matrix product, %*% is implemented for all our Matrix and also for sparseVector classes, fully analogously to R's base matrix and vector objects.

The functions crossprod and tcrossprod are matrix products or “cross products”, ideally implemented efficiently without computing t(.)’s unnecessarily. They also return symmetricMatrix classed matrices when easily detectable, e.g., in crossprod(m), the one argument case.

tcrossprod() takes the cross-product of the transpose of a matrix. tcrossprod(x) is formally equivalent to, but faster than, the call x %*% t(x), and so is tcrossprod(x, y) instead of x %*% t(y).

Boolean matrix products are computed via either %&% or boolArith = TRUE.

Usage

## S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y

## S4 method for signature 'dgeMatrix,missing'
crossprod(x, y = NULL, boolArith = NA, ...)

## S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)

## .... and for many more signatures

crossprod(x, y = NULL, boolArith = NA, ...)

crossprod(x, y = NULL, boolArith = NA, ...)

Arguments

x a matrix-like object

y a matrix-like object, or for [t]crossprod() NULL (by default); the latter case is formally equivalent to y = x.

boolArith logical, i.e., NA, TRUE, or FALSE. If true the result is (coerced to) a pattern matrix, i.e., "nMatrix", unless there are NA entries and the result will be a "lMatrix". If false the result is (coerced to) numeric. When NA, currently the default, the result is a pattern matrix when x and y are "nsparseMatrix" and numeric otherwise.

... potentially more arguments passed to and from methods.

Details

For some classes in the Matrix package, such as dgCMatrix, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product. boolArith = TRUE for regular (“non cross”) matrix products, %*% cannot be specified. Instead, we provide the %&% operator for boolean matrix products.
Value

A **Matrix** object, in the one argument case of an appropriate symmetric matrix class, i.e., inheriting from `symmetricMatrix`.

Methods

```%
%*% signature(x = "dgeMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dgeMatrix")`.  
%*% signature(x = "dtrMatrix", y = "matrix") and other signatures (use `showMethods("%*%", class="dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).

crossprod signature(x = "dgeMatrix", y = "dgeMatrix"): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.  
crossprod signature(x = "CsparseMatrix", y = "missing") returns `t(x) %*% x` as an `dsCMatrix` object.  
crossprod signature(x = "TsparseMatrix", y = "missing") returns `t(x) %*% x` as an `dsCMatrix` object.  
crossprod,tcrossprod signature(x = "dtrMatrix", y = "matrix") and other signatures, see "%*%" above.
```

Note

`boolArith = TRUE`, `FALSE` or `NA` has been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation has still not been tested extensively. Notably the behaviour for sparse matrices with `x` slots containing extra zeros had not been documented previously, see the `%&%` help page.

Currently, `boolArith = TRUE` is implemented via `CsparseMatrix` coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

See Also

`tcrossprod` in R’s base, and `crossprod` and `%*%`. **Matrix** package `%&%` for boolean matrix product methods.

Examples

```r
## A random sparse "incidence" matrix :
m <- matrix(0, 400, 500)  
set.seed(12)
m[runif(314, 0, length(m))] <- 1  
mm <- as(m, "CsparseMatrix")  
object.size(m) / object.size(mm) # smaller by a factor of > 200

## tcrossprod() is very fast:  
system.time(tCmm <- tcrossprod(mm)) # 0 (PIII, 933 MHz)  
system.time(cm <- crossprod(t(m))) # 0.16  
system.time(cm. <- tcrossprod(m)) # 0.02

stopifnot(cm == as(tCmm, "matrix"))

## show sparse sub matrix  
tCmm[1:16, 1:30]
```
MatrixClass

The Matrix (Super-) Class of a Class

Description

Return the (maybe super-)class of class cl from package Matrix, returning character(0) if there is none.

Usage

MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE, dropVirtual = TRUE, ...)

Arguments

- cl: string, class name
- cld: its class definition
- ...Matrix: logical indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind.
- dropVirtual: logical indicating if virtual classes are included or not.
- ...: further arguments are passed to .selectSuperClasses().

Value

a character string

Author(s)

Martin Maechler, 24 Mar 2009

See Also

Matrix, the mother of all Matrix classes.

Examples

mkA <- setClass("A", contains="dgCMatrix")
(A <- mkA())
stopifnot(identical(MatrixClass("A"), "dgCMatrix"))
Class "MatrixFactorization" of Matrix Factorizations

Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package Matrix.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from Matrix (and trivial sub class of "MatrixFactorization").

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

`Dim`: Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

Methods

- `dim(x)` simply returns `x@Dim`, see above.
- `expand` signature(`x = "MatrixFactorization"`): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original Matrix object.
- `show` signature(`object = "MatrixFactorization"`): simple printing, see `show`.
- `solve` signature(`a = "MatrixFactorization", b = .`): solve `Ax = b` for `x`; see `solve-methods`.

See Also

classes inheriting from "MatrixFactorization", such as LU, Cholesky, CHMfactor, and sparseQR.

Examples

```R
showClass("MatrixFactorization")
getClass("CholeskyFactorization")
```
ndenseMatrix-class

Virtual Class "ndenseMatrix" of Dense Logical Matrices

Description

ndenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

x: logical vector containing the entries of the matrix.

Dim, Dimnames: see Matrix.

Extends

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix". Class "Matrix", by class "denseMatrix".

Methods

%*% signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
%*% signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
coerce signature(from = "matrix", to = "ndenseMatrix"): ...
coerce signature(from = "ndenseMatrix", to = "matrix"): ...
crossprod signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
crossprod signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
as.vector signature(x = "ndenseMatrix", mode = "missing"): ...
diag signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic diag().

which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

See Also

Class ngeMatrix and the other subclasses.

Examples

showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
nearPD  Nearest Positive Definite Matrix

Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

Usage

nearPD(x, corr = FALSE, keepDiag = FALSE, base.matrix = FALSE, 
do2eigen = TRUE, doSym = FALSE, 
doDykstra = TRUE, only.values = FALSE, 
ensureSymmetry = !isSymmetric(x), 
eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08, 
maxit = 100, conv.norm.type = "I", trace = FALSE)

Arguments

x  numeric \(n \times n\) approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If \(x\) is not symmetric (and ensureSymmetry is not false), \(\text{symmpart}(x)\) is used.
corr  logical indicating if the matrix should be a correlation matrix.
keepDiag  logical, generalizing \(\text{corr}\): if TRUE, the resulting matrix should have the same diagonal \((\text{diag}(x))\) as the input matrix.
base.matrix  logical indicating if the resulting mat component should be a base matrix or (by default) a \(\text{Matrix}\) of class \(\text{dpoMatrix}\).
do2eigen  logical indicating if a \(\text{posdefify()}\) eigen step should be applied to the result of the Higham algorithm.
doSym  logical indicating if \(X \leftarrow (X + \text{t}(X))/2\) should be done, after \(X \leftarrow \text{tcrossprod(Qd, Q)}\); some doubt if this is necessary.
doDykstra  logical indicating if Dykstra’s correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration \(Y_k = P_U(P_S(Y_{k-1}))\).
only.values  logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.
ensureSymmetry  logical; by default, \(\text{symmpart}(x)\) is used whenever \(\text{isSymmetric}(x)\) is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. \textit{Beware} however that setting it FALSE for an asymmetric input \(x\), is typically nonsense!
eig.tol  defines relative positiveness of eigenvalues compared to largest one, \(\lambda_1\). Eigenvalues \(\lambda_k\) are treated as if zero when \(\lambda_k/\lambda_1 \leq \text{eig.tol}\).
conv.tol  convergence tolerance for Higham algorithm.
posd.tol  tolerance for enforcing positive definiteness (in the final posdefify step when do2eigen is TRUE).
maxit  maximum number of iterations allowed.
conv.norm.type  convergence norm type \((\text{norm}(\ast, \text{type}))\) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham’s proposal.
trace  logical or integer specifying if convergence monitoring should be traced.
Details

This implements the algorithm of Higham (2002), and then (if do2eigen is true) forces positive definiteness using code from posdefify. The algorithm of Knol and ten Berge (1989) (not implemented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting corr = TRUE just sets diag(.) <- 1 within the algorithm.

Higham (2002) uses Dykstra’s correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and still gave reasonable results; this simplification, now only used if doDykstra = FALSE, was active in nearPD() up to Matrix version 0.999375-40.

Value

If only.values = TRUE, a numeric vector of eigenvalues of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

- mat: a matrix of class dpoMatrix, the computed positive-definite matrix.
- eigenvalues: numeric vector of eigenvalues of mat.
- corr: logical, just the argument corr.
- normF: the Frobenius norm (norm(x-X, "F")) of the difference between the original and the resulting matrix.
- iterations: number of iterations needed.
- converged: logical indicating if iterations converged.

Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

References

See Also

A first version of this (with non-optional corr=TRUE) has been available as nearcor(); and more simple versions with a similar purpose posdefify(), both from package sfsmisc.

Examples

```r
## Higham(2002), p.334f - simple example
A <- matrix(1, 3,3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A$mat[1,2] # equivalent to all.equal(n.A$mat[1,2], 0.760689917, tolerance=1e-9)
```
all.equal(n.A.m, unname(as.matrix(n.A$mat)), tolerance = 1e-15)# seen rel.d.= 1.46e-16
}
set.seed(27)
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)

if(require("sfsmisc")) {
  m2 <- posdefify(m) # a simpler approach
  norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1, 0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1, 0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1, 0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1, 0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1, 0.798,
               0.826, 0.75, 0.742, 0.8, 0.798, 1),
nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.1$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr)# still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.1 $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF))# norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently :

norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805

### 3) a real data example from a 'systemfit' model (3 eq.):

(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"

dim(symW)# 24 x 24
class(symW)# "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) # looking more closely (EV sorted decreasingly):
tail(EV)# all 6 are negative
EV2 <- eigen(symW, only=TRUE)$values
stopifnot(EV > 0)
if(require("sfsmisc")) {
    plot(pmax(1e-3,EV), EV2, type="o", log="xy", xaxt="n",yaxt="n")
    eaxis(1); eaxis(2)
} else plot(pmax(1e-3,EV), EV2, type="o", log="xy")
abline(0,1, col="red3", lty=2)

---

**ngeMatrix-class**  
Class “ngeMatrix” of General Dense Nonzero-pattern Matrices

**Description**

This is the class of general dense nonzero-pattern matrices, see nMatrix.

**Slots**

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

**Methods**

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="ngeMatrix") for details.

**See Also**

Non-general logical dense matrix classes such as ntrMatrix, or nsyMatrix; sparse logical classes such as ngCMatrix.

**Examples**

showClass("ngeMatrix")
## "lgeMatrix" is really more relevant
Class "nMatrix" of Non-zero Pattern Matrices

Description

The nMatrix class is the virtual “mother” class of all non-zero pattern (or simply pattern) matrices in the Matrix package.

Slots

Common to all matrix object in the package:

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

Methods

There is a bunch of coercion methods (for as(...), e.g.,

```
coerce signature(from = "matrix", to = "nMatrix")
```
Note that these coercions (must) coerce NAs to non-zero, hence conceptually TRUE. This is particularly important when sparseMatrix objects are coerced to "nMatrix" and hence to nsparseMatrix.

```
coerce signature(from = "dMatrix", to = "nMatrix"), and
```
```
coerce signature(from = "lMatrix", to = "nMatrix")
```
For dense matrices with NAs, these coercions are valid since Matrix version 1.2.0 (still with a warning or a message if "Matrix.warn", or "Matrix.verbose" options are set.)

```
coerce signature(from = "nMatrix", to = "matrix")
```
```
coerce signature(from = "nMatrix", to = "dMatrix")
```
```
coerce signature(from = "nMatrix", to = "lMatrix")
```
---

Additional methods contain group methods, such as

```
Ops signature(e1 = "nMatrix", e2 = "...")
```
```
Arith signature(e1 = "nMatrix", e2 = "...")
```
```
Compare signature(e1 = "nMatrix", e2 = "...")
```
```
Logic signature(e1 = "nMatrix", e2 = "...")
```
```
Summary signature(x = "nMatrix", "...")
```

Examples

getClass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntC*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix")# currently "ngTMatrix"

### nnzero

#### The Number of Non-Zero Values of a Matrix

**Description**

Returns the number of non-zero values of a numeric-like R object, and in particular an object \( x \) inheriting from class \( \text{Matrix} \).

**Usage**

nnzero(\( x \), na.counted = NA)

**Arguments**

- **\( x \)**: an R object, typically inheriting from class \( \text{Matrix} \) or \( \text{numeric} \).
- **\( \text{na.counted} \)**: a logical describing how \( \text{NAs} \) should be counted. There are three possible settings for \( \text{na.counted} \):
  - **\( \text{TRUE} \)**: \( \text{NAs are counted as non-zero} \) (since “they are not zero”).
  - **\( \text{NA} \)** (default): the result will be \( \text{NA} \) if there are \( \text{NA}'s \) in \( x \) (since “\( \text{NA}'s \) are not known, i.e., may be zero”).
  - **\( \text{FALSE} \)**: \( \text{NAs are omitted} \) from \( x \) before the non-zero entries are counted.

For sparse matrices, you may often want to use \( \text{na.counted} = \text{TRUE} \).

**Value**

the number of non zero entries in \( x \) (typically integer).

Note that for a symmetric sparse matrix \( S \) (i.e., inheriting from class \( \text{symmetricMatrix} \)), \( \text{nnzero}(S) \) is typically twice the length(\( S@x \)).

**Methods**

- **signature(\( x = \"ANY\")**: the default method for non-\( \text{Matrix} \) class objects, simply counts the number of 0s in \( x \), counting NA’s depending on the \( \text{na.counted} \) argument, see above.
- **signature(\( x = \"denseMatrix\))**: conceptually the same as for traditional \( \text{matrix} \) objects, care has to be taken for “\( \text{symmetricMatrix} \)” objects.
- **signature(\( x = \"diagonalMatrix\))**, and **signature(\( x = \"indMatrix\))**: fast simple methods for these special “\( \text{sparseMatrix} \)” classes.
- **signature(\( x = \"sparseMatrix\))**: typically, the most interesting method, also carefully taking “\( \text{symmetricMatrix} \)” objects into account.
See Also

The Matrix class also has a length method; typically, length(M) is much larger than nnzero(M) for a sparse matrix M, and the latter is a better indication of the size of M.
drop0, zapsmall.

Examples

m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "TsparseMatrix"))

nnzero(mT)
(S <- crossprod(mT))

nnzero(S)
str(S) # slots are smaller than nnzero()

stopifnot(nnzero(S) == sum(as.matrix(S) != 0))# failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)

length(M); stopifnot(length(M) == prod(dim(M)))

nnzero(M) # more relevant than length

## the above are also visible from

str(M)

---

norm

Matrix Norms

Description

Computes a matrix norm of x, using Lapack for dense matrices. The norm can be the one ("O", or "1") norm, the infinity ("I" or "i") norm, the Frobenius ("F" or "f") norm, the maximum modulus ("M" or "m") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of type.

Usage

norm(x, type, ...)

Arguments

x

A real or complex matrix.

type

A character indicating the type of norm desired.

"O", "o" or "1" specifies the one norm, (maximum absolute column sum);
"I" or "i" specifies the infinity norm (maximum absolute row sum);
"F" or "f" specifies the Frobenius norm (the Euclidean norm of x treated as if it were a vector);
"M" or "m" specifies the maximum modulus of all the elements in x; and
"2" specifies the “spectral norm” or 2-norm, which is the largest singular value (svd) of x.

The default is "O". Only the first character of type[1] is used.

... further arguments passed to or from other methods.
Details
For dense matrices, the methods eventually call the Lapack functions dlange, dlansy, dlantr, zlange, zlansy, and zlantr.

Value
A numeric value of class "norm", representing the quantity chosen according to type.

References

See Also
onenormest(), an approximate randomized estimate of the 1-norm condition number, efficient for large sparse matrices.
The norm() function from R’s base package.

Examples
x <- Hilbert(9)
norm(x)# = "O" = "1"
stopifnot(identical(norm(x), norm(x, "1")))
norm(x, "1")# the same, because 'x' is symmetric

allnorms <- function(d) vapply(c("1","I","F","M","2"),
norm, x = d, double(1))
allnorms(x)
allnorms(Hilbert(10))

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
A <- sparseMatrix(i, j, x = x) ## 8 x 10 "dgCMatrix"
(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
(allnorms(A) -> nA)
allnorms(sA)
allnorms(tA)
stopifnot(all.equal(nA, allnorms(as(A, "matrix"))),
  all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)
A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error

nsparseMatrix-classes
Sparse "pattern" Matrices

Description
The nsparseMatrix class is a virtual class of sparse “pattern” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.
These can be stored in the “triplet” form (TsparseMatrix, subclasses ngTMatrix, nsTMatrix, and ntTMatrix which really contain pairs, not triplets) or in compressed column-oriented form (class CsparseMatrix, subclasses ngCMatrix, nsCMatrix, and ntCMatrix) or–rarely–in compressed
The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

**Objects from the Class**

Objects can be created by calls of the form `new("ngCMatrix", ...) and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

**Slots**

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.

- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.

- **p**: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.

- **i**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.

- **Dim**: Object of class "integer" - the dimensions of the matrix.

**Methods**

- **coerce**: signature(from = "dgCMatrix", to = "ngCMatrix"), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.

- **t**: signature(x = "ngCMatrix"): returns the transpose of x

- **which**: signature(x = "lsparseMatrix"), semantically equivalent to base function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

**See Also**

- the class `dgCMatrix`

**Examples**

```r
(m <- Matrix(c(0, 0, 2, 0), 3, 5, dimnames=list(LETTERS[1:3],NULL)))
## extract the nonzero-pattern of (m) into an nMatrix'
nn <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(nn) # no 'x' slot
```
nsyMatrix-class

Symmetric Dense Nonzero-Pattern Matrices

Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...).

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim`, `Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas "nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use `showClass("nsyMatrix")`, e.g., for details.

Methods

Currently, mainly `t()` and coercion methods (for `as()`; use, e.g., `showMethods(class="dsyMatrix")` for details.
ntrMatrix-class

Triangular Dense Logical Matrices

Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas
"ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, indirectly, use showClass("nsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="nsyMatrix") for details.

stopifnot(all.equal(nutp, pack(!nutp)))
```

description

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union (setClassUnion) of "numeric" and "complex".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

Examples

```
showClass("number")
stopifnot( is(1i, "number"), is(pi, "number"), is(1:3, "number") )
```

packedMatrix-class

Virtual class "packedMatrix" of Packed Dense Matrices

Description

Class "packedMatrix" is the virtual class of dense symmetric or triangular matrices in "packed" format, storing only the choose(n+1,2) == n*(n+1)/2 elements of the upper or lower triangle of an n-by-n matrix. It is used to define common methods for efficient subsetting, transposing, etc. of its proper subclasses: currently "[dl]spMatrix" (packed symmetric), "[dl]tpMatrix" (packed triangular), and subclasses of these, such as "dppMatrix", "pCholesky", and "pBunchKaufman".

Slots

- `uplo`: "character"; either "U", for upper triangular, and "L", for lower.
- `Dim, Dimnames`: as all `Matrix` objects.

showMethods(classes = "packedMatrix")

---

Description
The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.
Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the Matrix package; see the 'Details' below.

Details
Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix \( M \) and a permutation matrix \( P \) (where we assume matching dimensions):

\[
MP = M \times P = M[, i(p)] \\
P M = P \times M = M[ p, ] \\
P' M = \text{crossprod}(P, M) (\approx t(P) \times M) = M[i(p), ] \\
M P' = \text{tcrossprod}(M, P) (\approx M \times t(P)) = M[ , p ]
\]

where \( p \) is the "permutation vector" corresponding to the permutation matrix \( P \) (see first note), and \( i(p) \) is short for \text{invPerm}(p).
Also one could argue that these are really only two cases if you take into account that inversion (solve) and transposition (t) are the same for permutation matrices \( P \).

Objects from the Class
Objects can be created by calls of the form \text{new("pMatrix", ...)} or by coercion from an integer permutation vector, see below.

Slots
perm: An integer, 1-based permutation vector, i.e. an integer vector of length \text{Dim}[1] whose elements form a permutation of \( 1: \text{Dim}[1] \).
Dim: Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.
Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding \text{Dim} element.
Extends

Class "indMatrix", directly.

Methods

\%
\% signature(x = "matrix", y = "pMatrix") and other signatures (use
\showMethods("\%
\%
", class="pMatrix"): ...

\coerce signature(from = "integer", to = "pMatrix"): This is enables typical "pMatrix" con-
struction, given a permutation vector of 1:n, see the first example.

\coerce signature(from = "numeric", to = "pMatrix"): a user convenience, to allow as(perm, "pMatrix") for numeric perm with integer values.

\coerce signature(from = "pMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE
matrix of mode logical. (in earlier version of Matrix, it resulted in a 0/1-integer matrix;
logical makes slightly more sense, corresponding better to the “natural” sparseMatrix coun-
terpart, "ngTMatrix").

\coerce signature(from = "pMatrix", to = "ngTMatrix"): coercion to sparse logical matrix of
class ngTMatrix.

determinant signature(x = "pMatrix", logarithm="logical"): Since permutation matrices
are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the sign of the permuta-
tion.

\solve signature(a = "pMatrix", b = "missing"): return the inverse permutation matrix; note
that solve(P) is identical to t(P) for permutation matrices. See solve-methods for other
methods.

\t signature(x = "pMatrix"): return the transpose of the permutation matrix (which is also the
inverse of the permutation matrix).

Note

For every permutation matrix P, there is a corresponding permutation vector p (of indices, 1:n), and
these are related by

\[ P \leftarrow \text{as}(p, "pMatrix") \]
\[ p \leftarrow P@perm \]

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an "indMatrix". See "indMatrix" for all
other subsetting/indexing and subassignment (A[..] <- v) operations.

See Also

\invPerm(p) computes the inverse permutation of an integer (index) vector p.

Examples

(pm1 <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pm1) # is the same as
\solve(pm1)

pm1 \%
\% t(pm1) # check that the transpose is the inverse
\stopifnot(all(diag(3) == as(pm1 \%
\% t(pm1), "matrix")),
is.logical(as(pm1, "matrix")))
## random permutation matrix :
(p10 <- as(sample(10), "pMatrix"))

## Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))
mm %*% pm1
pm1 %*% mm
try(as(as.integer(c(3,3,1)), "pMatrix")) # Error: not a permutation

as(pm1, "TsparseMatrix")
p10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)

## row-indexing of a <pMatrix> keeps it as an <indMatrix>:
p10[1:3, ]

---

**printSpMatrix**

Format and Print Sparse Matrices Flexibly

**Description**

Format and print sparse matrices flexibly. These are the “workhorses” used by the `format`, `show` and `print` methods for sparse matrices. If `x` is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when `x` is too wide. `printSpMatrix()` basically prints the result of `formatSpMatrix()`.

**Usage**

```r
formatSpMatrix(x, digits = NULL, maxp = 1e9, cld = getClassDef(class(x)), zero.print = ".", col.names, note.dropping.colnames = TRUE, uniDiag = TRUE, align = c("fancy", "right"))
```

```r
printSpMatrix(x, digits = NULL, maxp = max(100L, getOption("max.print")), cld = getClassDef(class(x)), zero.print = ".", col.names, note.dropping.colnames = TRUE, uniDiag = TRUE, col.trailer = ",", align = c("fancy", "right"))
```

```r
printSpMatrix2(x, digits = NULL, maxp = max(100L, getOption("max.print")), zero.print = ".", col.names, note.dropping.colnames = TRUE, uniDiag = TRUE, suppRows = NULL, suppCols = NULL, col.trailer = if(suppCols) "......" else ",", align = c("fancy", "right"),
width = getOption("width"), fitWidth = TRUE)
```

**Arguments**

- **x**: an R object inheriting from class `sparseMatrix`.
- **digits**: significant digits to use for printing, see `print.default`, the default, `NULL`, corresponds to using `getOption("digits")`. 

---

---
maxp integer, default from `options(max.print)`, influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently “rounded up” to 100.

cld the class definition of x; must be equivalent to `getClassDef(class(x))` and exists mainly for possible speedup.

zero.print character which should be printed for structural zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like `print()`ing of non-sparse matrices.

col.names logical or string specifying if and how column names of x should be printed, possibly abbreviated. The default is taken from `options("sparse.colnames")` if that is set, otherwise FALSE unless there are less than ten columns. When TRUE the full column names are printed. When col.names is a string beginning with "abb" or "sub" and ending with an integer n (i.e., of the form "abb...<n>"), the column names are `abbreviate()`d or `substring()`ed to (target) length n, see the examples.

note.dropping.colnames logical specifying, when col.names is FALSE if the dropping of the column names should be noted, TRUE by default.

uniDiag logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1’s are “structural”).

col.trailer a string to be appended to the right of each column; this is typically made use of by `show(<sparseMatrix>)` only, when suppressing columns.

suppRows, suppCols logicals or NULL, for `printSpMatrix2()` specifying if rows or columns should be suppressed in printing. If NULL, sensible defaults are determined from `dim(x)` and `options(c("width", "max.print"))`. Setting both to FALSE may be a very bad idea.

align a string specifying how the zero.print codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical zero.print = "." with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas align = "right" just makes use of `print(*, right = TRUE)`.

width number, a positive integer, indicating the approximately desired (line) width of the output, see also `fitWidth`.

fitWidth logical indicating if some effort should be made to match the desired width or temporarily enlarge that if deemed necessary.

Details

`formatSpMatrix`: If x is large, only the first rows making up the approximately first maxp entries is used, otherwise all of x. `formatSparseSimple()` is applied to (a dense version of) the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without x slot.

Value

`formatSpMatrix()` returns a character matrix with possibly empty column names, depending on col.names etc, see above.

`printSpMatrix*()` return x invisibly, see `invisible`. 
Author(s)
Martin Maechler

See Also
the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

Examples

```r
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## show(X) == print(X)
t(X) ## shows column names, since only 5 columns
X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")), "sparseMatrix")
X2
## less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

## Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names = TRUE)
print(t(X2), zero.print = ",", col.names = "abbr. 1")
print(t(X2), zero.print = ",", col.names = "substring 2")
```

Description

The Matrix package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses `qr` as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

Usage

```r
qr(x, ...)
qrR(qr, complete = FALSE, backPermute = TRUE, row.names = TRUE)
```

Arguments

- `x` a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
- `qr` a QR decomposition of the type computed by `qr`.
- `complete` logical indicating whether the `R` matrix is to be completed by binding zero-value rows beneath the square upper triangle.
backPermute  logical indicating if the rows of the \( R \) matrix should be back permuted such that \( qr() \)'s result can be used directly to reconstruct the original matrix \( X \).

row.names  logical indicating if rownames should propagated to the result.

...  further arguments passed to or from other methods

Methods

\( x = \text{"dgCMatrix"} \)  QR decomposition of a general sparse double-precision matrix with \( \text{nrow}(x) \geq \text{ncol}(x) \). Returns an object of class \text{"sparseQR"}.

\( x = \text{"sparseMatrix"} \)  works via \text{"dgCMatrix"}.

See Also

\text{qr}; then, the class documentations, mainly \text{sparseQR}, and also \text{dgCMatrix}.

})
\end{verbatim}
## rankMatrix

### Description

Compute ‘the’ matrix rank, a well-defined functional in theory(*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(*) The rank of a \( n \times m \) matrix \( A \), \( \text{rk}(A) \), is the maximal number of linearly independent columns (or rows); hence \( \text{rk}(A) \leq \min(n,m) \).

### Usage

```r
rankMatrix(x, tol = NULL,
    method = c("tolNorm2", "qr.R", "qrLINPACK", "qr",
    "useGrad", "maybeGrad"),
    sval = svd(x, 0, 0)$d, warn.t = TRUE, warn.qr = TRUE)
```

### Arguments

- **x** numeric matrix, of dimension \( n \times m \), say.
- **tol** nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, \( \max(\text{dim}(x)) \times \text{.Machine}$double$.eps \) is according to Matlab’s default (for its only method which is our method="tolNorm2").
- **method** a character string specifying the computational method for the rank, can be abbreviated:
"tolNorm2": the number of singular values >= tol * max(sval);
"qrLINPACK": for a dense matrix, this is the rank of qr(x, tol, 
LAPACK=FALSE) (which is qr(...)$rank);
This ("qr*", dense) version used to be the recommended way to compute a 
matrix rank for a while in the past.
For sparse x, this is equivalent to "qr .R".
"qr .R": this is the rank of triangular matrix R, where qr() uses LAPACK or a 
"sparseQR" method (see qr-methods) to compute the decomposition QR.
The rank of R is then defined as the number of “non-zero” diagonal entries 
di of R, and “non-zero”s fulfill |di| ≥ tol · max(|di|).
"qr": is for back compatibility; for dense x, it corresponds to "qrLINPACK",
whereas for sparse x, it uses "qr .R".
For all the "qr*" methods, singular values sval are not used, which may be 
crucially important for a large sparse matrix x, as in that case, when sval is 
not specified, the default, computing svd() currently coerces x to a dense 
matrix.
"useGrad": considering the “gradient” of the (decreasing) singular values, the 
index of the smallest gap.
"maybeGrad": choosing method "useGrad" only when that seems reasonable; 
otherwise using "tolNorm2".
sval numeric vector of non-increasing singular values of x; typically unspecified and 
computed from x when needed, i.e., unless method = "qr".
warn. t logical indicating if rankMatrix() should warn when it needs t(x) instead of 
x. Currently, for method = "qr" only, gives a warning by default because the 
caller often could have passed t(x) directly, more efficiently.
warn.qr in the QR cases (i.e., if method starts with "qr"), rankMatrix() calls 
qr2rankMatrix(., do.warn = warn.qr), see below.
qr an R object resulting from qr(x,...), i.e., typically inheriting from class "qr" 
or "sparseQR".
isBqr logical indicating if qr is resulting from base qr(). (Otherwise, it is typically 
from Matrix package sparse qr.)
do.warn logical; if true, warn about non-finite (or in the sparseQR case negative) diagonal 
entries in the R matrix of the QR decomposition. Do not change lightly!

Details

qr2rankMatrix() is typically called from rankMatrix() for the "qr*" methods, but can be used 
directly - much more efficiently in case the qr-decomposition is available anyway.

Value

If x is a matrix of all 0 (or of zero dimension), the rank is zero; otherwise, typically a positive integer 
in 1:min(dim(x)) with attributes detailing the method used.
There are rare cases where the sparse QR decomposition “fails” in so far as the diagonal entries 
of R, the di (see above), end with non-finite, typically NaN entries. Then, a warning is signalled 
(unless warn.qr / do.warn is not true) and NA (specifically, NA_integer_) is returned.
rankMatrix

Note

For large sparse matrices \( x \), unless you can specify \( sval \) yourself, currently method = "qr" may be the only feasible one, as the others need \( sval \) and call \( svd() \) which currently coerces \( x \) to a \texttt{denseMatrix} which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse \( x \), method = "qr", all non-strictly zero diagonal entries \( d_i \) where counted, up to including \texttt{Matrix} version 1.1-0, i.e., that method implicitly used \( tol = 0 \), see also the \texttt{set.seed(42)} example below.

sapply(5:15, rMQL, M = H12) # result is platform dependent
## 7 7 8 10 10 11 11 12 12 12 (x86_64)
sapply(5:15, rMQL, M = 1000 * H12) # not identical unfortunately
## 7 7 8 10 11 11 12 12 12 12
sapply(5:15, rMQR, M = H12)
## 5 6 7 8 8 9 9 10 10 11 11
sapply(5:15, rMQR, M = 1000 * H12) # the *same*

## "sparse" case:
M15 <- kronecker(diag(x=c(100,1,10)), Hilbert(5))
sapply(meths, function(.m.) rankMatrix(M15, method = .m.))
##-- all 15, but 'useGrad' has 14.

## "large" sparse
n <- 250000; p <- 33; nnz <- 10000
L <- sparseMatrix(i = sample.int(n, nnz, replace=TRUE),
 j = sample.int(p, nnz, replace=TRUE), x = rnorm(nnz))
(st1 <- system.time(r1 <- rankMatrix(L)))
(st2 <- system.time(r2 <- rankMatrix(L, method = "qr")))

r1[[1]] == print(r2[[1]]) ## --> ( 33 TRUE )

## another sparse="qr" one, which "failed" till 2013-11-23:
\end{verbatim}
set.seed(42)
f1 <- factor(sample(50, 1000, replace=TRUE))
f2 <- factor(sample(50, 1000, replace=TRUE))
f3 <- factor(sample(50, 1000, replace=TRUE))
D <- t(do.call(rbind, lapply(list(f1,f2,f3), as,'sparseMatrix')))
dim(D); nnzero(D)  # 1000 x 150 // 3000 non-zeros (= 2%)
stopifnot(rankMatrix(D, method='qr') == 148,
         rankMatrix(crossprod(D), method='qr') == 148)

## zero matrix has rank 0 :
stopifnot(sapply(meths, function(.m.)
             rankMatrix(matrix(0, 2, 2), method = .m.) == 0))

---

### `rcond`

#### Estimate the Reciprocal Condition Number

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by `showMethods(rcond)`.

#### Usage

```r
rcond(x, norm, ...)  # S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)
```

#### Arguments

- **x**: an R object that inherits from the `Matrix` class.
- **norm**: character string indicating the type of norm to be used in the estimate. The default is "O" for the 1-norm ("0" is equivalent to "1"). For sparse matrices, when `useInv=TRUE`, `norm` can be any of the kinds allowed for `norm`; otherwise, the other possible value is "I" for the infinity norm, see also `norm`.
- **useInv**: logical (or "Matrix" containing `solve(x)`). If not false, compute the reciprocal condition number as `1/(||x|| : ||\(x^{-1}\)||)`, where \(x^{-1}\) is the inverse of \(x\), `solve(x)`. This may be an efficient alternative (only) in situations where `solve(x)` is fast (or known), e.g., for (very) sparse or triangular matrices.

#### Value

An estimate of the reciprocal condition number of \(x\).
BACKGROUND

The condition number of a regular (square) matrix is the product of the norm of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices $A$) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$ 

Whenever $x$ is not a square matrix, in our method definitions, this is typically computed via $\text{rcond}(\text{qr}(.R(\text{qr}(X))), \ldots)$ where $X$ is $x$ or $t(x)$.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

$r\text{cond}(\cdot)$ computes the reciprocal condition number $1/\kappa$ with values in $[0, 1]$ and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka “singular”).

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

$\text{norm}$, $\text{kappa()}$ from package *base* computes an approximate condition number of a “traditional” matrix, even non-square ones, with respect to the $p = 2$ (Euclidean) $\text{norm}$. $\text{solve}$.

$\text{condest}$, a newer approximate estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

Examples

```r
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9))  # should be about 9.1e-13

## For non-square matrices:
rcond(x1 <- cbind(1,1:10))  # 0.05278
rcond(x2 <- cbind(x1, 2:11))  # practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))
```
## Large sparse example ----------
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
  system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)
  system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
  c(r, r.) # 0.05555 0.013888
## for all 4 norms available for sparseMatrix :
  cbind(rr <- sapply(c("1","1","F","M"),
    function(N) rcond(M3, norm=N, useInv=TRUE)))

### `rep2abI`

**Replicate Vectors into `abIndex` Result**

**Description**

`rep2abI(x, times)` conceptually computes `rep.int(x, times)` but with an `abIndex` class result.

**Usage**

`rep2abI(x, times)`

**Arguments**

- `x` numeric vector
- `times` integer (valued) scalar: the number of repetitions

**Value**

a vector of class `abIndex`

**See Also**

`rep.int()`, the base function; `abIseq`, `abIndex`.

**Examples**

```r
(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
  rep(2:7, 4)))
```
replValue-class

Virtual Class "replValue" - Simple Class for Subassignment Values

Description

The class "replValue" is a virtual class used for values in signatures for sub-assignment of Matrix matrices.

In fact, it is a simple class union (setClassUnion) of "numeric" and "logical" (and maybe "complex" in the future).

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

Subassign-methods, also for examples.

Examples

showClass("replValue")

rleDiff-class

Class "rleDiff" of rle(diff(.)) Stored Vectors

Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of linear stretches. For such a vector x, diff(x) consists of constant stretches and is hence well compressable via rle().

Objects from the Class

Objects can be created by calls of the form new("rleDiff", ...).

Currently experimental, see below.

Slots

  first: A single number (of class "numLike", a class union of "numeric" and "logical").
  rle: Object of class "rle", basically a list with components "lengths" and "values", see rle(). As this is used to encode potentially huge index vectors, lengths may be of type double here.

Methods

There is a simple show method only.

Note

This is currently an experimental auxiliary class for the class abIndex, see there.
rsparsematrix

Random Sparse Matrix

Description

Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and rand.x = NULL generates random pattern matrices, i.e. inheriting from nsparseMatrix.

Usage

rsparsematrix(nrow, ncol, density, nnz = round(density * maxE), symmetric = FALSE, rand.x = function(n) signif(rnorm(n), 2), ...)

Arguments

nrow, ncol number of rows and columns, i.e., the matrix dimension (dim).
density optional number in \([0, 1]\), the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for nnz, otherwise nnz needs to be specified.
nnz number of non-zero entries, for a sparse matrix typically considerably smaller than nrow*ncol. Must be specified if density is not.
symmetric logical indicating if result should be a matrix of class symmetricMatrix. Note that in the symmetric case, nnz denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.
rand.x NULL or the random number generator for the x slot, a function such that rand.x(n) generates a numeric vector of length n. Typical examples are rand.x = rnorm, or rand.x = runif; the default is nice for didactical purposes.
...

... optionally further arguments passed to sparseMatrix(), notably repr.

Details

The algorithm first samples “encoded” \((i,j)\)s without replacement, via one dimensional indices, if not symmetric sample.int(nrow*ncol, nnz), then—if rand.x is not NULL—gets \(x \leftarrow \text{rand.x}(\text{nnz})\) and calls sparseMatrix(i=i, j=j, x=x, ...). When rand.x=NULL, sparseMatrix(i=i, j=j, ...) will return a pattern matrix (i.e., inheriting from nsparseMatrix).

Value

a sparseMatrix, say \(M\) of dimension \((\text{nrow}, \text{ncol})\), i.e., with \(\text{dim}(M) == c(\text{nrow}, \text{ncol})\), if symmetric is not true, with \(\text{nzM} \leftarrow \text{nnzero}(M)\) fulfilling \(\text{nzM} \leq \text{nnz}\) and typically, \(\text{nzM} == \text{nnz}\).
Description

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("RsparseMatrix") for its subclasses.

Slots

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
p: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

Dim, Dimnames: inherited from the superclass, see sparseMatrix.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Originally, few methods were defined on purpose, as we rather use the CsparseMatrix in Matrix. Then, more methods were added but beware that these typically do not return "RsparseMatrix" results, but rather Csparse* or Tsparse* ones; e.g., R[i, j] <- v for an "RsparseMatrix" R works, but after the assignment, R is a (triplet) "TsparsesMatrix".

t signature(x = "RsparseMatrix"): ...

coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"): ...

coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"): ...
See Also

its superclass, \texttt{spMatrix}, and, e.g., class \texttt{dgRMatrix} for the links to other classes.

Examples

\begin{verbatim}
showClass("RsparseMatrix")
\end{verbatim}

\section*{Description}

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

\section*{Usage}

\begin{verbatim}
Schur(x, vectors, ...)
\end{verbatim}

\section*{Arguments}

\begin{itemize}
  \item \texttt{x} \hspace{1cm} numeric square Matrix (inheriting from class "Matrix") or traditional \texttt{matrix}. Missing values (NAs) are not allowed.
  \item \texttt{vectors} \hspace{1cm} logical. When \texttt{TRUE} (the default), the Schur vectors are computed, and the result is a proper \texttt{MatrixFactorization} of class \texttt{Schur}.
  \item \texttt{...} \hspace{1cm} further arguments passed to or from other methods.
\end{itemize}

\section*{Details}

Based on the Lapack subroutine dgees.

\section*{Value}

If \texttt{vectors} are \texttt{TRUE}, as per default: If \texttt{x} is a \texttt{Matrix} an object of class \texttt{Schur}, otherwise, for a traditional \texttt{matrix} \texttt{x}, a list with components \texttt{T}, \texttt{Q}, and \texttt{EValues}.

If \texttt{vectors} are \texttt{FALSE}, a list with components

\begin{itemize}
  \item \texttt{T} \hspace{1cm} the upper quasi-triangular (square) matrix of the Schur decomposition.
  \item \texttt{EValues} \hspace{1cm} the vector of \texttt{numeric} or \texttt{complex} eigen values of \texttt{T} or \texttt{A}.
\end{itemize}

\section*{BACKGROUND}

If \texttt{A} is a square matrix, then \texttt{A = Q T t(Q)}, where \texttt{Q} is orthogonal, and \texttt{T} is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of \texttt{A} are the same as those of \texttt{T}, which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

\section*{References}

Examples

Schur(Hilbert(9))  # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE))# no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
  all.equal(eTA$values,
    local({z <- Sch.A@EValues
      z[order(Mod(z), decreasing=TRUE)]}), tolerance = 1e-13),
    identical(SchA$T, Sch.A@T),
    identical(SchA$EValues, Sch.A@EValues))

## For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
  T = a.m(Sch.A @ T),
  EValues = Sch.A@EValues)),
  all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))

---

Schur-class

Class "Schur" of Schur Matrix Factorizations

Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or "spectral") decompositions for general (possibly asymmetric) square matrices, see the Schur() function.

Objects from the Class

Objects of class "Schur" are typically created by Schur().

Slots

"Schur" has slots

T: Upper Block-triangular Matrix object.
Q: Square orthogonal "Matrix".
EValues: numeric or complex vector of eigenvalues of T.
Dim: the matrix dimension: equal to c(n,n) of class "integer".

Extends

Class "MatrixFactorization", directly.
solve-methods

## Trivial, of course:
str(Schur(Diagonal(5)))

## for more examples, see Schur()

solve-methods

Methods in Package Matrix for Function solve()

Description

Methods for generic function solve, for solving linear systems of equations. These solve for \( X \) in

\[
AX = B
\]

where \( A \) is a square matrix and \( X \) and \( B \) are matrices with compatible dimensions. The usual \texttt{R} syntax is

\[
x <- \texttt{solve}(a, b, \ldots)
\]

where \( b \) may also be a vector, in which case it is treated as a 1-column matrix. Methods support \( a \) inheriting from virtual classes \texttt{Matrix} and \texttt{MatrixFactorization} and \( b \) inheriting from virtual classes \texttt{Matrix} and \texttt{sparseVector}.

Usage

## solve(a, b, ...) # the two-argument version, almost always preferred to
## solve(a, ...) # the rarely needed one-argument version

## S4 method for signature 'dgCMatrix,missing'
solve(a, b, sparse = NA, \ldots)

## S4 method for signature 'dgCMatrix,matrix'
solve(a, b, sparse = FALSE, \ldots)

## S4 method for signature 'dgCMatrix,denseMatrix'
solve(a, b, sparse = FALSE, \ldots)

## S4 method for signature 'dgCMatrix,sparseMatrix'
solve(a, b, sparse = NA, tol = .Machine$double.eps, \ldots)

## S4 method for signature 'CHMfactor,denseMatrix'
solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), \ldots)
solve-methods

Arguments

- **a**: a square numeric matrix, typically of one of the classes in Matrix. Logical matrices are coerced to corresponding numeric ones.
- **b**: numeric vector or matrix (dense or sparse) as RHS of the linear system $Ax = b$.
- **sparse**: only when a is a sparseMatrix: logical specifying if the result should also (formally) be sparse.
- **tol**: only when a is a sparseMatrix and sparse is TRUE: an error is signaled if the ratio $\min(d)/\max(d)$, where $d = \text{abs(diag(U))}$ and $A = LU$, is less than tol, indicating (near-)singular $A$.
- **system**: only when a is a CHMfactor: character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does not solve the triangular system (but "L" does).

... potentially further arguments to the methods.

Methods

signature(a = "ANY", b = "ANY") is simply the base package’s S3 generic solve.

signature(a = "CHMfactor", b = "...."), system = The solve methods for a "CHMfactor" object take an optional third argument system whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve $Ax = b$ for $x$ where $A$ is sparse, positive-definite matrix that was factored to produce a. Analogously, system = "L" returns the solution $x$ of $Lx = b$; similarly, for all system codes but "P" and "Pt" where, e.g., $x <- \text{solve}(a, b, \text{system}="P")$ is equivalent to $x <- P %*% b$.

If b is a sparseMatrix, system is used as above the corresponding sparse CHOLMOD algorithm is called.

signature(a = "ddenseMatrix", b = "....") (for all b) work via as(a, "generalMatrix"), using its methods, see below.

signature(a = "denseLU", b = "missing") basically computes uses triangular forward- and back-solve.

signature(a = "dgCMatrix", b = "matrix") , and

signature(a = "dgCMatrix", b = "ddenseMatrix") with extra argument list ( sparse = FALSE, tol = .Machine$double.eps ): Uses the sparse lu(a) decomposition (which is cached in a’s factor slot). By default, sparse=FALSE, returns a denseMatrix, since $U^{-1} L^{-1} B$ may not be sparse at all, even when $L$ and $U$ are.

If sparse=TRUE, returns a sparseMatrix (which may not be very sparse at all, even if a was sparse).

signature(a = "dgCMatrix", b = "dsparseMatrix") , and

signature(a = "dgCMatrix", b = "missing") with extra argument list ( sparse=FALSE, tol = .Machine$double.eps ): Checks if a is symmetric, and in that case, coerces it to "symmetricMatrix", and then computes a sparse solution via sparse Cholesky factorization, independently of the sparse argument. If a is not symmetric, the sparse lu decomposition is used and the result will be sparse or dense, depending on the sparse argument, exactly as for the above (b = "ddenseMatrix") case.

signature(a = "dgeMatrix", b = ".....") solve the system via internal LU, calling LAPACK routines dgetri or dgetrs.

signature(a = "diagonalMatrix", b = "matrix") and other bs: Of course this is trivially implemented, as $D^{-1}$ is diagonal with entries $1/D[i, i]$. 
signature(a = \"dpoMatrix\", b = \"...\Matrix\") and
signature(a = \"dppMatrix\", b = \"...\Matrix\")  The Cholesky decomposition of a is calculated (if needed) while solving the system.
signature(a = \"dsCMatrix\", b = \"...\Matrix\")  All these methods first try Cholmod’s Cholesky factorization; if that works, i.e., typically if a is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the “general” matrices of class \"dgCMatrix\".
signature(a = \"dsyMatrix\", b = \"...\")  all end up calling LAPACK routines dsptri, dsptrs, dsytrs and dsytri.
signature(a = \"dtCMatrix\", b = \"CsparseMatrix\") , signature(a = \"dtCMatrix\", b = \"dgeMatrix\")  etc sparse triangular solve, in traditional S/R also known as backsolve, or forwardsolve. solve(a,b) is a sparseMatrix if b is, and hence a denseMatrix otherwise.
signature(a = \"dtrMatrix\", b = \"ddenseMatrix\")  and
signature(a = \"dtpMatrix\", b = \"matrix\")  and similar b, including \"missing\”, and \"diagonalMatrix\”:
all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.
signature(a = \"Matrix\", b = \"diagonalMatrix\")  works via as(b, \"CsparseMatrix\")
signature(a = \"sparseQR\", b = \"ANY\”) simply uses qr.coef(a, b).
signature(a = \"pMatrix\", b = \"...\”) these methods typically use crossprod(a,b), as the inverse of a permutation matrix is the same as its transpose.
signature(a = \"TsparseMatrix\", b = \"ANY\") all work via as(a, \"CsparseMatrix\”).

Examples

```r
## A close to symmetric example with “quite sparse” inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(ias <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [ TODO: assertError ]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$arch == \"x86_64\")

## Fails on 32-bit [ Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
stopifnot(all.equal(as.matrix(ias), as.matrix(iA0)))
a <- a + Diagonal(n)
iaad <- solve(a)
ias <- solve(a, sparse=TRUE)
stopifnot(all.equal(as(ias,\"denseMatrix\"), iad, tolerance=1e-14))
I. <- iad %*% a  ; image(I.)
```
```r
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %*% iad
.I0 <- drop0(zapsmall(.I))
stopifnot( all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
          all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)) )
```

---

**sparse.model.matrix**  
*Construct Sparse Design / Model Matrices*

**Description**

Construct a sparse model or “design” matrix, from a formula and data frame (`sparse.model.matrix`) or a single factor (`fac2sparse`).

The `fac2sparse()` functions are utilities, also used internally in the principal user level function `sparse.model.matrix()`.

**Usage**

```r
sparse.model.matrix(object, data = environment(object),
                    contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
                    drop.unused.levels = FALSE, row.names = TRUE,
                    sep = "", verbose = FALSE, ...)
```

```r
fac2sparse(from, to = c("d", "l", "n"),
            drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse)
fac2Sparse(from, to = c("d", "l", "n"),
           drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse,
           factorPatt12, contrasts.arg = NULL)
```

**Arguments**

- **object**: an object of an appropriate class. For the default method, a model formula or terms object.
- **data**: a data frame created with `model.frame`. If another sort of object, `model.frame` is called first.
- **contrasts.arg**: for `sparse.model.matrix()`: A list, whose entries are contrasts suitable for input to the `contrasts` replacement function and whose names are the names of columns of data containing factors.
  - for `fac2Sparse()`: character string or NULL or (coercable to) "sparseMatrix", specifying the contrasts to be applied to the factor levels.
- **xlev**: to be used as argument of `model.frame` if data has no "terms" attribute.
- **transpose**: logical indicating if the transpose should be returned; if the transposed is used anyway, setting `transpose = TRUE` is more efficient.
- **drop.unused.levels**: should factors have unused levels dropped? The default for `sparse.model.matrix` has been changed to `FALSE`, 2010-07, for compatibility with R’s standard (dense) `model.matrix()`.

---

**Description**

Construct a sparse model or “design” matrix, from a formula and data frame (`sparse.model.matrix`) or a single factor (`fac2sparse`).

The `fac2sparse()` functions are utilities, also used internally in the principal user level function `sparse.model.matrix()`.

**Usage**

```r
sparse.model.matrix(object, data = environment(object),
                    contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
                    drop.unused.levels = FALSE, row.names = TRUE,
                    sep = "", verbose = FALSE, ...)
```

```r
fac2sparse(from, to = c("d", "l", "n"),
            drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse)
fac2Sparse(from, to = c("d", "l", "n"),
           drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse,
           factorPatt12, contrasts.arg = NULL)
```

**Arguments**

- **object**: an object of an appropriate class. For the default method, a model formula or terms object.
- **data**: a data frame created with `model.frame`. If another sort of object, `model.frame` is called first.
- **contrasts.arg**: for `sparse.model.matrix()`: A list, whose entries are contrasts suitable for input to the `contrasts` replacement function and whose names are the names of columns of data containing factors.
  - for `fac2Sparse()`: character string or NULL or (coercable to) "sparseMatrix", specifying the contrasts to be applied to the factor levels.
- **xlev**: to be used as argument of `model.frame` if data has no "terms" attribute.
- **transpose**: logical indicating if the transpose should be returned; if the transposed is used anyway, setting `transpose = TRUE` is more efficient.
- **drop.unused.levels**: should factors have unused levels dropped? The default for `sparse.model.matrix` has been changed to `FALSE`, 2010-07, for compatibility with R’s standard (dense) `model.matrix()`.
sparse.model.matrix

row.names logical indicating if row names should be used.
sep character string passed to paste() when constructing column names from the
variable name and its levels.
verbose logical or integer indicating if (and how much) progress output should be
 printed.
... further arguments passed to or from other methods.
from (for fac2sparse()): a Factor.
to a character indicating the “kind” of sparse matrix to be returned. The default,
"d" is for double.
giveCsparse deprecated, replaced with repr; logical indicating if the result must be a
CsparseMatrix.
repr character string, one of "C", "T", or "R", specifying the sparse representation
to be used for the result, i.e., one from the super classes CsparseMatrix, TsparseMatrix, or RsparseMatrix.
factorPatt12 logical vector, say fp, of length two; when fp[1] is true, return “contrasted”
t(X); when fp[2] is true, the original ("dummy") t(X), i.e, the result of
dac2sparse().

Value

a sparse matrix, extending CsparseMatrix (for fac2sparse() if repr = "C" as per default; a
TsparseMatrix or RsparseMatrix, otherwise).
For fac2Sparse(), a list of length two, both components with the corresponding transposed
model matrix, where the corresponding factorPatt12 is true.
Note that model.Matrix(*, sparse=TRUE) from package MatrixModels may be often be preferable to sparse.model.matrix() nowadays, as model.Matrix() returns modelMatrix objects
with additional slots assign and contrasts which relate back to the variables used.
fac2sparse(), the basic workhorse of sparse.model.matrix(), returns the transpose (t) of the
model matrix.

Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

See Also

model.matrix in standard R’s package stats.
model.Matrix which calls sparse.model.matrix or model.matrix depending on its sparse
argument may be preferred to sparse.model.matrix.
as(f, "sparseMatrix") (see coerce(from = "factor", ..) in the class doc sparseMatrix) produces the transposed sparse model matrix for a single factor f (and no contrasts).

Examples

dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))
## Sparse method is equivalent to the traditional one:

```r
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
    Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
  all(sparse.model.matrix(~ 0+ a + b, dd) ==
    Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))
```

```r
(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
## X 1 1 1 . . . . . . . .
## Y . . . . 1 1 1 . . . .
## Z . . . . . . . . 1 1 1 1
## can also be computed via sparse.model.matrix():
f30 <- gl(3,0 )
f12 <- gl(3,0, 12)
stopifnot(
  all.equal(t( fac2sparse(ff ) ),
    sparse.model.matrix(~ 0+ff),
    tolerance = 0, check.attributes=FALSE),
  is(M <- fac2sparse(f30, drop= TRUE),"CsparseMatrix"), dim(M) == c(0, 0),
  is(M <- fac2sparse(f30, drop=FALSE),"CsparseMatrix"), dim(M) == c(3, 0),
  is(M <- fac2sparse(f12, drop= TRUE),"CsparseMatrix"), dim(M) == c(0,12),
  is(M <- fac2sparse(f12, drop=FALSE),"CsparseMatrix"), dim(M) == c(3,12)
)
```

sparseLU-class

### Sparse LU decomposition of a square sparse matrix

**Description**

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

**Objects from the Class**

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

**Slots**

- L: Object of class "dtCMatrix", the lower triangular factor from the left.
- U: Object of class "dtCMatrix", the upper triangular factor from the right.
- p: Object of class "integer", permutation applied from the left.
- q: Object of class "integer", permutation applied from the right.
- Dim: the dimension of the original matrix; inherited from class `MatrixFactorization`.

**Extends**

Class "LU", directly. Class "MatrixFactorization", by class "LU".
sparseLU-class

Methods

expand signature(x = "sparseLU") Returns a list with components P, L, U, and Q, where P and Q represent fill-reducing permutations, and L, and U the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product $P'LUQ$.

Note

The decomposition is of the form

$$A = P'LUQ,$$

or equivalently $PAQ' = LU$, where all matrices are sparse and of size $n \times n$. The matrices P and Q, and their transposes $P'$ and $Q'$ are permutation matrices, L is lower triangular and U is upper triangular.

sparseMatrix

General Sparse Matrix Construction from Nonzero Entries

Description

User-friendly construction of sparse matrices (inheriting from virtual class CsparseMatrix, RsparseMatrix, or TsparseMatrix) from the positions and values of their nonzero entries.

This interface is recommended over direct construction via calls such as new("..[CRT]Matrix", ...).

Usage

sparseMatrix(i, j, p, x, dims, dimnames,
        symmetric = FALSE, triangular = FALSE, index1 = TRUE,
        repr = c("C", "R", "T"), giveCsparse,
        check = TRUE, use.last.ij = FALSE)
Arguments

**i, j**
integer vectors of equal length specifying the positions (row and column indices) of the nonzero (or non-TRUE) entries of the matrix. Note that, when x is non-missing, the \( x_k \) corresponding to repeated pairs \((i_k, j_k)\) are added, for consistency with the definition of class `TsparseMatrix`, unless `use_last.ij` is TRUE, in which case only the last such \( x_k \) is used.

**p**
integer vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of \( i, j, \) and \( p \) must be missing.

**x**
optional, typically nonzero values for the matrix entries. If specified, then the length must equal that of \( i \) (or \( j \)) or equal 1, in which case \( x \) is recycled as necessary. If missing, then the result is a nonzero pattern matrix, i.e., inheriting from class `nsparseMatrix`.

**dims**
optional length-2 integer vector of matrix dimensions. If missing, then \( i+1+c(\max(i), \max(j)) \) is used.

**dimnames**
optional list of `dimnames`; if missing, then `NULL` ones are used.

**symmetric**
logical indicating if the resulting matrix should be symmetric. In that case, \((i, j, p)\) should specify only one triangle (upper or lower).

**triangular**
logical indicating if the resulting matrix should be triangular. In that case, \((i, j, p)\) should specify only one triangle (upper or lower).

**index1**
logical. If TRUE (the default), then \( i \) and \( j \) are interpreted as 1-based indices, following the R convention. That is, counting of rows and columns starts at 1. If FALSE, then they are interpreted as 0-based indices.

**repr**
character string, one of "C", "R", and "T", specifying the representation of the sparse matrix result, i.e., specifying one of the virtual classes `CsparseMatrix`, `RsparseMatrix`, and `TsparseMatrix`.

**giveCsparse**
(deprecated, replaced by `repr`) logical indicating if the result should inherit from `CsparseMatrix` or `TsparseMatrix`. Note that operations involving `CsparseMatrix` are very often (but not always) more efficient.

**check**
logical indicating whether to check that the result is formally valid before returning. Do not set to FALSE unless you know what you are doing!

**use.last.ij**
logical indicating if, in the case of repeated (duplicated) pairs \((i_k, j_k)\), only the last pair should be used. FALSE (the default) is consistent with the definition of class `TsparseMatrix`.

Details

Exactly one of the arguments \( i, j \) and \( p \) must be missing.

In typical usage, \( p \) is missing, \( i \) and \( j \) are vectors of positive integers and \( x \) is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If \( i \) or \( j \) is missing then \( p \) must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of \( p \), \( \text{rep}(\text{seq} \_\text{along}(dp), dp) \) where \( dp \leftarrow \text{diff}(p) \), is used as the (1-based) row or column indices.

You cannot set both `singular` and `triangular` to true; rather use `Diagonal()` (or its alternatives, see there).
The values of i, j, p and index1 are used to create 1-based index vectors i and j from which a `TsparseMatrix` is constructed, with numerical values given by x, if non-missing. Note that in that case, when some pairs \((i_k, j_k)\) are repeated (aka “duplicated”), the corresponding \(x_k\) are added, in consistency with the definition of the `TsparseMatrix` class, unless use.last.ij is set to true.

By default, when `repr = "C"`, the `CsparseMatrix` derived from this triplet form is returned, where `repr = "R"` now allows to directly get an `RsparseMatrix` and `repr = "T"` leaves the result as `TsparseMatrix`.

The reason for returning a `CsparseMatrix` object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in x then a `CsparseMatrix` is a unique representation of the sparse matrix.

### Value

A sparse matrix, by default in compressed sparse column format and (formally) without symmetric or triangular structure, i.e., by default inheriting from both `CsparseMatrix` and `generalMatrix`.

### Note

You do need to use `index1 = FALSE` (or add + 1 to i and j) if you want use the 0-based i (and j) slots from existing sparse matrices.

### See Also

`Matrix(*, sparse=TRUE)` for the constructor of such matrices from a *dense* matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like `sparseMatrix()` is needed. Further `bdiag` and `Diagonal` for (block-)diagonal and `bandSparse` for banded sparse matrix constructors.

Random sparse matrices via `rsparsematrix()`.

The standard `R xtabs(*, sparse=TRUE)`, for sparse tables and `sparse.model.matrix()` for building sparse model matrices.

Consider `CsparseMatrix` and similar class definition help files.

### Examples

```r
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
summary(A)
str(A) # note that *internally* 0-based row indices are used

(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
stopifnot( all(sA == tA + t(tA)) ,
          identical(sA, as(tA + t(tA), "symmetricMatrix")))

## dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)

## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))
```
## The slots are 0-index based, so
try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )
## fails and you should say so: 1-indexing is FALSE:
sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

## the (i,j) pairs can be repeated, in which case the x's are summed
( args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)) )
Aa <- do.call(sparseMatrix, args))
## explicitly ask for elimination of such duplicates, so
## that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, A. [1,2] == 2 ) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")])

## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
(nA <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)

m
str(m)
stopifnot(identical(dimnames(m), dn))

## pointers example in converting from other sparse matrix representations.
if(require(SparseM) && packageVersion("SparseM") >= 0.87 &&
nzchar(dfil <- system.file("extdata", "rua_32_ax.rua", package = "SparseM"))) {
X <- model.matrix(read.matrix.hb(dfil))
XX <- sparseMatrix(j = X@ja, p = X@ia - 1L, x = X@ra, dims = X@dimension)
validObject(XX)
## Alternatively, and even more user friendly :
X. <- as(X, "Matrix") # or also
X2 <- as(X, "sparseMatrix")
stopifnot(identical(XX, X.), identical(X., X2))
Virtual Class "sparseMatrix" — Mother of Sparse Matrices

Description

Virtual Mother Class of All Sparse Matrices

Slots

- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- **Dimnames**: a list of length two - inherited from class Matrix, see Matrix.

Extends

Class "Matrix", directly.

Methods

- **show** (object = "sparseMatrix"): The show method for sparse matrices prints "structural" zeroes as "." using printSpMatrix() which allows further customization.
- **print** signature(x = "sparseMatrix").
  The print method for sparse matrices by default is the same as show() but can be called with extra optional arguments, see printSpMatrix().
- **format** signature(x = "sparseMatrix").
  The format method for sparse matrices, see formatSpMatrix() for details such as the extra optional arguments.
- **summary** (object = "sparseMatrix", uniqT=FALSE): Returns an object of S3 class "sparseSummary" which is basically a data.frame with columns (i,j,x) (or just (i,j) for nsparseMatrix class objects) with the stored (typically non-zero) entries. The print method resembles Matlab's way of printing sparse matrices, and also the MatrixMarket format, see writeMM.
- **cbind2** (x = *, y = *): several methods for binding matrices together, column-wise, see the basic cbind and rbind functions.
  Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.
- **rbind2** (x = *, y = *): binding matrices together row-wise, see cbind2 above.
- **determinant** (x = "sparseMatrix", logarithm=TRUE): determinant() methods for sparse matrices typically work via Cholesky or lu decompositions.
- **diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.
- **dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to reshape a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill prod(value) == prod(dim(x)).
- **coerce** signature(from = "Factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator rows stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also colSums, norm, ... for methods with separate help pages.
sparsesparseQR-class

Note

In method selection for multiplication operations (i.e., \%*% and the two-argument form of \texttt{crossprod}) the \texttt{sparseMatrix} class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a \texttt{dgeMatrix} and the appropriate sparse matrix method is used.

See Also

\texttt{sparseMatrix}, and its references, such as \texttt{xtabs(*, sparse=TRUE)}, or \texttt{sparse.model.matrix()}, for constructing sparse matrices.

\texttt{T2graph} for conversion of “graph” objects (package \texttt{graph}) to and from sparse matrices.

Examples

\begin{verbatim}
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.()) method suppresses printing of the majority of rows

data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor -> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[-,i.mis] == X.[,-i.mis]))
\end{verbatim}

Description

Objects class \texttt{"sparseQR"} represent a QR decomposition of a sparse $m \times n$ (“long”: $m \geq n$) rectangular matrix $A$, typically resulting from \texttt{qr()}, see ‘Details’ notably about row and column permutations for pivoting.

Details

For a sparse $m \times n$ (“long”: $m \geq n$) rectangular matrix $A$, the sparse QR decomposition is either of the form $PA = QR$ with a (row) permutation matrix $P$, (encoded in the $p$ slot of the result) if the $q$ slot is of length 0,

or of the form $PAP^* = QR$ with an extra (column) permutation matrix $P^*$ (encoded in the $q$ slot). Note that the row permutation $PA$ in $R$ is simply $A[p+1, \ ]$ where $p$ is the $p$-slot, a 0-based permutation of $1:n$ applied to the rows of the original matrix.

If the $q$ slot has length $n$ it is a 0-based permutation of $1:n$ applied to the columns of the original matrix to reduce the amount of “fill-in” in the matrix $R$, and $AP^*$ in $R$ is simply $A[\ , q+1]$. 
sparseQR-class

2451

R is an \( m \times n \) matrix that is zero below the main diagonal, i.e., upper triangular \( (m \times m) \) with \( m - n \) extra zero rows.

The matrix \( Q \) is a "virtual matrix". It is the product of \( n \) Householder transformations. The information to generate these Householder transformations is stored in the \( V \) and beta slots.

Note however that \( qr.Q() \) returns the row permuted matrix \( Q^* := P^{-1}Q = P'Q \) as permutation matrices are orthogonal; and \( Q^* \) is orthogonal itself because \( Q \) and \( P \) are. This is useful because then, as in the dense matrix and base R matrix \( qr \) case, we have the mathematical identity

\[
P A = Q^* R,
\]

in R as

\[
A[p+1,] \equiv qr.Q(*) \%*\% R.
\]

The "sparseQR" methods for the \( qr.* \) functions return objects of class "dgeMatrix" (see \code{dgeMatrix}). Results from \( qr.coef, qr.resid \) and \( qr.fitted \) (when \( k = \text{ncol}(R) \)) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix \( Q \) is not uniquely defined, the results of \( qr.qy \) and \( qr.qty \) do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of \( qr.qy \) and \( qr.qty \) apply to the permuted column order when the \( q \) slot has length \( n \).

Objects from the Class

Objects can be created by calls of the form \code{new("sparseQR", ...)} but are more commonly created by function \code{qr} applied to a sparse matrix such as a matrix of class \code{dgCMatrix}.

Slots

\( V \): Object of class "\code{dgCMatrix}". The columns of \( V \) are the vectors that generate the Householder transformations of which the matrix \( Q \) is composed.

\( \beta \): Object of class "\code{numeric}". the normalizing factors for the Householder transformations.

\( p \): Object of class "\code{integer}". Permutation (of 0:(\( n-1 \))) applied to the rows of the original matrix.

\( R \): Object of class "\code{dgCMatrix}". An upper triangular matrix of the same dimension as \( X \).

\( q \): Object of class "\code{integer}". Permutation applied from the right, i.e., to the columns of the original matrix. Can be of length 0 which implies no permutation.

Methods

\( qr.R \) signature(\code{qr = "sparseQR"}): compute the upper triangular \( R \) matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical \( qr.R() \) result, and you can suppress these warnings by setting \code{options()} either "Matrix.quiet.qr.R" or (the more general) either "Matrix.quiet" to \code{TRUE}.

\( qr.Q \) signature(\code{qr = "sparseQR"}): compute the orthogonal \( Q \) matrix of the QR decomposition.

\( qr.coef \) signature(\code{qr = "sparseQR", y = \text{ddenseMatrix}"}): ...

\( qr.coef \) signature(\code{qr = "sparseQR", y = \text{matrix}"}): ...

\( qr.coef \) signature(\code{qr = "sparseQR", y = \text{numeric}"}): ...

\( qr.fitted \) signature(\code{qr = "sparseQR", y = \text{ddenseMatrix}"}): ...

\( qr.fitted \) signature(\code{qr = "sparseQR", y = \text{matrix}"}): ...

\( qr.fitted \) signature(\code{qr = "sparseQR", y = \text{numeric}"}): ...
sparseVector

Sparse Vector Construction from Nonzero Entries

Description

User friendly construction of sparse vectors, i.e., objects inheriting from class sparseVector, from indices and values of its non-zero entries.

Usage

sparseVector(x, i, length)

Arguments

x
vector of the non zero entries; may be missing in which case a "nsparseVector" will be returned.

i
integer vector (of the same length as x) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector.

length
length of the sparse vector.

See Also

qr, qr.Q, qr.R, qr.fitted, qr.resid, qr.coef, qr.qty, qr.qy,

Permutation matrices in the Matrix package: pMatrix; dgCMatrix, dgeMatrix.

Examples

data(KNex)
mm <- KNex $ mm
y <- KNex $ y
y. <- as(y, "CsparseMatrix")
str(qrm <- qr(mm))
qc <- qr.coef (qrm, y); qc. <- qr.coef (qrm, y.) # 2nd failed in Matrix <= 1.1-0
qf <- qr.fitted(qrm, y); qf. <- qr.fitted(qrm, y.)
qs <- qr.resid (qrm, y); qs. <- qr.resid (qrm, y.)
stopifnot(all.equal(qc, as.numeric(qc.), tolerance=1e-12),
  all.equal(qf, as.numeric(qf.), tolerance=1e-12),
  all.equal(qs, as.numeric(qs.), tolerance=1e-12),
  all.equal(qf+qs, y, tolerance=1e-12))
sparseVector-class

Details

zero entries in x are dropped automatically, analogously as drop0() acts on sparse matrices.

Value

a sparse vector, i.e., inheriting from class sparseVector.

Author(s)

Martin Maechler

See Also

sparseMatrix() constructor for sparse matrices; the class sparseVector.

Examples

str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

ss <- as(sx, "sparseVector")
stopifnot(identical(ss, sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
        i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns, new("nsparseVector", length = 10, i = c(2, 3, 7))))

sparsenVector-class  Sparse Vector Classes

Description

Sparse Vector Classes: The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the d*, l* and n* ones.

Slots

length: class "numeric" - the length of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", .Machine$integer.max, on purpose.

i: class "numeric" - the (1-based) indices of the non-zero entries. Must not be NA and strictly sorted increasingly.
  Note that "integer" is “part of” "numeric", and can (and often will) be used for non-huge sparseVectors.

x: (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.
  Note that "nsparseVector"s have no x slot. Further, mainly for ease of method definitions, we've defined the class union (see setClassUnion) of all sparse vector classes which have an x slot, as class "xsparseVector".
Methods

length signature(x = "sparseVector"): simply extracts the length slot.

show signature(object = "sparseVector"): The show method for sparse vectors prints "structural" zeroes as "." using the non-exported prSpVector function which allows further customization such as replacing "." by " " (blank).

Note that options(max.print) will influence how many entries of large sparse vectors are printed at all.

as.vector signature(x = "sparseVector", mode = "character") coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as as(x, "vector").

as ..: see coerce below

coerce signature(from = "sparseVector", to = "sparseMatrix"), and

coerce signature(from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices (sparseMatrix) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.

dim< signature(x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from sparseMatrix, of the appropriate dimension.

head signature(x = "sparseVector"): as with R's (package util) head, head(x,n) (for n >= 1) is equivalent to x[1:n], but here can be much more efficient, see the example.

tail signature(x = "sparseVector"): analogous to head, see above.

toeplitz signature(x = "sparseVector"): as toeplitz(x), produce the n × n Toeplitz matrix from x, where n = length(x).

rep signature(x = "sparseVector") repeat x, with the same argument list (x, times, length.out, each,...) as the default method for rep().

which signature(x = "nsparseVector") and

which signature(x = "lsparseVector") return the indices of the non-zero entries (which is trivial for sparse vectors).

Ops signature(e1 = "sparseVector", e2 = "+") define arithmetic, compare and logic operations, (see Ops).

Summary signature(x = "sparseVector"): define all the Summary methods.

[ signature(x = "atomicVector", i = ...): not only can you subset (aka "index into") sparseVectors x[i] using sparseVectors i, but we also support efficient subsetting of traditional vectors x by logical sparse vectors (i.e., i of class "nsparseVector" or "lsparseVector").

is.na, is.finite, is.infinite (x = "sparseVector") and

is.na, is.finite, is.infinite (x = "nsparseVector") return logical or "nsparseVector" of the same length as x, indicating if/where x is NA (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

c.sparseVector() is an S3 method for all "sparseVector"s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

See Also

c.sparseVector() for friendly construction of sparse vectors (apart from as(*, "sparseVector")).
Examples

getClass("sparseVector")
getClass("dsparseVector")
getClass("xsparseVector")# those with an 'x' slot

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(sx))
(is <- as(ix, "sparseVector")) ## an "isparseVector" (!)
(ns <- sparseVector(i= c(7, 3, 2), length = 10)) # "nsparseVector"
## rep() works too:
(ri <- rep(is, length.out= 25))

## Using "dim<-" as in base R :
(r <- ss)
dim(r) <- c(4,5) # becomes a sparse Matrix:
## or coercion (as as.matrix() in base R):
as(s, "Matrix")
stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

## currently has "non-structural" FALSE -- printing as ":."
(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE

## NA-case
sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
       "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)

system.time(for(i in 1:4) hv <- head(v, 1e6))
## user system elapsed
## 0.033 0.000 0.032
system.time(for(i in 1:4) h2 <- v[1:1e6])
## user system elapsed
## 1.317 0.000 1.319

**spMatrix**

**Sparse Matrix Constructor From Triplet**

**Description**

User friendly construction of a sparse matrix (inheriting from class `TsparseMatrix`) from the triplet representation.

This is much less flexible than `sparseMatrix()` and hence somewhat deprecated.

**Usage**

```r
spMatrix(nrow, ncol, i = integer(), j = integer(), x = double())
```

**Arguments**

- `nrow, ncol` integers specifying the desired number of rows and columns.
- `i, j` integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.
- `x` atomic vector of the same length as `i` and `j`, specifying the values of the non-zero entries.

**Value**

A sparse matrix in triplet form, as an R object inheriting from both `TsparseMatrix` and `generalMatrix`.

The matrix $M$ will have $M[i[k], j[k]] = x[k]$, for $k = 1, 2, \ldots, n$, where $n = \text{length}(i)$ and $M[i', j'] = 0$ for all other pairs $(i', j')$. 
symmetricMatrix-class

Virtual Class of Symmetric Matrices in Package Matrix

Description

The virtual class of symmetric matrices, "symmetricMatrix", from the package Matrix contains numeric and logical, dense and sparse matrices, e.g., see the examples with the "actual" subclasses. The main use is in methods (and C functions) that can deal with all symmetric matrices, and in as(*, "symmetricMatrix").
Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there. See below, about storing only one of the two Dimnames components.

factors: a list of matrix factorizations, also from the Matrix class.

Extends

Class "Matrix", directly.

Methods

coerce signature(from = "ddiMatrix", to = "symmetricMatrix"): and many other coercion methods, some of which are particularly optimized.

dimnames signature(object = "symmetricMatrix"): returns symmetric dimnames, even when the Dimnames slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

isSymmetric signature(object = "symmetricMatrix"): returns TRUE trivially. There's a C function symmetricMatrix_validate() called by the internal validity checking functions, and also from getValidity(getClass("symmetricMatrix")).

Validity and dimnames

The validity checks do not require a symmetric Dimnames slot, so it can be list(NULL, <character>), e.g., for efficiency. However, dimnames() and other functions and methods should behave as if the dimnames were symmetric, i.e., with both list components identical.

See Also

isSymmetric which has efficient methods (isSymmetric-methods) for the Matrix classes. Classes triangularMatrix, and, e.g., dsyMatrix for numeric dense matrices, or lscMatrix for a logical sparse matrix class.

Examples

## An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7), symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical
showClass("symmetricMatrix")

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

## Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
symmpart

Symmetric Part and Skew(symmetric) Part of a Matrix

Description

symmpart(x) computes the symmetric part \((x + t(x))/2\) and skewpart(x) the skew symmetric part \((x - t(x))/2\) of a square matrix \(x\), more efficiently for specific Matrix classes.

Note that \(x == \text{symmpart}(x) + \text{skewpart}(x)\) for all square matrices – apart from extraneous NA values in the RHS.

Usage

symmpart(x)
skewpart(x)

Arguments

x

a square matrix; either “traditional” of class "matrix", or typically, inheriting from the Matrix class.

Details

These are generic functions with several methods for different matrix classes, use e.g., showMethods(symmpart) to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

Value

symmpart() returns a symmetric matrix, inheriting from symmetricMatrix iff \(x\) inherited from Matrix.

skewpart() returns a skew-symmetric matrix, typically of the same class as \(x\) (or the closest "general" one, see generalMatrix).

See Also

isSymmetric.

Examples

m <- Matrix(1:4, 2,2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))

stopifnot(all(m == symmpart(m) + skewpart(m)))
colnames(m) <- NULL

stopifnot(all(m == symmpart(m) + skewpart(m)))
dimnames(m) <- unname(dn)

stopifnot(all(m == symmpart(m) + skewpart(m)))
## investigate the current methods:
showMethods(skewpart, include = TRUE)

---

### triangularMatrix-class

*Virtual Class of Triangular Matrices in Package Matrix*

**Description**

The virtual class of triangular matrices, "triangularMatrix", the package Matrix contains *square* (nrow == ncol) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

**Slots**

- **uplo**: String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when diag is "U". For denseMatrix classes, they need to be allocated though, such that the length of the x slot does not depend on diag.
- **Dim, Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

**Extends**

Class "Matrix", directly.

**Methods**

There’s a C function triangularMatrix_validity() called by the internal validity checking functions.

Currently, Schur, isSymmetric and as() (i.e. coerce) have methods with triangularMatrix in their signature.

**See Also**

isTriangular() for testing any matrix for triangularity; classes symmetricMatrix, and, e.g., dtrMatrix for numeric dense matrices, or ltCMatrix for a logical sparse matrix subclass of "triangularMatrix".

**Examples**

showClass("triangularMatrix")

## The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]
(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")

### Description

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See `showClass("TsparseMatrix")` for its subclasses.

### Slots

- **Dim, Dimnames**: from the "Matrix" class,
- **i**: Object of class "integer" - the row indices of non-zero entries in 0-base, i.e., must be in 0:(nrow(.)-1).
- **j**: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in 0:(ncol(.)-1). For numeric Tsparse matrices, (i,j) pairs can occur more than once, see `dgTMatrix`.

### Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

### Methods

Extraction ("[" methods, see `[-methods`.

### Note

Most operations with sparse matrices are performed using the compressed, column-oriented or CsparseMatrix representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a CsparseMatrix for further operations.

Note that all `new(.)`, `spMatrix` and `sparseMatrix(*, repr="T")` constructors for "TsparseMatrix" classes implicitly add (i.e., “sum up”) x_k’s that belong to identical (i_k,j_k) pairs, see, the example below, or also "dgTMatrix".

For convenience, methods for some operations such as %*% and crossprod are defined for TsparseMatrix objects. These methods simply coerce the TsparseMatrix object to a CsparseMatrix object then perform the operation.

### See Also

its superclass, sparseMatrix, and the dgTMatrix class, for the links to other classes.
Examples

showClass("TsparseMatrix")
## or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !

uniqTsparse

Unique (Sorted) TsparseMatrix Representations

Description

Detect or “unify” (or “standardize”) non-unique TsparseMatrix matrices, producing unique \((i, j, x)\) triplets which are sorted, first in \(j\), then in \(i\) (in the sense of \(\text{order}(j,i)\)).

Note that new(.,), spMatrix or sparseMatrix constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add \(x_k\)’s that belong to identical \((i_k,j_k)\) pairs.

anyDuplicatedT() reports the index of the first duplicated pair, or \(0\) if there is none.

uniqTsparse(x) replaces duplicated index pairs \((i, j)\) and their corresponding \(x\) slot entries by the triple \((i, j, sx)\) where \(sx = \text{sum}(x [\text{all pairs matching } (i, j)])\), and for logical \(x\), addition is replaced by logical or.

Usage

uniqTsparse(x, class.x = c(class(x)))
anyDuplicatedT(x, di = dim(x))

Arguments

\(x\) a sparse matrix stored in triplet form, i.e., inheriting from class TsparseMatrix.

class.x optional character string specifying class(x).

di the matrix dimension of \(x\), \(\text{dim}(x)\).

Value

uniqTsparse(x) returns a TsparseMatrix “like x”, of the same class and with the same elements, just internally possibly changed to “unique” \((i, j, x)\) triplets in sorted order.

anyDuplicatedT(x) returns an integer as anyDuplicated, the index of the first duplicated entry (from the \((i,j)\) pairs) if there is one, and \(0\) otherwise.

See Also

TsparseMatrix, for uniqueness, notably dgTMatrix.
Examples

```r
example("dgTMatrix-class", echo=FALSE)
## -> 'T2' with (i,j,x) slots of length 5 each
T2u <- uniqTsparse(T2)
stopifnot(## They "are" the same (and print the same):
  all.equal(T2, T2u, tol=0),
  ## but not internally:
  anyDuplicated(T2) == 2,
  anyDuplicated(T2u) == 0,
  length(T2 @x) == 5,
  length(T2u@x) == 3)

## is 'x' a "uniq Tsparse" Matrix ? [requires x to be TsparseMatrix!]
non_uniqT <- function(x, di = dim(x))
  is.unsorted(x@j) || anyDuplicatedT(x, di)
non_uniqT(T2) # TRUE
non_uniqT(T2u) # FALSE
T3 <- T2u
T3[1, c(1,3)] <- 10; T3[2, c(1,5)] <- 20
T3u <- uniqTsparse(T3)
str(T3u) # sorted in 'j', and within j, sorted in i
stopifnot(!non_uniqT(T3u))

## Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- uniqTsparse(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- uniqTsparse(N2))
stopifnot(N2u@i == L2u@i, L2u@i == T2u@i, N2@i == L2@i, L2@i == T2@i,
  N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)

# now with a nasty NA [partly failed in Matrix 1.1-5]:
L.0N <- L.1N <- L2
L.0N@x[1:2] <- c(FALSE, NA)
L.1N@x[1:2] <- c(TRUE, NA)
validObject(L.0N)
validObject(L.1N)
(m.0N <- as.matrix(L.0N))
(m.1N <- as.matrix(L.1N))
stopifnot(identical(10L, which(is.na(m.0N))), !anyNA(m.1N))
symnum(m.0N)
symnum(m.1N)
```

Description

pack() coerces dense symmetric and dense triangular matrices from unpacked format (storing the full matrix) to packed format (storing only one of the upper and lower triangles). unpack() performs the reverse coercion. The two formats are formalized by the virtual classes "packedMatrix" and "unpackedMatrix".
Usage

pack(x, ...)
## S4 method for signature 'dgeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
## S4 method for signature 'lgeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
## S4 method for signature 'ngeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
## S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)

Arguments

x
A dense symmetric or dense triangular matrix.

For pack(): typically an "unpackedMatrix" or a standard "matrix", though
"packedMatrix" are allowed and returned unchanged.

For unpack(): typically a "packedMatrix", though "unpackedMatrix" are
allowed and returned unchanged.

symmetric
logical (including NA) optionally indicating whether x is symmetric (or triangular).

upperTri
(for triangular x only) logical (including NA) indicating whether x is upper (or lower) triangular.

... further arguments passed to or from other methods.

Details

pack(x) checks matrices x not inheriting from one of the virtual classes "symmetricMatrix"
"triangularMatrix" for symmetry (via isSymmetric()) then for upper and lower triangularity
(via isTriangular()) in order to identify a suitable coercion. Setting one or both of symmetric
and upperTri to TRUE or FALSE rather than NA allows skipping of irrelevant tests for large matrices
known to be symmetric or (upper or lower) triangular.

Users should not assume that pack() and unpack() are inverse operations. Specifically, y <-
unpack(pack(x)) may not reproduce an "unpackedMatrix" x in the sense of identical(). See
the examples.

Value

For pack(): a "packedMatrix" giving the condensed representation of x.

For unpack(): an "unpackedMatrix" giving the full storage representation of x.

Examples

showMethods("pack")
(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s ) == dim(sp), all(s  == sp),
unpackedMatrix-class

Virtual Class "unpackedMatrix" of Unpacked Dense Matrices

Description

Class "unpackedMatrix" is the virtual class of dense matrices in "unpacked" format, storing all \( m \times n \) elements of an \( m \)-by-\( n \) matrix. It is used to define common methods for efficient subsetting, transposing, etc. of its proper subclasses: currently "[dl]geMatrix" (unpacked general), "[dl]syMatrix" (unpacked symmetric), "[dl]trMatrix" (unpacked triangular), and subclasses of these, such as "dpoMatrix", "Cholesky", and "BunchKaufman".

Slots

- Dim, Dimnames: as all Matrix objects.

Extends

Methods

- pack signature(x = "unpackedMatrix"): ...
- unpack signature(x = "unpackedMatrix"): ...
- isSymmetric signature(object = "unpackedMatrix"): ...
- isTriangular signature(object = "unpackedMatrix"): ...
- isDiagonal signature(object = "unpackedMatrix"): ...
- t signature(x = "unpackedMatrix"): ...
- diag signature(x = "unpackedMatrix"): ...
- diag< signature(x = "unpackedMatrix"): ...

---

Unused-classes Virtual Classes Not Yet Really Implemented and Used

Description

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all complex (S4) matrices. It extends the `Matrix` class directly.

Examples

```r
showClass("iMatrix")
showClass("zMatrix")
```

---

updown Up- and Down-Dating a Cholesky Decomposition

Description

Compute the up- or down-dated Cholesky decomposition

Usage

```r
updown(update, C, L)
```

Arguments

- `update` logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.
- `C` any R object, coercable to a sparse matrix (i.e., of subclass of `sparseMatrix`).
- `L` a Cholesky factor, specifically, of class "CHMfactor".

Value

an updated Cholesky factor, of the same dimension as L. Typically of class "dCHMsimpl" (a subclass of "CHMfactor").

Methods

```r
signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..
```

Cholesky.

Examples
dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1,3:2,2:1), p = c(0:2,4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA,"Matrix") ^ 2
uc1 <- updown("+", Diagonal(5), cA)
## Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA,"Matrix")))
image(show(c2 <- as(uc2,"Matrix")))# severely negative entries
##---> Warning

USCounties

USCounties Contiguity Matrix

Description
This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

Usage
data(USCounties)

Format
A 3111^2 symmetric sparse matrix of class dsCMatrix with 9101 non-zero entries.

Details
The data were read into R using read.gal, and row-standardised and transformed to symmetry using nb2listw and similar.listw. This spatial weights object was converted to class dsCMatrix using as_dsTMatrix_listw and coercion.

Source
The data were retrieved from http://sal.uiuc.edu/weights/zips/usc.zip, files “usc.txt” and “usc_q.GAL”, with permission for use and distribution from Luc Anselin (in early 2008).

wrld_1deg

World 1-degree grid contiguity matrix

Description

This matrix represents the distance-based contiguities of 15260 one-degree grid cells of land areas. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

Usage

data(wrld_1deg)

Format

A 15260^2 symmetric sparse matrix of class *dsCMatrix* with 55973 non-zero entries.
Details

The data were created into R using the coordinates of a ‘SpatialPixels’ object containing approximately one-degree grid cells for land areas only (world excluding Antarctica), using package spdep’s dnearneigh with a cutoff distance of sqrt(2), and row-standardised and transformed to symmetry using nb2listw and similar.listw. This spatial weights object was converted to a dsTMatrix using as_dsTMatrix_listw and then coerced (column-compressed).

Source

The shoreline data was read into R using Rgshhs from the GSHHS coarse shoreline database distributed with the maptools package, omitting Antarctica. A matching approximately one-degree grid was generated using Sobj_SpatialGrid, and the grids on land were found using the appropriate over method for the ‘SpatialPolygons’ and ‘SpatialGrid’ objects, yielding a ‘SpatialPixels’ one containing only the grid cells with centres on land.

   all.equal(MJ, MJ3),
   all.equal(MJ, MJ4))
Methods for "[", i.e., extraction or subsetting mostly of matrices, in package `Matrix`.

There are more than these:

- `x = "Matrix", i = "missing", j = "missing", drop= "ANY"` ...
- `x = "Matrix", i = "numeric", j = "missing", drop= "missing"` ...
- `x = "Matrix", i = "missing", j = "numeric", drop= "missing"` ...
- `x = "dsparseMatrix", i = "missing", j = "numeric", drop= "logical"` ...
- `x = "dsparseMatrix", i = "numeric", j = "missing", drop= "logical"` ...
- `x = "dsparseMatrix", i = "numeric", j = "numeric", drop= "logical"` ...

See Also

- `[<--methods` for subassignment to "Matrix" objects. `Extract` about the standard extraction.

Examples

```r
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
m[2, 3]  # simple number
m[2, 3:4]  # simple numeric of length 2
m[2, 3:4, drop=FALSE]  # sub matrix of class 'dgeMatrix'
## rows or columns only:
m[1,]  # first row, as simple numeric vector
m[,1:2]  # sub matrix of first two columns
showMethods("[", inherited = FALSE)
```

Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package `Matrix`.

Note: Contrary to standard `matrix` assignment in base R, in `x[...] <- val` it is typically an error (see `stop`) when the type or class of `val` would require the class of `x` to be changed, e.g., when `x` is logical, say "lsparseMatrix", and `val` is numeric. In other cases, e.g., when `x` is a "nsparseMatrix" and `val` is not TRUE or FALSE, a warning is signalled, and `val` is “interpreted” as `logical`, and (logical) `NA` is interpreted as TRUE.
Methods

There are many many more than these:

\[
\begin{align*}
x &= \text{"Matrix"}, i = \text{"missing"}, j = \text{"missing"}, \text{value} = \text{"ANY"} \quad \text{is currently a simple fallback method implementation which ensures "readable" error messages.} \\
x &= \text{"Matrix"}, i = \text{"ANY"}, j = \text{"ANY"}, \text{value} = \text{"ANY"} \quad \text{currently gives an error} \\
x &= \text{"denseMatrix"}, i = \text{"index"}, j = \text{"missing"}, \text{value} = \text{"numeric"} \\
x &= \text{"denseMatrix"}, i = \text{"index"}, j = \text{"index"}, \text{value} = \text{"numeric"} \\
x &= \text{"denseMatrix"}, i = \text{"missing"}, j = \text{"index"}, \text{value} = \text{"numeric"} \\
x &= \text{"denseMatrix"}, i = \text{"index"}, j = \text{"missing"}, \text{value} = \text{"numeric"}
\end{align*}
\]

See Also

\[-methods\] for subsetting "Matrix" objects; the \text{index} class; Extract about the standard subset assignment (and extraction).

Examples

```r
set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <<- replaces **every** entry
a
## as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
m[3, 3:4]<- 3:4 # simple numeric of length 2

## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

## rows or columns only:
m[1,] <- 10
m[,2] <- 1.7
m[-(1:6), ] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")
```

Boolean Arithmetic Matrix Products: %&% and Methods

**Description**

For boolean or “pattern” matrices, i.e., \text{R} objects of class \text{nMatrix}, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package \text{Matrix}, we use the binary operator %&% (aka “infix”) function for this and provide methods for all our matrices and the traditional \text{R} matrices (see \text{matrix}).
Value

a pattern matrix, i.e., inheriting from "nMatrix", or an "ldiMatrix" in case of a diagonal matrix.

Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and sparseVectors in package Matrix.

signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "mMatrix", y = "mMatrix")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "mMatrix")
signature(x = "mMatrix", y = "sparseVector")
signature(x = "sparseVector", y = "sparseVector")

Note

These boolean arithmetic matrix products had been newly introduced for Matrix 1.2.0 (March 2015). Its implementation has still not been tested extensively.

Originally, it was left unspecified how non-structural zeros, i.e., 0’s as part of the M@x slot should be treated for numeric ("dMatrix") and logical ("lMatrix") sparse matrices. We now specify that boolean matrix products should behave as if applied to drop0(M), i.e., as if dropping such zeros from the matrix before using it.

Equivalently, for all matrices M, boolean arithmetic should work as if applied to M != 0 (or M != FALSE).

The current implementation ends up coercing both x and y to (virtual) class nsparseMatrix which may be quite inefficient for dense matrices. A future implementation may well return a matrix with different class, but the “same” content, i.e., the same matrix entries $m_{i,j}$.

See Also

%*%, crossprod(), or tcrossprod(), for (regular) matrix product methods.

Examples

set.seed(7)
L <- Matrix(rnorm(20) > 1, 4,5)
(N <- as(L, "nMatrix"))
L. <- L; L[1:2,1] <- TRUE; L.@x[1:2] <- FALSE; L. # has "zeros" to drop0()
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %&% D
stopifnot(identical(L %&% D, N %&% D),
          all(L %&% D == as((L %&% abs(D)) > 0, "sparseMatrix")))

## cross products , possibly with boolArith = TRUE :

##
crossprod(N)  # -> sparse pattern' (TRUE/FALSE : boolean arithmetic)
crossprod(N +0)  # -> numeric Matrix (with same "pattern")

```r
stopifnot(all(crossprod(N) == t(N) %&% N),
          identical(crossprod(N), crossprod(N +0, boolArith=TRUE)),
          identical(crossprod(L), crossprod(N , boolArith=FALSE)))
```
crossprod(D, boolArith = TRUE)  # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE)  # ditto
crossprod(L, boolArith = FALSE)  # numeric: "dsCMatrix"
Chapter 18

The boot package

abc.ci  Nonparametric ABC Confidence Intervals

**Description**

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

**Usage**

```r
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95, 
       eps=0.001/n, ...)
```

**Arguments**

- **data**: A data set expressed as a vector, matrix or data frame.
- **statistic**: A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the ...() argument.
- **index**: If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.
- **strata**: A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.
- **conf**: A scalar or vector containing the confidence level(s) of the required interval(s).
- **eps**: The value of epsilon to be used for the numerical differentiation.
- **...**: Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.
Details

This function is based on the function abcnon written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is \(2n+2+2\times\text{length(conf)}\) where \(n\) is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A \text{length(conf)} by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

}
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
## IGNORE_RDIFF_BEGIN
abc.ci(grav1, mean.diff, strata = grav1$series)
## IGNORE_RDIFF_END
Description

The *acme* data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

Usage

acme

Format

This data frame contains the following columns:

- *month* A character string representing the month of the observation.
- *market* The excess return of the market as a whole.
- *acme* The excess return for the Acme Cleveland Corporation.

Source

The data were obtained from

References

Description

The *aids* data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

Usage

aids
Format

This data frame contains the following columns:

year The year of the diagnosis.
quarter The quarter of the year in which diagnosis was made.
delay The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).
dud An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.
time The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.
y The number of AIDS cases reported.

aircondit

Failures of Air-conditioning Equipment

Description

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The aircondit data frame contains the intervals for the ninth aircraft while aircondit7 contains those for the seventh aircraft. Both data frames have just one column. Note that the data have been sorted into increasing order.

Usage

aircondit

Format

The data frames contain the following column:

hours The time interval in hours between successive failures of the air-conditioning equipment

**amis**  
*Car Speeding and Warning Signs*

**Description**

The *amis* data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

**Usage**

*amis*

**Format**

This data frame contains the following columns:

- `speed`  
  Speeds of cars (in miles per hour).

- `period`  
  A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

- `warning`  
  A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

- `pair`  
  A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

**Source**

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

Remission Times for Acute Myelogenous Leukaemia

Description

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

Usage

`aml`

Format

This data frame contains the following columns:

- `time` The length of the complete remission (in weeks).
- `cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.
- `group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

Note

Package `survival` also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

beaver  

Beaver Body Temperature Data

Description

The beaver data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

Usage

beaver

Format

This data frame contains the following columns:

day  The day number. The data includes only data from day 307 and early 308.
time  The time of day formatted as hour-minute.
temp  The body temperature in degrees Celsius.
activ  The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

bigcity  

*Population of U.S. Cities*

**Description**

The bigcity data frame has 49 rows and 2 columns. The city data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The city data frame consists of the first 10 observations in bigcity.

**Usage**

bigcity

**Format**

This data frame contains the following columns:

- **u**: The 1920 population.
- **x**: The 1930 population.

**Source**

The data were obtained from Cochran, W.G. (1977) *Sampling Techniques*. Third edition. John Wiley

boot  

*Bootstrap Resampling*

**Description**

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to boot. Importance resampling weights may be specified.

**Usage**

```r
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
     strata = rep(1,n), L = NULL, m = 0, weights = NULL,
     ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ..., 
     parallel = c("no", "multicore", "snow"),
     ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```
Arguments

**data**

The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.

**statistic**

A function which when applied to data returns a vector containing the statistic(s) of interest. When `sim = "parametric"`, the first argument to `statistic` must be the data. For each replicate a simulated dataset returned by `ran.gen` will be passed. In all other cases `statistic` must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to `statistic` through the `. . .` argument.

**R**

The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case `R` would be a vector of integers where each component gives the number of resamples from each of the rows of weights.

**sim**

A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.

**stype**

A character string indicating what the second argument of `statistic` represents. Possible values of `stype` are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for `sim = "parametric"`.

**strata**

An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when `sim = "parametric"`. When `strata` is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.

**L**

Vector of influence values evaluated at the observations. This is used only when `sim` is "antithetic". If not supplied, they are calculated through a call to `empinf`. This will use the infinitesimal jackknife provided that `stype` is "w", otherwise the usual jackknife is used.

**m**

The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when `sim` is "ordinary". `m` will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of `statistic`, which should also take an argument giving the vector of indices of the errors to be used for the predictions.

**weights**

Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in `data`. When simulation from more than one set of weights is required, weights should be a matrix where each row of the matrix is one set of importance weights. If `weights` is a matrix then `R` must be a vector of length `nrow(weights)`. This parameter is ignored if `sim` is not "ordinary" or "balanced".

**ran.gen**

This function is used only when `sim = "parametric"` when it describes how random values are to be generated. It should be a function of two arguments.
The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to ran.gen. The returned value should be a simulated data set of the same form as the observed data which will be passed to statistic to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If ran.gen is not specified, the default is a function which returns the original data in which case all simulation should be included as part of statistic. Use of sim = "parametric" with a suitable ran.gen allows the user to implement any types of nonparametric resampling which are not supported directly.

mle

The second argument to be passed to ran.gen. Typically these will be maximum likelihood estimates of the parameters. For efficiency mle is often a list containing all of the objects needed by ran.gen which can be calculated using the original data set only.

simple

logical, only allowed to be TRUE for sim = "ordinary", stype = "i", n = 0 (otherwise ignored with a warning). By default a n by R index array is created: this can be large and if simple = TRUE this is avoided by sampling separately for each replication, which is slower but uses less memory.

... Other named arguments for statistic which are passed unchanged each time it is called. Any such arguments to statistic should follow the arguments which statistic is required to have for the simulation. Beware of partial matching to arguments of boot listed above, and that arguments named X and FUN cause conflicts in some versions of boot (but not this one).

parallel

The type of parallel operation to be used (if any). If missing, the default is taken from the option "boot.parallel" (and if that is not set, "no").

ncpus

integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

c1

An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the boot call.

Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. statistic is treated as a black box by the boot function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function ran.gen which will return a simulated data set from the observed data set and a set of parameter estimates specified in mle.

Value

The returned value is an object of class "boot", containing the following components:

t0

The observed value of statistic applied to data.
A matrix with \( \text{sum}(R) \) rows each of which is a bootstrap replicate of the result of calling `statistic`.

The value of `R` as passed to `boot`.

The data as passed to `boot`.

The value of `.Random.seed` when `boot` started work.

The function `statistic` as passed to `boot`.

Simulation type used.

Statistic type as passed to `boot`.

The original call to `boot`.

The strata used. This is the vector passed to `boot`, if it was supplied or a vector of ones if there were no strata. It is not returned if `sim` is "parametric".

The importance sampling weights as passed to `boot` or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if `sim` is not one of "ordinary" or "balanced".

If predictions are required \((m > 0)\) this is the matrix of indices at which predictions were calculated as they were passed to `statistic`. Omitted if \(m = 0\) or `sim` is not "ordinary".

The influence values used when `sim` is "antithetic". If no such values were specified and `stype` is not "w" then \(L\) is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when `sim` is not "antithetic".

The random generator function used if `sim` is "parametric". This component is omitted for any other value of `sim`.

The parameter estimates passed to `boot` when `sim` is "parametric". It is omitted for all other values of `sim`.

There are c, plot and print methods for this class.

**Parallel operation**

When `parallel = "multicore"` is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when `parallel = "snow"` is used: the worker processes are newly created \(R\) processes, and `statistic` needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when `statistic` is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for `jack.after.boot` where ancillary functions are nested inside the `statistic` function.) `parallel = "snow"` is primarily intended to be used on multi-core Windows machine where `parallel = "multicore"` is not available.

For most of the `boot` methods the resampling is done in the master process, but not if `simple = TRUE` nor \(\text{sim = "parametric"}\). In those cases (or where `statistic` itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by `censboot(sim = "wierd")` and by most of the schemes in `tsboot` (the exceptions being `sim == "fixed"` and `sim == "geom"` with the default \(\text{ran.gen}\)).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with `parallel = "multicore"` or `parallel = "snow"` using the default cluster, a second approach is used if
`RNGkind("L'Ecuyer-CMRG")` has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if `ncpus` is unchanged, and for `parallel = "multicore"` if `parallel::mc.reset.stream()` is called: see the examples for `mclapply`.

Note that loading the `parallel` namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

**References**

There are many references explaining the bootstrap and its variations. Among them are:

- `jack.after.boot`
- `tilt.boot`
- `tsboot`

**Examples**

```r
# Usual bootstrap of the ratio of means using the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

# Stratified resampling for the difference of means. In this
# example we will look at the difference of means between the final
# two series in the gravity data.
diff.means <- function(d, f)
{ n <- nrow(d)
gp1 <- 1:table(as.numeric(d$series))[1]
m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}
```
# In this example we show the use of boot in a prediction from
# regression based on the nuclear data. This example is taken
# from Example 6.8 of Davison and Hinkley (1997). Notice also
# that two extra arguments to 'statistic' are passed through boot.
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

# We set up a new data frame with the data, the standardized
# residuals and the fitted values for use in the bootstrap.
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))

# Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred) {
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
            data = dat)
pred.b <- predict(lm.b, x.pred)
c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}
nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
      fit.pred = new.fit, x.pred = new.data)
# The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
# Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
  }
khat <- nlm(ll, ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}

air.rg <- function(data, mle) {
  # Function to generate random exponential variates.
  # mle will contain the mean of the original data
out <- data
go(1/mle)

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric", ran.gen = air.rg, mle = mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

---

**boot.array**

**Bootstrap Resampling Arrays**

**Description**

This function takes a bootstrap object calculated by one of the functions boot, censboot, or tilt.boot and returns the frequency (or index) array for the bootstrap resamples.

**Usage**

```r
boot.array(boot.out, indices)
```

**Arguments**

- `boot.out` An object of class "boot" returned by one of the generation functions for such an object.
- `indices` A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

**Details**

The process by which the original index array was generated is repeated with the same value of .Random.seed. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by censboot the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of boot or "model" in the case of tsboot the array cannot be found. Note also that for post-blackened bootstraps from tsboot the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.
**Side Effects**

This function temporarily resets `Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

**See Also**

`boot.censboot freq.array, tilt.boot, tsboot`

**Examples**

```r
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x, d$y[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

**Description**

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

**Usage**

```r
boot.ci(boot.out, conf = 0.95, type = "all",
       index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
       var.t = NULL, t0 = NULL, t = NULL, L = NULL,
       h = function(t) t, hdot = function(t) rep(1,length(t)),
       hinv = function(t) t, ...)
```

**Arguments**

- `boot.out`: An object of class "boot" containing the output of a bootstrap calculation.
- `conf`: A scalar or vector containing the confidence level(s) of the required interval(s).
- `type`: A vector of character strings representing the type of intervals required. The value should be any subset of the values c("norm", "basic", "stud", "perc", "bca") or simply "all" which will compute all five types of intervals.
- `index`: This should be a vector of length 1 or 2. The first element of `index` indicates the position of the variable of interest in `boot.out$t0` and the relevant column in `boot.out$t`. The second element indicates the position of the variance of the variable of interest. If both `var.t0` and `var.t` are supplied then the second element of `index` (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in `boot.out$t0`).
If supplied, a value to be used as an estimate of the variance of the statistic for
the normal approximation and studentized intervals. If it is not supplied and
\texttt{length(index)} is 2 then var.t0 defaults to \texttt{boot.out$t0[index[2]]} otherwise var.t0 is undefined. For studentized intervals var.t0 must be defined.

For the normal approximation, if var.t0 is undefined it defaults to var(t0). If a transformation is supplied through the argument \texttt{h} then var.t0 should be the variance of the untransformed statistic.

This is a vector (of length \texttt{boot.out$R}) of variances of the bootstrap replicates
of the variable of interest. It is used only for studentized intervals. If it is not sup-
plied and \texttt{length(index)} is 2 then var.t defaults to \texttt{boot.out$t[,index[2]]},
otherwise its value is undefined which will cause an error for studentized inter-
vals. If a transformation is supplied through the argument \texttt{h} then var.t should
be the variance of the untransformed bootstrap statistics.

The observed value of the statistic of interest. The default value is
\texttt{boot.out$t0[index[1]]}. Specification of t0 and t allows the user to get inter-
vals for a transformed statistic which may not be in the bootstrap output object.

See the second example below. An alternative way of achieving this would be
to supply the functions \texttt{h}, hdot, and hinv below.

The bootstrap replicates of the statistic of interest. It must be a vector of length
\texttt{boot.out$R}. It is an error to supply one of t0 or t but not the other. Also if
studentized intervals are required and t0 and t are supplied then so should be
var.t0 and var.t. The default value is \texttt{boot.out$t[,index].}

The empirical influence values of the statistic of interest for the observed data.
These are used only for BCa intervals. If a transformation is supplied through
the parameter \texttt{h} then \texttt{L} should be the influence values for \texttt{t}; the values for \texttt{h(t)}
are derived from these and hdot within the function. If \texttt{L} is not supplied then
the values are calculated using \texttt{empinf} if they are needed.

A function defining a transformation. The intervals are calculated on the scale of
\texttt{h(t)} and the inverse function \texttt{hinv} applied to the resulting intervals. It must be a
function of one variable only and for a vector argument, it must return a vector of
the same length, i.e. \texttt{h(c(t1,t2,t3))} should return \texttt{c(h(t1),h(t2),h(t3)).}
The default is the identity function.

A function of one argument returning the derivative of \texttt{h}. It is a required argu-
ment if \texttt{h} is supplied and normal, studentized or BCa intervals are required. The
function is used for approximating the variances of \texttt{h(t0)} and \texttt{h(t)} using the
delta method, and also for finding the empirical influence values for BCa inter-
vals. Like \texttt{h} it should be able to take a vector argument and return a vector of
the same length. The default is the constant function \texttt{1}.

A function, like \texttt{h}, which returns the inverse of \texttt{h}. It is used to transform the
intervals calculated on the scale of \texttt{h(t)} back to the original scale. The default is
the identity function. If \texttt{h} is supplied but \texttt{hinv} is not, then the intervals returned
will be on the transformed scale.

Any extra arguments that \texttt{boot.out$statistic} is expecting. These arguments
are needed only if BCa intervals are required and \texttt{L} is not supplied since in that
case \texttt{L} is calculated through a call to \texttt{empinf} which calls \texttt{boot.out$statistic}.

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function \texttt{boot} must be run prior to running this function to create the object to be passed
as \texttt{boot.out}.
Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the R values in boot.out a warning is generated and such intervals should not be considered reliable.

Value

An object of type "bootci" which contains the intervals. It has components

- **R** The number of bootstrap replicates on which the intervals were based.
- **t0** The observed value of the statistic on the same scale as the intervals.
- **call** The call to boot.ci which generated the object. It will also contain one or more of the following components depending on the value of type used in the call to boot.ci.
  - **normal** A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
  - **basic** The intervals calculated using the basic bootstrap method.
  - **student** The intervals calculated using the studentized bootstrap method.
  - **percent** The intervals calculated using the bootstrap percentile method.
  - **bca** The intervals calculated using the adjusted bootstrap percentile (BCa) method. These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

brambles

Spatial Location of Bramble Canes

Description

The brambles data frame has 823 rows and 3 columns.
The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of
distance so that the plot can be thought of as a unit square. The bramble canes were also classified
by their age.

Usage

brambles
This data frame contains the following columns:

- **x** The x coordinate of the position of the cane in the plot.
- **y** The y coordinate of the position of the cane in the plot.
- **age** The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

---

**Description**

The *breslow* data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The *breslow* data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

*breslow*

**Format**

This data frame contains the following columns:

- **age** The mid-point of the 10 year age-group for the doctors.
- **smoke** An indicator of whether the doctors smoked (1) or not (0).
- **n** The number of person-years in the category.
- **y** The number of deaths attributed to coronary artery disease.
- **ns** The number of smoker years in the category (smoke*n).

calcium

*Calcium Uptake Data*

Description

The calcium data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

Usage

calcium

Format

This data frame contains the following columns:

time  The time (in minutes) that the cells were suspended in the solution.
cal   The amount of calcium uptake (nmoles/mg).

Sugar-cane Disease Data

Description

The cane data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

Usage
cane

Format

This data frame contains the following columns:

n  The total number of shoots in each plot.
r  The number of diseased shoots.
x  The number of pieces of the stems, out of 50, planted in each plot.
var A factor indicating the variety of sugar-cane in each plot.
block A factor for the blocks.

Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

Source

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de Sao Paolo, Brazil.

Weight Data for Domestic Cats

Description
The catsM data frame has 97 rows and 3 columns.
144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The catsM data frame consists of the data for the male cats. The full data are in dataset cats in package MASS.

Usage
catsM
The data frame contains the following columns:

- **Sex**: A factor for the sex of the cat (levels are F and M; all cases are M in this subset).
- **Bwt**: Body weight in kg.
- **Hwt**: Heart weight in g.

**References**

The data frame contains the following columns:

- **x**: The x coordinate of the caveola’s position in the region.
- **y**: The y coordinate of the caveola’s position in the region.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65mm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset caveolae.dat in the *spatial* package by B.D. Ripley (1994).

CD4 Counts for HIV-Positive Patients

Description
The cd4 data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

Usage

cd4

Format

This data frame contains the following columns:

- **baseline**: The CD4 counts (in 100’s) on admission to the trial.
- **oneyear**: The CD4 counts (in 100’s) after one year of treatment with the new drug.

Source

Nested Bootstrap of cd4 data

Description

This is an example of a nested bootstrap for the correlation coefficient of the cd4 data frame. It is used in a practical in Chapter 5 of Davison and Hinkley (1997).

References

See Also

cd4
Description

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
       sim = "ordinary", cox = NULL, index = c(1, 2), ....,
       parallel = c("no", "multicore", "snow"),
       ncpus = getOption("boot.ncpus", 1L), cl = NULL)

Arguments

data

The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for sim = "weird" when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of index are taken to be the times and censoring indicators.

statistic

A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the ... argument. In the case of sim = "weird", the data passed to statistic only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to statistic will be of the same form as the original data. When sim = "weird", the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if sim = "weird" and strata is supplied, statistic should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.

R

The number of bootstrap replicates.

F.surv

An object returned from a call to survfit giving the survivor function for the data. This is a required argument unless sim = "ordinary" or sim = "model" and cox is missing.

G.surv

Another object returned from a call to survfit but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to survfit. This is a required argument whenever sim = "cond" or when sim = "model" and cox is supplied.

strata

The strata used in the calls to survfit. It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When sim = "weird" only the strata for the survival distribution are used since the
censoring times are considered fixed. When \( \text{sim} = \text{"ordinary"} \), only one set of strata is used to stratify the observations, this is taken to be the first column of strata when it is a matrix.

\[ \text{sim} \]

The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if \( \text{cox} \) is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if \( \text{cox} \) is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

\[ \text{cox} \]

An object returned from \( \text{coxph} \). If it is supplied, then \( F.\text{surv} \) should have been generated by a call of the form \( \text{survfit}(\text{cox}) \). 

\[ \text{index} \]

A vector of length two giving the positions of the columns in \( \text{data} \) which correspond to the times and censoring indicators respectively.

\[ \ldots \]

Other named arguments which are passed unchanged to \( \text{statistic} \) each time it is called. Any such arguments to \( \text{statistic} \) must follow the arguments which \( \text{statistic} \) is required to have for the simulation. Beware of partial matching to arguments of \( \text{censboot} \) listed above, and that arguments named \( X \) and \( \text{FUN} \) cause conflicts in some versions of \( \text{boot} \) (but not this one).

\[ \text{parallel, ncpus, cl} \]

See the help for \( \text{boot} \).

**Details**

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of \( \text{Inf} \) and conversely if it is uncensored it is given a nominal censoring time of \( \text{Inf} \). This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (\( \text{sim} = \text{"model"} \)) or from the conditional censoring distribution as in the previous paragraph (\( \text{sim} = \text{"cond"} \)).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is at least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and \( \text{sim} \) is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of \( \text{Inf} \), also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of \( \text{Inf} \) and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.
When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

**Value**

An object of class "boot" containing the following components:

- `t0`: The value of `statistic` when applied to the original data.
- `t`: A matrix of bootstrap replicates of the values of `statistic`.
- `R`: The number of bootstrap replicates performed.
- `sim`: The simulation type used. This will usually be the input value of `sim` unless that was "model" but `cox` was not supplied, in which case it will be "ordinary".
- `data`: The data used for the bootstrap. This will generally be the input value of `data` unless `sim = "weird"`, in which case it will just be the columns containing the times and the censoring indicators.
- `seed`: The value of `.Random.seed` when `censboot` started work.
- `statistic`: The input value of `statistic`.
- `strata`: The strata used in the resampling. When `sim = "ordinary"` this will be a vector which stratifies the observations, when `sim = "weird"` it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
- `call`: The original call to `censboot`.

channing

Channing House Data

Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

Usage

channing

Format

This data frame contains the following columns:

- **sex** A factor for the sex of each resident ("Male" or "Female").
- **entry** The residents age (in months) on entry to the centre
- **exit** The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
time The length of time (in months) that the resident spent at Channing House.
(time=exit-entry)
cens The indicator of right censoring. 1 indicates that the resident died at Channing House, 0
indicates that they left the house prior to July 1, 1975 or that they were still alive and living in
the centre at that date.

Description
The claridge data frame has 37 rows and 2 columns.
The data are from an experiment which was designed to look for a relationship between a certain
genetic characteristic and handedness. The 37 subjects were women who had a son with mental
retardation due to inheriting a defective X-chromosome. For each such mother a genetic measure-
ment of their DNA was made. Larger values of this measurement are known to be linked to the
defective gene and it was hypothesized that larger values might also be linked to a progressive shift
away from right-handedness. Each woman also filled in a questionnaire regarding which hand they
used for various tasks. From these questionnaires a measure of hand preference was found for each
mother. The scale of this measure goes from 1, indicating someone who always favours their right
hand, to 8, indicating someone who always favours their left hand. Between these two extremes are
people who favour one hand for some tasks and the other for other tasks.

Usage
claridge

Format
This data frame contains the following columns:
dnan The genetic measurement on each woman’s DNA.
hand The measure of left-handedness on an integer scale from 1 to 8.

Source
The data were kindly made available by Dr. Gordon S. Claridge from the Department of Exper-
imental Psychology, University of Oxford.
cloth

References

cloth Number of Flaws in Cloth

Description
The cloth data frame has 32 rows and 2 columns.

Usage
cloth

Format
This data frame contains the following columns:
x The length of the roll of cloth.
y The number of flaws found in the roll.

c.co.transfer Carbon Monoxide Transfer

Description
The co.transfer data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

Usage
co.transfer
Format

This data frame contains the following columns:

- entry  Carbon monoxide transfer factor on entry to hospital.
- week  Carbon monoxide transfer one week after admittance to hospital.

control

Control Variate Calculations

Description

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

Usage

control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL, t = NULL, bias.adj = FALSE, alpha = NULL, ...)

Arguments

boot.out A bootstrap output object returned from boot. The bootstrap replicates must have been generated using the usual nonparametric bootstrap.

L The empirical influence values for the statistic of interest. If L is not supplied then empinf is called to calculate them from boot.out.

distn If present this must be the output from smooth.spline giving the distribution function of the linear approximation. This is used only if bias.adj is FALSE. Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by saddle.distn.

index The index of the variable of interest in the output of boot.out$statistic.

t0 The observed value of the statistic of interest on the original data set boot.out$data. This argument is used only if bias.adj is FALSE. The input value is ignored if t is not also supplied. The default value is boot.out$t0[index].

t The bootstrap replicate values of the statistic of interest. This argument is used only if bias.adj is FALSE. The input is ignored if t0 is not supplied also. The default value is boot.out$t[,index].

bias.adj A logical variable which if TRUE specifies that the adjusted bias estimate using post-simulation balance is all that is required. If bias.adj is FALSE (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.

alpha The alpha levels for the required quantiles if bias.adj is FALSE.

... Any additional arguments that boot.out$statistic requires. These are passed unchanged every time boot.out$statistic is called. boot.out$statistic is called once if bias.adj is TRUE, otherwise it may be called by empinf for empirical influence calculations if L is not supplied.

Details

If bias.adj is FALSE then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation $T^* = Tl^*+(T^*-Tl^*)$, moment estimates can be found. For quantile estimation the distribution of the linear approximation to t is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of t and hence to estimate the bootstrap quantiles of t.
Value

If bias.adj is TRUE then the returned value is the adjusted bias estimate.
If bias.adj is FALSE then the returned value is a list with the following components

- **L**: The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by `empinf`.
- **tL**: The linear approximations to the bootstrap replicates t of the statistic of interest.
- **bias**: The control estimate of bias using the linear approximation to t as a control variate.
- **var**: The control estimate of variance using the linear approximation to t as a control variate.
- **k3**: The control estimate of the third cumulant using the linear approximation to t as a control variate.
- **quantiles**: A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to t as a control variate.
- **distn**: An output object from `smooth.spline` describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to t. If distn was supplied on input then this is the same as the input otherwise it is calculated by a call to saddle.distn.

Examples

```r
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{  m <- mean(d$hours[i])
    n <- nrow(d)
    v <- (n-1)*var(d$hours[i])/n^2
    c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
                     t = log(air.boot$t[, 2]))
```
**corr**

**Correlation Coefficient**

**Description**

Calculates the weighted correlation given a data set and a set of weights.

**Usage**

```
corr(d, w = rep(1, nrow(d))/nrow(d))
```

**Arguments**

- `d` A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
- `w` A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so \( \sum(w) \) need not equal 1.

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between \( d[,1] \) and \( d[,2] \).

**See Also**

`cor`

---

**cum3**

**Calculate Third Order Cumulants**

**Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

```
cum3(a, b = a, c = a, unbiased = TRUE)
```
Arguments

a  A vector of observations.
b  Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.
c  Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a.

unbiased  A logical value indicating whether the unbiased estimator should be used.

Details

The unbiased estimator uses a multiplier of $n/((n-1)*(n-2))$ where $n$ is the sample size, if unbiased is FALSE then a multiplier of $1/n$ is used. This is multiplied by $\sum((a-\text{mean}(a))*(b-\text{mean}(b))*(c-\text{mean}(c)))$ to give the required estimate.

Value

The required estimate.

---

cv.glm  Cross-validation for Generalized Linear Models

Description

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

Usage

cv.glm(data, glmfit, cost, K)

Arguments

data  A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.

glmfit  An object of class "glm" containing the results of a generalized linear model fitted to data.

cost  A function of two vector arguments specifying the cost function for the cross-validation. The first argument to cost should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. cost must return a non-negative scalar value. The default is the average squared error function.

K  The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of K must be such that all groups are of approximately equal size. If the supplied value of K does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of K used. The default is to set K equal to the number of observations in data which gives the usual leave-one-out cross-validation.
The data is divided randomly into \( K \) groups. For each group the generalized linear model is fit to data omitting that group, then the function \texttt{cost} is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When \( K \) is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When \( K \) is less than the number of observations the \( K \) splits to be used are found by randomly partitioning the data into \( K \) groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in \texttt{delta} is the estimate adjusted by this method.

The returned value is a list with the following components.

- **call**: The original call to \texttt{cv.glm}.
- **\( K \)**: The value of \( K \) used for the \( K \)-fold cross validation.
- **\texttt{delta}**: A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.
- **seed**: The value of \texttt{.Random.seed} when \texttt{cv.glm} was called.

The value of \texttt{.Random.seed} is updated.

Examples

```r
# leave-one-out and 6-fold cross-validation prediction error for
# the mammals data set.
data(mammals, package="MASS")
mammals.glm <- glm(log(brain) ~ log(body), data = mammals)
(cv.err <- cv.glm(mammals, mammals.glm)$delta)
```
(cv.err.6 <- cv.glm(mammals, mammals.glm, K = 6)$delta)

# As this is a linear model we could calculate the leave-one-out
# cross-validation estimate without any extra model-fitting.
muhat <- fitted(mammals.glm)
mammals.diag <- glm.diag(mammals.glm)
(cv.err <- mean((mammals.glm$y - muhat)^4/(1 - mammals.diag$h)^2))

# leave-one-out and 11-fold cross-validation prediction error for
# the nodal data set. Since the response is a binary variable an
# appropriate cost function is

cost <- function(r, pi = 0) mean(abs(r-pi) > 0.5)
nodal.glm <- glm(r ~ stage+xray+acid, binomial, data = nodal)
(cv.err <- cv.glm(nodal, nodal.glm, cost, K = nrow(nodal))$delta)
(cv.11.err <- cv.glm(nodal, nodal.glm, cost, K = 11)$delta)

---

**Description**

The darwin data frame has 15 rows and 1 columns.  
Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

**Usage**

darwin

**Format**

This data frame contains the following column:

- **y** The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

**downs.bc**

*Incidence of Down’s Syndrome in British Columbia*

**Description**

The `downs.bc` data frame has 30 rows and 3 columns. Down’s syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down’s syndrome is highly dependent on the mother’s age and rises sharply after age 30. In the 1960’s a large scale study of the effect of maternal age on the incidence of Down’s syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

**Usage**

downs.bc

**Format**

This data frame contains the following columns:

- **age** The average age of all mothers in the age category.
- **m** The total number of live births to mothers in the age category.
- **r** The number of cases of Down’s syndrome.

ducks

Behavioral and Plumage Characteristics of Hybrid Ducks

Description

The ducks data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

Usage

ducks

Format

This data frame contains the following columns:

- plumage  The index of physical appearance based on the plumage of individual ducks.
- behaviour  The index of behavioural characteristics of the ducks.

Source

The data were obtained from

**Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```r
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)

EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)
```

**Arguments**

- **y**: A vector or matrix of data.
- **tmin**: The minimum value of the range over which the likelihood should be computed. This must be larger than `min(y)`.
- **tmax**: The maximum value of the range over which the likelihood should be computed. This must be smaller than `max(y)`.
- **n.t**: The number of points between `tmin` and `tmax` at which the value of the log-likelihood should be computed.
- **u**: A function of the data and the parameter.

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package boot for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the boot package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen’s empirical likelihood home page at the URL [https://artowen.su.domains/empirical/](https://artowen.su.domains/empirical/)

**Value**

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

empinf

Empirical Influence Values

Description

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

Usage

empinf(boot.out = NULL, data = NULL, statistic = NULL, type = NULL, stype = NULL, index = 1, t = NULL, strata = rep(1, n), eps = 0.001, ...)

Arguments

boot.out A bootstrap object created by the function boot. If type is “reg” then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of data, statistic, stype, and strata are taken from the components of boot.out and any values passed to empinf directly are ignored.

data A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if boot.out is not supplied. If boot.out is supplied then data is set to boot.out$data and any value supplied here is ignored.

statistic The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of stype. Any other arguments that it takes must be supplied to empinf and will be passed to statistic unchanged. This is a required argument if boot.out is not supplied, otherwise its value is taken from boot.out and any value supplied here will be ignored.

type The calculation type to be used for the empirical influence values. Possible values of type are “inf” (infinitesimal jackknife), “jack” (usual jackknife), “pos” (positive jackknife), and “reg” (regression estimation). The default value depends on the other arguments. If t is supplied then the default value of type is “reg” and boot.out should be present so that its frequency array can be found. It t is not supplied then if stype is “w”, the default value of type is “inf”; otherwise, if boot.out is present the default is “reg”. If none of these conditions apply then the default is ”jack”. Note that it is an error for type to be “reg” if boot.out is missing or to be “inf” if stype is not “w”.

stype A character variable giving the nature of the second argument to statistic. It can take on three values: “w” (weights), “f” (frequencies), or “i” (indices). If boot.out is supplied the value of stype is set to boot.out$stype and any value supplied here is ignored. Otherwise it is an optional argument which defaults to ”w”. If type is “inf” then stype MUST be “w”.
index  An integer giving the position of the variable of interest in the output of statistic.

t  A vector of length boot.out$R which gives the bootstrap replicates of the statistic of interest. t is used only when type is reg and it defaults to boot.out$t[,index].

strata  An integer vector or a factor specifying the strata for multi-sample problems. If boot.out is supplied the value of strata is set to boot.out$strata. Otherwise it is an optional argument which has default corresponding to the single sample situation.

eps  This argument is used only if type is "inf". In that case the value of epsilon to be used for numerical differentiation will be eps divided by the number of observations in data.

...  Any other arguments that statistic takes. They will be passed unchanged to statistic every time that it is called.

Details
If type is "inf" then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. sttype is "w"). If type is "jack" then the usual leave-one-out jackknife estimates of the empirical influence are returned. If type is "pos" then the positive (include-one-twice) jackknife values are used. If type is "reg" then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of statistic on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to boot.array. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call empinf when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

Value
A vector of the empirical influence values of statistic applied to data. The values will be in the same order as the observations in data.

Warning
All arguments to empinf must be passed using the name = value convention. If this is not followed then unpredictable errors can occur.

envelope

Confidence Envelopes for Curves

Description

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap
replicates of the curve evaluated at a number of fixed points.

Usage

envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))

Arguments

boot.out An object of class "boot" for which boot.out$t contains the replicates of the
curve at a number of fixed points.
mat A matrix of bootstrap replicates of the values of the curve at a number of fixed
points. This is a required argument if boot.out is not supplied and is set to
boot.out$t otherwise.
level  The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.

index  The numbers of the columns of mat which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of mat.

Value

A list with the following components:

point  A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.

overall  A matrix similar to point but containing the envelope which controls the overall error.

k.pt  The quantiles used for the pointwise envelope.

er.err.pt  A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.

k.ov  The quantiles used for the overall envelope.

er.err.ov  A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.

er.err.nom  A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

grav1 <- gravity$g[gravity$series == 8]
grav.z <- (grav1 - mean(grav1))/sqrt(var(grav1))
grav.gen <- function(dat, mle) rnorm(length(dat))
exp.tilt

Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

Usage

exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL, strata = rep(1, length(L)))

Arguments

L The empirical influence values for the statistic of interest based on the observed data. The length of L should be the same as the size of the original data set. Typically L will be calculated by a call to empinf.

theta The value at which the tilted distribution is to be centred. This is not required if lambda is supplied but is needed otherwise.

t0 The current value of the statistic. The default is that the statistic equals 0.

lambda The Lagrange multiplier(s). For each value of lambda a multinomial distribution is found with probabilities proportional to exp(lambda L[j]/n), where n is the number of data points. lambda is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value theta. Thus lambda is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function nlmin. If this minimum is not equal to zero then the method fails.

strata A vector or factor of the same length as L giving the strata for the observed data and the empirical influence values L.

Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean theta. The weights chosen to achieve this are given by p[j] proportional to exp(lambda*L[j]/n), where n is the number of data points. lambda is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value theta. Thus lambda is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function nlmin. If this minimum is not equal to zero then the method fails.
Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions imp.prob or imp.quantile to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of smooth.f. The function tilt.boot uses exp.tilt or smooth.f to find the weights for a tilted bootstrap.

Value

A list with the following components:

- \( p \) The tilted probabilities. There will be \( m \) distributions where \( m \) is the length of \( \theta \) (or \( \lambda \) if supplied). If \( m \) is 1 then \( p \) is a vector of length(L) probabilities. If \( m \) is greater than 1 then \( p \) is a matrix with \( m \) rows, each of which contain length(L) probabilities. In this case the vector \( p[i,] \) is the distribution tilted to \( \theta[i] \). \( p \) is in the form required by the argument weights of the function boot for importance resampling.

- \( \lambda \) The Lagrange multiplier used in the equation to determine the tilted probabilities. \( \lambda \) is a vector of the same length as \( \theta \).

- \( \theta \) The values of \( \theta \) to which the distributions have been tilted. In general this will be the input value of \( \theta \) but if \( \lambda \) was supplied then this is the vector of the corresponding \( \theta \) values.

Examples

# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2]) >=7 , ]
grav.fun <- function(dat, w, orig) {
    strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
    d <- dat[, 1]
    ns <- tabulate(strata)
    w <- w/tapply(w, strata, sum)[strata]
    mns <- as.vector(tapply(d * w, strata, sum)) # drop names
    mmn2 <- tapply(d * d * w, strata, sum)
    s2hat <- sum((mmn2 - mns^2)/ns)
    c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
                 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
```r
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p, 
     strata = grav1[,2], orig = grav.z0[1])
```

---

**fir**

*Counts of Balsam-fir Seedlings*

**Description**

The `fir` data frame has 50 rows and 3 columns. The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

**Usage**

`fir`

**Format**

This data frame contains the following columns:

- `count` The number of seedlings in the quadrant.
- `row` The row number of the quadrant.
- `col` The quadrant number within the row.

**Source**

---

**freq.array**

*Bootstrap Frequency Arrays*

**Description**

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

**Usage**

`freq.array(i.array)`

**Arguments**

- `i.array` This will be an matrix of integers between 1 and n, where n is the number of observations in a data set. The matrix will have n columns and R rows where R is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`. 
Value
A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

boot.array

frets

Head Dimensions in Brothers

Description
The frets data frame has 25 rows and 4 columns.
The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

Usage
frets

Format
This data frame contains the following columns:

11 The head length of the eldest son.
b1 The head breadth of the eldest son.
12 The head length of the second son.
b2 The head breadth of the second son.

Source
The data were obtained from

glm.diag

Generalized Linear Model Diagnostics

Description

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

Usage

glm.diag(glmfit)

Arguments

glmfit

glmfit is a glm.object - the result of a call to glm()

Value

Returns a list with the following components:

- res: The vector of jackknife deviance residuals.
- rd: The vector of standardized deviance residuals.
- rp: The vector of standardized Pearson residuals.
- cook: The vector of approximate Cook statistics.
- h: The vector of leverages of the observations.
- sd: The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1.

Note

See the help for glm.diag.plots for an example of the use of glm.diag.

References

See Also

glm, glm.diag.plots, summary.glm
glm.diag.plots

Diagnostics plots for generalized linear models

Description

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

Usage

```r
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
iden = FALSE, labels = NULL, ret = FALSE)
```

Arguments

- `glmfit` : glm.object: the result of a call to `glm()`
- `glmdiag` : Diagnostics of `glmfit` obtained from a call to `glm.diag`. If it is not supplied then it is calculated.
- `subset` : Subset of data for which glm fitting performed: should be the same as the subset option used in the call to `glm()` which generated `glmfit`. Needed only if the `subset=` option was used in the call to `glm`.
- `iden` : A logical argument. If TRUE then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke `identify()` on that plot. After exiting `identify()`, the user is again prompted, this loop continuing until the user responds to the prompt with 0. If `iden` is FALSE (default) the user cannot interact with the plots.
- `labels` : A vector of labels for use with `identify()` if `iden` is TRUE. If it is not supplied then the labels are derived from `glmfit`.
- `ret` : A logical argument indicating if `glmdiag` should be returned. The default is FALSE.

Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values. The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at $8/(n-2p)$ where n is the number of observations and p is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at $2p/(n-2p)$ and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.
Use of iden=T is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

**Value**

If ret is TRUE then the value of glm.diag is returned otherwise there is no returned value.

**Side Effects**

The current device is cleared and four plots are plotted by use of split.screen(c(2,2)). If iden is TRUE, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

glm.diag.plots(leuk.mod, leuk.diag)
```

**Description**

The `gravity` data frame has 81 rows and 2 columns. The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity, g, at Washington. Each experiment produced a number of replicate estimates of g using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.
hirose

Usage

gravity

Format

This data frame contains the following columns:

g  The deviation of the estimate from 980.000 centimetres per second squared.
series  A factor describing from which experiment the estimate was derived.

Source

Imp.Estimates

Importance Sampling Estimates

Description
Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

Usage

imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
            w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
         t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
             t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)

Arguments

boot.out
A object of class "boot" generated by a call to boot or tilt.boot. Use of
these functions makes sense only when the bootstrap resampling used unequal
weights for the observations. If the importance weights w are not supplied then
boot.out is a required argument. It is also required if t is not supplied.

alpha
The alpha levels for the required quantiles. The default is to calculate the 1%,
2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.

index
The index of the variable of interest in the output of boot.out$statistic. This
is not used if the argument t is supplied.

t0
The values at which tail probability estimates are required. For each value t0[i]
the function will estimate the bootstrap cdf evaluated at t0[i]. If imp.prob is
called without the argument t0 then the bootstrap cdf evaluated at the observed
value of the statistic is found.

t
The bootstrap replicates of a statistic. By default these are taken from the boot-
strap output object boot.out but they can be supplied separately if required (e.g.
when the statistic of interest is a function of the calculated values in boot.out).
Either boot.out or t must be supplied.

w
The importance resampling weights for the bootstrap replicates. If they are not
supplied then boot.out must be supplied, in which case the importance weights
are calculated by a call to imp.weights.

def
A logical value indicating whether a defensive mixture is to be used for weight
calculation. This is used only if w is missing and it is passed unchanged to
imp.weights to calculate w.

q
A vector of probabilities specifying the resampling distribution from which any
estimates should be found. In general this would correspond to the usual boot-
strap resampling distribution which gives equal weight to each of the original
observations. The estimates depend on this distribution only through the impor-
tance weights w so this argument is ignored if w is supplied. If w is missing then
q is passed as an argument to imp.weights and used to find w.
Imp.Estimates

Value

A list with the following components:

- **alpha**
  The alpha levels used for the quantiles, if `imp.quantile` is used.

- **t0**
  The values at which the tail probabilities are estimated, if `imp.prob` is used.

- **raw**
  The raw importance resampling estimates. For `imp.moments` this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For `imp.prob`, `raw` is of the same length as `t0`, and for `imp.quantile` it is of the same length as `alpha`.

- **rat**
  The ratio importance resampling estimates. In this method the weights are rescaled to have average value one before they are used. The format of this vector is the same as `raw`.

- **reg**
  The regression importance resampling estimates. In this method the weights which are used are derived from a regression of `t*w` on `w`. This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as `raw`.

}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
                 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
```
imp.weights

Importance Sampling Weights

Description

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities \( p \) when estimates are required assuming that simulation was from an alternative distribution with probabilities \( q \).

Usage

imp.weights(boot.out, def = TRUE, q = NULL)

Arguments

- **boot.out**: A object of class "boot" generated by boot or tilt.boot. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.
- **def**: A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in boot.out were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.
- **q**: A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. \( q \) must have length equal to the number of observations in the boot.out$data and all elements of \( q \) must be positive.

Details

The importance sampling weight for a bootstrap replicate with frequency vector \( f \) is given by \( \text{prod}(q/p)^f \). This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities \( q \) even though, in fact, they came from the distribution \( p \).
Value

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities \( q \).

Note

See the example in the help for `imp.moments` for an example of using `imp.weights`.

---

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```r
inv.logit(x)
```

**Arguments**

- `x` A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by \( \exp(x)/(1+\exp(x)) \). Values in \( x \) of \(-\infty\) or \( \infty \) return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as `x` containing the inverse logits of the input values.

**See Also**

`logit, plogis` for which this is a wrapper.
islay

*Jura Quartzite Azimuths on Islay*

**Description**

**Usage**

`islay`

**Format**

This data frame contains the following column:

*theta*  The angle of the azimuth in degrees East of North.

**Source**

The data were obtained from

**References**

---

jack.after.boot

*Jackknife-after-Bootstrap Plots*

**Description**

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

**Usage**

`jack.after.boot(boot.out, index = 1, t = NULL, L = NULL, useJ = TRUE, stinf = TRUE, alpha = NULL, main = "", ylab = NULL, ...)"
Arguments

boot.out  An object of class "boot" which would normally be created by a call to boot. It should represent a nonparametric bootstrap. For reliable results boot.out$R should be reasonably large.

index  The index of the statistic of interest in the output of boot.out$statistic.

t  A vector of length boot.out$R giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is boot.out$t[, index].

L  The empirical influence values for the statistic of interest. These are used only if useJ is FALSE. If they are not supplied and are needed, they are calculated by a call to empinf. If L is supplied then it is assumed that they are the infinitesimal jackknife values.

useJ  A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If FALSE the empirical influence values are used. The default is TRUE.

stinf  A logical variable indicating whether to standardize the jackknife values before plotting them. If TRUE then the jackknife values used are divided by their standard error.

alpha  The quantiles at which the plots are required. The default is c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95).

main  A character string giving the main title for the plot.

ylab  The label for the Y axis. If the default values of alpha are used and ylab is not supplied then a label indicating which percentiles are plotted is used. If alpha is supplied then the default label will not say which percentiles were used.

...  Any extra arguments required by boot.out$statistic. These are required only if useJ is FALSE and L is not supplied, in which case they are passed to empinf for use in calculation of the empirical influence values.

Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If useJ is TRUE then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If useJ is FALSE then empirical influence values are calculated by calling empinf.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

Value

There is no returned value but a plot is generated on the current graphics display.
Side Effects

A plot is created on the current graphics device.

    iv.d <- sqrt(diag(iv))
    iv <- diag(1/iv.d) %*% iv %*% diag(1/iv.d)
    q <- NULL
    n <- nrow(v)
    for (i in 1:(n-1))
      q <- rbind(q, c(v[i, 1:i], iv[i,(i+1):n]))
    q <- rbind(q, v[n, ])
    diag(q) <- round(diag(q))
  }
  d <- data[, i]
  v <- pcorr(d)
  c(v[1,], v[2,], v[3,], v[4,])
}

frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)
```

---

**k3.linear**

**Linear Skewness Estimate**

**Description**

Estimates the skewness of a statistic from its empirical influence values.
Usage
k3.linear(L, strata = NULL)

Arguments
L          Vector of the empirical influence values of a statistic. These will usually be calculated by a call to empinf.
strata     A numeric vector or factor specifying which observations (and hence which components of L) come from which strata.

Value
The skewness estimate calculated from L.

References

See Also
empinf, linear.approx, var.linear

Examples
# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))

linear.approx
Linear Approximation of Bootstrap Replicates

Description
This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

Usage
linear.approx(boot.out, L = NULL, index = 1, type = NULL,
t0 = NULL, t = NULL, ...)

Arguments
boot.out        An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function boot.
L               A vector containing the empirical influence values for the statistic of interest. If it is not supplied then L is calculated through a call to empinf.
index           The index of the variable of interest within the output of boot.out$statistic.
linear.approx

This gives the type of empirical influence values to be calculated. It is not used if L is supplied. The possible types of empirical influence values are described in the help for `empinf`.

t0

The observed value of the statistic of interest. The input value is used only if one of t or L is also supplied. The default value is `boot.out$t0[index]`. If t0 is supplied but neither t nor L are supplied then t0 is set to `boot.out$t0[index]` and a warning is generated.

t

A vector of bootstrap replicates of the statistic of interest. If t0 is missing then t is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in L).

...

Any extra arguments required by `boot.out$statistic`. These are needed if L is not supplied as they are used by `empinf` to calculate empirical influence values.

Details

The linear approximation to a bootstrap replicate with frequency vector f is given by t0 + sum(L * f)/n in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

**lines.saddle.distn**  
*Add a Saddlepoint Approximation to a Plot*

**Description**

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

**Usage**

```r
## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
      npts = 50, lty = 1, ...)
```

**Arguments**

- `x`  
  An object of class "saddle.distn" (see `saddle.distn.object` representing a saddlepoint approximation to a distribution.

- `dens`  
  A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.

- `h`  
  Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.

- `J`  
  When `dens=TRUE` this function specifies the Jacobian for any transformation that may be necessary. The first argument of `J` must the value at which the approximation is being performed and the function must be vectorized. If `h` is supplied `J` must also be supplied and both must have the same argument list.

- `npts`  
  The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.
The line type to be used.

Any additional arguments to `h` and `J`.

Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

Value

`sad.d` is returned invisibly.

Side Effects

A line is added to the current plot.

References

`saddle.distn`

Examples

```r
# In this example we show how a plot such as that in Figure 9.9 of
# Davison and Hinkley (1997) may be produced. Note the large number of
# bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
  n <- length(d)
  (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata, vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t)));
exp.sp <- saddle.distn(A = exp.L/12, wdist = "m", t0 = exp.t0)

# The saddlepoint approximation in this case is to the density of
# t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1,
  t0 = exp.boot$t0)
```
**logit**

*Logit of Proportions*

**Description**

This function calculates the logit of proportions.

**Usage**

```r
logit(p)
```

**Arguments**

- `p` A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

**Details**

If any elements of `p` are outside the unit interval then an error message is generated. Values of `p` equal to 0 or 1 (to within machine precision) will return -Inf or Inf respectively. Any NAs in the input will also be NAs in the output.

**Value**

A numeric object of the same type as `p` containing the logits of the input values.

**See Also**

- `inv.logit`, `qlogis` for which this is a wrapper.

**manaus**

*Average Heights of the Rio Negro river at Manaus*

**Description**

The `manaus` time series is of class "ts" and has 1080 observations on one variable. The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992. The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35,874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee. Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.
Source

The data were kindly made available by Professors H. O’Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

References

Description

The melanoma data frame has 205 rows and 7 columns. The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

Usage

melanoma

Format

This data frame contains the following columns:

- `time` Survival time in days since the operation, possibly censored.
- `status` The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.
- `sex` The patients sex; 1=male, 0=female.
- `age` Age in years at the time of the operation.
- `year` Year of operation.
- `thickness` Tumour thickness in mm.
- `ulcer` Indicator of ulceration; 1=present, 0=absent.

Note

This dataset is not related to the dataset in the `lattice` package with the same name.
**Source**

The data were obtained from

**References**

---

**Description**

The *motor* data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of `time` from the dataset *mcycle*. Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

```
motor
```

**Format**

This data frame contains the following columns:

- `times` The time in milliseconds since impact.
- `accel` The recorded head acceleration (in g).
- `strata` A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.
- `v` An estimate of the residual variance for the observation. `v` is constant within the strata but a different estimate is used for each of the three strata.

**Source**

The data were obtained from

neuro

Neurophysiological Point Process Data

Description

neuro is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

Note

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

Source

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

nitrofen

Toxicity of Nitrofen in Aquatic Systems

Description

The nitrofen data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (Ceriodaphnia dubia). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

Usage

nitrofen
Format

This data frame contains the following columns:

- **conc**: The nitrofen concentration in the solution (mug/litre).
- **brood1**: The number of live offspring in the first brood.
- **brood2**: The number of live offspring in the second brood.
- **brood3**: The number of live offspring in the third brood.
- **total**: The total number of live offspring in the first three broods.

Source

The data were obtained from

References

Description

The nodal data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

Usage

nodal

Format

This data frame contains the following columns:

- **m**: A column of ones.
- **r**: An indicator of nodal involvement.
- **aged**: The patients age dichotomized into less than 60 (0) and 60 or over (1).
- **stage**: A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.
grade Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

xray A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

acid The level of acid phosphatase in the blood serum.

Source

The data were obtained from

References

**norm.ci**

*Normal Approximation Confidence Intervals*

**Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

**Usage**

```r
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
       t0 = NULL, t = NULL, L = NULL, h = function(t) t,
       hdot = function(t) 1, hinv = function(t) t)
```

**Arguments**

- **boot.out** A bootstrap output object returned from a call to boot. If t0 is missing then boot.out is a required argument. It is also required if both var.t0 and t are missing.
- **conf** A scalar or vector containing the confidence level(s) of the required interval(s).
- **index** The index of the statistic of interest within the output of a call to boot.out$statistic. It is not used if boot.out is missing, in which case t0 must be supplied.
- **var.t0** The variance of the statistic of interest. If it is not supplied then var(t) is used.
- **t0** The observed value of the statistic of interest. If it is missing then it is taken from boot.out which is required in that case.
- **t** Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if var.t0 is not supplied. The default value is boot.out$t[, index].
- **L** The empirical influence values for the statistic of interest. These are used to calculate var.t0 if neither var.t0 nor boot.out are supplied. If a transformation is supplied through h then the influence values must be for the untransformed statistic t0.
norm.ci

A function defining a monotonic transformation, the intervals are calculated on the scale of \(h(t)\) and the inverse function \(h^{-1}\) is applied to the resulting intervals. \(h\) must be a function of one variable only and must be vectorized. The default is the identity function.

**hdot**

A function of one argument returning the derivative of \(h\). It is a required argument if \(h\) is supplied and is used for approximating the variance of \(h(t_0)\). The default is the constant function 1.

**hinv**

A function, like \(h\), which returns the inverse of \(h\). It is used to transform the intervals calculated on the scale of \(h(t)\) back to the original scale. The default is the identity function. If \(h\) is supplied but \(h^{-1}\) is not, then the intervals returned will be on the transformed scale.

**Details**

It is assumed that the statistic of interest has an approximately normal distribution with variance \(\text{var} \cdot \bar{t}_0\) and so a confidence interval of length \(2 \cdot \text{qnorm}((1+\text{conf})/2) \cdot \sqrt{\text{var} \cdot \bar{t}_0}\) is found. If \(\text{boot.out}\) or \(t\) are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at \(2 \cdot \bar{t}_0 - \text{mean}(t)\). Otherwise the interval is centred at \(\bar{t}_0\).

**Value**

If \(\text{length}(\text{conf})\) is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

**Note**

This function is primarily designed to be called by \(\text{boot.ci}\) to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as \(t_0\) and \(\text{var} \cdot \bar{t}_0\) can be supplied. See the examples below.

**References**

**Examples**

```
# In Example 5.1 of Davison and Hinkley (1997), normal approximation
# confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t0 = air.mean, var.t0 = air.v)
exp(norm.ci(t0 = log(air.mean), var.t0 = 1/air.n)[2:3])

# Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
  sum(d$x * w)/sum(d$u *w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t0 = ratio(city,rep(0.1,10)), var.t0 = city.v)
```
Description

The nuclear data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960’s and early 1970’s. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers’ subsidies may be hidden in the quoted capital costs.

Usage

nuclear

Format

This data frame contains the following columns:

cost  The capital cost of construction in millions of dollars adjusted to 1976 base.
date  The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.
t1  The time between application for and issue of the construction permit.
t2  The time between issue of operating license and construction permit.
cap  The net capacity of the power plant (MWe).
pr  A binary variable where 1 indicates the prior existence of a LWR plant at the same site.
ne  A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.
cp  A binary variable where 1 indicates the use of a cooling tower in the plant.
bw  A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.
cum.n  The cumulative number of power plants constructed by each architect-engineer.
pt  A binary variable where 1 indicates those plants with partial turnkey guarantees.

paulsen

Neurotransmission in Guinea Pig Brains

Description
The paulsen data frame has 346 rows and 1 columns.
Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

Usage
paulsen

Format
This data frame contains the following column:
y  The current flowing into individual brain cells. The currents are measured in pico-amperes.

Source
The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

plot.boot

Plots of the Output of a Bootstrap Simulation

Description
This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

Usage
```r
## S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```
Arguments

x
An object of class "boot" returned from one of the bootstrap generation functions.

index
The index of the variable of interest within the output of boot.out. This is ignored if t and t0 are supplied.

t0
The original value of the statistic. This defaults to boot.out$t0[index] unless t is supplied when it defaults to NULL. In that case no vertical line is drawn on the histogram.

t
The bootstrap replicates of the statistic. Usually this will take on its default value of boot.out$t[,index], however it may be useful sometimes to supply a different set of values which are a function of boot.out$t.

jack
A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.

qdist
The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.

nclass
An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to ceiling(length(t)/25).

df
If qdist is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.

...
When jack is TRUE additional parameters to jack.after.boot can be supplied. See the help file for jack.after.boot for details of the possible parameters.

Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that t0 is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of t0. This cannot be done if t is supplied but t0 is not and so, in that case, the breakpoints are computed by hist using the nclass argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept mean(t) and slope sqrt(var(t)) while for the chi-squared it has intercept 0 and slope 1.

If jack is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See jack.after.boot for further details of this plot.

Value

boot.out is returned invisibly.

Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

print.boot

Print a Summary of a Bootstrap Object

Description

This is a method for the function print() for objects of the class "boot" created by a call to boot, censboot, tilt.boot or tsboot.

Usage

## S3 method for class 'boot'
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)

Arguments

x A bootstrap output object of class "boot" generated by one of the bootstrap functions.
digits The number of digits to be printed in the summary statistics.
index Indices indicating for which elements of the bootstrap output summary statistics are required.
... further arguments passed to or from other methods.

Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If boot.out$t0 is missing (such as when it was created by a call to tsboot with orig.t = FALSE) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.
print.bootci

Value

The bootstrap object is returned invisibly.

See Also

`boot.ci`, `censboot`, `imp.moments`, `plot.boot`, `tilt.boot`, `tsboot`

print.bootci

Print Bootstrap Confidence Intervals

Description

This is a method for the function `print()` to print objects of the class "bootci".

Usage

```r
## S3 method for class 'bootci'
print(x, hinv = NULL, ...)
```

Arguments

- `x` The output from a call to `boot.ci`.
- `hinv` A transformation to be made to the interval end-points before they are printed.
- `...` further arguments passed to or from other methods.

Details

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

Warning: Intervals used Extreme Quantiles

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

Some intervals may be unstable

Value

The object `ci.out` is returned invisibly.

See Also

`boot.ci`
**print.saddle.distn**  
*Print Quantiles of Saddlepoint Approximations*

**Description**

This is a method for the function `print()` to print objects of class "saddle.distn".

**Usage**

```r
## S3 method for class 'saddle.distn'
print(x, ...)
```

**Arguments**

- `x`  
  An object of class "saddle.distn" created by a call to `saddle.distn`.
- `...`  
  Further arguments passed to or from other methods.

**Details**

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

**Value**

The input is returned invisibly.

**See Also**

`lines.saddle.distn`, `saddle.distn`, `print.simplex`

---

**print.simplex**  
*Print Solution to Linear Programming Problem*

**Description**

This is a method for the function `print()` to print objects of class "simplex".

**Usage**

```r
## S3 method for class 'simplex'
print(x, ...)
```

**Arguments**

- `x`  
  An object of class "simplex" created by calling the function `simplex` to solve a linear programming problem.
- `...`  
  Further arguments passed to or from other methods.
Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

Value

x is returned silently.

saddle

**Description**

This function calculates a saddlepoint approximation to the distribution of a linear combination of \( W \) at a particular point \( u \), where \( W \) is a vector of random variables. The distribution of \( W \) may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of \( W \) can be calculated for \( W \) having binary or Poisson distributions.

**Usage**

```r
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,
       d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
       strata = NULL, K.adj = NULL, K2 = NULL)
```

**Arguments**

- **A**
  A vector or matrix of known coefficients of the linear combinations of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.

- **u**
  The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.

- **wdist**
  The distribution of \( W \). This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If \( K.\text{adj} \) and \( K2 \) are given \( wdist \) is set to "o".

- **type**
  The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When \( wdist \) is "o" or "m", type is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.

- **d**
  This specifies the dimension of the whole statistic. This argument is required only when \( wdist = "o" \) and defaults to 1 if not supplied in that case. For other distributions it is set to \( \text{ncol}(A) \).

- **d1**
  When type is "cond" this is the dimension of the statistic of interest which must be less than \( \text{length}(u) \). Then the saddlepoint approximation to the conditional distribution of the first \( d1 \) linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of \( d1 \) is 1.

- **init**
  Used if \( wdist \) is either "m" or "o", this gives initial values to \( \text{nlin} \) which is used to solve the saddlepoint equation.

- **mu**
  The values of the parameters of the distribution of \( W \) when \( wdist \) is "m", "p" or "b". \( mu \) must be of the same length as \( W \) (i.e. \( \text{nrow}(A) \)). The default is that all values of \( mu \) are equal and so the elements of \( W \) are identically distributed.

- **LR**
  If \( \text{TRUE} \) then the Lugannani-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen’s \( r^* \).

- **strata**
  The strata for stratified data.
The adjusted cumulant generating function used when \texttt{wdist} is "o". This is a function of a single parameter, \(zeta\), which calculates \(K(zeta) - u * zeta\), where \(K(zeta)\) is the cumulant generating function of \(W\).

This is a function of a single parameter \(zeta\) which returns the matrix of second derivatives of \(K(zeta)\) for use when \texttt{wdist} is "o". If \texttt{K.adj} is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if \texttt{K.adj} is not supplied.

### Details

If \texttt{wdist} is "o" or "m", the saddlepoint equations are solved using \texttt{nlmin} to minimize \texttt{K.adj} with respect to its parameter \(zeta\). For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the \texttt{glm} must satisfy the equation \(t(A) %*% y = u\) (\(t()\) being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to \texttt{simplex}. The covariate matrix for the \texttt{glm} is given by \(A\).

### Value

A list consisting of the following components

- \texttt{spa}\(^1\): The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.
- \texttt{zeta.hat}\(^2\): The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.
- \texttt{zeta2.hat}\(^3\): If \texttt{type} is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of \texttt{type}.

\(^1\)\text{spa}\n
\(^2\)\text{zeta.hat}\n
\(^3\)\text{zeta2.hat}\n
# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t = 1.25 as follows.

ejacobian <- function(dat, t, zeta)
{
  p <- exp(zeta * (dat$x - t * dat$u))
  abs(sum(dat$u * p) / sum(p))
}

city.sp1 <- saddle(A = city$x - 1.25 * city$u, u = 0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1

saddle.distn

Saddlepoint Distribution Approximations for Bootstrap Statistics

Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple
and conditional saddlepoint distribution approximations for a univariate quantity of interest. For
the simple saddlepoint the quantity of interest is a linear combination of \( W \) where \( W \) is a vector of
random variables. For the conditional saddlepoint we require the distribution of one linear combi-
nation given the values of any number of other linear combinations. The distribution of \( W \) must
be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles
of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the
function control to approximate the distribution of the linear approximation to a statistic.

Usage

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
    type = "simp", npts = 20, t = NULL, t0 = NULL,
    init = rep(0.1, )), mu = rep(0.5, n), LR = FALSE,
    strata = NULL, ...
)

Arguments

A

This is a matrix of known coefficients or a function which returns such a matrix.
If a function then its first argument must be the point \( t \) at which a saddlepoint
is required. The most common reason for \( A \) being a function would be if the
statistic is not itself a linear combination of the \( W \) but is the solution to a linear
estimating equation.
If \( A \) is a function then \( u \) must also be a function returning a vector with length equal to the number of columns of the matrix returned by \( A \). Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If \( A \) is a matrix with more than one column (such as when \( \text{wdist} = \text{"cond"} \)) then \( u \) should be a vector with length one less than \( \text{ncol}(A) \). In this case \( u \) specifies the values of the conditioning variables. If \( A \) is a matrix with one column or a vector then \( u \) is not used.

**alpha**
The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.

**wdist**
The distribution of \( W \). Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).

**type**
The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If \( \text{wdist} \) is "m", \( \text{type} \) is set to "simp".

**npts**
The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.

**t**
A vector of points at which the saddlepoint approximations are calculated. These should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in \( t \) as the distribution function approximation breaks down at that point. The points should, however, cover the entire effective range of the distribution including close to the centre. If \( t \) is supplied then \( \text{npts} \) is set to \( \text{length}(t) \). When \( t \) is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range.

**t0**
If \( t \) is not supplied then a vector of length 2 should be passed as \( t0 \). The first component of \( t0 \) should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in \( t0[1] \).

**init**
When \( \text{wdist} \) is "m", this vector should contain the initial values to be passed to \( \text{nlmin} \) when it is called to solve the saddlepoint equations.

**mu**
The vector of parameter values for the distribution. The default is that the components of \( W \) are identically distributed.

**LR**
A logical flag. When \( \text{LR} \) is TRUE the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen’s \( r^* \).

**strata**
A vector giving the strata when the rows of \( A \) relate to stratified data. This is used only when \( \text{wdist} \) is "m".

... When \( A \) and \( u \) are functions any additional arguments are passed unchanged each time one of them is called.

**Details**

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of \( \text{alpha} \). The lower endpoint is found by evaluating the saddlepoint at the points \( t0[1]-2*t0[2], t0[1]-4*t0[2], t0[1]-8*t0[2] \) etc. until a point is found with a cdf approximation less than \( \text{min}(\text{alpha})/10 \), then a bisection method is used to find the endpoint which has cdf approximation in the range \( \text{min}(\text{alpha})/1000, \text{min}(\text{alpha})/10 \). Then a number of, equally spaced, points are chosen between the lower endpoint and \( t0[1] \) until
a total of \(npts/2\) approximations have been made. The remaining \(npts/2\) points are chosen to the right of \(t_0[1]\) in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of \(t_0[2]\) is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of \(t_0[2]\) will usually solve the problem.

Value

The returned value is an object of class "saddle.distn". See the help file for \texttt{saddle.distn.object} for a description of such an object.

Examples

```r
# The bootstrap distribution of the mean of the air-conditioning
# failure data: fails to find value on R (and probably on S too)
air.t0 <- c(mean(aircondit$hours), sqrt(var(aircondit$hours)/12))
## Not run: saddle.distn(A = aircondit$hours/12, t0 = air.t0)

# alternatively using the conditional poisson
saddle.distn(A = cbind(aircondit$hours/12, 1), u = 12, wdist = "p",
             type = "cond", t0 = air.t0)

# Distribution of the ratio of a sample of size 10 from the bigcity
# data, taken from Example 9.16 of Davison and Hinkley (1997).
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
bigcity.t0 <- c(mean(bigcity$x)/mean(bigcity$u), sqrt(city.v))
Afn <- function(t, data) cbind(data$x - t*data$u, 1)
ufn <- function(t, data) c(0,10)
saddle.distn(A = Afn, u = ufn, wdist = "b", type = "cond",
             t0 = bigcity.t0, data = bigcity)
```
From Example 9.16 of Davison and Hinkley (1997) again, we find the
c conditional distribution of the ratio given the sum of city$u.

```r
Afn <- function(t, data) cbind(data$x-t*data$u, data$u, 1)
ufn <- function(t, data) c(0, sum(data$u), 10)

city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.v))
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0,
  data = city)
```

**saddle.distn.object**  
*Saddlepoint Distribution Approximation Objects*

**Description**

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

**Generation**

This class of objects is returned from calls to the function `saddle.distn`.

**Methods**

The class "saddle.distn" has methods for the functions `lines` and `print`.

**Structure**

Objects of class "saddle.distn" are implemented as a list with the following components.

- **quantiles** A matrix with 2 columns. The first column contains the probabilities alpha and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

- **points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of t which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When type is "simp", there is only one of those. When type is "cond" there are 2*d-1 where d is the number of columns in A or the output of A(t,...{}). The first d of these correspond to the numerator and the remainder correspond to the denominator.

- **distn** An object of class smooth.spline. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see smooth.spline.

- **call** The original call to `saddle.distn` which generated the object.

- **LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

**See Also**

`lines.saddle.distn`, `saddle.distn`, `print.saddle.distn`
Description

The salinity data frame has 28 rows and 4 columns. Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

Usage

salinity

Format

This data frame contains the following columns:

sal  The average salinity of the water over two weeks.

lag  The average salinity of the water lagged two weeks. Since only spring is used, the value of lag is not always equal to the previous value of sal.

trend  A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

dis  The amount of river discharge during the two weeks for which sal is the average salinity.

Source

The data were obtained from

References

Description

This function will optimize the linear function a*x subject to the constraints A1*x <= b1, A2*x >= b2, A3*x = b3 and x >= 0. Either maximization or minimization is possible but the default is minimization.
simplex

Usage

```r
dsmpx(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL, b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

Arguments

- **a**: A vector of length \(n\) which gives the coefficients of the objective function.
- **A1**: An \(m_1\) by \(n\) matrix of coefficients for the \(\leq\) type of constraints.
- **b1**: A vector of length \(m_1\) giving the right hand side of the \(\leq\) constraints. This argument is required if \(A1\) is given and ignored otherwise. All values in \(b1\) must be non-negative.
- **A2**: An \(m_2\) by \(n\) matrix of coefficients for the \(\geq\) type of constraints.
- **b2**: A vector of length \(m_2\) giving the right hand side of the \(\geq\) constraints. This argument is required if \(A2\) is given and ignored otherwise. All values in \(b2\) must be non-negative. Note that the constraints \(x \geq 0\) are included automatically and so should not be repeated here.
- **A3**: An \(m_3\) by \(n\) matrix of coefficients for the equality constraints.
- **b3**: A vector of length \(m_3\) giving the right hand side of equality constraints. This argument is required if \(A3\) is given and ignored otherwise. All values in \(b3\) must be non-negative.
- **maxi**: A logical flag which specifies minimization if \(\text{FALSE}\) (default) and maximization otherwise. If \(\text{maxi}\) is \(\text{TRUE}\) then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
- **n.iter**: The maximum number of iterations to be conducted in each phase of the simplex method. The default is \(n + 2 \times (m_1 + m_2 + m_3)\).
- **eps**: The floating point tolerance to be used in tests of equality.

Details

The method employed by this function is the two phase tableau simplex method. If there are \(\geq\) or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each \(\geq\) or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the \(\leq\) form, the origin is a feasible solution and so the first stage can be omitted.

Value

An object of class "simplex": see \texttt{simplex.object}.

Note

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form \(x[i] \geq b2[i]\) they should be omitted by setting \(x[i] = x[i] - b2[i]\), changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.
References

Examples

# This example is taken from Exercise 7.5 of Gill, Murray and Wright (1991).
enj <- c(200, 6000, 3000, -200)
fat <- c(800, 6000, 1000, 400)
vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
b2 = c(600, 300, 550), maxi = TRUE)

simplex.object       Linear Programming Solution Objects

Description

Class of objects that result from solving a linear programming problem using simplex.

Generation

This class of objects is returned from calls to the function simplex.

Methods

The class "saddle.distn" has a method for the function print.

Structure

Objects of class "simplex" are implemented as a list with the following components.

soln The values of x which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

solved This indicates whether the problem was solved. A value of -1 indicates that no feasible solution could be found. A value of 0 that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of 1 indicates that an optimal solution has been found.

value The value of the objective function at soln.

val.aux This is NULL if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

obj The original coefficients of the objective function.

a The objective function coefficients re-expressed such that the basic variables have coefficient zero.

a.aux This is NULL if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.
A The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions $m_1+m_2+m_3$ by $n+m_1+m_2$, where the final $m_1+m_2$ columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional $m_1+m_2+m_3$ columns for the artificial variables introduced to solve the first phase of the problem.

basic The indices of the basic (non-zero) variables in the solution. Indices between $n+1$ and $n+m_1$ correspond to slack variables, those between $n+m_1+1$ and $n+m_2$ correspond to surplus variables and those greater than $n+m_2$ are artificial variables. Indices greater than $n+m_2$ should occur only if solved is $-1$ as the artificial variables are discarded in the second stage of the simplex method.

slack The final values of the $m_1$ slack variables which arise when the "$\leq"$ constraints are re-expressed as the equalities $A_1 \times x + \text{slack} = b_1$.

surplus The final values of the $m_2$ surplus variables which arise when the "$\leq"$ constraints are re-expressed as the equalities $A_2 \times x - \text{surplus} = b_2$.

artificial This is NULL if a feasible solution can be found. If no solution can be found then this contains the values of the $m_1+m_2+m_3$ artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

print.simplex, simplex

---

smooth.f Smooth Distributions on Data Points

Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, theta, of the statistic of interest. The method results in distributions which vary smoothly with theta.

Usage

smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index], width = 0.5)

Arguments

theta The required value for the statistic of interest. If theta is a vector, a separate distribution will be found for each element of theta.

boot.out A bootstrap output object returned by a call to boot.

index The index of the variable of interest in the output of boot.out$statistic. This argument is ignored if t is supplied. index must be a scalar.

t The bootstrap values of the statistic of interest. This must be a vector of length boot.out$R and the values must be in the same order as the bootstrap replicates in boot.out.

width The standardized width for the kernel smoothing. The smoothing uses a value of width*s for epsilon, where s is the bootstrap estimate of the standard error of the statistic of interest. width should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If width is too large then the distribution becomes closer to uniform.
smooth.f

Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of $t$ weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value $\theta$ but it will typically have a value which is close to $\theta$. The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

Value

If length($\theta$) is 1 then a vector with the same length as the data set boot.out$data is returned. The value in position 1 is the probability to be given to the data point in position 1 so that the distribution has parameter value approximately equal to $\theta$. If length($\theta$) is bigger than 1 then the returned value is a matrix with length($\theta$) rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of $\theta$.

boot, exp.tilt, tilt.boot

Examples

# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. In the book exponential tilting was used
# but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1],
  weights = grav.sm)

# Estimated p-values can be found from these as follows
mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

sunspot

**Annual Mean Sunspot Numbers**

**Description**

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by k(f+10g) where g is the number of sunspot groups observed, f is the total number of spots within the groups and k is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

---

**Description**

The tau data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970’s by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

tau

**Format**

This data frame contains the following columns:

- **rate**: The decay rate expressed as a percentage.
- **decay**: The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

**Source**

The data were obtained from:

References

tilt.boot  Non-parametric Tilted Bootstrap

Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
          strata = rep(1, n), L = NULL, theta = NULL,
          alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
          index = 1, ...)```

Arguments

- **data**: The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.
- **statistic**: A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to `tilt.boot` and will be passed unchanged to statistic each time it is called.
- **R**: The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta).
- **sim**: This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.
- **stype**: A character string indicating the type of second argument expected by statistic. The possible values that stype can take are "i" (indices), "w" (weights) and "f" (frequencies).
- **strata**: An integer vector or factor representing the strata for multi-sample problems.
The empirical influence values for the statistic of interest. They are used only for exponential tilting when `tilt` is `TRUE`. If `tilt` is `TRUE` and they are not supplied then `tilt.boot` uses `empinf` to calculate them.

The required parameter value(s) for the tilted distribution(s). There should be one value of `theta` for each of the non-uniform distributions. If `R[1]` is 0 `theta` is a required argument. Otherwise `theta` values can be estimated from the initial uniform bootstrap and the values in `alpha`.

The alpha level to which tilting is required. This parameter is ignored if `R[1]` is 0 or if `theta` is supplied, otherwise it is used to find the values of `theta` as quantiles of the initial uniform bootstrap. In this case `R[1]` should be large enough that \( \min(c(alpha, 1-alpha)) \times R[1] > 5 \), if this is not the case then a warning is generated to the effect that the `theta` are extreme values and so the tilted output may be unreliable.

A logical variable which if `TRUE` (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing (`smooth.f`) is used. If `tilt` is `FALSE` then `R[1]` must be positive. In fact in this case the value of `R[1]` should be fairly large (in the region of 500 or more).

This argument is used only if `tilt` is `FALSE`, in which case it is passed unchanged to `smooth.f` as the standardized bandwidth for the smoothing operation. The value should generally be in the range \((0.2, 1)\). See `smooth.f` for for more details.

The index of the statistic of interest in the output from `statistic`. By default the first element of the output of `statistic` is used.

Any additional arguments required by `statistic`. These are passed unchanged to `statistic` each time it is called.

An object of class "boot" with the following components

- `t0`: The observed value of the statistic on the original data.
- `t`: The values of the bootstrap replicates of the statistic. There will be \( \sum(R) \) of these, the first `R[1]` corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).
- `R`: The input vector of the number of bootstrap replicates.
- `data`: The original data as supplied.
- `statistic`: The statistic function as supplied.
- `sim`: The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".
- `stype`: The type of statistic supplied, it is the same as the input value `stype`.
- `call`: A copy of the original call to `tilt.boot`.
- `strata`: The strata as supplied.
- `weights`: The matrix of weights used. If `R[1]` is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If `R[1]` equals 0 then the uniform weights are omitted and only the tilted weights are output.
- `theta`: The values of `theta` used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and `alpha`.

```
tsboot

Bootstrapping of Time Series

Description

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

Usage

```r
tsboot(tseries, statistic, R, l = NULL, sim = "model", endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE, ran.gen, ran.args = NULL, norm = TRUE, ..., parallel = c("no", "multicore", "snow"), ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

Arguments

- `tseries`: A univariate or multivariate time series.
- `statistic`: A function which when applied to `tseries` returns a vector containing the statistic(s) of interest. Each time `statistic` is called it is passed a time series of length `n.sim` which is of the same class as the original `tseries`. Any other arguments which `statistic` takes must remain constant for each bootstrap replicate and should be supplied through the `...` argument to `tsboot`.
- `R`: A positive integer giving the number of bootstrap replicates required.
- `sim`: The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of `l`), "geom" (block resampling with block lengths having a geometric distribution with mean `l`) or "scramble" (phase scrambling).
- `l`: If `sim` is "fixed" then `l` is the fixed block length used in generating the replicate time series. If `sim` is "geom" then `l` is the mean of the geometric distribution used to generate the block lengths. `l` should be a positive integer less than the length of `tseries`. This argument is not required when `sim` is "model" but it is required for all other simulation types.
- `endcorr`: A logical variable indicating whether end corrections are to be applied when `sim` is "fixed". When `sim` is "geom", `endcorr` is automatically set to `TRUE`; `endcorr` is not used when `sim` is "model" or "scramble".
- `n.sim`: The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which `n.sim` is larger than the original length is if `tseries` is a residual time series from fitting some model to the original time series. In this case, `n.sim` would usually be the length of the original time series.
- `orig.t`: A logical variable which indicates whether `statistic` should be applied to `tseries` itself as well as the bootstrap replicate series. If `statistic` is expecting a longer time series than `tseries` or if applying `statistic` to `tseries` will not yield any useful information then `orig.t` should be set to `FALSE`. 

- `ran.gen`, `ran.args`: Arguments for generating random numbers.
- `norm`: A logical variable indicating whether the statistic should be normalized.
- `parallel`, `ncpus`, `cl`: Arguments for parallel processing.
This is a function of three arguments. The first argument is a time series. If sim is "model" then it will always be tseries that is passed. For other simulation types it is the result of selecting n.sim observations from tseries by some scheme and converting the result back into a time series of the same form as tseries (although of length n.sim). The second argument to ran.gen is always the value n.sim, and the third argument is ran.args, which is used to supply any other objects needed by ran.gen. If sim is "model" then the generation of the replicate time series will be done in ran.gen (for example through use of arima.sim). For the other simulation types ran.gen is used for ‘post-blackening’. The default is that the function simply returns the time series passed to it.

This will be supplied to ran.gen each time it is called. If ran.gen needs any extra arguments then they should be supplied as components of ran.args. Multiple arguments may be passed by making ran.args a list. If ran.args is NULL then it should not be used within ran.gen but note that ran.gen must still have its third argument.

A logical argument indicating whether normal margins should be used for phase scrambling. If norm is FALSE then margins corresponding to the exact empirical margins are used.

Extra named arguments to statistic may be supplied here. Beware of partial matching to the arguments of tsboot listed above.

See the help for boot.

If sim is "fixed" then each replicate time series is found by taking blocks of length l, from the original time series and putting them end-to-end until a new series of length n.sim is created. When sim is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean l. Post-blackening can be carried out on these replicate time series by including the function ran.gen in the call to tsboot and having tseries as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function boot with the argument sim = "parametric".

An object of class "boot" with the following components.

t0 If orig.t is TRUE then t0 is the result of statistic(tseries,...{}) otherwise it is NULL.

t The results of applying statistic to the replicate time series.

R The value of R as supplied to tsboot.

tseries The original time series.

statistic The function statistic as supplied.

```r
lynx.fun <- function(tsb) {
  ar.fit <- ar(tsb, order.max = 25)
  c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their data, we set orig.t to FALSE since the function applied to the residual # time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res, n.sim, ran.args) {
  # random generation of replicate series using arima.sim
  rg1 <- function(n, res) sample(res, n, replace = TRUE)
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig)+ts(arima.sim(model = ts.mod, n = n.sim, rand.gen = rg1, res = as.vector(res)))
}
tuna <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114, orig.t = FALSE, ran.gen = lynx.sim, ran.args = list(ts = log(lynx), model = lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed", n.sim = 114, orig.t = FALSE, ran.gen = lynx.black, ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom", n.sim = 114, orig.t = FALSE, ran.gen = lynx.black, ran.args = list(ts = log(lynx), model = lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])

# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

---

### tuna

#### Tuna Sighting Data

**Description**

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

**Usage**

- tuna

**Format**

This data frame contains the following column:

- **y** The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.
urine

Source

Example Data Table

<table>
<thead>
<tr>
<th></th>
<th>Urine Analysis Data</th>
</tr>
</thead>
</table>

Description
The urine data frame has 79 rows and 7 columns.
79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

Usage
Current

Format
This data frame contains the following columns:
r Indicator of the presence of calcium oxalate crystals.
gravity The specific gravity of the urine.
ph The pH reading of the urine.
osmo The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.
cond The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.
urea The urea concentration in millimoles per litre.
calc The calcium concentration in millimoles per litre.

var.linear  

**Linear Variance Estimate**

**Description**

Estimates the variance of a statistic from its empirical influence values.

**Usage**

```r
var.linear(L, strata = NULL)
```

**Arguments**

- `L`: Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`.
- `strata`: A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

**Value**

The variance estimate calculated from `L`.

**References**

**See Also**

- `empinf`, `linear.approx`, `k3.linear`

**Examples**

```r
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))
```

---

wool  

**Australian Relative Wool Prices**

**Description**

`wool` is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

batchSOM  Self-Organizing Maps: Batch Algorithm

Description
Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage
batchSOM(data, grid = somgrid(), radii, init)

Arguments
data      a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
grid      A grid for the representatives: see somgrid.
radii     the radii of the neighbourhood to be used for each pass: one pass is run for each element of radii.
init      the initial representatives. If missing, chosen (without replacement) randomly from data.

Details
The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

Value
An object of class "SOM" with components
grid      the grid, an object of class "somgrid".
codes     a matrix of representatives.

References

```

condense

Condense training set for k-NN classifier

Description

Condense training set for k-NN classifier

Usage

```r
condense(train, class, store, trace = TRUE)
```

Arguments

- `train`: matrix for training set
- `class`: vector of classifications for test set
- `store`: initial store set. Default one randomly chosen element of the set.
- `trace`: logical. Trace iterations?

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

Index vector of cases to be retained (the final store set).
knn

k-Nearest Neighbour Classification

Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the \( k \) nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the \( k \)th nearest vector, all candidates are included in the vote.

Usage

\[
\text{knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)}
\]

Arguments

- **train**: matrix or data frame of training set cases.
- **test**: matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
- **cl**: factor of true classifications of training set
- **k**: number of neighbours considered.
- **l**: minimum vote for definite decision, otherwise doubt. (More precisely, less than \( k-1 \) dissenting votes are allowed, even if \( k \) is increased by ties.)
- **prob**: If this is true, the proportion of the votes for the winning class are returned as attribute \( \text{prob} \).
- **use.all**: controls handling of ties. If true, all distances equal to the \( k \)th largest are included. If false, a random selection of distances equal to the \( k \)th is chosen to use exactly \( k \) neighbours.

Examples

\[
\begin{align*}
\text{train} & \leftarrow \text{rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])} \\
\text{test} & \leftarrow \text{rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])} \\
\text{cl} & \leftarrow \text{factor(c(rep("s",25), rep("c",25), rep("v",25)))} \\
\text{keep} & \leftarrow \text{condense(train, cl)} \\
\text{knn(train[keep, , drop=FALSE], test, cl[keep])} \\
\text{keep2} & \leftarrow \text{reduce.nn(train, keep, cl)} \\
\text{knn(train[keep2, , drop=FALSE], test, cl[keep2])}
\end{align*}
\]
Value

Factor of classifications of test set. doubt will be returned as NA.

Examples

```r
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)
```

### Description

k-Nearest Neighbour Cross-Validatory Classification

k-nearest neighbour cross-validatory classification from training set.

### Usage

```r
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

### Arguments

- **train**: matrix or data frame of training set cases.
- **cl**: factor of true classifications of training set
- **k**: number of neighbours considered.
- **l**: minimum vote for definite decision, otherwise doubt. (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)
- **prob**: If this is true, the proportion of the votes for the winning class are returned as attribute prob.
- **use.all**: controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

### Details

This uses leave-one-out cross validation. For each row of the training set train, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.
knn1

Value

Factor of classifications of training set. doubt will be returned as NA.

attributes(.Last.value)
```

---

knn1  1-Nearest Neighbour Classification

Description

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

Usage

```r
knn1(train, test, cl)
```

Arguments

- **train**: matrix or data frame of training set cases.
- **test**: matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
- **cl**: factor of true classification of training set.

Value

Factor of classifications of test set.

cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn1(train, test, cl)
```

---

**Learning Vector Quantization I**

### Description

Moves examples in a codebook to better represent the training set.

### Usage

```r
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

### Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

### Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

### Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

cd1 <- lvq1(train, cl, cd0)
lvqtest(cd1, train)
```

---

**lvq2**

*Learning Vector Quantization 2.1*

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03, win = 0.3)
```

**Arguments**

- `x` a matrix or data frame of examples
- `cl` a vector or factor of classifications for the examples
- `codebk` a codebook
- `niter` number of iterations
- `alpha` constant for training
- `win` a tolerance for the closeness of the two nearest vectors.

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**References**

lvq3

Learning Vector Quantization 3

Description

Moves examples in a codebook to better represent the training set.

Usage

lvq3(x, c1, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
     win = 0.3, epsilon = 0.1)

Arguments

x a matrix or data frame of examples
c1 a vector or factor of classifications for the examples
codebk a codebook
niter number of iterations
alpha constant for training
win a tolerance for the closeness of the two nearest vectors.
epsilon proportion of move for correct vectors

Details

Selects niter examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

Value

A codebook, represented as a list with components x and c1 giving the examples and classes.

lvqinit

Initialize a LVQ Codebook

Description
Construct an initial codebook for LVQ methods.

Usage
lvqinit(x, cl, size, prior, k = 5)

Arguments
x  a matrix or data frame of training examples, n by p.
cl  the classifications for the training examples. A vector or factor of length n.
size  the size of the codebook. Defaults to \( \min(\text{round}(0.4 \times n \times (n-1 + p/2), 0), n) \) where \( n \) is the number of classes.
prior  Probabilities to represent classes in the codebook. Default proportions in the training set.
k  k used for k-NN test of correct classification. Default is 5.

Details
Selects size examples from the training set without replacement with proportions proportional to the prior or the original proportions.

Value
A codebook, represented as a list with components \( x \) and \( cl \) giving the examples and classes.

**lvqtest**

Classify Test Set from LVQ Codebook

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```r
lvqtest(codebk, test)
```

Arguments

- `codebk`: codebook object returned by other LVQ software
- `test`: matrix of test examples

Details

Uses 1-NN to classify each test example against the codebook.

Value

Factor of classification for each row of `x`

multiedit                             Multiedit for k-NN Classifier

Description

Multiedit for k-NN classifier

Usage

multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)

Arguments

x                matrix of training set.
class            vector of classification of training set.
k                number of neighbours used in k-NN.
V                divide training set into V parts.
I                number of null passes before quitting.
trace            logical for statistics at each pass.

Value

Index vector of cases to be retained.

```

olvq1  

Optimized Learning Vector Quantization 1

Description

Moves examples in a codebook to better represent the training set.

Usage

```r
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

Arguments

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

References

reduce.nn

Reduce Training Set for a k-NN Classifier

Description

Reduce training set for a k-NN classifier. Used after condense.

Usage

reduce.nn(train, ind, class)

Arguments

- **train**: matrix for training set
- **ind**: Initial list of members of the training set (from condense).
- **class**: vector of classifications for test set

Details

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

Value

Index vector of cases to be retained.

References

cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep,], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2,], test, cl[keep2])
```

---

**SOM**

**Self-Organizing Maps: Online Algorithm**

**Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```r
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

- `data` a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
- `grid` A grid for the representatives: see `somgrid`.
- `rlen` the number of updates: used only in the defaults for `alpha` and `radii`.
- `alpha` the amount of change: one update is done for each element of `alpha`. Default is to decline linearly from 0.05 to 0 over `rlen` updates.
- `radii` the radii of the neighbourhood to be used for each update: must be the same length as `alpha`. Default is to decline linearly from 4 to 1 over `rlen` updates.
- `init` the initial representatives. If missing, chosen (without replacement) randomly from `data`.

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

- `grid` the grid, an object of class "somgrid".
- `codes` a matrix of representatives.
References

See Also

somgrid, batchSOM

Examples

```r
require(graphics)
data(crabs, package = "MASS")
lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")%rep(1:4, rep(50,4)))
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)
## 2-phase training

## 2-phase training

## S3 method for class 'somgrid'
plot(x, type = "p", ...)
## S3 method for class 'SOM'
plot(x, ...)
```

Arguments

- `xdim, ydim`: dimensions of the grid
- `topo`: the topology of the grid.
- `x`: an object inheriting from class "somgrid" or "SOM".
- `type, ...`: graphical parameters.

Description

Plotting functions for SOM results.

Usage

```r
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))
```

## S3 method for class 'somgrid'
plot(x, type = "p", ...)

## S3 method for class 'SOM'
plot(x, ...)

somgrid

Plot SOM Fits

Copyright (C) 1998-2005 W. Venables, B. Ripley, R Core Team.
Details

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a \texttt{stars} plot of the representative at each grid point.

Value

For \texttt{somgrid}, an object of class "somgrid", a list with components

\begin{description}
\item[\texttt{pts}] a two-column matrix giving locations for the grid points.
\item[\texttt{xdim}, \texttt{ydim}, \texttt{topo}] as in the arguments to \texttt{somgrid}.
\end{description}

Chapter 20

The cluster package

agnes (Agglomerative Nesting (Hierarchical Clustering))

Description
Computes agglomerative hierarchical clustering of the dataset.

Usage
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
    stand = FALSE, method = "average", par.method,
    keep.diss = n < 100, keep.data = !diss, trace.lev = 0)

Arguments

x data matrix or data frame, or dissimilarity matrix, depending on the value of the
diss argument.
   In case of a matrix or data frame, each row corresponds to an observation, and
each column corresponds to a variable. All variables must be numeric. Missing
values (NAs) are allowed.
   In case of a dissimilarity matrix, x is typically the output of daisy or dist.
   Also a vector with length n*(n-1)/2 is allowed (where n is the number of ob-
servations), and will be interpreted in the same way as the output of the above-
mentioned functions. Missing values (NAs) are not allowed.

diss logical flag: if TRUE (default for dist or dissimilarity objects), then x is
   assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix of
   observations by variables.

metric character string specifying the metric to be used for calculating dissimilarities
   between observations. The currently available options are "euclidean" and
   "manhattan". Euclidean distances are root sum-of-squares of differences, and
   manhattan distances are the sum of absolute differences. If x is already a dis-
   similarity matrix, then this argument will be ignored.

stand logical flag: if TRUE, then the measurements in x are standardized before cal-
   culating the dissimilarities. Measurements are standardized for each variable
(column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

**method** character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-group arithMetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward’s method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the par.method argument, and "gaverage" a generalized "average" aka “flexible UPGMA” method also using the Lance-Williams formula and par.method.

The default is "average".

**par.method** If method is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.

**keep.diss, keep.data** logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

**trace.lev** integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

### Details

agnes is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as hclust, agnes has the following features: (a) it yields the agglomerative coefficient (see agnes.object) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see plot.agnes).

The agnes-algorithm constructs a hierarchy of clusterings. At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two nearest clusters are combined to form one larger cluster.

For method="average", the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In method="single", we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When method="complete", we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The method = "flexible" allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters C1 and C2 are agglomerated into a new cluster, the dissimilarity between their union and another cluster Q is given by

\[
D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,
\]

where the four coefficients \((\alpha_1, \alpha_2, \beta, \gamma)\) are specified by the vector par.method, either directly as vector of length 4, or (more conveniently) if par.method is of length 1, say = \(\alpha\), par.method is extended to give the “Flexible Strategy” (K&R(1990), p.236 f) with Lance-Williams coefficients \((\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)\).

Also, if length(par.method) == 3, \(\gamma = 0\) is set.
Care and expertise is probably needed when using method = "flexible" particularly for the case when par.method is specified of longer length than one. Since cluster version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The weighted average (method="weighted") is the same as method="flexible", par.method = 0.5. Further, method="single" is equivalent to method="flexible", par.method = c(.5,.5,.5,.5), and method="complete" is equivalent to method="flexible", par.method = c(.5,.5,0,.5).

The method = "gaverage" is a generalization of "average", aka "flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with \( \alpha \) not constant, but proportional to the sizes \( n_1 \) and \( n_2 \) of the clusters \( C_1 \) and \( C_2 \) respectively, i.e,

\[
\alpha_j = \alpha_j' \frac{n_1}{n_1 + n_2},
\]

where \( \alpha_j' \) and \( \alpha_j'' \) are determined from par.method, either directly as \( (\alpha_1, \alpha_2, \beta, \gamma) \) or \( (\alpha_1, \alpha_2, \beta) \) with \( \gamma = 0 \), or (less flexibly, but more conveniently) as follows:

Belbin et al proposed "flexible beta", i.e. the user would only specify \( \beta \) (as par.method), sensibly in

\[-1 \leq \beta \leq 1,\]

and \( \beta \) determines \( \alpha_j' \) and \( \alpha_j'' \) as

\[\alpha_j' = 1 - \beta,\]

and \( \gamma = 0 \).

This \( \beta \) may be specified by par.method (as length 1 vector), and if par.method is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a \( \beta \) value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that method = "gaverage", par.method = 0 (or par.method = c(1,1,0,0)) is equivalent to the agnes() default method "average".

Value

an object of class "agnes" (which extends "twins") representing the clustering. See agnes.object for details, and methods applicable.

BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

Hierarchical methods like agnes, diana, and mona construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

Partitioning methods like pam, clara, and fanny require that the number of clusters be given by the user.

Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

data(agriculture)

## Plot similar to Figure 7 in ref  
## Not run: plot(agnes(agriculture), ask = TRUE)

data(animals)

aa.a <- agnes(animals) # default method = "average"
aa.ga <- agnes(animals, method = "gaverage")
agnes.object

Description
The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

Value
A legitimate agnes object is a list with the following components:

order
a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.

order.lab
a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.

height
a vector with the distances between merging clusters at the successive stages.

ac
the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation i, denote by m(i) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The ac is the average of all 1 - m(i). It can also be seen as the average width (or the percentage filled) of the banner plot. Because ac grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

merge
an (n-1) by 2 matrix, where n is the number of observations. Row i of merge describes the merging of clusters at step i of the clustering. If a number j in the row is negative, then the single observation |j| is merged at this stage. If j is positive, then the merger is with the cluster formed at stage j of the algorithm.

diss
an object of class "dissimilarity" (see dissimilarity.object), representing the total dissimilarity matrix of the dataset.

data
a matrix containing the original or standardized measurements, depending on the stand option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.

GENERATION
This class of objects is returned from agnes.
METHODS

The "agnes" class has methods for the following generic functions: print, summary, plot, and as.dendrogram.

In addition, cutree(x, *) can be used to “cut” the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions pltree and as.hclust are available for agnes objects. After applying as.hclust(), all its methods are available, of course.

See Also

agnes, diana, as.hclust, hclust, plot.agnes, twins.object.
cutree.

Examples

data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

## cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))

agriculture

European Union Agricultural Workforces

description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

data(agriculture)

Format

A data frame with 12 observations on 2 variables:

[ , 1] x numeric per capita GNP
[ , 2] y numeric percentage in agriculture

The row names of the data frame indicate the countries.
Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

Examples

data(animals)

```r
## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(animals, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(animals, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(animals), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(animals), ask = TRUE)
```

<table>
<thead>
<tr>
<th>animals</th>
<th>Attributes of Animals</th>
</tr>
</thead>
</table>

Description

This data set considers 6 binary attributes for 20 animals.

Usage

data(animals)
Format

A data frame with 20 observations on 6 variables:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>[.1]</td>
<td>war</td>
</tr>
<tr>
<td>[.2]</td>
<td>fly</td>
</tr>
<tr>
<td>[.3]</td>
<td>ver</td>
</tr>
<tr>
<td>[.4]</td>
<td>end</td>
</tr>
<tr>
<td>[.5]</td>
<td>gro</td>
</tr>
<tr>
<td>[.6]</td>
<td>hai</td>
</tr>
</tbody>
</table>

All variables are encoded as 1 = ‘no’, 2 = ‘yes’.

Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

Examples

data(animals)
apply(animals,2, table) # simple overview

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

Description

Draws a “banner”, i.e. basically a horizontal barplot visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

Usage

bannerplot(x, w = rev(x$height), fromLeft = TRUE,
main=NULL, sub=NULL, xlab = "Height", adj = 0,
col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
rev.xax = !fromLeft, xax.pretty = TRUE,
labels = NULL, nmax.lab = 35, max.strlen = 5,
yax.do = axes && length(x$order) <= nmax.lab,
yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)

bannerplot
Plot Banner (of Hierarchical Clustering)
Arguments

- **x**: a list with components `order`, `order.lab` and `height` when `w`, the next argument is not specified.
- **w**: non-negative numeric vector of bar widths.
- **fromLeft**: logical, indicating if the banner is from the left or not.
- **main,sub**: main and sub titles, see `title`.
- **xlab**: x axis label (with ‘correct’ default e.g. for `plot.agnes`).
- **adj**: passed to `title(main, sub)` for string adjustment.
- **col**: vector of length 2, for two horizontal segments.
- **border**: color for bar border; now defaults to background (no border).
- **axes**: logical indicating if axes (and labels) should be drawn at all.
- **frame.plot**: logical indicating the banner should be framed; mainly used when `border = 0` (as per default).
- **rev.xax**: logical indicating if the x axis should be reversed (as in `plot.diana`).
- **xax.pretty**: logical or integer indicating if `pretty()` should be used for the x axis.
  - `xax.pretty = FALSE` is mainly for back compatibility.
- **labels**: labels to use on y-axis; the default is constructed from `x`.
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- **max.strlen**: positive integer giving the length to which strings are truncated in banner plot labeling.
- **yax.do**: logical indicating if a y axis and banner labels should be drawn.
- **yaxRight**: logical indicating if the y axis is on the right or left.
- **y.mar**: positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.

Additional arguments `...` graphical parameters (see `par`) may also be supplied as arguments to this function.

Note

This is mainly a utility called from `plot.agnes`, `plot.diana` and `plot.mona`.

Author(s)

Martin Maechler (from original code of Kaufman and Rousseeuw).

Examples

data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
**chorSub**

**Subset of C-horizon of Kola Data**

**Description**

This is a small rounded subset of the C-horizon data `chorizon` from package `mvoutlier`.

**Usage**

```r
data(chorSub)
```

**Format**

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

**Details**

This data set was produced from `chorizon` via these statements:

```r
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110])[190:250,])
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_*", "" , colnames(chorSub))
```

**Source**

**See Also**

`chorizon` in package `mvoutlier` and other Kola data in the same package.

**Examples**

```r
data(chorSub)
summary(chorSub)
pairs(chorSub, gap=.1)# some outliers
```
Description

Clustering Large Applications

Computes a "clara" object, a list representing a clustering of the data into k clusters.

Usage

clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
       stand = FALSE, cluster.only = FALSE, samples = 5,
       sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
       keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)

Arguments

x     data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.

k     integer, the number of clusters. It is required that 0 < k < n where n is the number of observations (i.e., n = nrow(x)).

metric character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", and "jaccard".

Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

stand logical, indicating if the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation.

cluster.only logical; if true, only the clustering will be computed and returned, see details.

samples integer, say N, the number of samples to be drawn from the dataset. The default, N = 5, is rather small for historical (and now back compatibility) reasons and we recommend to set samples an order of magnitude larger.

csampsize integer, say j, the number of observations in each sample. sampsize should be higher than the number of clusters (k) and at most the number of observations (n = nrow(x)). While computational effort is proportional to j^2, see note below, it may still be advisable to set j = sampsize to a larger value than the (historical) default.

trace integer indicating a trace level for diagnostic output during the algorithm.

medoids.x logical indicating if the medoids should be returned, identically to some rows of the input data x. If FALSE, keep.data must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (i.e., med component), and the algorithm saves space by needing one copy less of x.

keep.data logical indicating if the (scaled if stand is true) data should be kept in the result. Setting this to FALSE saves memory (and hence time), but disables clusplot()ing of the result. Use medoids.x = FALSE to save even more memory.
rngR logical indicating if R’s random number generator should be used instead of the primitive clara()-builtin one. If true, this also means that each call to clara() returns a different result – though only slightly different in good situations.

pamLike logical indicating if the “swap” phase (see pam, in C code) should use the same algorithm as pam(). Note that from Kaufman and Rousseeuw’s description this should have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, pamLike = FALSE has been chosen to remain back compatible rather than “PAM compatible”.

correct.d logical or integer indicating that — only in the case of NAs present in x — the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016. Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies correct.d.

Details

clara is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as pam, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (sampsize) such that the time and storage requirements become linear in n rather than quadratic.

Each sub-dataset is partitioned into k clusters using the same algorithm as in pam. Once k representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until sampsize has been reached.

When cluster.only is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e., clara(x,k, cluster.only=TRUE) is the same as clara(x,k)$clustering but computed more efficiently.

Value

If cluster.only is false (as by default), an object of class "clara" representing the clustering. See clara.object for details.

If cluster.only is true, the result is the ”clustering”, an integer vector of length n with entries from 1:k.

Note

By default, the random sampling is implemented with a very simple scheme (with period $2^{16} = 65536$) inside the Fortran code, independently of R’s random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting rngR = TRUE which uses R’s random number generators. Then, clara() results are made reproducible typically by using set.seed() before calling clara.

The storage requirement of clara computation (for small k) is about $O(n \times p) + O(j^2)$ where $j = \text{sampsize}$, and $(n, p) = \text{dim}(x)$. The CPU computing time (again assuming small k) is about $O(n \times p \times j^2 \times N)$, where $N = \text{samples}$.
For “small” datasets, the function `pam` can be used directly. What can be considered small, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “small (say with fewer than 200 observations)”; as of 2006, you can use `pam` with several thousand observations.

Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. Metric "jaccard": Kamil Kozlowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from trace on, and most R documentation and all tests by Martin Maechler.

Examples

```R
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
         cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
calla(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)
## cluster.only = TRUE -- save some memory/time :
clclus <- clara(x, 2, samples=50, cluster.only = TRUE)
stopifnot(identical(clclus, clarax$clustering))
## 'xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)
## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421)# (reproducibility)
cl <- matrix(NA,nrow(xclara), nSim)
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tcl <- apply(cl,1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim)))))
if(length(iDoubt)) { # (not for all seeds)
```

```
```
tabD <- tcl[,iDoubt, drop=FALSE]
dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
t(tabD) # how many times in which clusters
```

---

### clara.object

**Clustering Large Applications (CLARA) Object**

#### Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from `clara`.

#### Value

A legitimate `clara` object is a list with the following components:

- **sample**: labels or case numbers of the observations in the best sample, that is, the sample used by the `clara` algorithm for the final partition.
- **medoids**: the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from `clara(*, medoids.x=FALSE)`. Use the following `i.med` in that case.
- **i.med**: the indices of the medoids above: `medoids <- x[i.med,]` where `x` is the original data matrix in `clara(x,*)`.
- **clustering**: the clustering vector, see `partition.object`.
- **objective**: the objective function for the final clustering of the entire dataset.
- **clusinfo**: matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster’s medoid, divided by the minimal dissimilarity between the cluster’s medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
- **diss**: dissimilarity (maybe NULL), see `partition.object`.
- **silinfo**: list with silhouette width information for the best sample, see `partition.object`.
- **call**: generating call, see `partition.object`.
- **data**: matrix, possibly standardized, or NULL, see `partition.object`.

#### Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a `clara` object.

#### See Also

`clara`, `dissimilarity.object`, `partition.object`, `plot.partition`
clusGap() calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters \( k \), it compares \( \log(W(k)) \) with \( E^*[\log(W(k))] \) where the latter is defined via bootstrapping, i.e., simulating from a reference \((H_0)\) distribution, a uniform distribution on the hypercube determined by the ranges of \( x \), after first centering, and then \texttt{svd} (aka ‘PCA’)-rotating them when (as by default) \( \text{spaceH0} = "scaledPCA" \).

\texttt{maxSE(f, SE.f)} determines the location of the maximum of \( f \), taking a “1-SE rule” into account for the \texttt{*SE*} methods. The default method “firstSEmax” looks for the smallest \( k \) such that its value \( f(k) \) is not more than 1 standard error away from the first local maximum. This is similar but not the same as "Tibs2001SEmax", Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

**Usage**

```r
clusGap(x, FUNcluster, K.max, B = 100, d.power = 1, 
       spaceH0 = c("scaledPCA", "original"), 
       verbose = interactive(), ...)
```

```r
maxSE(f, SE.f, 
      method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax", 
                  "firstmax", "globalmax"), 
      SE.factor = 1)
```

```r
## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

## S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]), 
     main = NULL, do.arrows = TRUE, 
     arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)
```

**Arguments**

- **x** numeric matrix or \texttt{data.frame}.
- **FUNcluster** a \texttt{function} which accepts as first argument a (data) matrix like \( x \), second argument, say \( k, k \geq 2 \), the number of clusters desired, and returns a \texttt{list} with a component named (or shortened to) \texttt{cluster} which is a vector of length \( n = \text{nrow}(x) \) of integers in 1:k determining the clustering or grouping of the \( n \) observations.
- **K.max** the maximum number of clusters to consider, must be at least two.
- **B** integer, number of Monte Carlo (“bootstrap”) samples.
- **d.power** a positive integer specifying the power \( p \) which is applied to the euclidean distances (\texttt{dist}) before they are summed up to give \( W(k) \). The default, \( d.\text{power} = 1 \), corresponds to the “historical” \texttt{R} implementation, whereas \( d.\text{power} = 2 \) corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.
spaceH0 a character string specifying the space of the $H_0$ distribution (of no cluster). Both "scaledPCA" and "original" use a uniform distribution in a hyper cube and had been mentioned in the reference; "original" been added after a proposal (including code) by Juan Gonzalez.

verbose integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.

... (for clusGap()) optionally further arguments for FUNcluster(), see kmeans example below.

f numeric vector of ‘function values’, of length $K$, whose (“1 SE respected”) maximum we want.

SE.f numeric vector of length $K$ of standard errors of $f$.

method character string indicating how the “optimal” number of clusters, $\hat{k}$, is computed from the gap statistics (and their standard deviations), or more generally how the location $\hat{k}$ of the maximum of $f_k$ should be determined.

"globalmax": simply corresponds to the global maximum, i.e., is which.max(f)

"firstmax": gives the location of the first local maximum.

"Tibs2001SEmax": uses the criterion, Tibshirani et al (2001) proposed: “the smallest $k$ such that $f(k) \geq f(k+1) - s_{k+1}$”. Note that this chooses $k = 1$ when all standard deviations are larger than the differences $f(k+1) - f(k)$.

"firstSEmax": location of the first $f()$ value which is not smaller than the first local maximum minus SE.factor * SE.f[], i.e, within an “f S.E.” range of that maximum (see also SE.factor). This, the default, has been proposed by Martin Maechler in 2012, when adding clusGap() to the cluster package, after having seen the "globalSEmax" proposal (in code) and read the "Tibs2001SEmax" proposal.

"globalSEmax": (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first $f()$ value which is not smaller than the global maximum minus SE.factor * SE.f[], i.e, within an “f S.E.” range of that maximum (see also SE.factor).

See the examples for a comparison in a simple case.

SE.factor [When method contains "SE"] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an SE.factor $f$, the “fS.E.”-rule is used, more generally.

type, xlab, ylab, main arguments with the same meaning as in plot.default(), with different default.

do.arrows logical indicating if (1 SE -)"error bars" should be drawn, via arrows().

arrowArgs a list of arguments passed to arrows(); the default, notably angle and code, provide a style matching usual error bars.

Details

The main result <res>$Tab[, "gap"] of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see set.seed()). On the other hand, in our experience, using B = 500 gives quite precise results such that the gap plot is basically unchanged after an another run.
clusGap

Value

clusGap(...) returns an object of S3 class "clusGap", basically a list with components:

Tab
a matrix with K.max rows and 4 columns, named "logW", "E.logW", "gap", and "SE.sim", where gap = E.logW - logW, and SE.sim corresponds to the standard error of gap, SE.sim[k] = sk, where sk := \sqrt{1 + 1/Bsd^2(gap_j)}, and sd^2() is the standard deviation of the simulated ("bootstrapped") gap values.

call
the clusGap(...) call.

spaceH0
the spaceH0 argument (match.arg() ed).

n
number of observations, i.e., nrow(x).

B
input B

FUNcluster
input function FUNcluster

Author(s)

This function is originally based on the functions gap of former (Bioconductor) package SAGx by Per Broberg, gapStat() from former package SLmisc by Matthias Kohl and ideas from gap() and its methods of package lga by Justin Harrington.

The current implementation is by Martin Maechler.

The implementation of spaceH0 = "original" is based on code proposed by Juan Gonzalez.

```
plot(gsP.Z, main = "clusGap(<iid_rnorm_p=3>) ==> k = 1 cluster is optimal")
gsP.Z
```
Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

Usage

clusplot(x, ...)

## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)

Arguments

- **x**: an R object, here, specifically an object of class "partition", e.g. created by one of the functions `pam`, `clara`, or `fanny`.
- **main**: title for the plot; when NULL (by default), a title is constructed, using `x$call`.
- **dist**: when `x` does not have a `diss` nor a data component, e.g., for `pam(dist(*), keep.diss=FALSE)`, `dist` must specify the dissimilarity for the clusplot.
- **...**: optional arguments passed to methods, notably the `clusplot.default` method (except for the `diss` one) may also be supplied to this function. Many graphical parameters (see `par`) may also be supplied as arguments here.

Details

The `clusplot.partition()` method relies on `clusplot.default`.

If the clustering algorithms `pam`, `fanny` and `clara` are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with `pam` or `fanny`, the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm `clara` was applied to a data matrix with NAs then `clusplot()` will replace the missing values as described in `clusplot.default`, because a dissimilarity matrix is not available.

Value

For the partition (and default) method: An invisible list with components Distances and Shading, as for `clusplot.default`, see there.

Side Effects

a 2-dimensional clusplot is created on the current graphics device.

See Also

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.
Examples

```r
## For more, see ?clusplot.default
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
            cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

### clusplot.default

Bivariate Cluster Plot (clusplot) Default Method

#### Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observations are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

#### Usage

```r
## Default S3 method:
clusplot(x, clus, diss = FALSE,
s.x.2d = mkCheckX(x, diss), stand = FALSE,
lines = 2, shade = FALSE, color = FALSE,
labels = 0, plotchar = TRUE,
col.p = "dark green", col.txt = col.p,
col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
span = TRUE,
add = FALSE,
xlim = NULL, ylim = NULL,
main = paste("CLUSPLOT("), deparse1(substitute(x)), ")"),
sub = paste("These two components explain",
round(100 * var.dec, digits = 2), ",% of the point variability.")",
xlab = "Component 1", ylab = "Component 2",
verbose =getOption("verbose"),
...)
```

#### Arguments

- `x` matrix or data frame, or dissimilarity matrix, depending on the value of the `diss` argument.
  In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.
  In case of a dissimilarity matrix, `x` is the output of `daisy` or `dist` or a symmetric matrix. Also, a vector of length `n*(n-1)/2` is allowed (where `n` is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
clus

a vector of length n representing a clustering of x. For each observation the 
vector lists the number or name of the cluster to which it has been assigned. 
clus is often the clustering component of the output of pam, fanny or clara.

diss

logical indicating if x will be considered as a dissimilarity matrix or a matrix of 
observations by variables (see x arugment above).

s.x.2d

a list with components named x (a n × 2 matrix; typically something like 
principal components of original data), labs and var.dec.

stand

logical flag: if true, then the representations of the n observations in the 2-
dimensional plot are standardized.

lines

integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. 
The distance between two ellipses E1 and E2 is measured along the line 
connecting the centers $m_1$ and $m_2$ of the two ellipses.

In case E1 and E2 overlap on the line through $m_1$ and $m_2$, no line is drawn. 
Otherwise, the result depends on the value of lines: If

lines = 0, no distance lines will appear on the plot;
lines = 1, the line segment between $m_1$ and $m_2$ is drawn;
lines = 2, a line segment between the boundaries of E1 and E2 is drawn (along 
the line connecting $m_1$ and $m_2$).

shade

logical flag: if TRUE, then the ellipses are shaded in relation to their density. 
The density is the number of points in the cluster divided by the area of the 
ellipse.

color

logical flag: if TRUE, then the ellipses are colored with respect to their density. 
With increasing density, the colors are light blue, light green, red and purple. To 
see these colors on the graphics device, an appropriate color scheme should be 
selected (we recommend a white background).

labels

integer code, currently one of 0,1,2,3,4 and 5. If

labels= 0, no labels are placed in the plot;
labels= 1, points and ellipses can be identified in the plot (see identify);
labels= 2, all points and ellipses are labelled in the plot;
labels= 3, only the points are labelled in the plot;
labels= 4, only the ellipses are labelled in the plot.
labels= 5, the ellipses are labelled in the plot, and points can be identified.

The levels of the vector clus are taken as labels for the clusters. The labels 
of the points are the rownames of x if x is matrix like. Otherwise (diss = 
TRUE), x is a vector, point labels can be attached to x as a "Labels" attribute 
(attr(x,"Labels")), as is done for the output of daisy.

A possible names attribute of clus will not be taken into account.

plotchar

logical flag: if TRUE, then the plotting symbols differ for points belonging to 
different clusters.

span

logical flag: if TRUE, then each cluster is represented by the ellipse with small-
est area containing all its points. (This is a special case of the minimum volume 
ellipsoid.)

If FALSE, the ellipse is based on the mean and covariance matrix of the same 
points. While this is faster to compute, it often yields a much larger ellipse.

There are also some special cases: When a cluster consists of only one point, a 
tiny circle is drawn around it. When the points of a cluster fall on a straight line, 
span=FALSE draws a narrow ellipse around it and span=TRUE gives the exact 
line segment.
clusplot.default

add logical indicating if ellipses (and labels if labels is true) should be added to an already existing plot. If false, neither a title or sub title, see sub, is written.

col.p color code(s) used for the observation points.

col.txt color code(s) used for the labels (if labels >= 2).

col.clus color code for the ellipses (and their labels); only one if color is false (as per default).

cex, cex.txt character expansion (size), for the point symbols and point labels, respectively.

xlim, ylim numeric vectors of length 2, giving the x- and y- ranges as in plot.default.

main main title for the plot; by default, one is constructed.

sub sub title for the plot; by default, one is constructed.

xlab, ylab x- and y- axis labels for the plot, with defaults.

verbose a logical indicating, if there should be extra diagnostic output; mainly for ‘de-bugging’.

... Further graphical parameters may also be supplied, see par.

Details
clusplot uses function calls princomp(*, cor = (ncol(x) > 2)) or cmdscale(*, add=TRUE), respectively, depending on diss being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.

Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

Value
An invisible list with components:

Distances When lines is 1 or 2 we obtain a k by k matrix (k is the number of clusters).
The element in [i,j] is the distance between ellipse i and ellipse j.
If lines = 0, then the value of this component is NA.

Shading A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, y[i] and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put shading = y/z * 37 + 3.

Side Effects
a visual display of the clustering is plotted on the current graphics device.

Note
When we have 4 or fewer clusters, then the color=TRUE gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function pam to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. col.clus specifies the colors used.
The col.p and col.txt arguments, added for R, are recycled to have length the number of observations. If col.p has more than one value, using color = TRUE can be confusing because of a mix of point and ellipse colors.

clusplot(iris.x, c13, color = TRUE, xlim = c(0,2), ylim = c(-1,1))
```
### coef.hclust

**Agglomerative / Divisive Coefficient for 'hclust' Objects**

**Description**

Computes the “agglomerative coefficient” (aka “divisive coefficient” for `diana`), measuring the clustering structure of the dataset.

For each observation $i$, denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all $1 - m(i)$. It can also be seen as the average width (or the percentage filled) of the banner plot.

`coefHier()` directly interfaces to the underlying C code, and “proves” that only `object$heights` is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

**Usage**

```r
coefHier(object)
c coef.hclust(object, ...)
```

**Arguments**

- `object` an object of class "hclust" or "twins", i.e., typically the result of `hclust()`, `agnes()`, or `diana()`.

Since `coef.hclust` only uses `object$heights`, and `object$merge`, `object` can be any list-like object with appropriate `merge` and `heights` components.

For `coefHier`, even only `object$heights` is needed.

**Value**

a number specifying the agglomerative (or divisive for `diana` objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object$ac` or `diana.object$dc`. 
Examples

```r
data( agriculture )
aa <- agnes( agriculture )
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
coefHier(aa) # ditto
```

---

**daisy**  
**Dissimilarity Matrix Calculation**

**Description**

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower’s formula is used, see ‘Details’ below.

**Usage**

```r
daisy(x, metric = c("euclidean", "manhattan", "gower"),
     stand = FALSE, type = list(), weights = rep.int(1, p),
     warnBin = warnType, warnAsym = warnType, warnConst = warnType,
     warnType = TRUE)
```

**Arguments**

- `x`: numeric matrix or data frame, of dimension \( n \times p \), say. Dissimilarities will be computed between the rows of `x`. Columns of mode numeric (i.e. all columns when `x` is a matrix) will be recognized as interval scaled variables, columns of class factor will be recognized as nominal variables, and columns of class ordered will be recognized as ordinal variables. Other variable types should be specified with the `type` argument. Missing values (\( \text{NAs} \)) are allowed.
- `metric`: character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. “Gower’s distance” is chosen by metric "gower" or automatically if some columns of `x` are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the “distance” between two units is the sum of all the variable-specific distances, see the details section.
- `stand`: logical flag: if TRUE, then the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If not all columns of `x` are numeric, `stand` will be ignored and Gower’s standardization (based on the range) will be applied in any case, see argument `metric`, above, and the details section.
- `type`: list for specifying some (or all) of the types of the variables (columns) in `x`. The list may contain the following components:
"asymm" Asymmetric binary variable, aka "A" in result Types, see dissimilarity.object.
"symm" Symmetric binary variable, aka "S".
"factor" Nominal – the default for factor variables, aka "N".
"ordered" Ordinal – the default for ordered (factor) variables, aka "O", see dissimilarity.object.
"logratio" ratio scaled numeric variables that are to be logarithmically transformed (\(\log_{10}\)) and then treated as numeric ("I"): must be positive numeric variable.
"ordratio" "raTio"-like variable to be treated as ordered (using the factor codes unclass(as.ordered(x[,j]))), aka "T".
"numeric"/"integer" Interval scaled – the default for all numeric (incl integer) columns of \(x\), aka "I" in result Types, see dissimilarity.object.

Each component is a (character or numeric) vector, containing either the names or the numbers of the corresponding columns of \(x\).

Variables not mentioned in type are interpreted as usual, see argument \(x\), and also 'default' above. Consequently, the default type = list() may often be sufficient.

weights an optional numeric vector of length \(p(=\text{ncol}(x))\); to be used in “case 2” (mixed variables, or metric = "gower"), specifying a weight for each variable (\(x[,k]\)) instead of 1 in Gower's original formula.

warnBin, warnAsym, warnConst
logicals indicating if the corresponding type checking warnings should be signalled (when found).

warnType logical indicating if all the type checking warnings should be active or not.

Details

The original version of daisy is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to dist whose input must be numeric variables, the main feature of daisy is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If \(x\) contains any columns of these data-types, both arguments metric and stand will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by metric = "gower". With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range \([0, 1]\), exactly.

Note that setting the type to symm (symmetric binary) gives the same dissimilarities as using nominal (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that daisy signals a warning when 2-valued numerical variables do not have an explicit type specified, because the reference authors recommend to consider using "asymm"; the warning may be silenced by warnBin = FALSE.

In the daisy algorithm, missing values in a row of \(x\) are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and metric is not "gower"), the metric is "euclidean", and \(n_g\) is the number of columns in which neither row \(i\) and \(j\) have NAs, then the dissimilarity
$d(i,j)$ returned is $\sqrt{p/n_g}$ ($p = \text{ncol}(x)$) times the Euclidean distance between the two vectors of length $n_g$ shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is $p/n_g$. If $n_g = 0$, the dissimilarity is NA.

2. When some variables have a type other than interval scaled, or if metric = "gower" is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

$$d_{ij} = \frac{\sum_{k=1}^{p} w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^{p} w_k \delta_{ij}^{(k)}}$$

In other words, $d_{ij}$ is a weighted mean of $d_{ij}^{(k)}$ with weights $w_k \delta_{ij}^{(k)}$, where $w_k = \text{weights}[k]$. $\delta_{ij}^{(k)}$ is 0 or 1, and $d_{ij}^{(k)}$, the k-th variable contribution to the total distance, is a distance between $x[i,k]$ and $x[j,k]$, see below.

The 0-1 weight $\delta_{ij}^{(k)}$ becomes zero when the variable $x[,k]$ is missing in either or both rows (i and j), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution $d_{ij}^{(k)}$ of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that "standard scoring" is applied to ordinal variables, i.e., they are replaced by their integer codes $1:K$. Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions $d_{ij}^{(k)}$ are in $[0, 1]$, the dissimilarity $d_{ij}$ will remain in this range. If all weights $w_k \delta_{ij}^{(k)}$ are zero, the dissimilarity is set to NA.

Value

an object of class "dissimilarity" containing the dissimilarities among the rows of $x$. This is typically the input for the functions pam, fanny, agnes or diana. For more details, see dissimilarity.object.

Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version. Martin Maechler improved the NA handling and type specification checking, and extended functionality to metric = "gower" and the optional weights argument.

References

dissimilarity.object, dist, pam, fanny, clara, agnes, diana.
Examples

```r
data(agriculture)
## Example 1 in ref:
## Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy(agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
## compare with
as.matrix(daisy(agriculture, metric = "gower"))

data(flower)
## Example 2 in ref
summary(dfl1 <- daisy(flower, type = list(asymm = 3)))
summary(dfl2 <- daisy(flower, type = list(asymm = c(1, 3), ordratio = 7)))
## this failed earlier:
summary(dfl3 <- daisy(flower,
    type = list(asymm = c("V1", "V3"), symm= 2,
    ordratio= 7, logratio= 8)))
```

---

diana

**D**Ivisive ANAlysis Clustering

Description

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

Usage

```r
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
    stop.at.k = FALSE,
    keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

Arguments

- `x` data matrix or data frame, or dissimilarity matrix or object, depending on the value of the diss argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
  - In case of a dissimilarity matrix, x is typically the output of `daisy` or `dist`. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
- `diss` logical flag: if TRUE (default for dist or dissimilarity objects), then x will be considered as a dissimilarity matrix. If FALSE, then x will be considered as a matrix of observations by variables.
- `metric` character string specifying the metric to be used for calculating dissimilarities between observations.
  - The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the
sum of absolute differences. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

**stand**

logical; if true, the measurements in \( x \) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

**stop.at.k**

logical or integer, \( \text{FALSE} \) by default. Otherwise must be integer, say \( k \), in \( \{1, 2, \ldots, n\} \), specifying that the \texttt{diana} algorithm should stop early.

Non-default NOT YET IMPLEMENTED.

**keep.diss, keep.data**

logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to \( \text{FALSE} \) can give much smaller results and hence even save memory allocation time.

**trace.lev**

integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

**Details**

diana is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, diana provides (a) the divisive coefficient (see \texttt{diana.object}) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see \texttt{plot.diana}).

The diana-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all \( n \) observations. Clusters are divided until each cluster contains only a single observation. At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

**Value**

an object of class "diana" representing the clustering; this class has methods for the following generic functions: \texttt{print}, \texttt{summary}, \texttt{plot}.

Further, the class "diana" inherits from "twins". Therefore, the generic function \texttt{pltree} can be used on a \texttt{diana} object, and \texttt{as.hclust} and \texttt{as.dendrogram} methods are available.

A legitimate \texttt{diana} object is a list with the following components:

- **order**
  
a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.

- **order.lab**
  
a vector similar to \texttt{order}, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.

- **height**
  
a vector with the diameters of the clusters prior to splitting.

- **dc**
  
the divisive coefficient, measuring the clustering structure of the dataset. For each observation \( i \), denote by \( d(i) \) the diameter of the last cluster to which it
dissimilarity.object

**Description**

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.
Value

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for `i < j <= n`, the dissimilarity between (row) `i` and `j` is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is `n * (n - 1)/2`, i.e., of order `n^2`.

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that `d_{ij}` from above is just `as.matrix(do)[i,j]`.

The object has the following attributes:

- **Size**: the number of observations in the dataset.
- **Metric**: the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".
- **Labels**: optionally, contains the labels, if any, of the observations of the dataset.
- **NA.message**: optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.
- **Types**: when a mixed metric was used, the types for each variable as one-letter codes, see also type in `daisy()`:
  - `A`: Asymmetric binary
  - `S`: Symmetric binary
  - `N`: Nominal (factor)
  - `O`: Ordinal (ordered factor)
  - `I`: Interval scaled, possibly after log transform "logratio" (numeric)
  - `T`: raTio treated as ordered

GENERATION

daisy returns this class of objects. Also the functions pam, clara, fanny, agnes, and diana return a dissimilarity object, as one component of their return objects.

METHODS

The "dissimilarity" class has methods for the following generic functions: print, summary.

See Also

daisy, dist, pam, clara, fanny, agnes, diana.

ellipsoidhull

Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set

Description

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.
ellipsoidhull

Usage

ellipsoidhull(x, tol=0.01, maxit=5000,
        ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
## S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)

Arguments

x          the \( n \times p \) matrix.
tol        convergence tolerance for Titterington’s algorithm. Setting this to much smaller
            values may drastically increase the number of iterations needed, and you may
            want to increas maxit as well.
maxit      integer giving the maximal number of iteration steps for the algorithm.
ret.wt, ret.sqdist, ret.pr
            logicals indicating if additional information should be returned, ret.wt specifying
            the weights, ret.sqdist the squared distances and ret.pr the final
            probabilities in the algorithms.
digits,...  the usual arguments to print methods.

Details

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al (1999)
who use it for clusplot.default.
The problem can be seen as a special case of the “Min.V ol.” ellipsoid of which a more more flexible
and general implementation is cov.mve in the MASS package.

Value

an object of class "ellipsoid", basically a list with several components, comprising at least

\( p \times p \) covariance matrix description the ellipsoid.

\( p \)-dimensional location of the ellipsoid center.

average squared radius. Further, \( d^2 = t^2 \), where \( t \) is “the value of a t-statistic on
the ellipse boundary” (from ellipse in the ellipse package), and hence, more
usefully, \( d^2 = qchisq(alpha, df = p) \), where \( alpha \) is the confidence level for
p-variate normally distributed data with location and covariance loc and cov to
lie inside the ellipsoid.

the vector of weights iff ret.wt was true.

the vector of squared distances iff ret.sqdist was true.

the vector of algorithm probabilities iff ret.pr was true.

number of iterations used.

just the input argument, see above.

the achieved tolerance which is the maximal squared radius minus \( p \).

error code as from the algorithm; \( 0 \) means ok.

logical indicating if the converged. This is defined as \( \text{it} < \text{maxit} \&\& \text{ierr} == 0 \).

Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original
code.
References

predict.ellipsoid which is also the predict method for ellipsoid objects.
volume.ellipsoid for an example of 'manual' ellipsoid object construction;
further ellipse from package ellipse and ellipsePoints from package sfsmisc.
chull for the convex hull, clusplot which makes use of this; cov.mve.

Examples

```r
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy. <- ellipsoidhull(xy)
exy. # >> calling print.ellipsoid()
plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy.), col="blue")
points(rbind(exy.$loc), col = "red", cex = 3, pch = 13)
exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
## --> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii],3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
      col="blue", bg = adjustcolor("blue",0.25))
```

Fanny

Fuzzy Analysis Clustering

Description

Computes a fuzzy clustering of the data into k clusters.

Usage

```r
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
metric = c("euclidean", "manhattan", "SqEuclidean"),
stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
keep.diss = !diss && !cluster.only && n < 100,
keep.data = !diss && !cluster.only,
maxit = 500, tol = 1e-15, trace.lev = 0)
```
Arguments

x  data matrix or data frame, or dissimilarity matrix, depending on the value of the diss argument.
   In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
   In case of a dissimilarity matrix, x is typically the output of daisy or dist. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

k  integer giving the desired number of clusters. It is required that 0 < k < n/2 where n is the number of observations.

diss logical flag: if TRUE (default for dist or dissimilarity objects), then x is assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix of observations by variables.

memb.exp number r strictly larger than 1 specifying the membership exponent used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.

metric character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the squared euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”. If x is already a dissimilarity matrix, then this argument will be ignored.

stand logical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

iniMem.p numeric n × k matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.

cluster.only logical; if true, no silhouette information will be computed and returned, see details.

keep.diss, keep.data logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation time.

maxit, tol maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults maxit = 500 and tol = 1e-15 used to be hardwired inside the algorithm.

trace.lev integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.
Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by $u_{iv}$ the membership of observation $i$ to cluster $v$.

The memberships are nonnegative, and for a fixed observation $i$ they sum to 1. The particular method fanny stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in daisy) and has been extended by Martin Maechler to allow user specified memb.exp, iniMem.p, maxit, tol, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^{k} \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} u_{ir}^r u_{jr}^r d(i, j)}{2 \sum_{j=1}^{n} u_{jv}^r}$$

where $n$ is the number of observations, $k$ is the number of clusters, $r$ is the membership exponent memb.exp and $d(i, j)$ is the dissimilarity between observations $i$ and $j$.

Note that $r \to 1$ gives increasingly crisper clusterings whereas $r \to \infty$ leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default, $r = 2$ can lead to complete fuzzyness, i.e., memberships $u_{iv} \equiv 1/k$. In that case a warning is signalled and the user is advised to chose a smaller memb.exp ($= r$).

Compared to other fuzzy clustering methods, fanny has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see plot.partition).

Value

an object of class “fanny” representing the clustering. See fanny.object for details.

See Also

agnes for background and references; fanny.object, partition.object, plot.partition, daisy, dist.

Examples

```r
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
  x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
             cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
             cbind(rnorm( 3,3.2,0.5), rnorm( 3,3.2,0.5)))
  fannyx <- fanny(x, 2)
  ## Note that observations 26:28 are "fuzzy" (closer to # 2):
  fannyx
  summary(fannyx)
  plot(fannyx)

  (fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crisper' for obs. 26:28
  (fanny(x, 2, memb.exp = 3)) # more fuzzy in general
```

data(ruspini)
  f4 <- fanny(ruspini, 4)
  stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
  plot(f4, which = 1)
  ## Plot similar to Figure 6 in Stryuf et al (1996)
  plot(fanny(ruspini, 5))
```
**fanny.object**

**Fuzzy Analysis (FANNY) Object**

**Description**

The objects of class "fanny" represent a fuzzy clustering of a dataset.

**Value**

A legitimate fanny object is a list with the following components:

- **membership** matrix containing the memberships for each pair consisting of an observation and a cluster.
- **memb.exp** the membership exponent used in the fitting criterion.
- **coeff** Dunn’s partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all squared membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1. The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$, and ranges between 0 and 1. A low value of Dunn’s coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
- **clustering** the clustering vector of the nearest crisp clustering, see partition.object.
- **k.crisp** integer ($\leq k$) giving the number of crisp clusters; can be less than $k$, where it's recommended to decrease memb.exp.
- **objective** named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.
- **convergence** named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).
- **diss** an object of class "dissimilarity", see partition.object.
- **call** generating call, see partition.object.
- **silinfo** list with silhouette information of the nearest crisp clustering, see partition.object.
- **data** matrix, possibly standardized, or NULL, see partition.object.

**GENERATION**

These objects are returned from fanny.

**METHODS**

The “fanny” class has methods for the following generic functions: print, summary.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

**See Also**

fanny, print.fanny, dissimilarity.object, partition.object, plot.partition.
**Description**

8 characteristics for 18 popular flowers.

**Usage**

data(flower)

**Format**

A data frame with 18 observations on 8 variables:

<p>| | | |</p>
<table>

</table>

- **V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.
- **V2** shadow, is binary and shows whether the plant needs to stand in the shadow.
- **V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.
- **V4** color, is nominal and specifies the flower’s color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).
- **V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.
- **V6** preference, is ordinal and gives someone’s preference ranking going from 1 to 18.
- **V7** height, is interval scaled, the plant’s height in centimeters.
- **V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

**References**

Struyf, Hubert and Rousseeuw (1996), see *agnes*.

**Examples**

daisy(flower, type = list(asymm = c(1, 3), ordratio = 7))
```
lower.to.upper.tri.inds

Permute Indices for Triangular Matrices

Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

Usage

lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)

Arguments

n integer larger than 1.

Value

integer vector containing a permutation of 1:N where N = n(n - 1)/2.

See Also

upper.tri, lower.tri with a related purpose.

Examples

m5 <- matrix(NA,5,5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
lower.to.upper.tri.inds(3) == 1:3,
upper.to.lower.tri.inds(3) == 1:3,
sort(upper.to.lower.tri.inds(5)) == 1:10,
sort(lower.to.upper.tri.inds(6)) == 1:15)

medoids

Compute pam-consistent Medoids from Clustering

Description

Given a data matrix or dissimilarity x for say n observational units and a clustering, compute the pam()-consistent medoids.

Usage

medoids(x, clustering, diss = inherits(x, "dist"), USE.NAMES = FALSE, ...)

Arguments

x
  Either a data matrix or data frame, or dissimilarity matrix or object, see also pam.

clustering
   an integer vector of length n, the number of observations, giving for each ob-
   servation the number (‘id’) of the cluster to which it belongs. In other words,
   clustering has values from 1:k where k is the number of clusters, see also
   partition.object and cutree(), for examples where such clustering vectors
   are computed.

diss
   see also pam.

USE.NAMES
   a logical, typical false, passed to the vapply() call computing the medoids.

...
   optional further argument passed to pam(xj, k=1,...), notably metric, or
   variant="f_5" to use a faster algorithm, or trace.lev = k.

Value

   a numeric vector of length

Author(s)

   Martin Maechler, after being asked how pam() could be used instead of kmeans(),
   starting from a previous clustering.

See Also

   pam, kmeans. Further, cutree() and agnes (or hclust).

Examples

   # From example(agnes):
   data(votes.repub)
   agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
   agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
   agnS <- agnes(votes.repub, method = "flexible", par.meth = 0.625)

   for(k in 2:11) {
     print(table(cl.k <- cutree(agnS, k=k)))
     stopifnot(length(cl.k) == nrow(votes.repub), 1 <= cl.k, cl.k <= k, table(cl.k) >= 2)
     m.k <- medoids(votes.repub, cl.k)
     cat("k =", k,"; sort(medoids) = ");
     dput(sort(m.k), control={})
   }

Description

   Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

Usage

   mona(x, trace.lev = 0)
Arguments

x  
data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from NA. No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical is not allowed.

trace.lev  
logical or integer indicating if (and how much) the algorithm should produce progress output.

Details

mona is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including agnes and diana) are “polythetic”, i.e. they use all variables together.

The mona-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables. At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables f and g is given by a(f,g)*d(f,g) - b(f,g)*c(f,g), where a(f,g), b(f,g), c(f,g), and d(f,g) are the numbers in the contingency table of f and g. [That is, a(f,g) (resp. d(f,g)) is the number of observations for which f and g both have value 0 (resp. value 1); b(f,g) (resp. c(f,g)) is the number of observations for which f has value 0 (resp. 1) and g has value 1 (resp. 0).] The total association of a variable f is the sum of its associations to all variables.

Value

an object of class "mona" representing the clustering. See mona.object for details.

Missing Values (NAs)

The mona-algorithm requires “pure” 0-1 values. However, mona(x) allows x to contain (not too many) NAs. In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable f has missing values, the variable g with the largest absolute association to f is looked up. When the association between f and g is positive, any missing value of f is replaced by the value of g for the same observation. If the association between f and g is negative, then any missing value of f is replaced by the value of 1-g for the same observation.

Note

In cluster versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one variable, i.e., ncol(x) == 1, which currently signals an error (because the algorithm now in C, haes not correctly taken account of this special case).

See Also

agnes for background and references; mona.object, plot.mona.
Examples

```r
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

## One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3 )
ani.idNA <- within(animals, end[lis.na(end)] <- 1 )
try( mona(ani.NA) ) ## error: .. object with all values missing
try( mona(aniNA) ) ## error: .. more than half missing values
try( mona(aniN2) ) ## error: all have at least one missing
try( mona(ani.non2) ) ## error: all must be binary
try( mona(ani.idNA) ) ## error: ditto
```

Description

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from mona.

Value

A legitimate mona object is a list with the following components:

- **data**: matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
- **order**: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- **order.lab**: a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- **variable**: vector of length n-1 where n is the number of observations, specifying the variables used to separate the observations of order.
- **step**: vector of length n-1 where n is the number of observations, specifying the separation steps at which the observations of order are separated.

METHODS

The "mona" class has methods for the following generic functions: print, summary, plot.

See Also

mona for examples etc, plot.mona.
Partitioning Around Medoids

Description

Partitioning (clustering) of the data into \( k \) clusters “around medoids”, a more robust version of K-means.

Usage

\[
\text{pam}(x, k, \text{diss} = \text{inherits}(x, \text{"dist"}), \\
\text{metric} = \text{c}(\"euclidean\", \"manhattan\"), \\
\text{medoids} = \text{if(is.numeric(nstart)) \"random\",} \\
\text{nstart} = \text{if(variant == \"faster\") 1 else NA,} \\
\text{stand} = \text{FALSE, cluster.only} = \text{FALSE,} \\
\text{do.swap} = \text{TRUE,} \\
\text{keep.diss} = \text{!diss && !cluster.only && n < 100,} \\
\text{keep.data} = \text{!diss && !cluster.only,} \\
\text{variant} = \text{c(\"original\", \"o_1\", \"o_2\", \"f_3\", \"f_4\", \"f_5\", \"faster\"),} \\
\text{pamonce} = \text{FALSE, trace.lev} = \text{0)
}\]

Arguments

- \( x \) : data matrix or data frame, or dissimilarity matrix or object, depending on the value of the \text{diss} argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (\textsc{NAs}) are allowed—as long as every pair of observations has at least one case not missing.
  - In case of a dissimilarity matrix, \( x \) is typically the output of \text{daisy} or \text{dist}. Also a vector of length \( n*(n-1)/2 \) is allowed (where \( n \) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (\textsc{NAs}) are not allowed.

- \( k \) : positive integer specifying the number of clusters, less than the number of observations.

- \text{diss} : logical flag: if \text{TRUE} (default for \text{dist} or dissimilarity objects), then \( x \) will be considered as a dissimilarity matrix. If \text{FALSE}, \( x \) will be considered as a matrix of observations by variables.

- \text{metric} : character string specifying the metric to be used for calculating dissimilarities between observations.
  - The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

- \text{medoids} : \text{NULL} (default) or length-\( k \) vector of integer indices (in 1:\( n \)) specifying initial medoids instead of using the 'build' algorithm.

- \text{nstart} : used only when \text{medoids} = "random": specifies the \text{number} of random "starts"; this argument corresponds to the one of \text{kmeans}() (from R’s package \text{stats}).
**stand** logical; if true, the measurements in \( x \) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

**cluster.only** logical; if true, only the clustering will be computed and returned, see details.

**do.swap** logical indicating if the **swap** phase should happen. The default, **TRUE**, correspond to the original algorithm. On the other hand, the **swap** phase is much more computer intensive than the **build** one for large \( n \), so can be skipped by **do.swap = FALSE**.

**keep.diss, keep.data** logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to **FALSE** can give much smaller results and hence even save memory allocation time.

**pamonce** logical or integer in \( 0:6 \) specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019, 2021) see below.

**variant** a character string denoting the variant of PAM algorithm to use; a more self-documenting version of **pamonce** which should be used preferably; note that “faster” not only uses pamonce = 6 but also nstart = 1 and hence medoids = “random” by default.

**trace.lev** integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default \( 0 \) does not print anything; higher values print increasingly more.

**Details**

The basic pam algorithm is fully described in chapter 2 of Kaufman and Rousseeuw(1990). Compared to the k-means approach in **kmeans**, the function pam has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see **plot.partition**) (d) it allows to select the number of clusters using \( \text{mean(silhouette(pr)[, "sil_width"])} \) on the result \( pr \leftarrow \text{pam}(...) \), or directly its component \( pr$\text{silinfo}$$\text{avg.width} \), see also **pam.object**.

When **cluster.only** is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e., **pam**(\( x, k, \text{cluster.only}=\text{TRUE} \)) is the same as **pam**(\( x, k \))$\text{clustering$ but computed more efficiently.

The pam-algorithm is based on the search for \( k \) representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of \( k \) medoids, \( k \) clusters are constructed by assigning each observation to the nearest medoid. The goal is to find \( k \) representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when **medoids** are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid (i.e. a ‘swap’) that will decrease the objective (this is called the **swap** phase).

When the **medoids** are specified (or randomly generated), their order does not matter; in general, the algorithms have been designed to not depend on the order of the observations.

The pamonce option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.
The default FALSE (or integer 0) corresponds to the original “swap” algorithm, whereas pamonce = 1 (or TRUE), corresponds to the first proposal ... and pamonce = 2 additionally implements the second proposal as well.

The key ideas of ‘FastPAM’ (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

pamonce = 3: reduces the runtime by a factor of O(k) by exploiting that points cannot be closest to all current medoids at the same time.

pamonce = 4: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.

pamonce = 5: adds minor optimizations copied from the pamonce = 2 approach, and is expected to be the fastest of the ‘FastPam’ variants included.

‘FasterPAM’ (Schubert and Rousseeuw, 2021) is implemented via

pamonce = 6: execute each swap which improves results immediately, and hence typically multiple swaps per iteration; this swapping algorithm runs in $O(n^2)$ rather than $O(n(n - k)k)$ time which is much faster for all but small $k$.

In addition, ‘FasterPAM’ uses random initialization of the medoids (instead of the ‘build’ phase) to avoid the $O(n^2k)$ initialization cost of the build algorithm. In particular for large $k$, this yields a much faster algorithm, while preserving a similar result quality.

One may decide to use repeated random initialization by setting nstart > 1.

Value

an object of class "pam" representing the clustering. See ?pam.object for details.

Note

For large datasets, pam may need too much memory or too much computation time since both are $O(n^2)$. Then, clara() is preferable, see its documentation.

There is hard limit currently, $n \leq 65536$, at $2^{16}$ because for larger $n$, $n(n - 1)/2$ is larger than the maximal integer (.Machine$integer.max = 2^{31} - 1)$.

Author(s)

Kaufman and Rousseeuw’s orginal Fortran code was translated to C and augmented in several ways, e.g. to allow cluster.only=TRUE or do.swap=FALSE, by Martin Maechler. Matthias Studer, Univ.Geneva provided the pamonce (1 and 2) implementation. Erich Schubert, TU Dortmund contributed the pamonce (3 to 6) implementation.

Examples

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
          cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx # Medoids: '7' and '25' ...

summary(pamx)
plot(pamx)

## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))

## no _build_ *and* no _swap_ phase: just cluster all obs. around (1, 16):
p2.s <- pam(x, 2, medoids = c(1,16), do.swap = FALSE)
p2.s

p3m <- pam(x, 3, trace = 2)

## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

daisy(x, metric = "manhattan"), 2, diss = TRUE)

data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)
any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.

clusinfo matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).

silinfo list with silhouette width information, see partition.object.

diss dissimilarity (maybe NULL), see partition.object.

call generating call, see partition.object.

data (possibly standardized) see partition.object.

GENERATION

These objects are returned from pam.

METHODS

The "pam" class has methods for the following generic functions: print, summary.

INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a pam object.

See Also

pam, dissimilarity.object, partition.object, plot.partition.

Examples

```r
## Use the silhouette widths for assessing the best number of clusters, following a one-dimensional example from Christian Hennig:

x <- c(rnorm(50), rnorm(50, mean=5), rnorm(30, mean=15))
asw <- numeric(20)
for (k in 2:20)
  asw[k] <- pam(x, k)$silinfo$avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters: ", k.best, "\n")

plot(1:20, asw, type="h", main="pam() clustering assessment",
     xlab="k (# clusters)", ylab="average silhouette width")
axis(1, k.best, paste("best", k.best, sep="\n"), col="red", col.axis="red")
```
Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

Value

a "partition" object is a list with the following (and typically more) components:

- clustering: the clustering vector. An integer vector of length \( n \), the number of observations, giving for each observation the number ("id") of the cluster to which it belongs.
- call: the matched call generating the object.
- silinfo: a list with all silhouette information, only available when the number of clusters is non-trivial, i.e., \( 1 < k < n \) and then has the following components, see silhouette.
  - widths: an (n x 3) matrix, as returned by silhouette(), with for each observation \( i \) the cluster to which \( i \) belongs, as well as the neighbor cluster of \( i \) (the cluster, not containing \( i \), for which the average dissimilarity between its observations and \( i \) is minimal), and the silhouette width \( s(i) \) of the observation.
  - clus.avg.widths: the average silhouette width per cluster.
  - avg.width: the average silhouette width for the dataset, i.e., simply the average of \( s(i) \) over all observations \( i \).

This information is also needed to construct a silhouette plot of the clustering, see plot.partition.

Note that avg.width can be maximized over different clusterings (e.g. with varying number of clusters) to choose an optimal clustering.

- objective: value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
- diss: an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for clara).
- data: a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

GENERATION

These objects are returned from pam, clara or fanny.

METHODS

The "partition" class has a method for the following generic functions: plot, clusplot.

INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See pam.object, clara.object and fanny.object for details.
See Also

pam, clara, fanny.

---

### plantTraits

**Plant Species Traits Data**

**Description**

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive).

**Usage**

```r
data(plantTraits)
```

**Format**

A data frame with 136 observations on the following 31 variables.

- `pdias` Diaspore mass (mg)
- `longindex` Seed bank longevity
- `durflow` Flowering duration
- `height` Plant height, an ordered factor with levels 1 < 2 < ... < 8.
- `begflow` Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9
- `mycor` Mycorrhizas, an ordered factor with levels 0:never < 1:sometimes < 2:always
- `vegaer` Aerial vegetative propagation, an ordered factor with levels 0:never < 1:present but limited < 2:important.
- `vegsout` Underground vegetative propagation, an ordered factor with 3 levels identical to `vegaer` above.
- `autopoll` Selfing pollination, an ordered factor with levels 0:never < 1:rare < 2:often < the rule
- `insects` Insect pollination, an ordered factor with 5 levels 0 < ... < 4.
- `wind` Wind pollination, an ordered factor with 5 levels 0 < ... < 4.
- `lign` A binary factor with levels 0:1, indicating if plant is woody.
- `piq` A binary factor indicating if plant is thorny.
- `ros` A binary factor indicating if plant is rosette.
- `semiros` Semi-rosette plant, a binary factor (0: no; 1: yes).
- `leafy` Leafy plant, a binary factor.
- `suman` Summer annual, a binary factor.
- `winan` Winter annual, a binary factor.
- `monocarp` Monocarpic perennial, a binary factor.
- `polycarp` Polycarpic perennial, a binary factor.
- `seasaes` Seasonal aestival leaves, a binary factor.
- `seashiv` Seasonal hibernal leaves, a binary factor.
- `seasver` Seasonal vernal leaves, a binary factor.
everalw leaves always evergreen, a binary factor.
everparti leaves partially evergreen, a binary factor.
elaio fruits with an elaiosome (dispersed by ants), a binary factor.
endozoo endozoocchorous fruits, a binary factor.
epizoo epizoocchorous fruits, a binary factor.
aquat aquatic dispersal fruits, a binary factor.
windgl wind dispersed fruits, a binary factor.
unsp unspecialized mechanism of seed dispersal, a binary factor.

Details
Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by
insects but sometimes self-pollination can occured.

Vallet, Jeanne (2005) *Structuration de communautés végétales et analyse comparative de traits*
biologiques le long d’un gradient d’urbanisation. Mémoire de Master 2 'Ecologie-Biodiversité-
Evolution'; Université Paris Sud XI, 30p.+ annexes (in french)

Examples

```
data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
   type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
cmdsdai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

plot.agnes

*Plots of an Agglomerative Hierarchical Clustering*

Description
Creates plots for visualizing an agnes object.

Usage
```
## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
   sub = paste("Agglomerative Coefficient = ",round(x$ac, digits = 2)),
   adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```
Arguments

x an object of class "agnes", typically created by agnes(.)
ask logical; if true and which.plots is NULL, plot.agnes operates in interactive mode, via menu.
which.plots integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".
main, sub main and sub title for the plot, with convenient defaults. See documentation for these arguments in plot.default.
adj for label adjustment in bannerplot().
nmax.lab integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
max.strlen positive integer giving the length to which strings are truncated in banner plot labeling.
xax.pretty logical or integer indicating if pretty(*, n = xax.pretty) should be used for the x axis. xax.pretty = FALSE is for back compatibility.
... graphical parameters (see par) may also be supplied and are passed to bannerplot() or pltree() (see pltree.twins), respectively.

Details

When ask = TRUE, rather than producing each plot sequentially, plot.agnes displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask=TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the agnes algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call bannerplot and pltree(), i.e., its method pltree.twins, respectively.

directly with corresponding arguments, e.g., xlab or ylab.

Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:
Banner
Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

For the dendrogram, more flexibility than via pltree() is provided by dg <- as.dendrogram(x) and plotting dg via plot.dendrogram.
References

See Also

`agnes` and `agnes.object`; `bannerplot`, `pltree.twins`, and `par`.

Examples

```r
## Can also pass 'labels' to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "g"
ai <- agnes(iris[, 1:4])
plot.ai, labels = cS, nmax = 150)# bannerplot labels are mess
```

Description

Creates plots for visualizing a diana object.

Usage

```r
## S3 method for class 'diana'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
    sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
    adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

Arguments

- `x`: an object of class "diana", typically created by `diana(.)`.
- `ask`: logical; if true and `which.plots` is NULL, `plot.diana` operates in interactive mode, via menu.
- `which.plots`: integer vector or NULL (default), the latter producing both plots. Otherwise, `which.plots` must contain integers of 1 for a `banner` plot or 2 for a dendrogram or "clustering tree".
- `main`, `sub`: main and sub title for the plot, each with a convenient default. See documentation for these arguments in `plot.default`.
- `adj`: for label adjustment in `bannerplot()`.
nmax.lab integer indicating the number of labels which is considered too large for single-name labelling the banner plot.

max.strlen positive integer giving the length to which strings are truncated in banner plot labeling.

xax.pretty logical or integer indicating if pretty(*, n = xax.pretty) should be used for the x axis. xax.pretty = FALSE is for back compatibility.

... graphical parameters (see par) may also be supplied and are passed to bannerplot() or pltree(), respectively.

Details

When ask = TRUE, rather than producing each plot sequentially, plot.diana displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set par(ask = TRUE) before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the diana algorithm, and the numbers in the height vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

References

see those in plot.agnes.

See Also
diana, diana.object, twins.object, par.

Examples

eexample(diana)# -> dv <- diana(....)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0,0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
Description

Creates the banner of a mona object.

Usage

```r
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse1(x$call)),
     sub = NULL, xlab = "Separation step",
     col = c(2,0), axes = TRUE, adj = 0,
     nmax.lab = 35, max.strlen = 5, ...)
```

Arguments

- **x**: an object of class "mona", typically created by mona(.).
- **main,sub**: main and sub titles for the plot, with convenient defaults. See documentation in plot.default.
- **xlab**: x axis label, see title.
- **col,adj**: graphical parameters passed to bannerplot().
- **axes**: logical, indicating if (labeled) axes should be drawn.
- **nmax.lab**: integer indicating the number of labels which is considered too large for labeling.
- **max.strlen**: positive integer giving the length to which strings are truncated in labeling.
- **...**: further graphical arguments are passed to bannerplot() and text.

Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the mona algorithm, the numbers in the step vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

Side Effects

A banner is plotted on the current graphics device.

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

References

see those in plot.agnes.
plot.partition

Plot of a Partition of the Data Set

Description

Creates plots for visualizing a partition object.

Usage

```r
## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
stand = FALSE, lines = 2,
shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

Arguments

- `x`: an object of class "partition", typically created by the functions `pam`, `clara`, or `fanny`.
- `ask`: logical; if true and which.plots is NULL, plot.partition operates in interactive mode, via menu.
- `which.plots`: integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a clusplot or 2 for silhouette.
- `nmax.lab`: integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
- `max.strlen`: positive integer giving the length to which strings are truncated in silhouette plot labeling.
- `data`: numeric matrix with the scaled data; per default taken from the partition object `x`, but can be specified explicitly.
- `dist`: when `x` does not have a diss component as for `pam(*, keep.diss=FALSE)`, dist must be the dissimilarity if a clusplot is desired.
- `stand`, `lines`, `shade`, `color`, `labels`, `plotchar`, `span`, `xlim`, `ylim`, `main`, ...

All optional arguments available for the `clusplot.default` function (except for the diss one) and graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

When ask= TRUE, rather than producing each plot sequentially, plot.partition displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par (ask= TRUE)` before invoking the plot command.

The `clusplot` of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see `clusplot.partition` for more details).

See Also

`mona`, `mona.object.par`. 

---

Copyright © 2023 R Core Team
The silhouette plot of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation i, a bar is drawn, representing its silhouette width s(i), see silhouette for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large s(i) (almost 1) are very well clustered, a small s(i) (around 0) means that the observation lies between two clusters, and observations with a negative s(i) are probably placed in the wrong cluster.

A clustering can be performed for several values of k (the number of clusters). Finally, choose the value of k with the largest overall average silhouette width.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:
- Clusplot
- Silhouette plot

Note

In the silhouette plot, observation labels are only printed when the number of observations is less than nmax.lab (40, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

For more flexibility, use plot(silhouette(x), ...), see plot.silhouette.

References

Further, the references in plot.agnes.

See Also

partition.object, clusplot.partition, clusplot.default, pam, pam.object, clara, clara.object, fanny, fanny.object.par.

Examples

```r
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
x <- clara(xclara, 3, keep.data = FALSE)
x$data # is NULL
plot(x, data = xclara)
```
Description

`pltree()` Draws a clustering tree ("dendrogram") on the current graphics device. We provide the `twins` method draws the tree of a `twins` object, i.e., hierarchical clustering, typically resulting from `agnes()` or `diana()`.

Usage

```r
pltree(x, ...)  
## S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse1(x$call)),
       labels = NULL, ylab = "Height", ...)
```

Arguments

- `x`: in general, an R object for which a `pltree` method is defined; specifically, an object of class "twins", typically created by either `agnes()` or `diana()`.
- `main`: main title with a sensible default.
- `labels`: labels to use; the default is constructed from `x`.
- `ylab`: label for y-axis.
- `...`: graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

Value

A NULL value is returned.

See Also

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`. 
Examples

data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0,2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
    nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
    main = deparse(agn$call))
par(op)

pluton  
Isotopic Composition Plutonium Batches

Description

The pluton data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

Usage

data(pluton)

Format

This data frame contains the following columns:

- **Pu238**: the percentages of $^{238}Pu$, always less than 2 percent.
- **Pu239**: the percentages of $^{239}Pu$, typically between 60 and 80 percent (from neutron capture of Uranium, $^{238}U$).
- **Pu240**: percentage of the plutonium 240 isotope.
- **Pu241**: percentage of the plutonium 241 isotope.

Details

Note that the percentage of plutonium–242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

Source

Available as `pluton.dat` from the archive of the University of Antwerpen, ‘.../datasets/clusplot-examples.tar.gz’, no longer available.

References

Examples

```r
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

**predict.ellipsoid**

*Predict Method for Ellipsoid Objects*

**Description**

Compute points on the ellipsoid boundary, mostly for drawing.

**Usage**

```r
predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
```

**Arguments**

- `object`: an object of class `ellipsoid`, typically from `ellipsoidhull`; alternatively any list-like object with proper components, see details below.
- `n.out`, `n.half`: half the number of points to create.
- `A`, `d2`, `loc`: arguments of the auxiliary `ellipsoidPoints`, see below.
- `...`: passed to and from methods.

**Details**

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see `ellipsoidhull`. The class of object is not checked; it must solely have valid components `loc` (length `p`), the `p x p` matrix `cov` (corresponding to `A`) and `d2` for the center, the shape ("covariance") matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Unfortunately, this is only implemented for `p = 2`, currently; contributions for `p ≥ 3` are very welcome.

**Value**

A numeric matrix of dimension `2*n.out` times `p`.

**See Also**

`ellipsoidhull`, `volume.ellipsoid`
Examples

## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix

print.agnes  

Print Method for AGNES Objects

Description

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an agnes object.

This is a method for the generic print() function for objects inheriting from class agnes, see agnes.object.

Usage

## S3 method for class 'agnes'
print(x, ...)

Arguments

x  an agnes object.

... potential further arguments (required by generic).

See Also

summary.agnes producing more output; agnes, agnes.object, print, print.default.
print.clara  

**Print Method for CLARA Objects**

**Description**

Prints the best sample, medoids, clustering vector and objective function of clara object. This is a method for the function `print()` for objects inheriting from class `clara`.

**Usage**

```r
## S3 method for class 'clara'
print(x, ...)
```

**Arguments**

- `x` a clara object.
- `...` potential further arguments (require by generic).

**See Also**

`summary.clara` producing more output; `clara, clara.object, print, print.default`.

print.diana  

**Print Method for DIANA Objects**

**Description**

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object. This is a method for the function `print()` for objects inheriting from class `diana`.

**Usage**

```r
## S3 method for class 'diana'
print(x, ...)
```

**Arguments**

- `x` a diana object.
- `...` potential further arguments (require by generic).

**See Also**

diana, diana.object, print, print.default.
print.dissimilarity

Print and Summary Methods for Dissimilarity Objects

Description

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions print() and summary() for dissimilarity objects. See print, print.default, or summary for the general behavior of these.

Usage

```r
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
        digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)
```

Arguments

- `x, object`: a dissimilarity object or a summary.dissimilarity one for print.summary.dissimilarity().
- `digits`: the number of digits to use, see print.default.
- `diag, upper, justify, right`: optional arguments specifying how the triangular dissimilarity matrix is printed; see print.dist.
- `...`: potential further arguments (require by generic).

See Also

daisy, dissimilarity.object, print, print.default, print.dist.

Examples

```r
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20,5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```
print.fanny

Print and Summary Methods for FANNY Objects

Description
Prints the objective function, membership coefficients and clustering vector of fanny object. This is a method for the function print() for objects inheriting from class fanny.

Usage

## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)  
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)

Arguments

x, object a fanny object.
digits number of significant digits for printing, see print.default.
... potential further arguments (required by generic).

See Also
fanny, fanny.object, print, print.default.

print.mona

Print Method for MONA Objects

Description
Prints the ordering of objects, separation steps, and used variables of a mona object. This is a method for the function print() for objects inheriting from class mona.

Usage

## S3 method for class 'mona'
print(x, ...)  

Arguments

x a mona object.
... potential further arguments (require by generic).

See Also
mona, mona.object, print, print.default.
Print Method for PAM Objects

Description

Prints the medoids, clustering vector and objective function of pam object.
This is a method for the function print() for objects inheriting from class pam.

Usage

## S3 method for class 'pam'
print(x, ...)

Arguments

x a pam object.
...
potential further arguments (require by generic).

See Also

pam, pam.object, print, print.default.

Ruspini Data

Description

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

Usage

data(ruspini)

Format

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

Source

References

see those in agnes.
Examples

data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))

silhouette

Compute or Extract Silhouette Information from Clustering

Description

Compute silhouette information according to a given clustering in \( k \) clusters.

Usage

silhouette(x, ...)

## Default S3 method:

silhouette(x, dist, dmatrix, ...)

## S3 method for class 'partition'

distmat <- silhouette(x, ...)

## S3 method for class 'clara'

silhouette(x, full = FALSE, subset = NULL, ...)

sortSilhouette(object, ...)

## S3 method for class 'silhouette'

summary(object, FUN = mean, ...)

## S3 method for class 'silhouette'

plot(x, nmax.lab = 40, max.strlen = 5,

main = NULL, sub = NULL, xlab = expression("Silhouette width \( * s[i] \)),

col = "gray", do.col.sort = length(col) > 1, border = 0,

cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

Arguments

x

an object of appropriate class; for the default method an integer vector with \( k \) different integer cluster codes or a list with such an x$clustering component. Note that silhouette statistics are only defined if \( 2 \leq k \leq n - 1 \).

dist

a dissimilarity object inheriting from class dist or coercible to one. If not specified, dmatrix must be.

dmatrix

a symmetric dissimilarity matrix \((n \times n)\), specified instead of dist, which can be more efficient.

full

logical or number in \([0, 1]\) specifying if a full silhouette should be computed for clara object. When a number, say \( f \), for a random sample \( \text{sample.int}(n, \text{size} = f*n) \) of the data the silhouette values are computed. This requires \( O((f*n)^2) \) memory, since the full dissimilarity of the (sub)sample (see daisy) is needed internally.
subset

a subset from 1:n, specified instead of full to specify the indices of the observations to be used for the silhouette computations.

do.col.sort

logical indicating if the colors col should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.

do.n.k

logical indicating if n and k “title text” should be written.

do.clus.stat

logical indicating if cluster size and averages should be written right to the silhouettes.

Details

For each observation i, the silhouette width $s(i)$ is defined as follows:

Put $a(i)$ = average dissimilarity between i and all other points of the cluster to which i belongs (if i is the only observation in its cluster, $s(i) := 0$ without further calculations). For all other clusters C, put $d(i, C) =$ average dissimilarity of i to all observations of C. The smallest of these $d(i, C)$ is $b(i) := \min_C d(i, C)$, and can be seen as the dissimilarity between i and its “neighbor” cluster, i.e., the nearest one to which it does not belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}$$

silhouette.default() is now based on C code donated by Romain Francois (the R version being still available as cluster:::silhouette.default.R).

Observations with a large $s(i)$ (almost 1) are very well clustered, a small $s(i)$ (around 0) means that the observation lies between two clusters, and observations with a negative $s(i)$ are probably placed in the wrong cluster.

Value

silhouette() returns an object, sil, of class silhouette which is an $n \times 3$ matrix with attributes. For each observation i, sil[i, ] contains the cluster to which i belongs as well as the neighbor cluster of (the cluster, not containing i, for which the average dissimilarity between its observations and i is minimal), and the silhouette width $s(i)$ of the observation. The colnames correspondingly are c("cluster", "neighbor", "sil_width").

summary(sil) returns an object of class summary.silhouette, a list with components

si.summary: numerical summary of the individual silhouette widths $s(i)$. 

... further arguments passed to and from methods.
clus.avg.widths: numeric (rank 1) array of clusterwise means of silhouette widths where mean = FUN is used.

avg.width: the total mean FUN(s) where s are the individual silhouette widths.

clus.sizes: table of the k cluster sizes.
call: if available, the call creating sil.

Ordered: logical identical to attr(sil, "Ordered"), see below.

sortSilhouette(sil) orders the rows of sil as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width s(i).

attr(sil, "Ordered") is a logical indicating if sil is ordered as by sortSilhouette(). In that case, rownames(sil) will contain case labels or numbers, and attr(sil, "iOrd") the ordering index vector.

Note

While silhouette() is intrinsic to the partition clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from silhouette.default() with cutree() and distance as input.

By default, for clara() partitions, the silhouette is just for the best random subset used. Use full = TRUE to compute (and later possibly plot) the full silhouette.

References

chapter 2 of Kaufman and Rousseeuw (1990), see the references in plot.agnes.

See Also

partition.object, plot.partition.

Examples

data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"s fault

for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), col = c("red", "green", "blue", "purple") )# with cluster-wise coloring

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
mgp= c(1.6,.8,0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
  outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

  # the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
  for(k in 2:6)
sizeDiss

Sample Size of Dissimilarity Like Object

Description
Returns the number of observations (sample size) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of \( f(n) = \frac{n(n-1)}{2} \).

Usage
sizeDiss(d)

Arguments
d any R object with length (typically) \( n(n-1)/2 \).

Value
a number; \( n \) if length(d) = \( n(n-1)/2 \), NA otherwise.

See Also
dissimilarity.object and also as.dist for class dissimilarity and dist objects which have a Size attribute.
Examples

```r
sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply(n*(n-1)/2, function(n) sizeDiss(logical(n)))))
```

---

### summary.agnes

**Summary Method for 'agnes' Objects**

**Description**

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

**Usage**

```r
## S3 method for class 'agnes'
summary(object, ...)
## S3 method for class 'summary.agnes'
print(x, ...)
```

**Arguments**

- `x, object` a `agnes` object.
- `...` potential further arguments (require by generic).

**See Also**

`agnes, agnes.object`.

**Examples**

```r
data(agriculture)
summary(agnes(agriculture))
```

---

### summary.clara

**Summary Method for 'clara' Objects**

**Description**

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

**Usage**

```r
## S3 method for class 'clara'
summary(object, ...)
## S3 method for class 'summary.clara'
print(x, ...)
```
Arguments

x, object a clara object.

... potential further arguments (require by generic).

See Also
c personalize.object

Examples

## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0, 4), rnorm(400, 0, 4)),
            cbind(rnorm(400, 10, 8), rnorm(400, 40, 6)),
            cbind(rnorm(400, 30, 4), rnorm(400, 0, 4)),
            cbind(rnorm(400, 40, 4), rnorm(400, 20, 2)),
            cbind(rnorm(400, 50, 4), rnorm(400, 50, 4))
)
clx5 <- clara(x, 5)
## Mis'classification' table:

table(rep(1:5, rep(400, 5)), clx5$clust) # -> 1 "error"
summary(clx5)
## Graphically:
par(mfrow = c(3, 1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0, 0, 2, 0))
plot(x, col = rep(2:6, rep(400, 5)))
plot(clx5)

---

summary.diana

Summary Method for 'diana' Objects

Description

Returns (and prints) a summary list for a diana object.

Usage

## S3 method for class 'diana'
summary(object, ...)

## S3 method for class 'summary.diana'
print(x, ...)

Arguments

x, object a diana object.

... potential further arguments (require by generic).

See Also
diana, diana.object.
Summary Method for 'mona' Objects

Description

Returns (and prints) a summary list for a mona object.

Usage

```r
## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)
```

Arguments

- `x, object` a `mona` object.
- `...` potential further arguments (require by generic).

See Also

`mona, mona.object`.

Summary Method for PAM Objects

Description

Summarize a pam object and return an object of class summary.pam. There's a print method for the latter.

Usage

```r
## S3 method for class 'pam'
summary(object, ...)
## S3 method for class 'summary.pam'
print(x, ...)
```

Arguments

- `x, object` a `pam` object.
- `...` potential further arguments (require by generic).

See Also

`pam, pam.object`. 
twins.object  

Hierarchical Clustering Object

Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

Value

See agnes.object and diana.object for details.

GENERATION

This class of objects is returned from agnes or diana.

METHODS

The "twins" class has a method for the following generic function: pltree.

INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

See Also

agnes, diana.

volume.ellipsoid  

Compute the Volume (of an Ellipsoid)

Description

Compute the volume of geometric R object. This is a generic function and has a method for ellipsoid objects (typically resulting from ellipsoidhull()).

Usage

volume(object, ...)  
## S3 method for class 'ellipsoid'
volume(object, log = FALSE, ...)

Arguments

object an R object the volume of which is wanted; for the ellipsoid method, an object of that class (see ellipsoidhull or the example below).
log logical indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.
... potential further arguments of methods, e.g. log.
Value

a number, the volume \( V \) (or \( \log(V) \) if \( \log = \text{TRUE} \)) of the given object.

Author(s)

Martin Maechler (2002, extracting from former \texttt{clusplot} code); Keefe Murphy (2019) provided code for dimensions \( d > 2 \).

See Also

\texttt{ellipsoidhull} for spanning ellipsoid computation.

Examples

```r
## example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                      class = "ellipsoid")
volume(myEl)# i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100,5)
e5 <- ellipsoidhull(d5)
```

Description

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

Usage

data(votes.repub)

Source

Data from 1964 to 1976 is from R. M. Scammon, \textit{American Votes 12}, Congressional Quarterly.
Description

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

Usage

data(xclara)

Format

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the x and y coordinates of the points, respectively.

Note

Our version of the xclara is slightly more rounded than the one from read.table("xclara.dat") and the relative difference measured by all.equal is 1.15e-7 for V1 and 1.17e-7 for V2 which suggests that our version has been the result of a options(digits = 7) formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. pam(*, 3) gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices {1 : 900}, {901 : 2050}, and {2051 : 3000}, see the example.

Source

Sample data set accompanying the reference below (file ‘xclara.dat’ in side ‘clus_examples.tar.gz’).

References

Examples

## Visualization: Assuming groups are defined as {1:1000}, {1001:2000}, {2001:3000}
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535) ## PAM's medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3) ## takes ~2 seconds
cxcl <- px$clustering ; iCl <- split(seq_along(cxcl), cxcl)
boxplot(iCl, range = 0.7, horizontal=TRUE,

## Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
## We see 3 + 2 + 2 = 7 clear "outlier"s or "wrong group" observations:
with(bxCl, rbind(out, group))
## out       1038 1451 1610  30 327 562 770
## group 1 1 1 2 2 3 3
## Apart from these, what are the robust ranges of indices? -- Robust range:
t(iR <- bxCl$stats[1:5,])
## 1 900
## 901 2050
## 2051 3000
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
Chapter 21

The codetools package

checkUsage | Check R Code for Possible Problems

Description

Check R code for possible problems.

Usage

checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
suppressLocal = FALSE, suppressParamAssigns = !all,
suppressParamUnused = !all, suppressFundefMismatch = FALSE,
suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
skipWith = FALSE, suppressUndefined = df1tSuppressUndefined,
suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)

Arguments

fun closure.
name character; name of closure.
env environment containing closures to check.
pack character naming package to check.
... options to be passed to checkUsage.
report function to use to report possible problems.
all logical; report all possible problems if TRUE.
suppressLocal suppress all local variable warnings.
suppressParamAssigns suppress warnings about assignments to formal parameters.
suppressParamUnused suppress warnings about unused formal parameters.
suppressFundefMismatch
suppress warnings about multiple local function definitions with different formal argument lists

suppressLocalUnused
suppress warnings about unused local variables

suppressNoLocalFun
suppress warnings about using local variables as functions with no apparent local function definition

skipWith
logical; if true, do no examine code portion of with expressions.
suppressUndefined
suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
suppress warnings about partial argument matching

Details

checkUsage checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use suppressLocal=TRUE to suppress all information related to local variable usage. The suppressXYZ values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

checkUsageEnv and checkUsagePackage are convenience functions that apply checkUsage to all closures in an environment or a package. checkUsagePackage requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

Author(s)

Luke Tierney

Examples

checkUsage(checkUsage)
checkUsagePackage("codetools",all=TRUE)
## Not run: checkUsagePackage("base",suppressLocal=TRUE)

Description

These functions provide some tools for analysing R code. Mainly intended to support the other tools in this package and byte code compilation.

Usage

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
    startCollectLocals, finishCollectLocals, warn, signal)
walkCode(e, w = makeCodeWalker())

Arguments

- **e**: R expression.
- **elist**: list of R expressions.
- **v**: R object.
- **fun**: closure.
- **formals**: formal arguments of a closure.
- **body**: body of a closure.
- **name**: character.
- **env**: character.
- **envir**: environment.
- **w**: code walker.
- **...**: extra elements for code walker.
- **collect**: function.
- **fail**: function.
- **handler**: function.
- **call**: function.
- **leaf**: function.
- **isLocal**: function.
- **exit**: function.
- **enterLocal**: function.
- **enterGlobal**: function.
- **enterInternal**: function.
- **startCollectLocals**: function.
- **finishCollectLocals**: function.
- **warn**: function.
- **signal**: function.

Author(s)

Luke Tierney
findGlobals

Find Global Functions and Variables Used by a Closure

Description

Finds global functions and variables used by a closure.

Usage

findGlobals(fun, merge = TRUE)

Arguments

fun function object; usually a closure.
merge logical

Details

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of assign and rm).

Value

Character vector if merge is true; otherwise, a list with functions and variables character vector components. Character vectors are of length zero For non-closures.

Author(s)

Luke Tierney

Examples

findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)

showTree

Print Lisp-Style Representation of R Expression

Description

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

Usage

showTree(e, write = cat)

Arguments

e R expression.
write function of one argument to write the result.
**Author(s)**
Luke Tierney

**Examples**
- `showTree(quote(-3))`
- `showTree(quote("x"<-1))`
- `showTree(quote("f"(x)))`
Chapter 22

The foreign package

lookup.xport  Lookup Information on a SAS XPORT Format Library

Description
Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

Usage
lookup.xport(file)

Arguments
file character variable with the name of the file to read. The file must be in SAS XPORT format.

Value
A list with one component for each dataset in the XPORT format library.

Author(s)
Saikat DebRoy

References

See Also
read.xport
Examples

```r
## Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

## End(Not run)
```

---

**read.arff**

*Read Data from ARFF Files*

### Description

Reads data from Weka Attribute-Relation File Format (ARFF) files.

### Usage

```r
read.arff(file)
```

### Arguments

- `file`: a character string with the name of the ARFF file to read from, or a `connection` which will be opened if necessary, and if so closed at the end of the function call.

### Value

A data frame containing the data from the ARFF file.

### References

### See Also

- `write.arff` functions `write.arff` and `read.arff` in package RWeka which provide some support for logicals via conversion to or from factors.

---

**read.dbf**

*Read a DBF File*

### Description

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

### Usage

```r
read.dbf(file, as.is = FALSE)
```
read.dbf

Arguments

file  name of input file
as.is should character vectors not be converted to factors?

Details

DBF is the extension used for files written for the ‘XBASE’ family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' ([https://www.clicketyclick.dk/databases/xbase/format/](https://www.clicketyclick.dk/databases/xbase/format/)). Most of these follow the file structure used by Ashton-Tate’s dBase II, III or 4 (later owned by Borland).

read.dbf is based on C code from [http://shapelib.maptools.org/](http://shapelib.maptools.org/) which implements the ‘XBASE’ specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names(unique=TRUE)`.

There is an attribute "data_type" giving the single-character dBase types for each field.

Note

Not to be able to read a particular ‘DBF’ file is not a bug: this is a convenience function especially for shapefiles.

Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

References

`write.dbf`

Examples

```r
x <- read.dbf(system.file("files/sids.dbf", package="foreign")[1])
str(x)
summary(x)
```
Description

Reads a file in Stata version 5–12 binary format into a data frame.
Frozen: will not support Stata formats after 12.

Usage

```r
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
         missing.type = FALSE,
         convert.underscore = FALSE, warn.missing.labels = TRUE)
```

Arguments

- `file`: a filename or URL as a character string.
- `convert.dates`: Convert Stata dates to `Date` class, and date-times to `POSIXct` class?
- `convert.factors`: Use Stata value labels to create factors? (Version 6.0 or later).
- `missing.type`: For version 8 or later, store information about different types of missing data?
- `convert.underscore`: Convert "_" in Stata variable names to "." in R names?
- `warn.missing.labels`: Warn if a variable is specified with value labels and those value labels are not present in the file.

Details

If the filename appears to be a URL (of schemes ‘http:’, ‘ftp:’ or ‘https:’) the URL is first downloaded to a temporary file and then read. (‘https:’ is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R’s `Date` class, and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata’s date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If `missing.type` is `TRUE` a separate list is created with the same variable names as the loaded data. For string variables the list value is `NULL`. For other variables the value is `NA` where the observation is not missing and 0–26 when the observation is missing. This is attached as the “missing” attribute of the returned value.

The default file format for Stata 13, format-115, is substantially different from those for Stata 5–12.
Value

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, ‘format-111’), 8 (Stata 8 and 9, ‘format-113’), 10 (Stata 10 and 11, ‘format-114’) and 12 (Stata 12, ‘format-115’).

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

Author(s)

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

References

Stata Users Manual (versions 5 & 6), Programming manual (version 7), or online help (version 8 and later) describe the format of the files. Or directly at https://www.stata.com/help.cgi?dta_114 and https://www.stata.com/help.cgi?dta_113, but note that these have been changed since first published.

See Also

Different approaches are available in package memisc (see its help for Stata.file), function read_dta in package haven and package readstata13.

Examples

write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)

Description

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

Usage

read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE, thisyear = NULL, lower.case.names = FALSE)
Arguments

- **file**: A filename, URL, or connection.
- **read.deleted**: Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.
- **guess.broken.dates**: Attempt to convert dates with 0 or 2 digit year information (see ‘Details’).
- **thisyear**: A 4-digit year to use for dates with no year. Defaults to the current year.
- **lower.case.names**: Convert variable names to lowercase?

Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to `Date` class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system’s default method (see Date) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the “deleted” attribute of the data frame indicates the deleted records.

Value

A data frame.

Note

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be readable with the RODBC package.

DateTimeClasses

Examples

```r
## Not run: ## That file is not available
read.epiinfo("oswego.rec", guess.broken.dates = TRUE, thisyear = "1972")
## End(Not run)
```

Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

Usage

```r
read.mtp(file)
```
**Arguments**

file character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

**Value**

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

**Note**

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

**Author(s)**

Douglas M. Bates

**References**

https://www.minitab.com/

**Examples**

```r
## Not run:
read.mtp("ex1-10.mtp")
## End(Not run)
```

---

**read.octave Read Octave Text Data Files**

**Description**

Read a file in Octave text data format into a list.

**Usage**

```r
read.octave(file)
```

**Arguments**

file a character string with the name of the file to read.

**Details**

This function is used to read in files in Octave text data format, as created by `save -text` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and N-d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and NULL is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave’s load and save (as text) facilities as an intermediary step.
Value

A list with one named component for each variable in the file.

https://octave.org/

read.spss  Read an SPSS Data File

Description

read.spss reads a file stored by the SPSS save or export commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

Usage

read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
       max.value.labels = Inf, trim.factor.names = FALSE,
       trim_values = TRUE, reencode = NA, use.missings = to.data.frame,
       sub = ".", add.undeclared.levels = c("sort", "append", "no"),
       duplicated.value.labels = c("append", "condense"),
       duplicated.value.labels.infix = ".\_duplicated\_", ...)

Arguments

file character string: the name of the file or URL to read.
use.value.labels logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching label are returned as NA).
to.data.frame logical: return a data frame?
max.value.labels logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.
trim.factor.names logical: trim trailing spaces from factor levels?
trim_values logical: should values and value labels have trailing spaces ignored when matching for use.value.labels = TRUE?
reencode logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in UTF-8 or latin-1 locales, only. Alternatively a character string specifying an encoding to assume for the file.
use.missings logical: should information on user-defined missing values be used to set the corresponding values to NA?
sub character string: If not NA it is used by `iconv` to replace any non-convertible bytes in character/factor input. Default is ".". For back compatibility with `foreign` versions <= 0.8-68 use sub=NA.

add.undeclared.levels character: specify how to handle variables with at least one value label and further non-missing values that have no value label (like a factor levels in R). For "sort" (the default) it adds undeclared factor levels to the already declared levels (and labels) and sort them according to level, for "append" it appends undeclared factor levels to declared levels (and labels) without sorting, and for "no" this does not convert to factor in case of numeric SPSS levels (not labels), and still converts to factor if the SPSS levels are characters and to.data.frame=TRUE. For back compatibility with `foreign` versions <= 0.8-68 use add.undeclared.levels="no" (not recommended as this may convert some values with missing corresponding value labels to NA).

duplicated.value.labels character: what to do with duplicated value labels for different levels. For "append" (the default), the first original value label is kept while further duplicated labels are renamed to paste0(label, duplicated.value.labels.infix, level), for "condense", all levels with identical labels are condensed into exactly the first of these levels in R. Back compatibility with `foreign` versions <= 0.8-68 is not given as R versions >= 3.4.0 no longer support duplicated factor labels.

duplicated.value.labels.infix character: the infix used for labels of factor levels with duplicated value labels in SPSS (default "._duplicated_.") if duplicated.value.labels="append".

... passed to `as.data.frame` if to.data.frame = TRUE.

Details

This uses modified code from the PSPP project (http://www.gnu.org/software/pspp/) for reading the SPSS formats.

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is supported where supported by `download.file` with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting max.value.labels you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels.

If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument trim.values=TRUE causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for sub for ways to remove trailing spaces in character data.

URL https://learn.microsoft.com/en-us/windows/win32/intl/code-page-identifiers provides a list of translations from Windows codepage numbers to encoding names that `iconv` is likely to know about and so suitable values for reencode. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 or latin-1 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see iconvlist).
Value

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute "codepage" to the result.

There may be attributes "label.table" and "variable.labels". Attribute "label.table" is a named list of value labels with one element per variable, either NULL or a named character vector. Attribute "variable.labels" is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute "Missings". This is a named list with one list element per variable. Each element has an element type, a length-one character vector giving the type of missingness, and may also have an element value with the values corresponding to missingness. This is a complex subject (where the R and C source code for read.spss is the main documentation), but the simplest cases are types "one", "two" and "three" with a corresponding number of (real or string) values whose labels can be found from the "label.table" attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value.

Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, ....

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 and latin-1 locales: see argument reencode.

Author(s)

Saikat DebRoy and the R-core team

See Also

A different interface also based on the PSPP codebase is available in package memisc: see its help for spss.system.file.

Examples

```r
(sav <- system.file("files", "electric.sav", package = "foreign"))
dat <- read.spss(file=sav)
str(dat)  # list structure with attributes
dat <- read.spss(file=sav, to.data.frame=TRUE)
str(dat)  # now a data.frame
```

### Now we use an example file that is not very well structured and hence may need some special treatment with appropriate argument settings.
### Expect lots of warnings as value labels (corresponding to R factor labels) are incomplete, and an unsupported long string variable is present in the data

```r
(sav <- system.file("files", "testdata.sav", package = "foreign"))
```
## Examples for `add.undeclared.levels`:
### `add.undeclared.levels = "sort"` (default):
```r
x.sort <- read.spss(file=sav, to.data.frame = TRUE)
```
### `add.undeclared.levels = "append"`:
```r
x.append <- read.spss(file=sav, to.data.frame = TRUE, 
                      add.undeclared.levels = "append")
```
### `add.undeclared.levels = "no"`:
```r
x.no <- read.spss(file=sav, to.data.frame = TRUE, 
                   add.undeclared.levels = "no")
```

```r
levels(x.sort$factor_n_undeclared)
levels(x.append$factor_n_undeclared)
str(x.no$factor_n_undeclared)
```

## Examples for `duplicated.value.labels`:
### `duplicated.value.labels = "append"` (default):
```r
x.append <- read.spss(file=sav, to.data.frame=TRUE)
```
### `duplicated.value.labels = "condense"`:
```r
x.condense <- read.spss(file=sav, to.data.frame=TRUE, 
                         duplicated.value.labels = "condense")
```
```r
levels(x.append$factor_n_duplicated)
levels(x.condense$factor_n_duplicated)
as.numeric(x.append$factor_n_duplicated)
as.numeric(x.condense$factor_n_duplicated)
```

## Long Strings (>255 chars) are imported in consecutive separate variables
### (see warning about subtype 14):
```r
x <- read.spss(file=sav, to.data.frame=TRUE, stringsAsFactors=FALSE)
```
```r
cat.long.string <- function(x, w=70) cat(paste(strwrap(x, width=w), "\n"))
```
```r
## first part: x$string_500:
cat.long.string(x$string_500)
```
```r
## second part: x$STRIN0:
cat.long.string(x$STRIN0)
```
```r
## complete long string:
long.string <- apply(x[,c("string_500", "STRIN0")], 1, paste, collapse="")
cat.long.string(long.string)
```

### Description

Generates a SAS program to convert the ssd contents to SAS transport format and then uses `read.xport` to obtain a data frame.

### Usage

```r
read.ssd(libname, sectionnames, 
          tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```
Arguments

libname character string defining the SAS library (usually a directory reference)

sectionnames character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended.

tmpXport character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.

tmpProgLoc character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.

sascmd character string giving full path to SAS executable.

Details

Creates a SAS program and runs it.

Error handling is primitive.

Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

Note

This requires SAS to be available. If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as .csv, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

R> baseline <- read.ssd("trialdata", "baseline")
**read.systat**

Obtain a Data Frame from a Systat File

**Description**

read.systat reads a rectangular data file stored by the Systat `SAVE` command as (legacy) *.*sys or more recently *.*syd files.

**Usage**

```r
read.systat(file, to.data.frame = TRUE)
```

**Arguments**

- `file` character variable with the name of the file to read
- `to.data.frame` return a data frame (otherwise a list)

**Details**

The function only reads those Systat files that are rectangular data files (mtype = 1), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is FALSE, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

**Value**

A data frame (or list) with one component for each variable in the saved data set.

**Author(s)**

Roger Bivand
read.xport

Read a SAS XPORT Format Library

Description

Reads a file as a SAS XPORT format library and returns a list of data.frames.

Usage

read.xport(file, ...)

Arguments

file character variable with the name of the file to read. The file must be in SAS XPORT format.

... passed to as.data.frame when creating the data frames.

Value

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by ._, .A to .Z by SAS) are mapped to R NA. Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or ''; these are not treated as R missing values.

## End(Not run)

S3 read functions

Read an S3 Binary or data.dump File

Description

Reads binary data files or data.dump files that were produced in S version 3.

Usage

data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)

Arguments

file the filename of the S-PLUS data.dump or binary file.
print whether to print the name of each object as read from the file.
verbose whether to print the name of every subitem within each object.
env environment within which to create the restored object(s).

Details

read.S can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.
data.restore can read a similar range of files produced by data.dump and for newer versions of S-PLUS, those from data.dump(....., oldStyle=TRUE).

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

Value

For read.S, an R version of the S3 object.
For data.restore, the name of the file.

Duncan Murdoch
write.arff

Write Data into ARFF Files

Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

Usage

write.arff(x, file, eol = \"\n\", relation = deparse(substitute(x)))

Arguments

x the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.
file either a character string naming a file, or a connection. \"\" indicates output to the standard output connection.
eol the character(s) to print at the end of each line (row).
relation The name of the relation to be written in the file.

Details

relation will be passed through make.names before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have X prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

References

See Also

read.arff; functions write.arff and read.arff in package RWeka which provide some support for logicals via conversion to or from factors.

Examples

write.arff(iris, file = \"")
Write a DBF File

Description
The function tries to write a data frame to a DBF file.

Usage
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)

Arguments
- dataframe: a data frame object.
- file: a file name to be written to.
- factor2char: logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.
- max_nchar: The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

Details
Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase max_nchar only if you are sure the intended reader supports wider character fields.

Value
Invisible NULL.

Note
Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

Author(s)
Nicholas J. Lewin-Koh, modified by Roger Bivand and Brian Ripley; shapelib by Frank Warmerdam.
write.dta

Write Files in Stata Binary Format

Description

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be drop-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

Usage

write.dta(dataframe, file, version = 7L,

   convert.dates = TRUE, tz = "GMT",
   convert.factors = c("labels", "string", "numeric", "codes"))

Arguments

dataframe a data frame.

file character string giving filename.

version integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10.

convert.dates logical: convert Date and POSIXct objects: see section ‘Dates’.

tz timezone for date conversion.

convert.factors how to handle factors.
Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The abbreviate function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata ‘value labels’ for the factor levels. With convert.factors = "string", the factor levels are written as strings (the name of the value label is taken from the "val.labels" attribute if it exists or the variable name otherwise). With convert.factors = "numeric" the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, convert.factors = "codes" writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the "label.table" attribute contains value labels with names not already attached to a variable (not the variable name or name from "val.labels") then these will be written out as well.

If the "datalabel" attribute contains a string, it is written out as the dataset label otherwise the dataset label is "Written by R.".

If the "expansion.table" attribute exists expansion fields are written. This attribute should contain a list where each element is character vector of length three. The first vector element contains the name of a variable or "_dta" (meaning the dataset). The second element contains the characteristic name. The third contains the associated data.

If the "val.labels" attribute contains a character vector with a string label for each value then this is written as the value labels. Otherwise the variable names are used.

If the "var.labels" attribute contains a character vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

For Stata 8 or later use the default version = 7 – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn’t have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

Value

NULL

Dates

Unless disabled by argument convert.dates = FALSE, R date and date-time objects (POSIXt classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

format xdate %td;
It is possible to pass objects of class POSIXct to Stata to be treated as one of its versions of datetimes. Stata uses the number of milliseconds since 1960-01-01, either excluding (format %tc) or counting (format %tC) leap seconds. So either an object of class POSIXct can be passed to Stata with `convert.dates = FALSE` and converted in Stata, or `315619200` should be added and then multiplied by 1000 before passing to `write.dta` and assigning format %tc. Stata’s comments on the first route are at https://www.stata.com/manuals13/ddatetime.pdf, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

**Author(s)**

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

**References**

`read.dta, attributes, DateTimeClasses, abbreviate`

**Examples**

```r
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

---

**write.foreign**  
*Write Text Files and Code to Read Them*

**Description**

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

**Usage**

```r
write.foreign(df, datafile, codefile, 
               package = c("SPSS", "Stata", "SAS"), ...)
```

**Arguments**

- **df**  
  A data frame
- **datafile**  
  Name of file for data output
- **codefile**  
  Name of file for code output
- **package**  
  Name of package
- **...**  
  Other arguments for the individual writeForeign functions
Details

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, e.g., Systat, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (Date, dates, date, and POSIXt classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname = "rdata"` taking a string that will be the SAS data set name, `validvarname` taking either "V6" or "V7", and `libpath = NULL` taking a string that will be the directory where the target SAS datset will be written when the generated SAS code been run.

For `package="SPSS"` there is an optional argument `maxchars = 32L` taking an integer that causes the variable names (not variable labels) to be abbreviated to not more than `maxchars` chars. For compatibility with SPSS version 12 and before, change this to `maxchars = 8L`. In single byte locales with SPSS versions 13 or later, this can be set to `maxchars = 64L`.

For `package="SPSS"`, as a side effect, the decimal indicator is always set by `SET DECIMAL=DOT`. which may override user settings of the indicator or its default derived from the current locale.

Value

Invisible `NULL`.

Thomas Lumley and Stephen Weigand

Examples

```r
## Not run:
datafile <- tempfile()
codefile <- tempfile()
write.foreign(esoph, datafile, codefile, package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)

## End(Not run)
```
Chapter 23

The lattice package

A_01_Lattice  Lattice Graphics

Description

The lattice add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland's 1993 book Visualizing Data. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several 'high-level' generic functions (listed below in the “See Also” section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for xyplot, which also includes a discussion of the important topics of conditioning and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see trellis.par.set. For other settings, see lattice.options. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see trellis.device.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the print.trellis help page. See update.trellis to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including locator-like functionality) are described in the trellis.focus help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading...
the PDF reference manual available at https://cran.r-project.org/package=lattice. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer’s ‘Use R’ series; see the “References” section below.

Note

High-level lattice functions like `xyplot` are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then `print`-ed or `plot`-ted to create the actual plot. Due to R’s automatic printing rule, it is usually not necessary to explicitly carry out the second step, and lattice functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often `source`) or in other contexts where automatic printing is suppressed (e.g., `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

The lattice package is based on the Grid graphics engine and requires the grid add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing `par()` settings usually has no effect on Lattice plots; lattice provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

Bell Lab’s Trellis Page contains several documents outlining the use of Trellis graphics; these provide a holistic introduction to the Trellis paradigm: http://web.archive.org/web/20081020164041/http://cm.bell-labs.com/cm/ms/departments/sia/project/trellis/display.writing.html

See Also

The following is a list of high-level functions in the lattice package and their default displays. In all cases, the actual display is produced by the so-called “panel” function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as “panel.” followed by the name of the corresponding high-level function; i.e., the default panel function for `xyplot` is `panel.xyplot`, the one for `histogram` is `panel.histogram`, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

Univariate:

`barchart`: Bar plots.
bwplot: Box-and-whisker plots.
densityplot: Kernel density estimates.
dotplot: Cleveland dot plots.
histogram: Histograms.
qqmath: Theoretical quantile plots.
stripplot: One-dimensional scatterplots.

Bivariate:

qq: Quantile plots for comparing two distributions.
xyplot: Scatterplots and time-series plots (and potentially a lot more).

Trivariate:

levelplot: Level plots (similar to image plots).
contourplot: Contour plots.
cloud: Three-dimensional scatter plots.
wireframe: Three-dimensional surface plots (similar to persp plots).

Hypervariate:

splom: Scatterplot matrices.
parallel: Parallel coordinate plots.

Miscellaneous:

rfs: Residual and fitted value plots (also see oneway).
tmd: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in panel.functions. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives lines, points, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like llines or panel.lines and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the latticeExtra package.

Common Bivariate Trellis Plots

Description

This help page documents several commonly used high-level Lattice functions. xyplot produces bivariate scatterplots or time-series plots, bwplot produces box-and-whisker plots, dotplot produces Cleveland dot plots, barchart produces bar plots, and stripplot produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

Usage

xyplot(x, data, ...)  
dotplot(x, data, ...)  
barchart(x, data, ...)  
stripplot(x, data, ...)  
bwplot(x, data, ...)  

## S3 method for class 'formula'  
xyplot(x,  
data,  
allow.multiple = is.null(groups) || outer,

**Arguments**

x

All high-level function in `lattice` are generic. `x` is the object on which method dispatch is carried out.

For the “formula” methods, `x` must be a formula describing the primary vari-
ables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form \( y \sim x \mid g_1 \times g_2 \times \ldots \) (or equivalently, \( y \sim x \mid g_1 + g_2 + \ldots \)), indicating that plots of \( y \) (on the y-axis) versus \( x \) (on the x-axis) should be produced conditional on the variables \( g_1, g_2, \ldots \). Here \( x \) and \( y \) are the primary variables, and \( g_1, g_2, \ldots \) are the conditioning variables. The conditioning variables may be omitted to give a formula of the form \( y \sim x \), in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., \( \sqrt{} \), \( \log() \), etc. See the data argument below for rules regarding evaluation of the terms in the formula.

With the exception of \( xyplot \), the functions documented here may also be supplied a formula of the form \( ~ x \mid g_1 \times g_2 \times \ldots \). In that case, \( y \) defaults to \( \text{names}(x) \) if \( x \) is named, and a factor with a single level otherwise.

Cases where \( x \) is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For \( barchart \) and \( dotplot \), non-trivial methods exist for tables and arrays, documented at \( \text{barchart.table} \).

The conditioning variables \( g_1, g_2, \ldots \) must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of \( \text{shingle} \) for details. Like factors, they have a “levels” attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the \( \text{shingle} \) function; however, using \( \text{equal.count} \) may be more appropriate in many cases. Character variables are coerced to factors.

Extended formula interface: As a useful extension of the interface described above, the primary variable terms (both the LHS \( y \) and RHS \( x \)) may consist of multiple terms separated by a ‘+’ sign, e.g., \( y_1 + y_2 \sim x \mid a \times b \). This formula would be taken to mean that the user wants to plot both \( y_1 \sim x \mid a \times b \) and \( y_2 \sim x \mid a \times b \), but with the \( y_1 \sim x \) and \( y_2 \sim x \) superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the groups argument (see below) would produce, if \( y_1 \) and \( y_2 \) were concatenated to produce a longer vector, with the groups argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the \( \text{reshape} \) function. This feature cannot be used in conjunction with the groups argument.

To interpret \( y_1 + y_2 \) as a sum, one can either set \( \text{allow.multiple}=\text{FALSE} \) or use \( I(y_1+y_2) \).

A variation on this feature is when the outer argument is set to \( \text{TRUE} \). In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

Primary variables: The \( x \) and \( y \) variables should both be numeric in \( xyplot \), and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of \( x \) and \( y \) should be numeric, and the other a factor or shingle. Which of these will happen is determined by the horizontal argument — if \( \text{horizontal}=\text{TRUE} \), then \( y \) will be coerced to be a factor or shingle, otherwise \( x \). The default value of \( \text{horizontal} \) is \( \text{FALSE} \) if \( x \) is a factor or shingle, \( \text{TRUE} \) otherwise. (The functionality provided by \( \text{horizontal}=\text{FALSE} \) is not S-compatible.)
Note that the x argument used to be called formula in earlier versions (when the high-level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

**data**
For the formula methods, a data frame (or more precisely, anything that is a valid envir argument in eval, e.g., a list or an environment) containing values for any variables in the formula, as well as groups and subset if applicable. If not found in data, or if data is unspecified, the variables are looked for in the environment of the formula. For other methods (where x is not a formula), data is usually ignored, often with a warning if it is explicitly specified.

**allow.multiple**
Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to TRUE whenever sensible.

**outer**
Logical flag controlling what happens with formulas using the extended interface described above (see the entry for x for details). Defaults to FALSE, except when groups is explicitly specified or grouping does not make sense for the default panel function.

**box.ratio**
Applicable to barchart and bwplot. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the box.width argument in the respective default panel functions.

**horizontal**
Logical flag applicable to bwplot, dotplot, barchart, and stripplot. Determines which of x and y is to be a factor or shingle (y if TRUE, x otherwise). Defaults to FALSE if x is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of scales in this case may be abbreviate = TRUE, in which case long labels which would usually overlap will be abbreviated. scales could also contain a minlength argument in this case, which would be passed to the abbreviate function.

**Common arguments:**
The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

**panel**
Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding x and y variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the panel argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “panel.” followed by the name of the corresponding high-level function (e.g., panel.xyplot, panel.barchart, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named x and y, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as xyplot) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a ... argument. Such extra arguments typically control graphical
parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the \( x \) and \( y \) arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, \texttt{panel.grid}, \texttt{panel.loess}, etc. There are also some Grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, \texttt{lines} can be replaced by \texttt{llines} (or equivalently, \texttt{panel.lines}). Note that traditional graphics functions like \texttt{lines} will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the \texttt{groups} argument is not \texttt{NULL}. In that case, the panel function should also accept arguments named \texttt{groups} and \texttt{subscripts} (see below for details). A useful panel function predefined for use in such cases is \texttt{panel.superpose}, which can be combined with different \texttt{panel.groups} functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the \texttt{groups} argument, including the default ones for \texttt{xyplot}, \texttt{barchart}, \texttt{dotplot}, and \texttt{stripplot}.

Even when \texttt{groups} is not present, the panel function can have \texttt{subscripts} as a formal argument. In either case, the \texttt{subscripts} argument passed to the panel function are the indices of the \( x \) and \( y \) data for that panel in the original data, BEFORE taking into account the effect of the subset argument. Note that \texttt{groups} remains unaffected by any subsetting operations, so \texttt{groups[subscripts]} gives the values of \texttt{groups} that correspond to the data in that panel.

This interpretation of \texttt{subscripts} does not hold when the extended formula interface is in use (i.e., when \texttt{allow.multiple} is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function \texttt{latticeParseFormula}), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, \texttt{subscripts} needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of \texttt{subset}, in which case \texttt{subscripts} may have no relationship with corresponding rows in the original data frame.

One can also use functions called \texttt{panel.number} and \texttt{packet.number}, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using \texttt{trellis.focus} etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using \texttt{perm.cond} and \texttt{index.cond} respectively), in which case \texttt{packet.number} gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

\texttt{panel.xyplot} has an argument called \texttt{type} which is worth mentioning here
because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

**aspect**

This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are "fill" (the default) which tries to make the panels as big as possible to fill the available space; "xy", which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Not all default `prepanel` functions produce sensible banking calculations.

**groups**

A variable or expression to be evaluated in `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping. It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

**auto.key**

A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns = 2)` will create a legend split into two columns (`columns` is documented in the entry for `key`). More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a `key` is created with `simpleKey` with `levels(groups)` as the first (`text`) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the `key`, and the `key` is drawn even if `groups` is not specified.

Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the `key`, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The `par.settings` argument, possibly in conjunction with `simpleTheme`, may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the `key` are absolutely determined at the time when the
"trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with auto.key, the key is actually created at plotting time, so the settings will match.

prepanel

A function that takes the same arguments as the panel function and returns a list, possibly containing components named xlim, ylim, dx, and dy (and less frequently, xat and yat). The return value of a user-supplied prepanel function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The xlim and ylim components are similar to the high level xlim and ylim arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the xlim and ylim arguments are not explicitly specified (possibly as components in scales) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the prepanel function. This happens globally if the relation component of scales is "same", and on a per-panel basis otherwise.

The dx and dy components are used for banking computations in case aspect is specified as "xy". See documentation of banking for details.

If xlim or ylim is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first n integers, where n is the length of xlim or ylim, as the case may be. The elements of the character vector are used as the default labels for these n integers. Thus, to make this information consistent between panels, the xlim or ylim values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component xat or yat may be returned by the prepanel function, which should be a subset of 1:n, indicating which of the n values (levels) are actually represented in the panel. This is useful when calculating the limits with relation="free" or relation="sliced" in scales. The prepanel function is responsible for providing a meaningful return value when the x, y (etc.) variables are zero-length vectors. When nothing else is appropriate, values of NA should be returned for the xlim and ylim components.

strip

A logical flag or function. If FALSE, strips are not drawn. Otherwise, strips are drawn using the strip function, which defaults to strip.default. See documentation of strip.default to see the arguments that are available to the strip function. This description also applies to the strip.left argument (see ... below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

xlab

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for x in the formula defining the plot. Can be specified as NULL to omit the label altogether. Finer control is possible, as described in the entry for main, with the modification that if the label component is omitted from the list, it is replaced by the default xlab.

ylab

Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for y in the formula defining the plot. Finer control is possible, see entries for main and xlab.

scales

Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in name=value form, and may also contain two other lists called x and y of the same form (described below). Components of x and y affect the respective axes only, while those in scales affect both.
When parameters are specified in both lists, the values in x or y are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., 

```
bwplot
```

has alternating=FALSE for the categorical axis only); these can only be overridden by an entry in the corresponding component of scales. As a special exception, scales (or its x and y components) can also be a character string, in which case it is interpreted as the relation component.

The possible components are:

- **relation**: A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For `relation="same"`, the same limits, usually large enough to encompass all the data, are used for all the panels. For `relation="free"`, limits for each panel is determined by just the points in that panel. Behavior for `relation="sliced"` is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the `prepanel` function, which can be overridden by `xlim`, `ylim` or `scales$limits` (except when `relation="sliced"`, in which case explicitly specified limits are ignored with a warning). When `relation` is "free", `xlim` or `ylim` can be a list, in which case it is treated as if its components were the limit values obtained from the prepanel calculations for each panel (after being replicated if necessary).

- **tick.number**: An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see `xlim`.

- **draw**: A logical flag, defaulting to `TRUE`, that determines whether to draw the axis (i.e., tick marks and labels) at all.

- **alternating**: Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, alternating can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers:
  - 0: do not draw tick labels
  - 1: bottom/left
  - 2: top/right
  - 3: both.

  alternating applies only when `relation="same"`. The default is `TRUE`, or equivalently, `c(1, 2)`

- **limits**: Same as `xlim` and `ylim`.

- **at**: The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

- **labels**: Vector of labels (characters or expressions) to go along with `at`. Can also be a list like at.

- **cex**: A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.

- **font, fontface, fontfamily**: Specifies the font to be used for axis labels.

- **lineheight**: Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for `cloud`.)

- **tck**: Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.
col  Color of tick marks and labels.

rot  Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.

abbreviate A logical flag, indicating whether to abbreviate the labels using the abbreviate function. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength Argument passed to abbreviate if abbreviate=TRUE.

log Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x = list(log = 2)) is equivalent to y ~ log2(x).

See entry for equispaced.log below for details on how to control axis labeling.

equispaced.log A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to TRUE.

Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If equispaced.log is FALSE, the choice made is similar to how log scales are annotated in traditional graphics. If TRUE, tick mark locations are chosen as 'pretty' equispaced values in the transformed scale, and labeled in the form "base^loc", where base is the base of the logarithm transformation, and loc are the locations in the transformed scale.

See also xscale.components.logpower in the latticeExtra package.

format The format to use for POSIXct variables. See strptime for description of valid values.

axs A character string, "r" (default) or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

subscripts A logical flag specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified, or if the panel function accepts an argument named subscripts. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using panel.identify.

subset An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If subsets is TRUE, the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the drop.unused.levels argument.

xlim Normally a numeric vector (or a DateTime object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of x. The latter form is interpreted as a range containing c(1, length(xlim)), with the character vector determining labels at tick positions 1:length(xlim).
\texttt{ylim} could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when \texttt{scales$\texttt{x}$relation} is "\texttt{free}"; in which case these are treated as if they were the corresponding limit components returned by \texttt{prepanel} calculations.

\texttt{ylim}  Similar to \texttt{xlim}, applied to the y-axis.

\texttt{drop.unused.levels}

A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an \texttt{interaction} is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components \texttt{cond} and \texttt{data}, both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by \texttt{lattice.getOption("drop.unused.levels")}, which is initially set to \texttt{TRUE} for both components. Note that this argument does not control dropping of levels of the \texttt{groups} argument.

\texttt{default.scales}  A list giving the default values of \texttt{scales} for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.

\texttt{default.prepanel}  A function or character string giving the name of a function that serves as the (component-wise) fallback \texttt{prepanel} function when the \texttt{prepanel} argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of \texttt{lattice.options}.

\texttt{lattice.options}

A list that could be supplied to \texttt{lattice.options}. These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the \texttt{par.settings} argument described below for a similar treatment of graphical settings.

Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high-level functions in a similar manner, and those that are meant for the specific panel function being used.

The first group of arguments are processed by a common, unexported function called \texttt{trellis.skeleton}. These arguments affect all high-level functions, but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as "\texttt{panel."} followed by the name of the high-level function; for example, the default panel function for \texttt{bwplot} is \texttt{panel.bwplot}. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:
as.table: A logical flag that controls the order in which panels should be displayed: if FALSE (the default), panels are drawn left to right, bottom to top (as in a graph); if TRUE, left to right, top to bottom (as in a table).

between: A list with components x and y (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). x and y are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi-page display. In other words, it is not possible to use different between values for different pages.

key: A list that defines a legend to be drawn on the plot. This list is used as an argument to the draw.key function, which produces a “grob” (grid object) eventually plotted by the print method for "trellis" objects. The structure of the legend is constrained in the ways described below. Although such a list can be and often is created explicitly, it is also possible to generate such a list using the simpleKey function: the latter is more convenient but less flexible. The auto.key argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by key, use the legend argument.

The position of the key can be controlled in either of two possible ways. If a component called space is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of space, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components x, y and corner. x and y determine the location of the corner of the key given by corner, which is usually one of c(0,0), c(1,0), c(1,1) and c(0,1), which denote the corners of the unit square. Fractional values are also allowed, in which case x and y determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

x and y should be numbers between 0 and 1, giving coordinates with respect to the “display area”. Depending on the value of the "legend.bbox" option (see lattice.getOption), this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for rep below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in key and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- cex=1 (text, lines, points)
- col="black" (text, rectangles, lines, points)
In addition, the component border can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, border controls the border of the entire key (see below). angle and density are unimplemented. size determines the width of columns of rectangles and lines in character widths. type is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. height gives heights of rectangles as a fraction of the default.

Other possible components of key are:

reverse.rows Logical flag, defaulting to FALSE. If TRUE, all components are reversed after being replicated (the details of which may depend on the value of rep). This is useful in certain situations, e.g., with a grouped barchart with stack = TRUE with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless reverse.rows = TRUE. Note that in this case, unless all columns have the same number or rows, they will no longer be aligned.

between Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

title String or expression giving a title for the key.

rep Logical flag, defaults to TRUE. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying rep=FALSE, in which case the length of each column will be determined by components of that column alone.

cex.title Zoom factor for the title.

lines.title The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.

padding.text The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently 0.2 * "lines". This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.
background  Background color for the legend. Defaults to the global background color.
alpha.background An alpha transparency value between 0 and 1 for the background.
border  Either a color for the border, or a logical flag. In the latter case, the border color is black if border is TRUE, and no border is drawn if it is FALSE (the default).
transparent=FALSE Logical flag, whether legend should have a transparent background.
just  A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See grid.layout for more precise details.
columns  The number of column-blocks (drawn side by side) the legend is to be divided into.
between.columns  Space between column blocks, in addition to between.
divide  Number of point symbols to divide each line when type is "b" or "o" in lines.

legend: The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.
If used, legend must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the space component of key. If key (or colorkey for levelplot and wireframe) is specified, their space component must not conflict with the name of any component of legend.
Each component of legend must have a component called fun. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called args. For components named "inside", there can be additional components called x, y and corner, which work in the same way as for key.

page: A function of one argument (page number) to be called after drawing each page. The function must be ‘grid-compliant’, and is called with the whole display area as the default viewport.

xlab.top, ylab.right: Labels for the x-axis on top, and y-axis on the right. Similar to xlab and ylab, but less commonly used.

main: Typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL.
main (as well as xlab, ylab and sub) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in plotmath. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for ylab). This feature can be used to provide column or row labels rather than a single axis label. When main (etc.) is a list, the actual label should be specified as the label component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (xlab and ylab usually have defaults, but main and sub do not). Further named arguments are passed on to textGrob; this can include arguments controlling positioning
like just and rot as well as graphical parameters such as col and font (see gpar for a full list).
main, sub, xlab, ylab, xlab.top, and ylab.right can also be arbitrary "grob"s (grid graphical objects).

sub: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for main for finer control options.

par.strip.text: A list of parameters to control the appearance of strip text. Notable components are col, cex, font, and lines. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains \"n\"s) or if the default height seems too small or too large.
Additionally, the lineheight component can control the space between multiple lines. The labels can be abbreviated when shown by specifying abbreviate = TRUE, in which case the components minlength and dot (passed along to the abbreviate function) can be specified to control the details of how this is done.

layout: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. layout determines this arrangement.
layout is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is c(0,n), where n is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via par("din"). If NA is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.
The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.

skip: A logical vector (default FALSE), replicated to be as long as the number of panels (spanning all pages). For elements that are TRUE, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

strip.left: strip.left can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for strip for detailed usage.

xlab.default, ylab.default: Fallback default for xlab and ylab when they are not specified. If NULL, the defaults are parsed from the Trellis formula.
This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

xscale.components, yscale.components: Functions that determine axis an-
notation for the x and y axes respectively. See documentation for `xscale.components.default`, the default values of these arguments, to learn more.

**axis**: Function responsible for drawing axis annotation. See documentation for `axis.default`, the default value of this argument, to learn more.

**perm.cond**: An integer vector, a permutation of 1:n, where n is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument does in `aperm`.

**index.cond**: Whereas `perm.cond` permutes the dimensions of the multidimensional array of panels, `index.cond` can be used to subset (or reorder) margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the i-th component has to be a valid indexing vector for `levels(g_i)`, where `g_i` is the i-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the `subset` and `drop.unused.levels` arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to `TRUE`.

Note that the components of `index.cond` are interpreted in the order of the conditioning variables in the original call, and is not affected by `perm.cond`. Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing “trellis” object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update.trellis` method, both can be set to `NULL`, which reverts these back to their defaults.

**par.settings**: A list that could be supplied to `trellis.par.set`. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the `lattice.options` argument described above for a similar treatment of non-graphical options.

**plot.args**: A list containing possible arguments to `plot.trellis`, which will
be used by the \texttt{plot} or \texttt{print} methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the \texttt{trellis} object itself. Partial matching is not performed.

\textbf{Details}

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the \texttt{formula} method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables $g_1, g_2, \ldots$, a separate “packet” is produced, consisting of the points $(x, y)$ for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the \texttt{layout} argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for \texttt{index.cond} above).

The coordinate system used by \texttt{lattice} by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless \texttt{as.table = TRUE}, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to \texttt{as.table = TRUE}; this can be done by setting \texttt{lattice.options(default.args = list(as.table = TRUE))}. Default values can be set in this manner for the following arguments: \texttt{as.table}, \texttt{aspect}, \texttt{between}, \texttt{page}, \texttt{main}, \texttt{sub}, \texttt{par.strip.text}, \texttt{layout}, \texttt{skip} and \texttt{strip}. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with $g_1$ varying fastest, followed by $g_2$, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the \texttt{index.cond} and \texttt{perm.cond} arguments, possibly using the \texttt{update} (and other related) method(s).

\textbf{Value}

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class “\texttt{trellis}”. The \texttt{update} method can be used to subsequently update components of the object, and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.

\textbf{Note}

Most of the arguments documented here are also applicable for the other high-level functions in the \texttt{lattice} package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

## Time series plotting methods

### Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.
Usage

## S3 method for class 'ts'
xyplot(x, data = NULL,
    screens = if (superpose) 1 else colnames(x),
    ..., 
    superpose = FALSE,
    cut = FALSE,
    type = "l",
    col = NULL,
    lty = NULL,
    lwd = NULL,
    pch = NULL,
    cex = NULL,
    fill = NULL,
    auto.key = superpose,
    panel = if (superpose) "panel.superpose"
    else "panel.superpose.plain",
    par.settings = list(),
    layout = NULL, as.table = TRUE,
    xlab = "Time", ylab = NULL,
    default.scales = list(y = list(relation =
      if (missing(cut)) "free" else "same")))

Arguments

x
  an object of class ts, which may be multi-variate, i.e. have a matrix structure
  with multiple columns.

data
  not used, and must be left as NULL.
...
  additional arguments passed to xyplot, which may pass them on to
  panel.xyplot.
screens
  factor (or coerced to factor) whose levels specify which panel each series is to
  be plotted in. screens = c(1, 2, 1) would plot series 1, 2 and 3 in panels 1, 2
  and 1. May also be a named list, see Details below.
superpose
  overlays all series in one panel (via screens = 1) and uses grouped style settings
  (from trellis.par.get("superpose.line"), etc). Note that this is just a
  convenience argument: its only action is to change the default values of other
  arguments.
cut
  defines a cut-and-stack plot. cut can be a list of arguments to the function
  equal.count, i.e. number (number of intervals to divide into) and overlap (the
  fraction of overlap between cuts, default 0.5). If cut is numeric this is passed as
  the number argument.
cut = TRUE tries to choose an appropriate number of cuts (up to a maximum of
  6), using banking, and assuming a square plot region. This should have the
  effect of minimising wasted space when aspect = "xy".
type, col, lty, lwd, pch, cex, fill
  graphical arguments, which are processed and eventually passed to
  panel.xyplot. These arguments can also be vectors or (named) lists, see De-
  tails for more information.
auto.key
  a logical, or a list describing how to draw a key. See the auto.key entry in
  xyplot. The default here is to draw lines, not points, and any specified style
  arguments should show up automatically.
the panel function. It is recommended to leave this alone, but one can pass a
`panel.groups` argument which is handled by `panel.superpose` for each series.

The handling of several graphical parameters is more flexible for multivariate series. These param-
eters can be vectors of the same length as the number of series plotted or are recycled if shorter.
They can also be (partially) named list, e.g., `list(A = c(1,2), c(3,4))` in which `c(3, 4)` is the
default value and `c(1, 2)` the value only for series `A`. The `screens` argument can be specified in a
similar way.

Some examples are given below.

An object of class "trellis". The `update` method can be used to update components of the object
and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <felix@nfrac.org>.
The first two authors developed `xyplot.ts` in their `zoo` package, including the `screens` approach.
The third author developed a different `xyplot.ts` for cut-and-stack plots in the `latticeExtra` pack-
age. The final author fused these together.

`xyplot, panel.xyplot, plot.ts, ts, xyplot.zoo` in the `zoo` package.

xyplot(ts(c(1:10,10:1)))

```r
## Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
```
### A multivariate example; first juxtaposed, then superposed

```r
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
       type = c("l", "g"), ylim = c(0, max(EuStockMarkets)))
```

### Examples using screens (these two are identical)

```r
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))
```

### Automatic group styles

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)
```

### Specifying styles for series by name

```r
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)
```

### Example with simpler data, few data points

```r
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
```

```r
xyplot(z, screens = list(a = "primary (a)", "other (b & c)",
                        type = list(a = c("p", "h"), b = c("p", "s"), "o"),
pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

## Description

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

## Usage

```r
### S3 method for class 'table'
barchart(x, data, groups = TRUE,
         origin = 0, stack = TRUE, ..., horizontal = TRUE)
```

```r
### S3 method for class 'array'
barchart(x, data, ...)
```
## S3 method for class 'matrix'
barchart(x, data, ...)

## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)

### Arguments

- **x**: A table, array or matrix object.
- **data**: Should not be specified. If specified, will be ignored with a warning.
- **groups**: A logical flag, indicating whether to use the last dimension as a grouping variable in the display.
- **origin, stack**: Arguments to `panel.barchart`. The defaults for the table method are different.
- **horizontal**: Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
- **...**: Other arguments, passed to the underlying `formula` method.

### Details

The first dimension is used as the variable on the categorical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument beforehand using `t` or `aperm`). For more flexibility, use the formula method after converting the table to a data frame using the relevant `as.data.frame` method.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Histograms and Kernel Density Plots

Description

Draw Histograms and Kernel Density Plots, possibly conditioned on other variables.

Usage

```r
histogram(x, data, ...)
densityplot(x, data, ...)
## S3 method for class 'formula'
histogram(x, data, allow.multiple, outer = TRUE, auto.key = FALSE, aspect = "fill", panel = lattice.getOption("panel.histogram"), prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, type = c("percent", "count", "density"), nint = if (is.factor(x)) nlevels(x) else round(log2(length(x)) + 1), endpoints = extend.limits(range(as.numeric(x), finite = TRUE), prop = 0.04), breaks, equal.widths = TRUE, drop.unused.levels = lattice.getOption("drop.unused.levels"), ..., lattice.options = NULL, default.scales = list(), default.prepanel = lattice.getOption("prepanel.default.histogram"), subscripts, subset)
## S3 method for class 'numeric'
histogram(x, data = NULL, xlab, ...)
## S3 method for class 'factor'
histogram(x, data = NULL, xlab, ...)
## S3 method for class 'formula'
densityplot(x, data, allow.multiple = is.null(groups) || outer, outer = !is.null(groups), auto.key = FALSE, aspect = "fill", panel = lattice.getOption("panel.densityplot"), prepanel, scales, strip, groups, weights,
```
xlab, xlim, ylab, ylim,
bw, adjust, kernel, window, width, give.Rkern,
n = 512, from, to, cut, na.rm,
drop.unused.levels =
  lattice.getOption("drop.unused.levels"),
..., lattice.options = NULL,
default.scales = list(),
default.prepanel =
  lattice.getOption("prepanel.default.densityplot"),
subscripts,
subset)

## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...) 
do.broken(endpoints, nint)

Arguments

x
  The object on which method dispatch is carried out.
  For the formula method, x can be a formula of the form \( ~x \mid g1 \ast g2 \ast \ldots \),
  indicating that histograms or kernel density estimates of the x variable should
  be produced conditioned on the levels of the (optional) variables g1, g2, \ldots
  x should be numeric (or possibly a factor in the case of histogram), and each of
  g1, g2, \ldots should be either factors or shingles.
  As a special case, the right hand side of the formula can contain more than one
  term separated by '+' signs (e.g., \( ~x1 + x2 \mid g1 \ast g2 \)). What happens in this
  case is described in the documentation for xyplot. Note that in either form, all
  the terms in the formula must have the same length after evaluation.
  For the numeric and factor methods, x is the variable whose histogram or
  Kernel density estimate is drawn. Conditioning is not allowed in these cases.

data
  For the formula method, an optional data source (usually a data frame) in which
  variables are to be evaluated (see xyplot for details). data should not be speci-
  fied for the other methods, and is ignored with a warning if it is.

type
  A character string indicating the type of histogram that is to be drawn.
  "percent" and "count" give relative frequency and frequency histograms re-
  spectively, and can be misleading when breakpoints are not equally spaced.
  "density" produces a density histogram.
  type defaults to "density" when the breakpoints are unequally spaced, and
  when breaks is NULL or a function, and to "percent" otherwise.

nint
  An integer specifying the number of histogram bins, applicable only when
  breaks is unspecified or NULL in the call. Ignored when the variable being
  plotted is a factor.

drop.unused.levels =
  lattice.getOption("drop.unused.levels"),
...,

lattice.options = NULL,
default.scales = list(),
default.prepanel =
  lattice.getOption("prepanel.default.densityplot"),
subscripts,
subset)

## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...) 
do.broken(endpoints, nint)

Arguments

x
  The object on which method dispatch is carried out.
  For the formula method, x can be a formula of the form \( ~x \mid g1 \ast g2 \ast \ldots \),
  indicating that histograms or kernel density estimates of the x variable should
  be produced conditioned on the levels of the (optional) variables g1, g2, \ldots
  x should be numeric (or possibly a factor in the case of histogram), and each of
  g1, g2, \ldots should be either factors or shingles.
  As a special case, the right hand side of the formula can contain more than one
  term separated by '+' signs (e.g., \( ~x1 + x2 \mid g1 \ast g2 \)). What happens in this
  case is described in the documentation for xyplot. Note that in either form, all
  the terms in the formula must have the same length after evaluation.
  For the numeric and factor methods, x is the variable whose histogram or
  Kernel density estimate is drawn. Conditioning is not allowed in these cases.

data
  For the formula method, an optional data source (usually a data frame) in which
  variables are to be evaluated (see xyplot for details). data should not be speci-
  fied for the other methods, and is ignored with a warning if it is.

type
  A character string indicating the type of histogram that is to be drawn.
  "percent" and "count" give relative frequency and frequency histograms re-
  spectively, and can be misleading when breakpoints are not equally spaced.
  "density" produces a density histogram.
  type defaults to "density" when the breakpoints are unequally spaced, and
  when breaks is NULL or a function, and to "percent" otherwise.

default.prepanel =
  lattice.getOption("prepanel.default.densityplot"),
subscripts,
subset)

## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...) 
do.broken(endpoints, nint)

Arguments

x
  The object on which method dispatch is carried out.
  For the formula method, x can be a formula of the form \( ~x \mid g1 \ast g2 \ast \ldots \),
  indicating that histograms or kernel density estimates of the x variable should
  be produced conditioned on the levels of the (optional) variables g1, g2, \ldots
  x should be numeric (or possibly a factor in the case of histogram), and each of
  g1, g2, \ldots should be either factors or shingles.
  As a special case, the right hand side of the formula can contain more than one
  term separated by '+' signs (e.g., \( ~x1 + x2 \mid g1 \ast g2 \)). What happens in this
  case is described in the documentation for xyplot. Note that in either form, all
  the terms in the formula must have the same length after evaluation.
  For the numeric and factor methods, x is the variable whose histogram or
  Kernel density estimate is drawn. Conditioning is not allowed in these cases.

data
  For the formula method, an optional data source (usually a data frame) in which
  variables are to be evaluated (see xyplot for details). data should not be speci-
  fied for the other methods, and is ignored with a warning if it is.

type
  A character string indicating the type of histogram that is to be drawn.
  "percent" and "count" give relative frequency and frequency histograms re-
  spectively, and can be misleading when breakpoints are not equally spaced.
  "density" produces a density histogram.
  type defaults to "density" when the breakpoints are unequally spaced, and
  when breaks is NULL or a function, and to "percent" otherwise.

nint
  An integer specifying the number of histogram bins, applicable only when
  breaks is unspecified or NULL in the call. Ignored when the variable being
  plotted is a factor.

drop.unused.levels =
  lattice.getOption("drop.unused.levels"),
...,
When `breaks` is unspecified, the value of `lattice.getOption("histogram.breaks")` is first checked. If this value is `NULL`, then the default is to use

```
breaks = seq_len(1 + nlevels(x)) - 0.5
```

when `x` is a factor, and

```
breaks = do.breaks(endpoints, nint)
```

otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not `NULL`, or if `breaks` is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the `breaks` argument in `hist`. In particular, this allows specification of `breaks` as an integer giving the number of bins (similar to `nint`), as a character string denoting a method, or as a function.

When specified explicitly, a special value of `breaks` is `NULL`, in which case the number of bins is determined by `nint` and then breakpoints are chosen according to the value of `equal.widths`.

`equal.widths` A logical flag, relevant only when `breaks=NULL`. If `TRUE`, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints).

`n` Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to `density`.

`panel` A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions `panel.histogram` and `panel.densityplot` are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

`allow.multiple`, `outer` See `xyplot`.

`auto.key` See `xyplot`.

`aspect` See `xyplot`.

`prepanel` See `xyplot`.

`scales` See `xyplot`.

`strip` See `xyplot`.

`groups` See `xyplot`. Note that the default panel function for `histogram` does not support grouped displays, whereas the one for `densityplot` does.

`xlab`, `ylab` See `xyplot`.

`xlim`, `ylim` See `xyplot`.

`drop.unused.levels` See `xyplot`.

`lattice.options` See `xyplot`.

`default.scales` See `xyplot`.

`subscripts` See `xyplot`.

`subset` See `xyplot`.
default.prepanel
   Fallback prepanel function. See xyplot.

weights
   numeric vector of weights for the density calculations, evaluated in the non-
   standard manner used for groups and terms in the formula, if any. If this is
   specified, it is subbed using subscripts inside the panel function to match it
   to the corresponding x values.
   At the time of writing, weights do not work in conjunction with an extended
   formula specification (this is not too hard to fix, so just bug the maintainer if you
   need this feature).

bw, adjust, width
   Arguments controlling bandwidth. Passed on as arguments to density.

kernel, window
   The choice of kernel. Passed on as arguments to density.

give.Rkern
   Logical flag, passed on as argument to density. This argument is made avail-
   able only for ease of implementation, and will produce an error if TRUE.

from, to, cut
   Controls range over which density is evaluated. Passed on as arguments to
   density.

na.rm
   Logical flag specifying whether NA values should be ignored. Passed on as ar-
   gument to density, but unlike in density, the default is TRUE.

...
   Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

histogram draws Conditional Histograms, and densityplot draws Conditional Kernel Density
Plots. The default panel function uses the density function to compute the density estimate, and
all arguments accepted by density can be specified in the call to densityplot to control the output.
See documentation of density for details.

These and all other high level Trellis functions have several arguments in common. These are
extensively documented only in the help page for xyplot, which should be consulted to learn more
detailed usage.

do.breaks is an utility function that calculates breakpoints given an interval and the number of
pieces to break it into.

Value

An object of class "trellis". The update method can be used to update components of the object
and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

The form of the arguments accepted by the default panel function panel.histogram is different
from that in S-PLUS. Whereas S-PLUS calculates the heights inside histogram and passes only the
breakpoints and the heights to the panel function, lattice simply passes along the original variable x
along with the breakpoints. This approach is more flexible; see the example below with an estimated
density superimposed over the histogram.

            panel.histogram(x, ...)
            panel.mathdensity(dmath = dnorm, col = "black",
                              args = list(mean=mean(x),sd=sd(x)))
          }
)

densityplot(~ height | voice.part, data = singer, layout = c(2, 4),
            xlab = "Height (inches)", bw = 5)
```

**Q-Q Plot with Theoretical Distribution**

Description

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

Usage

```r
qqmath(x, data, ...)
```

## S3 method for class 'formula'
```
qqmath(x, data, allow.multiple = is.null(groups) || outer,
       outer = !is.null(groups), distribution = qnorm,
       f.value = NULL,
       auto.key = FALSE,
       aspect = "fill",
       panel = lattice.getOption("panel.qqmath",)
       prepanel = NULL,
       scales, strip, groups,
       xlab, xlim, ylab, ylim,
       drop.unused.levels = lattice.getOption("drop.unused.levels"),
```
...,
lattice.options = NULL,
default.scales = list(),
default.prepanel = lattice.getOption("prepanel.default.qqmath"),
subscripts,
subset)

## S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)

Arguments

x The object on which method dispatch is carried out.
For the "formula" method, x should be a formula of the form ~ x | g1 * g2 * ...
where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.
data For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see `xyplot` for details). data should not be specified for the other methods, and is ignored with a warning if it is.
distribution A quantile function that takes a vector of probabilities as argument and produces
the corresponding quantiles from a theoretical distribution. Possible values are `qnorm`, `qunif`, etc. Distributions with other required arguments need to be provided as user-defined functions (see example with `qt`).
f.value An optional numeric vector of probabilities, quantiles corresponding to which
should be plotted. This can also be a function of a single integer (representing
sample size) that returns such a numeric vector. A typical value for this argument is the function `ppoints`, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the `quantile` function for the sample, and the function specified as the `distribution` argument for the theoretical distribution.
f.value defaults to `NULL`, which has the effect of using `ppoints` for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for `qqnorm`, but different from the S-PLUS default of `f.value=ppoints`.
For large `x`, this argument can be used to restrict the number of points plotted. See also the `tails.n` argument in `panel.qqmath`.
panel A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function `panel.qqmath` is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.
allow.multiple, outer
See `xyplot`.
auto.key See `xyplot`.
aspect See `xyplot`.
prepanel See `xyplot`.
scales See `xyplot`.
strip See `xyplot`.
groups See `xyplot`.
xlab, ylab See `xyplot`.
qqmath produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of qqmath is different from the corresponding S-PLUS function, but is similar to qqnorm. See the entry for f.value for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not qqmath itself. In fact, both the arguments distribution and f.value are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for panel.qqmath for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

qqmath(~ height | voice.part, aspect = "xy", data = singer,
      prepanel = prepanel.qqmathline,
      panel = function(x, ...) {
        panel.qqmathline(x, ...)
        panel.qqmath(x, ...)
      })

vp.comb <- factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
                      "[", 1),
              levels = c("Bass", "Tenor", "Alto", "Soprano"))
```
vp.group <-
    factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
             "[", 2))
qqmath(~ height | vp.comb, data = singer,
       groups = vp.group, auto.key = list(space = "right"),
       aspect = "xy",
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
            panel.qqmathline(x, ...) 
            panel.qqmath(x, ...) 
       })

Quantile-Quantile Plots of Two Samples

Description
Quantile-Quantile plots for comparing two Distributions

Usage
qq(x, data, ...)
## S3 method for class 'formula'
qq(x, data, aspect = "fill",
    panel = lattice.getOption("panel.qq"),
    prepanel, scales, strip,
    groups, xlab, xlim, ylab, ylim, f.value = NULL,
    drop.unused.levels = lattice.getOption("drop.unused.levels"),
    ..., 
    lattice.options = NULL,
    qtype = 7,
    default.scales = list(),
    default.prepanel = lattice.getOption("prepanel.default.qq"),
    subscripts,
    subset)

Arguments
x The object on which method dispatch is carried out.
For the "formula" method, x should be a formula of the form y ~ x | g1 * g2 * 
   ..., where x should be a numeric variable, and y a factor, shingle, character, or
   numeric variable, with the restriction that there must be exactly two levels of y,
   which divide the values of x into two groups. Quantiles for these groups will be
   plotted against each other along the two axes.
data For the formula method, an optional data source (usually a data frame) in which
   variables are to be evaluated (see xyplot for details).
f.value An optional numeric vector of probabilities, quantiles corresponding to which
   should be plotted. This can also be a function of a single integer (representing
   sample size) that returns such a numeric vector. A typical value for this argument
   is the function ppoints, which is also the S-PLUS default. If specified, the
The probabilities generated by this function is used for the plotted quantiles, through the quantile function.

\( f \).value defaults to NULL, which is equivalent to

\[
f \text{.value} = \text{function}(n) \, \text{ppoints}(n, a = 1)
\]

This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for qqplot but different from the default behaviour of qq in S-PLUS.

For large \( x \), this argument can be used to restrict the number of quantiles plotted.

**panel**

A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function `panel.qq` is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

**qtype**

The type argument for quantile.

**aspect**

See `xyplot`.

**prepanel**

See `xyplot`.

**scales**

See `xyplot`.

**strip**

See `xyplot`.

**groups**

See `xyplot`.

**xlab, ylab**

See `xyplot`.

**xlim, ylim**

See `xyplot`.

**drop.unused.levels**

See `xyplot`.

**lattice.options**

See `xyplot`.

**default.scales**

See `xyplot`.

**subscripts**

See `xyplot`.

**subset**

See `xyplot`.

**default.prepanel**

Fallback prepanel function. See `xyplot`.

... Further arguments. See corresponding entry in `xyplot` for non-trivial details.

**Details**

qq produces Q-Q plots of two samples. The default behaviour of qq is different from the corresponding S-PLUS function. See the entry for \( f \).value for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

## S3 method for class 'array'
levelplot(x, data = NULL, ...)  

## S3 method for class 'array'
contourplot(x, data = NULL, ...)  

### Arguments

- **x**: for the formula method, a formula of the form \( z \sim x \times y | g_1 \times g_2 \times \ldots \), where \( z \) is a numeric response, and \( x, y \) are numeric values evaluated on a rectangular grid. \( g_1, g_2, \ldots \) are optional conditional variables, and must be either factors or shingles if present.
  
  Calculations are based on the assumption that all \( x \) and \( y \) values are evaluated
on a grid (defined by their unique values). The function will not return an error
if this is not true, but the display might not be meaningful. However, the x and
y values need not be equally spaced.

Both levelplot and wireframe have methods for matrix, array, and table
objects, in which case x provides the z vector described above, while its rows
and columns are interpreted as the x and y vectors respectively. This is similar
to the form used in filled.contour and image. For higher-dimensional arrays
and tables, further dimensions are used as conditioning variables. Note that
the dimnames may be duplicated; this is handled by calling make.unique to make
the names unique (although the original labels are used for the x- and y-axes).

data
For the formula methods, an optional data frame in which variables in the for-
maula (as well as groups and subset, if any) are to be evaluated. Usually ignored
with a warning in other cases.

row.values, column.values
Optional vectors of values that define the grid when x is a matrix. row.values
and column.values must have the same lengths as nrow(x) and ncol(x) re-
spectively. By default, row and column numbers.

panel
panel function used to create the display, as described in xyplot

aspect
For the matrix methods, the default aspect ratio is chosen to make each cell
square. The usual default is aspect="fill", as described in xyplot.

at
A numeric vector giving breakpoints along the range of z. Contours (if any) will
be drawn at these heights, and the regions in between would be colored using
col.regions. In the latter case, values outside the range of at will not be drawn
at all. This serves as a way to limit the range of the data shown, similar to what
a zlim argument might have been used for. However, this also means that when
supplying at explicitly, one has to be careful to include values outside the range
of z to ensure that all the data are shown.

at can have length one only if region=FALSE.

col.regions
color vector to be used if regions is TRUE. The general idea is that this should be
a color vector of moderately large length (longer than the number of regions. By
default this is 100). It is expected that this vector would be gradually varying in
color (so that nearby colors would be similar). When the colors are actually chosen,
they are chosen to be equally spaced along this vector. When there are more
regions than colors in col.regions, the colors are recycled. The actual color
assignment is performed by level.colors, which is documented separately.

alpha.regions
Numeric, specifying alpha transparency (works only on some devices)

colorkey
A logical flag specifying whether a colorkey is to be drawn alongside the plot, or
a list describing the colorkey. The list may contain the following components:

space: location of the colorkey, can be one of "left", "right", "top" and
"bottom". Defaults to "right".

x, y: location, currently unused

col: A color ramp specification, as in the col.regions argument in

level.colors

at: A numeric vector specifying where the colors change. must be of length 1
more than the col vector.

tri.lower, tri.upper: Logical or numeric controlling whether the first and
last intervals should be triangular instead of rectangular. With the default
value (NA), this happens only if the corresponding extreme at values are
-Inf or Inf respectively, and the triangles occupy 5% of the total length
of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5\% when specified as \texttt{TRUE}.

**labels:** A character vector for labelling the \texttt{at} values, or more commonly, a list describing characteristics of the labels. This list may include components \texttt{labels}, \texttt{at}, \texttt{cex}, \texttt{col}, \texttt{rot}, \texttt{font}, \texttt{fontface} and \texttt{fontfamily}.

**title:** Usually a character vector or expression providing a title for the colorkey, or a list controlling the title in further detail, or an arbitrary "grob". For details of how the list form is interpreted, see the entry for \texttt{main} in \texttt{xyplot}; generally speaking, the actual label should be specified as the label component (which may be unnamed if it is the first component), and the remaining arguments are used as appropriate in a call to \texttt{textGrob}. Further control of the placement of the title is possible through the component \texttt{title.control}. In particular, if a \texttt{rot} component is not specified, its default depends on the value of \texttt{title.control$side} (0 for top or bottom, and 90 for left or right).

\texttt{title} defaults to \texttt{NULL}, which means no title is drawn.

**tick.number:** The approximate number of ticks desired.

**tck:** A (scalar) multiplier for tick lengths.

**corner:** Interacts with \texttt{x}, \texttt{y}; currently unimplemented.

**width:** The width of the key.

**height:** The length of key as a fraction of the appropriate side of plot.

**raster:** A logical flag indicating whether the colorkey should be rendered as a raster image using \texttt{grid.raster}. See also \texttt{panel.levelplot.raster}.

**interpolate:** Logical flag, passed to \texttt{rasterGrob} when \texttt{raster=TRUE}.

**axis.line:** A list giving graphical parameters for the color key boundary and tick marks. Defaults to \texttt{trellis.par.get("axis.line")}.

**axis.text:** A list giving graphical parameters for the tick mark labels on the color key. Defaults to \texttt{trellis.par.get("axis.text")}.

**contour:** A logical flag, indicating whether to draw contour lines.

**cuts:** The number of levels the range of \texttt{z} would be divided into.

**labels** Typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for \texttt{panel.levelplot}, to which this argument is passed on unchanged. That help page also documents the \texttt{label.style} argument, which affects how the labels are rendered.

**pretty** A logical flag, indicating whether to use pretty cut locations and labels.

**region** A logical flag, indicating whether regions between contour lines should be filled as in a level plot.

**allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset** These arguments are described in the help page for \texttt{xyplot}.

**default.prepanel** Fallback prepanel function. See \texttt{xyplot}.
Further arguments may be supplied. Some are processed by levelplot or contourplot, and those that are unrecognized are passed on to the panel function.

**useRaster**

A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to TRUE changes the default panel function from `panel.levelplot` to `panel.levelplot.raster`, and sets the default value of `colorkey$raster` to TRUE.

Note that `panel.levelplot.raster` provides only a subset of the features of `panel.levelplot`, but setting `useRaster=TRUE` will not check whether any of the additional features have been requested.

Not all devices support raster images. For devices that appear to lack support, `useRaster=TRUE` will be ignored with a warning.

**Details**

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**B_07_cloud**

**3d Scatter Plot and Wireframe Surface Plot**

**Description**

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

**Usage**

```r
cloud(x, data, ...)
wireframe(x, data, ...)
```

### S3 method for class 'formula'
```r
cloud(x, data,
   allow.multiple = is.null(groups) || outer,
   outer = FALSE,
   auto.key = FALSE,
   aspect = c(1,1),
   panel.aspect = 1,
   panel = lattice.getOption("panel.cloud"),
   prepanel = NULL,
   scales = list(),
   strip = TRUE,
   groups = NULL,
   xlim, xlab,
   ylim, ylab,
   zlim, zlab,
   x1lim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
   y1lim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
   z1lim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
```

cloud(x, data = NULL, groups = FALSE,
zlab = deparse(substitute(x)),
type = "h", ...)

## S3 method for class 'matrix'
wireframe(x, data = NULL,
zlab = deparse(substitute(x)), aspect, ...,
xlim, ylim, row.values, column.values)

Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula of the form z ~ x * y | g1 * g2 * ...., where z is a numeric response, and x, y are numeric values. g1, g2, ..., if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of wireframe, calculations are based on the assumption that the x and y values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.

For wireframe, x, y and z may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.
Missing values are allowed, either as \texttt{NA} values in the \texttt{z} vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but \texttt{NA}-s in \texttt{z} are.

Both \texttt{wireframe} and \texttt{cloud} have methods for \texttt{matrix} objects, in which case \texttt{x} provides the \texttt{z} vector described above, while its rows and columns are interpreted as the \texttt{x} and \texttt{y} vectors respectively. This is similar to the form used in \texttt{persp}.

\texttt{data} for the "formula" methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. \texttt{data} should not be specified except when using the "formula" method.

\texttt{row.values, column.values} Optional vectors of values that define the grid when \texttt{x} is a matrix. \texttt{row.values} and \texttt{column.values} must have the same lengths as \texttt{nrow(x)} and \texttt{ncol(x)} respectively. By default, row and column numbers.

\texttt{allow.multiple}, \texttt{outer}, \texttt{auto.key}, \texttt{prepanel}, \texttt{strip}, \texttt{groups}, \texttt{xlab}, \texttt{xlim}, \texttt{ylab}, \texttt{ylim}, \texttt{drop.unused.levels}, \texttt{subsets}

These arguments are documented in the help page for \texttt{xyplot}. For the \texttt{cloud.table} method, \texttt{groups} must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.

\texttt{type} type of display in \texttt{cloud} (see \texttt{panel.3dscatter} for details). Defaults to "h" for the \texttt{matrix} method.

\texttt{aspect, panel.aspect}

Unlike other high level functions, \texttt{aspect} is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the aspect argument in determining the aspect ratio of the panel (see \texttt{xyplot} for details) is played by \texttt{panel.aspect}, except that it can only be a numeric value.

For the \texttt{matrix} methods, the default y/x aspect is \texttt{ncol(x) / nrow(x)} and the z/x aspect is the smaller of the y/x aspect and 1.

\texttt{panel} panel function used to create the display. See \texttt{panel.cloud} for (non-trivial) details.

\texttt{default.prepanel}

Fallback prepanel function. See \texttt{xyplot}.

\texttt{scales} a list describing the scales. As with other high level functions (see \texttt{xyplot} for details), this list can contain parameters in name=value form. It can also contain components with the special names \texttt{x}, \texttt{y} and \texttt{z}, which can be similar lists with axis-specific values overriding the ones specified in \texttt{scales}.

The most common use for this argument is to set \texttt{arrows=FALSE}, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by \texttt{draw=FALSE}. Another special component is \texttt{distance}, which specifies the relative distance of the axis label from the bounding box. If specified as a component of \texttt{scales} (as opposed to one of \texttt{scales$x} etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the \texttt{x}, \texttt{y} and \texttt{z} labels respectively.

Other components that work in the \texttt{scales} argument of \texttt{xyplot} etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)
Note, however, that for these functions scales cannot contain information that is specific to particular panels. If you really need that, consider using the scales.3d argument of panel.cloud.

**axs.default**

Unlike 2-D display functions, cloud does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in wireframe, which uses the same code. axs.default is intended to provide a different default for cloud. However, this feature has not yet been implemented.

**zlab**

Specifies a label describing the z variable in ways similar to xlab and ylab (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if zlab (and xlab and ylab) is a list, it can contain a component called rot, controlling the rotation for the label.

**zlim**

limits for the z-axis. Similar to xlim and ylim in other high level functions.

**drape**

logical, whether the wireframe is to be draped in color. If TRUE, the height of a facet is used to determine its color in a manner similar to the coloring scheme used in levelplot. Otherwise, the background color is used to color the facets. This argument is ignored if shade = TRUE (see panel.3dwire).

**at, col.regions, alpha.regions**

these arguments are analogous to those in levelplot, if drape=TRUE, at gives the vector of cutpoints where the colors change, and col.regions the vector of colors to be used in that case, alpha.regions determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for col.regions and alpha.regions is derived from the Trellis setting "regions".

**cuts**

if at is unspecified, the approximate number of cutpoints if drape=TRUE

**pretty**

whether automatic choice of cutpoints should be prettified

**colorkey**

logical indicating whether a color key should be drawn alongside, or a list describing such a key. See levelplot for details.

... Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments distance, perspective, screen and R.mat are very important in determining the 3-D display. The argument shade can be useful for wireframe calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for panel.cloud. Additionally, an argument called zoom may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default prepanel function.

**Details**

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the [-0.5, 0.5] cube (even smaller for non-default values of aspect). The viewing direction is given by a sequence of rotations specified by the screen argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of 1/distance from the origin. If perspective=FALSE, distance is set to 0 (i.e., the viewing point is at an infinite distance).

cloud draws a 3-D Scatter Plot, while wireframe draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by wireframe using the groups argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying groups with cloud results in a panel.superpose-like effect (via panel.3dscatter).
wireframe can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for `panel.3dwire`. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form \( f(u,v) = (x(u,v), y(u,v), z(u,v)) \), where values of \((u,v)\) lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula \( x \) of the form \( z~x*y \), where \( x, y \) and \( z \) are all matrices of the same dimension, representing the values of \( x(u,v), y(u,v) \) and \( z(u,v) \) evaluated on a discrete rectangular grid (the actual values of \((u,v)\) are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the \( z \) values, but the distances of \((x,y,z)\) from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

There is a known problem with grouped `wireframe` displays when the \((x, y)\) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an `NA` response \((z)\) in rows that were previously missing.

parallelplot(x, data = NULL, ..., groups = NULL, subset = TRUE)

## S3 method for class 'data.frame'
parallelplot(x, data = NULL, ..., groups = NULL, subset = TRUE)

### Arguments

- **x**
  - The object on which method dispatch is carried out.
  - For the "formula" method, a formula describing the structure of the plot, which should be of the form ~ x | g1 * g2 * .... where x is a data frame or matrix. Each of g1, g2, ... must be either factors or shingles. The conditioning variables g1, g2, ... may be omitted.
  - For the data.frame methods, a data frame.

- **data**
  - For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated.

- **aspect**
  - aspect ratio of each panel (and subpanel), square by default for splom.

- **between**
  - to avoid confusion between panels and subpanels, the default is to show the panels of a splom plot with space between them.

- **panel**
  - For parallelplot, this has the usual interpretation, i.e., a function that creates the display within each panel.
  - For splom, the terminology is slightly complicated. The role played by the panel function in most other high-level functions is played here by the superpanel function, which is responsible for the display for each conditional data subset. panel is simply an argument to the default superpanel function panel.pairs, and is passed on to it unchanged. It is used there to create each pairwise display. See panel.pairs for more useful options.

- **superpanel**
  - function that sets up the splom display, by default as a scatterplot matrix.

- **pscales**
  - a numeric value or a list, meant to be a less functional substitute for the scales argument in xyplot etc. This argument is passed to the superpanel function, and is handled by the default superpanel function panel.pairs. The help page for the latter documents this argument in more detail.

- **varnames**
  - A character or expression vector or giving names to be used for the variables in x. By default, the column names of x.

- **horizontal.axis**
  - logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).

- **auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset**
  - See xyplot

- **default.prepanel**
  -Fallback prepanel function. See xyplot.

- **...**
  - Further arguments. See corresponding entry in xyplot for non-trivial details.
Details

splom produces Scatter Plot Matrices. The role usually played by panel is taken over by superpanel, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both x- and y-limits from 0.5 to ncol(z) + 0.5. The only built-in option currently available is panel.pairs, which calls a further panel function for each pair (i, j) of variables in z inside a rectangle of unit width and height centered at c(i, j) (see panel.pairs for details).

Many of the finer customizations usually done via arguments to high level function like xyplot are instead done by panel.pairs for splom. These include control of axis limits, tick locations and prepanel calculations. If you are trying to fine-tune your splom plot, definitely look at the panel.pairs help page. The scales argument is usually not very useful in splom, and trying to change it may have undesired effects.

parallelplot draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value

An object of class “trellis”. The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Examples

```r
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
    panel = panel.superpose,
    key = list(title = "Three Varieties of Iris",
               columns = 3,
               points = list(pch = super.sym$pch[1:3],
                              col = super.sym$col[1:3]),
               text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3]|Species, data = iris,
    layout=c(2,2), pscales = 0,
    varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
    page = function(...) {
        ltext(x = seq(.6, .8, length.out = 4),
              y = seq(.9, .6, length.out = 4),
              labels = c("Three", "Varieties", "of", "Iris"),
              cex = 2)
    })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
              horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```
**Tukey Mean-Difference Plot**

**Description**

`tmd` creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The prepanel and panel functions are used as appropriate. The formula method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```r
 tmd(object, ...)  
```

### S3 method for class 'trellis'

```r
 tmd(object,  
 xlab = "mean",  
 ylab = "difference",  
 panel,  
 prepanel,  
 ...)  
```

```r
 prepanel.tmd.qqmath(x,  
 f.value = NULL,  
 distribution = qnorm,  
 qtype = 7,  
 groups = NULL,  
 subscripts, ...)  
```

```r
 panel.tmd.qqmath(x,  
 f.value = NULL,  
 distribution = qnorm,  
 qtype = 7,  
 groups = NULL,  
 subscripts, ...,  
 identifier = "tmd")  
```

```r
 panel.tmd.default(x, y, groups = NULL, ...,  
 identifier = "tmd")  
```

```r
 prepanel.tmd.default(x, y, ...)  
```

**Arguments**

- `object` An object of class "trellis" returned by `xyplot`, `qq` or `qqmath`.
- `xlab` x label
- `ylab` y label
- `panel` panel function to be used. See details below.
- `prepanel` prepanel function. See details below.
- `f.value, distribution, qtype` see `panel.qqmath`
- `groups, subscripts` see `xyplot`.

---

**Description**

`tmd` creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The prepanel and panel functions are used as appropriate. The formula method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```r
tmd(object, …)
```

### S3 method for class 'trellis'

```r
tmd(object,  
 xlab = "mean",  
 ylab = "difference",  
 panel,  
 prepanel,  
 …)
```

```r
prepanel.tmd.qqmath(x,  
 f.value = NULL,  
 distribution = qnorm,  
 qtype = 7,  
 groups = NULL,  
 subscripts, …)
```

```r
panel.tmd.qqmath(x,  
 f.value = NULL,  
 distribution = qnorm,  
 qtype = 7,  
 groups = NULL,  
 subscripts, …,  
 identifier = "tmd")
```

```r
panel.tmd.default(x, y, groups = NULL, …,  
 identifier = "tmd")
```

```r
prepanel.tmd.default(x, y, …)
```

**Arguments**

- `object` An object of class "trellis" returned by `xyplot`, `qq` or `qqmath`.
- `xlab` x label
- `ylab` y label
- `panel` panel function to be used. See details below.
- `prepanel` prepanel function. See details below.
- `f.value, distribution, qtype` see `panel.qqmath`
- `groups, subscripts` see `xyplot`.
x, y  
data as passed to panel functions in original call.
...
other arguments
identifier  
A character string that is prepended to the names of grobs that are created by this panel function.

Details
The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows:
the new coordinates are given by $x=(x+y)/2$ and $y=y-x$, which are then plotted. The default panel function(s) add a reference line at $y=0$ as well.
tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. tmd uses these panel arguments to set up its own scales (using its prepanel argument) and display (using panel). It is thus important to provide suitable prepanel and panel functions to tmd depending on the original call.
Such functions currently exist for xyplot, qq (the ones with default in their name) and qqmath, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the prepanel and panel arguments default to suitable choices.
tmd uses the update method for "trellis" objects, which processes all extra arguments supplied to tmd.

Value
An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Examples
```r
tmd(qqmath(~height | voice.part, data = singer))
```

Residual and Fit Spread Plots

Description
Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

Usage
```r
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL, distribution = qunif, panel, prepanel, strip, ...)
```
Arguments

model a fitted model object with methods fitted.values and residuals. Can be the value returned by oneway
layout default layout is c(2,1)
xlab defaults to "f.value"
distribution the distribution function to be used for qqmath
ylab, panel, prepanel, strip
See xyplot
...
other arguments, passed on to qqmath.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Fit One-way Model

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using rfs

Usage

oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))

Arguments

formula formula of the form y ~ x where y is the numeric response and x is the grouping factor
data data frame in which the model is to be evaluated
location function or numeric giving the location statistic to be used for centering the observations, e.g. median, 0 (to avoid centering).
spread function or numeric giving the spread statistic to be used for scaling the observations, e.g. sd, 1 (to avoid scaling).
Value

A list with components

- location: vector of locations for each group.
- spread: vector of spreads for each group.
- fitted.values: vector of locations for each observation.
- residuals: residuals (y - fitted.values).
- scaled.residuals: residuals scaled by spread for their group.

rfs, Lattice

Description

Initialization of a display device with appropriate graphical parameters.

Usage

trellis.device(device = getOption("device"),
               color = !(dev.name == "postscript"),
               theme = lattice.getOption("default.theme"),
               new = TRUE,
               retain = FALSE,
               ...)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()

Arguments

- device: function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see Devices), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.
- color: logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to trellis.par.set (and by arguments supplied directly in high level calls for some settings).
theme list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters.

A possible use of this argument is to change the default settings by specifying `lattice.options(default.theme = "col.whitebg")`. For back-compatibility, this is initially (when lattice is loaded) set to `getOption(lattice.theme)`. If `theme` is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use `.Device` inside the function to ascertain what device has been opened.

new logical flag indicating whether a new device should be started. If `FALSE`, the options for the current device are changed to the defaults determined by the other arguments.

retain logical. If `TRUE` and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).

name name of the device for which the setting is required, as returned by `.Device`

... additional parameters to be passed to the device function, most commonly file for non-screen devices, as well as height, width, etc. See the help file for individual devices for admissible arguments.

Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable "settings" list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which "theme" will be in effect when a new device is opened. `trellis.device` is called automatically when a "trellis" object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default theme argument, e.g. by putting `lattice.options(default.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the theme argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`. 
col.whitebg returns a similar (but smaller) list that is suitable as the theme argument to 
trellis.device and \texttt{trellis.par.set}. It contains settings values which provide colors suitable 
for plotting on a white background. Note that the name \texttt{col.whitebg} is somewhat of a misnomer, 
since it actually sets the background to transparent rather than white.

\textbf{Note}

Earlier versions of \texttt{trellis.device} had a \texttt{bg} argument to set the background color, but this is no 
longer supported. If supplied, the \texttt{bg} argument will be passed on to the device function; however, 
this will have no effect on the Trellis settings. It is rarely meaningful to change the background 
alone; if you feel the need to change the background, consider using the theme argument instead.

\textbf{See Also}

\texttt{Lattice} for an overview of the lattice package.
\texttt{Devices} for valid choices of device on your platform.
\texttt{trellis.par.get} and \texttt{trellis.par.set} can be used to query and modify the settings \textit{after} a 
device has been initialized. The \texttt{par.settings} argument to high level functions, described in 
\texttt{xyplot}, can be used to attach transient settings to a "trellis" object.
theme 

A list describing how to change the settings, similar to what is returned by `trellis.par.get()`. This is purely for convenience, allowing multiple calls to `trellis.par.set` to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.

As in `trellis.device`, theme can also be a function that produces such a list when called. The function name can be supplied as a quoted string.

Multiple settings can be specified in `name = value` form. Equivalent to calling with `theme = list(...)`

warn

A logical flag, indicating whether a warning should be issued when `trellis.par.get` is called when no graphics device is open.

strict

Usually a logical flag, indicating whether the value should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from value but not currently NULL are retained. By specifying `strict = TRUE`, such values will be removed.

An even stricter interpretation is allowed by specifying `strict` as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use.

x

Optional list of components that change the settings (any valid value of `theme`). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the name argument present, it returns that component only. `trellis.par.set` sets the value of the name component of the current active device settings to value.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```r
add.line <- trellis.par.get("add.line")
```
add.line$col <- "red"
trellis.par.set("add.line", add.line)

More convenient (but not S compatible) ways to do this are
trellis.par.set(list(add.line = list(col = "red")))
and
trellis.par.set(add.line = list(col = "red"))

The actual list of the components in trellis.settings has not been finalized, so I'm not attempting to list them here. The current value can be obtained by print(trellis.par.get()). Most names should be self-explanatory.

show.settings provides a graphical display summarizing some of the values in the current settings.

Value

trellis.par.get returns a list giving parameters for that component. If name is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

grid.pars  Grid graphical parameters that are in effect globally unless overridden by specific settings.

fontsize A list of two components (each a numeric scalar), text and points, for text and symbols respectively.

clip A list of two components (each a character string, either "on" or "off"), panel and strip.

axis.components A list with four components (left, top, right, bottom), each a list giving numeric multipliers named tck, pad1, and pad2 for corresponding grid layout units.

layout.heights A list with numeric multipliers for grid layout heights.

layout.widths A list with numeric multipliers for grid layout widths.

Note

In some ways, trellis.par.get and trellis.par.set together are a replacement for the par function used in traditional R graphics. In particular, changing par settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system does have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the grid.pars component (see gpar for a list of valid parameter names).

C_03_simpleTheme

Function to generate a simple theme

Description

Simple interface to generate a list appropriate as a theme, typically used as the par.settings argument in a high level call

Usage

simpleTheme(col, alpha,
            cex, pch, lty, lwd, font, fill, border,
            col.points, col.line,
            alpha.points, alpha.line)

Arguments

col, col.points, col.line
A color specification. col is used for components "plot.symbol", "plot.line", "plotpolygon", "superpose.symbol", "superpose.line", and "superposepolygon". col.points overrides col, but is used only for
"plot.symbol" and "superpose.symbol". Similarly, col.line overrides col for "plot.line" and "superpose.line". The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

alpha, alpha.points, alpha.line
A numeric alpha transparency specification. The same rules as col, etc., apply.

cex, pch, font
Parameters for points. Applicable for components plot.symbol (for which only the first component is used) and superpose.symbol (for which the arguments can be vectors).

lty, lwd
Parameters for lines. Applicable for components plot.line (for which only the first component is used) and superpose.line (for which the arguments can be vectors).

fill
fill color, applicable for components plot.symbol, plot.polygon, superpose.symbol, and superpose.polygon.

border
border color, applicable for components plot.polygon and superpose.polygon.

Details
The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see trellis.device for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the auto.key argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the par.settings argument, which is usually tedious to construct as it is a nested list. The simpleTheme function can be used in such situations as a wrapper that generates a suitable list given parameters in simple name-value form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

Value
A list that would work as the theme argument to trellis.device and trellis.par.set, or as the par.settings argument to any high level lattice function such as xyplot.

Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

dotplot(variety ~ yield | site, data = barley, groups = year,
    auto.key = list(space = "right"),
    par.settings = simpleTheme(pch = 16),
    xlab = "Barley Yield (bushels/acre) ",
    aspect=0.5, layout = c(1,6))
Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

Usage

lattice.options(...)
lattice.getOption(name)

Arguments

name character giving the name of a setting
...
new options can be defined, or existing ones modified, using one or more arguments of the form name = value or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

Details

These functions are modeled on options and getOption, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

panel.error A function, or NULL. If the former, every call to the panel function will be wrapped inside tryCatch with the specified function as an error handler. The default is to use the panel.error function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to NULL, errors in panel functions will not be caught using tryCatch.

save.object Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to TRUE.

layout.widths, layout.heights Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the grid function unit (x, units, and optionally data). Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using trellis.par.set.

drop.unused.levels A list of two components named cond and data, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See xyplot for more details. Note that this does not control dropping of levels of the 'groups' argument.

legend.bbox A character string, either "full" or "panel". This determines the interpretation of x and y when space="inside" in key (determining the legend; see xyplot): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

default.args A list giving default values for various standard arguments: as.table, aspect, between, skip, strip, xscale.components, yscale.components, and axis.
highlight.gpar A list giving arguments to gpar used to highlight a viewport chosen using trellis.focus.

banking The banking function. See banking.

axis.padding List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

skip.boundary.labels Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

interaction.sep The separator for creating interactions with the extended formula interface (see xyplot).

axis.units List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., panel.xyplot and prepanel.default.xyplot for xyplot. The options for the others have similarly patterned names.

Value

lattice.getOption returns the value of a single component, whereas lattice.options always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by lattice.options. If called without any arguments, the full list is returned.

summary(object, ...)
## S3 method for class 'trellis'
dim(x)
## S3 method for class 'trellis'
dimnames(x)

panel.error(e)
```

## Arguments

- `x, object` an object of class "trellis"
- `position` a vector of 4 numbers, typically c(xmin, ymin, xmax, ymax) that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of x is to be positioned. The coordinate system for this rectangle is [0-1] in both the x and y directions.
- `split` a vector of 4 integers, c(x,y,nx,ny), that says to position the current plot at the x,y position in a regular array of nx by ny plots. (Note: this has origin at top left)
- `more` A logical specifying whether more plots will follow on this page.
- `newpage` A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).
- `packet.panel` a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function `packet.panel.default`, whose help page details the arguments supplied to whichever function is specified as the `packet.panel` argument.
draw.in An optional (grid) viewport (used as the name argument in downViewport) in which the plot is to be drawn. If specified, the newpage argument is ignored. This feature is not well-tested.

panel.width, panel.height lists with 2 components, that should be valid x and units arguments to unit() (the data argument cannot be specified currently, but can be considered for addition if needed). The resulting unit object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.

Note that this option should not be used in conjunction with non-default values of the aspect argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).

save.object logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel’s data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the update method on the current plot, even if it was not assigned to a variable explicitly. For more details, see trellis.focus.

panel.error a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using tryCatch) and supplied as the only argument to panel.error. The default behaviour (implemented as the panel.error function) is to print the corresponding error message in the panel and continue. To stop execution on error, use panel.error = stop.

Normal error recovery and debugging tools are unhelpful when tryCatch is used. tryCatch can be completely bypassed by setting panel.error to NULL.

prefix A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently ":").

e an error condition caught by tryCatch

... extra arguments, ignored by the print method. All arguments to the plot method are passed on to the print method.

Details

This is the default print method for objects of class "trellis", produced by calls to functions like xyplot, bwplot etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments split and position.

When newpage = FALSE, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The draw.in argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in x (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.
Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see trellis.focus.

**Note**

Unlike S-PLUS, trying to position a multipage display (using position and/or split) will mess things up.

**Examples**

```r
p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab="Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

## Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport

## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
       layout = c(3, 2),
       panel = function(x, y, ...){
            panel.xyplot(x, y, ...)
            fm <- lm(y ~ poly(x, panel.number()))
            llines(x, predict(fm))
        })
```

```r
## Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:\n")
ltext(grid::grid.locator(), lab = "linear")
```

```r
## End(Not run)
grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")
grid::seekViewport(trellis.vpname("panel", 2, 1))
```
Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

Usage

```r
## S3 method for class 'trellis'
update(object,
panel,
aspect,
as.table,
between,
key,
auto.key,
legend,
layout,
main,
page,
par.strip.text,
prepanel,
scales,
skip,
strip,
strip.left,
sub,
xlab,
ylab,
xlab.top,
ylab.right,
xlim,
ylim,
xscale.components,
yscale.components,
axis,
```
Arguments

object, x  The object to be updated, of class \"trellis\".
i, j indices to be used. Names are not currently allowed.
drop logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip.text, prepanel arguments that will be used to update object. See details below.
prefix A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See \emph{trellis.focus}.

Details

All high level lattice functions such as \texttt{xyplot} produce an object of (S3) class \"trellis\", which is usually displayed by its \texttt{print} method. However, the object itself can be manipulated and modified to a large extent using the \texttt{update} method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the \texttt{update} method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the \texttt{formula}, \texttt{data}, \texttt{groups}, \texttt{subscripts} and \texttt{subset}). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by \texttt{update}, but the ones listed above should work. The purpose of these arguments are described in the help page for \texttt{xyplot}. Any other argument is added to the list of arguments to be passed to the \texttt{panel} function. Because of their somewhat special nature, updates to objects produced by \texttt{cloud} and \texttt{wireframe} do not work very well yet.

The \"[\" method is a convenient shortcut for updating \texttt{index.cond}. The \texttt{t} method is a convenient shortcut for updating \texttt{perm.cond} in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching (\textquote{transposing}) their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, \texttt{trellis.last.object} can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate
2762

C_07_shingles

prefix argument. If trellis.last.object is called with arguments, these are used to update the
retrieved object before returning it.
Value
An object of class trellis, by default plotted by print.trellis. trellis.last.object returns
NULL is no saved object is available.

C_07_shingles

shingles

Description
Functions to handle shingles
Usage
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)
## S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)
## S3 method for class 'shingle'
print(x, showValues = TRUE, ...)
## S3 method for class 'shingleLevel'
as.character(x, ...)
## S3 method for class 'shingleLevel'
print(x, ...)


## S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)

### Arguments

- **x**: numeric variable or R object, shingle in `plot.shingle` and `x[]`. An object (list of intervals) of class "shingleLevel" in `print.shingleLevel`
- **object**: shingle object to be summarized
- **showValues**: logical, whether to print the numeric part. If FALSE, only the intervals are printed
- **intervals**: numeric vector or matrix with 2 columns
- **subset**: logical vector
- **drop**: whether redundant shingle levels are to be dropped
- **panel, xlab, ylab**: standard Trellis arguments (see `xyplot`)
- **...**: other arguments, passed down as appropriate. For example, extra arguments to `equal.count` are passed on to `co.intervals`. Graphical parameters can be passed as arguments to the `plot` method.

### Details

A shingle is a data structure used in Trellis, and is a generalization of factors to 'continuous' variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the 'levels' of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

equal.count converts x to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

shingle creates a shingle using the given intervals. If `intervals` is a vector, these are used to form 0 length intervals.

as.shingle returns `shingle(x)` if x is not a shingle.

is.shingle tests whether x is a shingle.

plot.shingle displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

### Value

- x$intervals for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

print(levels(z))
Produce a Legend or Key

Description

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

Usage

draw.key(key, draw=FALSE, vp=NULL, ...)

Arguments

key A list determining the key. See documentation for xyplot, in particular the section describing the key argument, for details.
draw logical, whether the grob is to be drawn.
vp viewport
... ignored

Value

A Grid frame object (that inherits from ‘grob’).

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

xyplot

A function to compute false colors representing a numeric or categorical variable

Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

Usage

level.colors(x, at, col.regions, colors = TRUE, ...)

Arguments

x  A numeric or factor variable.
at  A numeric variable of breakpoints defining intervals along the range of x.
col.regions  A specification of the colors to be assigned to each interval defined by at. This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below.
colors  logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by at) each value in x falls into is returned.
...  Extra arguments, ignored.

Details

If at has length n, then it defines n-1 intervals. Values of x outside the range of at are not assigned to an interval, and the return value is NA for such values.

Colors are chosen by assigning a color to each of the n-1 intervals. If col.regions is a palette function (such as topo.colors, or the result of calling colorRampPalette), it is called with n-1 as an argument to obtain the colors. Otherwise, if there are exactly n-1 colors in col.regions, these get assigned to the intervals. If there are fewer than n-1 colors, col.regions gets recycled. If there are more, a more or less equally spaced (along the length of col.regions) subset is chosen.

Value

A vector of the same length as x. Depending on the colors argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of x fall in.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

levelplot, colorRampPalette.

Examples

depth.col <-
  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
    col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
  strip = strip.custom(var.name = "Stations"),
  colours = depth.col,
  panel = function(x, y, colours, subscripts, ...) {
    panel.xyplot(x, y, pch = 21, col = "transparent",
     fill = colours[subscripts], ...)
  })

D_make.groups

Grouped data from multiple vectors

Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

Usage

make.groups(...)

Arguments

... one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

Value

When all the input arguments are vectors, a data frame with two columns

data all the vectors supplied, concatenated

which factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of rbind applied to them, along with an additional which column as described above.

exponential = rexp(175),
lognormal = rlnorm(150),
normal = rnorm(125))
qqmath(~data | which, sim.dat, scales = list(y = "free"))
D_simpleKey

Function to generate a simple key

Description
Simple interface to generate a list appropriate for draw.key

Usage

dsimpleKey(text, points = TRUE,
rectangles = FALSE,
lines = FALSE,
col, cex, alpha, font,
fontface, fontfamily,
lineheight, ...)

Arguments

text character or expression vector, to be used as labels for levels of the grouping variable
points logical
rectangles logical
lines logical
col, cex, alpha, font, fontface, fontfamily, lineheight

... further arguments added to the list, eventually passed to draw.key

Details
A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as xyplot. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. simpleKey is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The simpleKey function produces a suitable key argument using a simpler interface. The resulting list will use the text argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the text component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling simpleKey directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the auto.key argument is supplied in a high-level plot with a groups argument. In that case, the text argument of simpleKey defaults to levels(groups), and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying auto.key as a list containing the replacement values.

Value
A list that would work as the key argument to xyplot, etc.
D_strip.default

---

D_strip.default  Default Trellis Strip Function

Description

strip.default is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling strip.default with a slightly different arguments. strip.custom provides a convenient way to obtain new strip functions that differ from strip.default only in the default values of certain arguments.

Usage

```r
strip.default(which.given, which.panel, var.name, factor.levels, shingle.intervals, strip.names = c(FALSE, TRUE), strip.levels = c(TRUE, FALSE), sep = " : ", style = 1, horizontal = TRUE, bg = trellis.par.get("strip.background")$col[which.given], fg = trellis.par.get("strip.shingle")$col[which.given], par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

Arguments

- **which.given**: integer index specifying which of the conditioning variables this strip corresponds to.
- **which.panel**: vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of `which.packet`, which is a more accurate name.
- **var.name**: vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of `strip.names` and `style` (see below). By default, the names are shown for shingles, but not for factors.
factor.levels  vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with which.given. Whether these levels are shown on the strip depends on the values of strip.levels and style (see below). factor.levels may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in par.strip.text (see xyplot)

shingle.intervals
if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by printing levels(shingle)). Otherwise, it should be NULL

strip.names  a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when style is not one of 1 and 3.

strip.levels  a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.

sep  character or expression, serving as a separator if the name and level are both to be shown.

style  integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when shingle.intervals is non-null.
The best way to find out what effect the value of style has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level. Note that unlike S-PLUS, the default value of style is 1. strip.names and strip.levels have no effect if style is not 1 or 3.

horizontal  logical, specifying whether the labels etc should be horizontal. horizontal=FALSE is useful for strips on the left of panels using strip.left=TRUE

par.strip.text  list with parameters controlling the text on each strip, with components col, cex, font, etc.

bg  strip background color.

fg  strip foreground color.

...  arguments to be passed on to strip.default, overriding whatever value it would have normally assumed

Details

default strip function for trellis functions. Useful mostly because of the style argument — non-default styles are often more informative, especially when the names of the levels of the factor x are
small. Traditional use is as `strip = function(...) strip.default(style=2,...), though this
  can be simplified by the use of `strip.custom`.

Value

  `strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel
  Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but
  with different defaults for the arguments specified in the call.

Author(s)

  Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

  `xyplot`, `Lattice`

Examples

  ```
  ## Traditional use
  xyplot(Petal.Length ~ Petal.Width | Species, iris,
        strip = function(..., style) strip.default(..., style = 4))
  ## equivalent call using strip.custom
  xyplot(Petal.Length ~ Petal.Width | Species, iris,
        strip = strip.custom(style = 4))
  xyplot(Petal.Length ~ Petal.Width | Species, iris,
        strip = FALSE,
        strip.left = strip.custom(style = 4, horizontal = FALSE))
  ```

---

**D_trellis.object**

*A Trellis Plot Object*

Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by
its `print` method.

Details

A trellis object, as returned by high level lattice functions like `xyplot`, is a list with the "class"
attribute set to "trellis". Many of the components of this list are simply the arguments
to the high level function that produced the object. Among them are: `as.table`, `layout`,
`page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab`, `ylab`, `par.settings`,
`lattice.options` and `plot.args`. Some other typical components are:

- `formula` the Trellis formula used in the call
- `index.cond` list with index for each of the conditioning variables
- `perm.cond` permutation of the order of the conditioning variables
- `aspect.fill` logical, whether aspect is "fill"
- `aspect.ratio` numeric, aspect ratio to be used if aspect.fill is FALSE
call call that generated the object.
condlevels list with levels of the conditioning variables
legend list describing the legend(s) to be drawn
panel.args a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.
panel.args.common a list containing the arguments common to all the panel functions in name=value form
x.scales list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"
y.scales list describing y-scale, similar to x.scales
x.between numeric vector of interpanel x-space
y.between numeric vector of interpanel y-space
x.limits numeric vector of length 2 or list, giving x-axis limits
y.limits similar to x.limits
packet.sizes array recording the number of observations in each packet

Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also
Lattice, xyplot, print.trellis

Description
The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

Usage

```r
panel.identify(x, y = NULL,
    subscripts = seq_along(x),
    labels = subscripts,
    n = length(x), offset = 0.5,
    threshold = 18, ## in points, roughly 0.25 inches
    panel.args = trellis.panelArgs(),
    ...
)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
    panel.args = trellis.panelArgs(),
    ...
)
panel.identify.cloud(x, y, z, subscripts,
```
perspective, distance,
xlim, ylim, zlim,
screen, R.mat, aspect, scales.3d,
..., 
panel.3d.identify,
n = length(subscripts),
offset = 0.5,
threshold = 18,
labels = subscripts,
panel.args = trellis.panelArgs()

panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
"figure", "panel", "strip", "strip.left",
"legend", "legend.region", "main", "sub",
"xlab", "ylab", "xlab.top", "ylab.right", "page"),
column, row,
side = c("left", "top", "right", "bottom", "inside"),
clip.off = FALSE, prefix)
trellis.grobname(name,
type = c("", "panel", "strip", "strip.left",
"key", "colorkey"),
group = 0,
which.given = lattice.getStatus("current.which.given",
prefix = prefix),
which.panel = lattice.getStatus("current.which.panel",
prefix = prefix),
column = lattice.getStatus("current.focus.column",
prefix = prefix),
row = lattice.getStatus("current.focus.row",
prefix = prefix),
prefix = lattice.getStatus("current.focus.prefix"))
trellis.focus(name, column, row, side, clip.off,
highlight = interactive(), ..., prefix,
guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ..., prefix)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

Arguments

x, y, z variables defining the contents of the panel. In the case of trellis.panelArgs,
a "trellis" object.

n the number of points to identify by default (overridden by a right click)

subscripts an optional vector of integer indices associated with each point. See details
below.

labels an optional vector of labels associated with each point. Defaults to subscripts
distribution, groups
typical panel arguments of panel.qqmath. These will usually be obtained from
panel.args
offset          the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The offset specifies (in "char" units) how far from the identified point the labels should be printed.

threshold       threshold in grid’s "points" units. Points further than these from the mouse click position are not considered

panel.args      list that contains components names x (and usually y), to be used if x is missing. Typically, when called after trellis.focus, this would appropriately be the arguments passed to that panel.

perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d arguments as passed to panel.cloud. These are required to recompute the relevant three-dimensional projections in panel.identify.cloud.

panel.3d.identify the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to panel.identify is used.

name            A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. trellis.vpname and trellis.focus deal with viewport names only, and only accept the values explicitly listed above. trellis.grobname is meant to create names for grobs, and can currently accept any value.

If name, as well as column and row is missing in a call to trellis.focus, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.

When name is "panel", "strip", or "strip.left", column and row must also be specified. When name is "legend", side must also be specified.

column, row     integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with as.table=TRUE

guess           logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to trellis.focus.

side            character string, relevant only for legends (i.e., when name="legend"), indicating their position. Partial specification is allowed, as long as it is unambiguous.

clip.off        logical, whether clipping should be off, relevant when name is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting clip.off=FALSE does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.

type            A character string specifying whether the grob is specific to a particular panel or strip.

When type is "panel", "strip", or "strip.left", information about the panel is added to the grob name.

group           An integer specifying whether the grob is specific to a particular group within the plot.

When group is greater than zero, information about the group is added to the grob name.
which.given, which.panel

integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables.

When which.panel has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.

prefix

A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the prefix argument in print.trellis.

Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last.

For switchFocus, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.

highlight

logical, whether the viewport being assigned focus should be highlighted. For trellis.focus, the default is TRUE in interactive mode, and trellis.switchFocus by default preserves the setting currently active.

packet.number

integer, which panel to get data from. See packet.number for details on how this is calculated

verbose

whether details will be printed...

For panel.identify.qqmath, extra parameters are passed on to panel.identify. For panel.identify, extra arguments are treated as graphical parameters and are used for labelling. For trellis.focus and trellis.switchFocus, these are used (in combination with lattice.options) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for panel.link.splom.

Details

panel.identify is similar to identify. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to trellis.focus first is necessary.

panel.link.splom is meant for use with splom, and requires a panel to be chosen using trellis.focus before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. panel.brush.splom is a (misnamed) alias for panel.link.splom, retained for back-compatibility.

panel.identify.qqmath is a specialized wrapper meant for use with the display produced by qqmath. panel.identify.qqmath is a specialized wrapper meant for use with the display produced by cloud. It would be unusual to call them except in a context where default panel function arguments are available through trellis.panelArgs (see below).

One way in which panel.identify etc. are different from identify is in how it uses the subscripts argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that subscripts is available is to specify subscripts = TRUE in the high level call such as xyplot. If subscripts is not explicitly specified in the call to panel.identify, but is available in panel.args, then those values will be used. Otherwise, they default to seq_along(x). In either case, the final return value will be the subscripts that were marked.
The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

trellis.focus can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, trellis.focus will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to trellis.focus, the desired viewport (typically panel or strip area) will be made the ‘current’ viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through trellis.currentLayout.

trellis.unfocus unsets the focus, and makes the top level viewport the current viewport.

trellis.switchFocus is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, trellis.panelArgs can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). trellis.panelArgs can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the packet.number (as described under the panel entry in xyplot) and not the position in the layout, because a layout determines the panel only after the object has been printed.

It is usually not necessary to call trellis.vpname and trellis.grobname directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

### Value

panel.identify returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of identify with pos=TRUE is not yet implemented, but can be considered for addition if requested.

trellis.panelArgs returns a named list of arguments that were available to the panel function for the chosen panel.

trellis.vpname and trellis.grobname return character strings.

trellis.focus has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components col and row giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is NULL. If click was outside a panel, both col and row are set to 0.
Note

The viewports created by lattice are accessible to the user through `trellis.focus` as described above. Functions from the grid package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` provides a portable way to access the appropriate viewports and grobs by name.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

**F_1_panel.barchart**  
*Default Panel Function for barchart*

**Description**

Default panel function for barchart.

**Usage**

```r
panel.barchart(x, y, box.ratio = 1, box.width,
               horizontal = TRUE,
               origin = NULL, reference = TRUE,
               stack = FALSE,
               groups = NULL,
               col = if (is.null(groups)) plot.polygon$col
               else superpose.polygons$col,
               border = if (is.null(groups)) plot.polygon$border
               else superpose.polygons$border,
               lty = if (is.null(groups)) plot.polygon$lty
               else superpose.polygons$lty,
```
lwd = if (is.null(groups)) plot.polygon$lwd
    else superpose.polygon$lwd,
..., identifier = "barchart")

Arguments

x Extent of Bars. By default, bars start at left of panel, unless origin is specified, in which case they start there.
y Horizontal location of bars. Possibly a factor.
box.ratio Ratio of bar width to inter-bar space.
box.width Thickness of bars in absolute units; overrides box.ratio. Useful for specifying thickness when the categorical variable is not a factor, as use of box.ratio alone cannot achieve a thickness greater than 1.
horizontal Logical flag. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
origin The origin for the bars. For grouped displays with stack = TRUE, this argument is ignored and the origin set to 0. Otherwise, defaults to NULL, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, origin = 0 is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
reference Logical, whether a reference line is to be drawn at the origin.
stack logical, relevant when groups is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.
groups Optional grouping variable.
col, border, lty, lwd Graphical parameters for the bars. By default, the trellis parameter plot.polygon is used if there is no grouping variable, otherwise superpose.polygon is used. col gives the fill color, border the border color, and lty and lwd the line type and width of the borders.
... Extra arguments will be accepted but ignored.
identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level barchart call directly.

scales = list(x = list(abbreviate = TRUE,
    minlength = 5)))

F_1_panel.bwplot  Default Panel Function for bwplot

Description

This is the default panel function for bwplot.

Usage

panel.bwplot(x, y, box.ratio = 1,
    box.width = box.ratio / (1 + box.ratio),
    horizontal = TRUE,
    pch, col, alpha, cex,
    font, fontfamily, fontface,
    fill, varwidth = FALSE,
    notch = FALSE, notch.frac = 0.5,
    ...,
    levels.fos,
    stats = boxplot.stats,
    coef = 1.5,
    do.out = TRUE,
    identifier = "bwplot")

Arguments

x, y  numeric vector or factor. Boxplots drawn for each unique value of y (x) if horizontal is TRUE (FALSE)

box.ratio  ratio of box thickness to inter box space

box.width  thickness of box in absolute units; overrides box.ratio. Useful for specifying thickness when the categorical variable is not a factor, as use of box.ratio alone cannot achieve a thickness greater than 1.

horizontal  logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.

pch, col, alpha, cex, font, fontfamily, fontface  graphical parameters controlling the dot. pch="|" is treated specially, by replacing the dot with a line (similar to boxplot)

fill  color to fill the boxplot

varwidth  logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.
notch

If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See `boxplot.stats` for the calculations used.

notch.frac

Numeric in (0,1). When `notch=TRUE`, the fraction of the box width that the notches should use.

stats

A function, defaulting to `boxplot.stats`, that accepts a numeric vector and returns a list similar to the return value of `boxplot.stats`. The function must accept arguments `coef` and `do.out` even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot.

coeff, do.out

Passed to `stats`

levels.fos

Numeric values corresponding to positions of the factor or shingle variable. For internal use.

... further arguments, ignored.

identifier

A character string that is prepended to the names of grobs that are created by this panel function.

details

Creates Box and Whisker plot of x for every level of y (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

col.groups = superposepolygon$col, 
polynum = 100,
```
\[
\ldots
s\text{cale} = \text{FALSE},
d\text{rape} = \text{FALSE},
unt,
col.\text{regions} = \text{regions}\$\text{col},
alpha.\text{regions} = \text{regions}\$\text{alpha},
\text{identifier} = "3\text{wire}"
\]

**Arguments**

\(x, y, z\) numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For \texttt{panel.cloud} these are essentially the same as the data passed to the high level plot (except if \texttt{formula} was a matrix, the appropriate \(x\) and \(y\) vectors are generated). By the time they are passed to \texttt{panel.3dscatter} and \texttt{panel.3dwire}, they have been appropriately subsetted (using \texttt{subscripts}) and scaled (to lie inside a bounding box, usually the \([-0.5, 0.5]\) cube).

Further, for \texttt{panel.3dwire}, \(x\) and \(y\) are shorter than \(z\) and represent the sorted locations defining a rectangular grid. Also in this case, \(z\) may be a matrix if the display is grouped, with each column representing one surface.

In \texttt{panel.cloud} (called from \texttt{wireframe}) and \texttt{panel.3dwire}, \(x\), \(y\) and \(z\) could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

\texttt{subscripts} index specifying which points to draw. The same \(x\), \(y\) and \(z\) values (representing the whole data) are passed to \texttt{panel.cloud} for each panel. \texttt{subscripts} specifies the subset of rows to be used for the particular panel.

\texttt{groups} specification of a grouping variable, passed down from the high level functions.

\texttt{perspective} logical, whether to plot a perspective view. Setting this to \texttt{FALSE} is equivalent to setting \texttt{distance} to 0

\texttt{distance} numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is \(1 / \text{distance}\). This is described in a little more detail in the documentation for \texttt{cloud}

\texttt{screen} A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive \(z\)-axis, and the \(x\) and \(y\) axes in the usual position. Each component of the list should be named one of "\(x\)", "\(y\)" or "\(z\)" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.

\texttt{R.mat} initial rotation matrix in homogeneous coordinates, to be applied to the data before \texttt{screen} rotates the view further.

\texttt{par.box} graphical parameters for box, namely, \texttt{col}, \texttt{lty} and \texttt{lwd}. By default obtained from the parameter \texttt{boxed.3d}.

\texttt{xlim, ylim, zlim} limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.

\texttt{panel.3d.cloud, panel.3d.wireframe} functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in \texttt{cloud} and \texttt{wireframe}. This function is called after the ‘back’ of the bounding box is drawn, but before the ‘front’ is drawn.
Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called xlim, ylim, zlim which give the bounding box ranges in the original data scale and xlim.scaled, ylim.scaled, zlim.scaled which give the bounding box ranges in the transformed scale. More arguments can be considered on request.

- **aspect**
  - as aspect as in cloud

- **xlab, ylab, zlab**
  - Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to cloud directly.

- **xlab.default**
  - for internal use

- **ylab.default**
  - for internal use

- **zlab.default**
  - for internal use

- **scales.3d**
  - list defining the scales

- **proportion**
  - numeric scalar, gives the length of arrows as a proportion of the sides

- **scpos**
  - A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are: x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of panel.cloud to see the details of this enumeration.)

- **wireframe**
  - logical, indicating whether this is a wireframe plot

- **drape**
  - logical, whether the facets will be colored by height, in a manner similar to levelplot. This is ignored if shade=TRUE.

- **at, col.regions, alpha.regions**
  - deals with specification of colors when drape=TRUE in wireframe. at can be a numeric vector, col.regions a vector of colors, and alpha.regions a numeric scalar controlling transparency. The resulting behaviour is similar to levelplot, at giving the breakpoints along the z-axis where colors change, and the other two determining the colors of the facets that fall in between.

- **rot.mat**
  - 4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and R.mat arguments to panel.cloud

- **type**
  - Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean ‘points’ and ‘lines’ respectively, and "b" means ‘both’. "h" stands for ‘histogram’, and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing z = 0), or the lower (or upper) bounding box face, whichever is closer.

- **xlim.scaled, ylim.scaled, zlim.scaled**
  - axis limits (after being scaled to the bounding box)

- **zero.scaled**
  - z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when type = "h"

- **cross**
  - logical, defaults to TRUE if pch = "+". panel.3dscatter can represent each point by a 3d ‘cross’ of sorts (it’s much easier to understand looking at an example than from a description). This is different from the usual pch argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.

  This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.
shade logical, indicating whether the surface is to be colored using an illumination model with a single light source

shade.colors.palette a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits. All three numbers should be between 0 and 1. The shade.colors.palette function should return a valid color. The default function is obtained from the trellis settings.

light.source a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube

polynum quadrilateral faces are drawn in batches of polynum at a time. Drawing too few at a time increases the total number of calls to the underlying grid.polygon function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.

col.groups colors for different groups

col, col.point, col.line, lty, lwd, cex, pch, fill, alpha Graphical parameters. Some other arguments (such as lwd for line width) may also be passed through the ... argument.

... other parameters, passed down when appropriate

.scale Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting .scale=TRUE may be helpful for calls to panel.3d.scatter and panel.3d.wire in user-supplied panel functions.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details These functions together are responsible for the content drawn inside each panel in cloud and wireframe. panel.wireframe is a wrapper to panel.cloud, which does the actual work. panel.cloud is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether wireframe is TRUE, it calls either panel.3d.wireframe or panel.3d.cloud, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For cloud, the data is unstructured, and x, y and z are all passed to the panel.3d.cloud function. For wireframe, on the other hand, x and y are increasing vectors with unique values, defining a rectangular grid. z must be a matrix with length(x) * length(y) rows, and as many columns as the number of groups.

panel.3d.scatter is the default panel.3d.cloud function. It has a type argument similar to panel.xyplot, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)
panel.3d.wire is the default panel.3d.wireframe function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about polygons facets, and draws them all at once. This avoids the overhead of drawing grid.polygon repeatedly, speeding up the rendering considerably. If shade = TRUE, these attempt to color the surface as being illuminated from a light source at light.source. palette.shade is a simple function that provides the default shading colors.

Multiple surfaces are drawn if groups is non-null in the call to wireframe, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

F_1_panel.densityplot Default Panel Function for densityplot

Description
This is the default panel function for densityplot.

Usage
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
groups = NULL, weights = NULL,
jitter.amount, type, ...,
identifier = "density")

Arguments
x data points for which density is to be estimated
darg list of arguments to be passed to the density function. Typically, this should be a list with zero or more of the following components: bw, adjust, kernel, window, width, give.Rkern, n, from, to, cut, na.rm (see density for details)
plot.points logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case panel.rug is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points.
ref logical, whether to draw x-axis
groups an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup
weights numeric vector of weights for the density calculations. If this is specified, the ... part must also include a subscripts argument that matches the weights to x.
jitter.amount when plot.points="jitter", the value to use as the amount argument to jitter.
type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a type argument, if specified, from affecting the density curve.

extra graphical parameters. Note that additional arguments to `panel.dotplot` cannot be passed on through `panel densityplot`.

A character string that is prepended to the names of grobs that are created by this panel function.

Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also
`densityplot`, `jitter`

Description
Default panel function for `dotplot`.

Usage
```r
panel.dotplot(x, y, horizontal = TRUE, pch, col, lty, lwd, col.line, levels.fos, groups = NULL, ..., identifier = "dotplot")
```

Arguments
- `x, y` variables to be plotted in the panel. Typically `y` is the 'factor'
- `horizontal` logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of `x` and `y` are switched. `x` is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- `pch, col, lty, lwd, col.line` graphical parameters
- `levels.fos` locations where reference lines will be drawn
- `groups` grouping variable (affects graphical parameters)
- `...` extra parameters, passed to `panel.xyplot` which is responsible for drawing the foreground points (`panel.dotplot` only draws the background reference lines).
- `identifier` A character string that is prepended to the names of grobs that are created by this panel function.

Details
Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

F_1_panel.histogram  Default Panel Function for histogram

Description
This is the default panel function for histogram.

Usage
panel.histogram(x,
               breaks,
               equal.widths = TRUE,
               type = "density",
               nint = round(log2(length(x)) + 1),
               alpha, col, border, lty, lwd,
               ...,
               identifier = "histogram")

Arguments
x The data points for which the histogram is to be drawn
breaks The breakpoints for the histogram
equal.widths logical used when breaks==NULL
type Type of histogram, possible values being "percent", "density" and "count"
nint Number of bins for the histogram
alpha, col, border, lty, lwd
   graphical parameters for bars; defaults are obtained from the plot.polygon
   settings.
... other arguments, passed to hist when deemed appropriate
identifier A character string that is prepended to the names of grobs that are created by
   this panel function.

Panel Functions for `levelplot` and `contourplot`

Description

These are the default panel functions for `levelplot` and `contourplot`. Also documented is an alternative raster-based panel function for use with `levelplot`.

Usage

```r
panel.levelplot(x, y, z,
                subscripts,
                at = pretty(z),
                shrink,
                labels,
                label.style = c("mixed", "flat", "align"),
                contour = FALSE,
                region = TRUE,
                col = add.line$col,
                lty = add.line$lty,
                lwd = add.line$lwd,
                border = "transparent",
                border.lty = 1,
                border.lwd = 0.1,

                col.regions = regions$col,
                alpha.regions = regions$alpha,
                identifier = "levelplot")

panel.contourplot(...)

panel.levelplot.raster(x, y, z,
                        subscripts,
                        at = pretty(z),
                        ...
                        col.regions = regions$col,
                        interpolate = FALSE,
                        identifier = "levelplot")
```

Arguments

- `x, y, z` Variables defining the plot.
- `subscripts` Integer vector indicating what subset of `x, y, z` to draw.
- `at` Numeric vector giving breakpoints along the range of `z`. See `levelplot` for details.
- `shrink` Either a numeric vector of length 2 (meant to work as both x and y components), or a list with components x and y which are numeric vectors of length 2. This
allows the rectangles to be scaled proportional to the z-value. The specification can be made separately for widths (x) and heights (y). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of z).

labels
Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the at values. Alternatively, labels can be a list with the following components:
labels: a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.
col, cex, alpha: graphical parameters for label texts
fontfamily, fontface, font: font used for the labels

label.style
Controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.

contour
A logical flag, specifying whether contour lines should be drawn.

region
A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.

col, lty, lwd
Graphical parameters for contour lines.

border
Border color for rectangles used when region=TRUE.

border.lty, border.lwd
Graphical parameters for the border

...Extra parameters.

col.regions
A vector of colors, or a function to produce a vector of colors, to be used if region=TRUE. Each interval defined by at is assigned a color, so the number of colors actually used is one less than the length of at. See level.colors for details on how the color assignment is done.

alpha.regions
numeric scalar controlling transparency of facets

interpolate
numeric scalar controlling transparency of facets

identifier
A character string that is prepended to the names of grobs that are created by this panel function.

Details
The same panel function is used for both levelplot and contourplot (which differ only in default values of some arguments). panel.contourplot is a simple wrapper to panel.levelplot.

When contour=TRUE, the contourLines function is used to calculate the contour lines.
panel.levelplot.raster is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through grid.raster). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using panel.levelplot.raster, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see levelplot for details.

Examples

require(grid)

levelplot(rnorm(10) ~ 1:10 + sort(runif(10)), panel = panel.levelplot)

suppressWarnings(plot(levelplot(rnorm(10) ~ 1:10 + sort(runif(10)),
panel = panel.levelplot.raster,
interpolate = TRUE)))

levelplot(volcano, panel = panel.levelplot.raster)

levelplot(volcano, panel = panel.levelplot.raster,
  col.regions = topo.colors, cuts = 30, interpolate = TRUE)

Description

This is the default superpanel function for splom.

Usage

```
panel.pairs(z,
  panel = lattice.getOption("panel.splom"),
  lower.panel = panel,
  upper.panel = panel,
  diag.panel = "diag.panel.splom",
  as.matrix = FALSE,
  groups = NULL,
  panel.subscripts,
  subscripts,
  pscales = 5,
  prepanel.limits = scale.limits,
  varnames = colnames(z),
  varname.col, varname.cex, varname.font,
  varname.fontfamily, varname.fontface,
  axis.text.col, axis.text.cex, axis.text.font,
  axis.text.fontfamily, axis.text.fontface,
  axis.text.lineheight,
  axis.line.col, axis.line.lty, axis.line.lwd,
  axis.line.alpha, axis.line.tck,
  ...
)
```

diag.panel.splom(x = NULL,
  varname = NULL, limits, at = NULL, labels = NULL,
  draw = TRUE, tick.number = 5,
  varname.col, varname.cex,
Arguments

z  The data frame used for the plot.
panel, lower.panel, upper.panel  
The panel function used to display each pair of variables. If specified, 
lower.panel and upper.panel are used for panels below and above the di-
agonal respectively.
In addition to extra arguments not recognized by panel.pairs, the list of argu-
ments passed to the panel function also includes arguments named i and j, with 
values indicating the row and column of the scatterplot matrix being plotted.
diag.panel  The panel function used for the diagonals. See arguments to diag.panel.splom 
to know what arguments this function is passed when called. Use 
diag.panel=NULL to suppress plotting on the diagonal panels.
as.matrix  logical. If TRUE, the layout of the panels will have origin on the top left instead 
of bottom left (similar to pairs). This is in essence the same functionality as 
provided by as.table for the panel layout
groups  Grouping variable, if any
panel.subscripts  
logical specifying whether the panel function accepts an argument named 
subscripts.
subscripts  The indices of the rows of z that are to be displayed in this (super)panel.
pscales  Controls axis labels, passed down from splom. If pscales is a single number, it 
indicates the approximate number of equally-spaced ticks that should appear on 
each axis. If pscales is a list, it should have one component for each column in 
z, each of which itself a list with the following valid components:
at: a numeric vector specifying tick locations
labels: character vector labels to go with at
limits: numeric 2-vector specifying axis limits (should be made more flexible 
at some point to handle factors)
These are specifications on a per-variable basis, and used on all four sides in the 
diagonal cells used for labelling. Factor variables are labelled with the factor 
names. Use pscales=0 to suppress the axes entirely.
prepanel.limits  
A function to calculate suitable axis limits given a single argument x containing 
a data vector. The return value of the function should be similar to the xlim 
or ylim argument documented in xyplot: that is, it should be a numeric or 
DateTime vector of length 2 defining a range, or a character vector representing 
levels of a factor.
Most high-level lattice plots (such as `xyplot`) use the `prepanel` function for deciding on axis limits from data. This function serves a similar function by calculating the per-variable limits. These limits can be overridden by the corresponding `limits` component in the `pscales` list.

- `x`: data vector corresponding to that row / column (which will be the same for diagonal 'panels').
- `varname`: (scalar) character string or expression that is to be written centred within the panel.
- `limits`: numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing).
- `at`: locations of tick marks.
- `labels`: optional labels for tick marks.
- `draw`: A logical flag specifying whether to draw the tick marks and labels. If `FALSE`, variable names are shown but axis annotation is omitted.
- `tick.number`: A numeric scalar giving the suggested number of tick marks.
- `varnames`: A character or expression vector or giving names to be used for the variables in `x`. By default, the column names of `x`.
- `varname.col`: Color for the variable name in each diagonal panel. See `gpar` for details on this and the other graphical parameters listed below.
- `varname.cex`: Size multiplier for the variable name in each diagonal panel.
- `varname.lineheight`: Line height for the variable name in each diagonal panel.
- `varname.font`, `varname.fontfamily`, `varname.fontface`: Font specification for the variable name in each diagonal panel.
- `axis.text.col`: Color for axis label text.
- `axis.text.cex`: Size multiplier for axis label text.
- `axis.text.font`, `axis.text.fontfamily`, `axis.text.fontface`: Font specification for axis label text.
- `axis.text.lineheight`: Line height for axis label text.
- `axis.text.alpha`: Alpha-transparency for axis label text.
- `axis.line.col`: Color for the axes.
- `axis.line.lty`: Line type for the axes.
- `axis.line.lwd`: Line width for the axes.
- `axis.line.alpha`: Alpha-transparency for the axes.
- `axis.line.tck`: A numeric multiplier for the length of tick marks in diagonal panels.

... Further arguments, passed on to `panel`, `lower.panel`, `upper.panel`, and `diag.panel` from `panel.pairs`. Currently ignored by `diag.panel.splom`.

### Details

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`. 
Author(s)

See Also

splom

Examples

Cmat <- outer(1:6, 1:6,
    function(i,j) rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE,
    panel = function(x, y, i, j, ...) {
        panel.fill(Cmat[i,j])
        panel.text(.5,.5, paste("(" , i , ",", j, ")", sep=""))
    })
common.scale  logical, whether a common scale should be used columns of z. Defaults to FALSE, in which case the horizontal range for each column is different (as determined by lower and upper).

lower, upper  numeric vectors replicated to be as long as the number of columns in z. Determines the lower and upper bounds to be used for scaling the corresponding columns of z after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.

...  other arguments (ignored)

horizontal.axis  logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).

identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for parallel.

parallel

Description

This is the default panel function for qqmath.

Usage

panel.qqmath(x, f.value = NULL, distribution = qnorm, qtype = 7, groups = NULL, ..., tails.n = 0, identifier = "qqmath")
Arguments

- **x**  
  vector (typically numeric, coerced if not) of data values to be used in the panel.

- **f.value, distribution**  
  Defines how quantiles are calculated. See `qqmath` for details.

- **qtype**  
  The type argument to be used in `quantile`

- **groups**  
  An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.

- **tails.n**  
  number of data points to represent exactly on each tail of the distribution. This reproduces the effect of `f.value = NULL` for the extreme data values, while approximating the remaining data. It has no effect if `f.value = NULL`. If `tails.n` is given, `qtype` is forced to be 1.

- **identifier**  
  A character string that is prepended to the names of grobs that are created by this panel function.

Details

 Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

- `qqmath`

Examples

```r
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "+", distribution = qnorm,
        grid = TRUE, abline = c(0, 1),
        xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
        panel = function(..., f.value) {
          switch(panel.number(),
            panel.qqmath(..., f.value = NULL),
            panel.qqmath(..., f.value = ppoints(100)),
            panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
        }, layout = c(3, 1))[[c(1,1,1)]]
```
Default Panel Function for stripplot

Description

This is the default panel function for stripplot. Also see panel.superpose

Usage

panel.stripplot(x, y, jitter.data = FALSE,
                  factor = 0.5, amount = NULL,
                  horizontal = TRUE, groups = NULL,
                  ..., 
                  identifier = "stripplot")

Arguments

x, y coordinates of points to be plotted
jitter.data whether points should be jittered to avoid overplotting. The actual jittering is performed inside panel.xyplot, using its jitter.x or jitter.y argument (depending on the value of horizontal).
factor, amount amount of jittering, see jitter
horizontal logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of x and y are switched. x is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
groups optional grouping variable
... additional arguments, passed on to panel.xyplot
identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates stripplot (one dimensional scatterplot) of x for each level of y (or vice versa, depending on the value of horizontal)

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

stripplot, jitter
Description

This is the default panel function for xyplot. Also see panel.superpose. The default panel functions for splom and qq are essentially the same function.

Usage

```r
panel.xyplot(x, y, type = "p",
             groups = NULL,
pch, col, col.line, col.symbol,
font, fontfamily, fontface,
1ty, cex, fill, lwd,
horizontal = FALSE, ..., 
grid = FALSE, abline = NULL,
jitter.x = FALSE, jitter.y = FALSE,
factor = 0.5, amount = NULL,
identifier = "xyplot")
panel.splom(..., identifier = "splom")
panel.qq(..., identifier = "qq")
```

Arguments

- `x, y`: variables to be plotted in the scatterplot
- `type`: character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth", and "spline". If type has more than one element, an attempt is made to combine the effect of each of the components.

The behaviour if any of the first six are included in type is similar to the effect of type in `plot` (type "b" is actually the same as "o"). "r" adds a linear regression line (same as `panel.lmline`, except for default graphical parameters). "smooth" adds a loess fit (same as `panel.loess`). "spline" adds a cubic smoothing spline fit (same as `panel.spline`). "g" adds a reference grid using `panel.grid` in the background (but using the grid argument is now the preferred way to do so). "a" has the effect of calling `panel.average`, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of horizontal.

Type "s" (and "S") sorts the values along one of the axes (depending on horizontal); this is unlike the behavior in plot. For the latter behavior, use `type = "s"` with `panel = panel.points`.

See `example(xyplot)` and `demo(lattice)` for examples.

- `groups`: an optional grouping variable. If present, `panel.superpose` will be used instead to display each subgroup
- `col, col.line, col.symbol`: default colours are obtained from `plot.symbol` and `plot.line` using `trellis.par.get`.
- `font, fontface, fontfamily`: font used when `pch` is a character
pch, lty, cex, lwd, fill

other graphical parameters. fill serves the purpose of bg in points for certain values of pch

horizontal

A logical flag controlling the orientation for certain type’s, e.g., "h", "s", ans "S".

... Extra arguments, if any, for panel.xyplot. In most cases panel.xyplot ignores these. For types "r" and "smooth", these are passed on to panel.lmline and panel.loess respectively.

grid

A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as type="g", but is the preferred alternative as the effect type="g" is conceptually different from that of other type values (which are all data-dependent). Using the grid argument also allows more flexibility.

Most generally, grid can be a list of arguments to be supplied to panel.grid, which is called with those arguments. Three shortcuts are available:

TRUE: roughly equivalent to list(h = -1, v = -1)
"h": roughly equivalent to list(h = -1, v = 0)
"v": roughly equivalent to list(h = 0, v = -1)

No grid is drawn if grid = FALSE.

abline

A numeric vector or list, specifying arguments arguments for panel.abline, which is called with those arguments. If specified as a (possibly named) numeric vector, abline is coerced to a list. This allows arguments of the form abline = c(0, 1), which adds the diagonal line, or abline = c(h = 0, v = 0), which adds the x- and y-axes to the plot. Use the list form for finer control; e.g., abline = list(h = 0, v = 0, col = "grey").

For more flexibility, use panel.abline directly.

jitter.x, jitter.y

logical, whether the data should be jittered before being plotted.

factor, amount controls amount of jittering.

identifier

A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates scatterplot of x and y, with various modifications possible via the type argument. panel.qq draws a 45 degree line before calling panel.xyplot.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. xyplot) call.

Examples

```r
types.plain <- c("p", "l", "o", "r", "g", "s", "S", "h", "a", "smooth")
types.horiz <- c("s", "S", "h", "a", "smooth")
horiz <- rep(c(FALSE, TRUE), c(length(types.plain), length(types.horiz)))

types <- c(types.plain, types.horiz)
x <- sample(seq(-10, 10, length.out = 15), 30, TRUE)
y <- x + 0.25 * (x + 1)^2 + rnorm(length(x), sd = 5)

xyplot(y ~ x | gl(1, length(types)),
    xlab = "type",
    ylab = list(c("horizontal=TRUE", "horizontal=FALSE"), y = c(1/6, 4/6)),
    as.table = TRUE, layout = c(5, 3),
    between = list(y = c(0, 1)),
    strip = function(...) {
        type <- types[panel.number()]
        grid::grid.text(label = sprintf("%s", type),
                        x = 0.5, y = 0.5)
        grid::grid.rect()
    },
    scales = list(alternating = c(0, 2), tck = c(0, 0.7), draw = FALSE),
    par.settings =
        list(layout.widths = list(strip.left = c(1, 0, 0, 0, 0))),
    panel = function(...) {
        type <- types[panel.number()]
        horizontal <- horiz[panel.number()]
        panel.xyplot(...,
                    type = type,
                    horizontal = horizontal)
    }[rep(1, length(types))]
```

Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

Usage

```r
lplot.xy(xy, type, pch, lty, col, cex, lwd,
    font, fontfamily, fontface,
    col.line, col.symbol, alpha, fill,
    origin = 0, ..., identifier, name.type)
llines(x, ...)
lpoints(x, ...)
```

panel.lines(...)  
panel.points(...)  
panel.segments(...)  
panel.text(...)  
panel.rect(...)  
panel.arrows(...)  
panel.polygon(...)
Arguments

x, y, x0, y0, x1, y1, x2, y2, xy

Arguments for specifying line locations. x2 and y2 are available for S compatibility.

length, unit

determines extent of arrow head. length specifies the length in terms of unit, which can be any valid grid unit as long as it doesn’t need a data argument. unit defaults to inches, which is the only option in the base version of the function, arrows.

angle, code, type, labels, srt, adj, pos, offset

arguments controlling behaviour. See respective base functions for details. For arrows and panel.arrows, type is either "open" or "closed", indicating the type of arrowhead.

dends

serves the same function as code, using descriptive names rather than integer codes. If specified, this overrides code

col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, col.symbol, border

graphical parameters. fill applies to points when pch is in 21:25 and specifies the fill color, similar to the bg argument in the base graphics function points. For devices that support alpha-transparency, a numeric argument alpha between 0 and 1 can control transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0.

fill, font and fontface are included in lrect, larrows, lpolygon, and lsegments only to ensure that they are not passed down (as gpar does not like them).

origin

for type="h" or type="H", the value to which lines drop down.

xleft, ybottom, xright, ytop

see rect

width, height, just, hjust, vjust

finer control over rectangles, see grid.rect

... extra arguments, passed on to lower level functions as appropriate.

identifier

A character string that is prepended to the name of the grob that is created.

name.type

A character value indicating whether the name of the grob should have panel or strip information added to it. Typically either "panel", "strip", "strip.left", or "" (for no extra information).

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions panel.* are essentially identical to the l* versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

Note

There is a new type="H" option wherever appropriate, which is similar to type="h", but with horizontal lines.

F_2_panel.functions  Useful Panel Function Components

Description

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

Usage

panel.abline(a = NULL, b = 0,
         h = NULL, v = NULL,
         reg = NULL, coef = NULL,
         col, col.line, lty, lwd, alpha, type,
         ..., reference = FALSE,
         identifier = "abline")
panel.refline(...)

panel.curve(expr, from, to, n = 101,
         curve.type = "l",
         col, lty, lwd, type,
         ..., identifier = "curve")
panel.rug(x = NULL, y = NULL,
        regular = TRUE,
        start = if (regular) 0 else 0.97,
        end = if (regular) 0.03 else 1,
        x.units = rep("npc", 2),
        y.units = rep("npc", 2),
        col, col.line, lty, lwd, alpha,
        ..., identifier = "rug")
panel.average(x, y, fun = mean, horizontal = TRUE,
         lwd, lty, col, col.line, type,
         ..., identifier = "linejoin")
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
         lwd, lty, col, col.line, type,
         ..., identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
    n = 50, col, col.line, lwd, lty, type,
    ..., identifier = "mathdensity")

Arguments

\[ x, y \]
Variables defining the contents of the panel. In `panel.grid` these are optional and are used only to choose an appropriate method of `pretty`.

\[ a, b \]
Coefficients of the line to be added by `panel.abline`. \( a \) can be a vector of length 2, representing the coefficients of the line to be added, in which case \( b \) should be missing. \( a \) can also be an appropriate ‘regression’ object, i.e., an object which has a `coef` method that returns a length 2 numeric vector. The corresponding line will be plotted. The `reg` argument overrides `a` if specified.

\[ coef \]
Coefficients of the line to be added as a vector of length 2.

\[ reg \]
A (linear) regression object, with a `coef` method that gives the coefficients of the corresponding regression line.

\[ h, v \]
For `panel.abline`, these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For `panel.grid`, these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. \( h=-1 \) and \( v=-1 \) are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using `pretty`, which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). \( h \) and \( v \) can be negative numbers other than \(-1\), in which case \(-h\) and \(-v\) (as appropriate) is supplied as the \( n \) argument to `pretty`.

If \( x \) and/or \( y \) are specified in `panel.grid`, they will be used to select an appropriate method for `pretty`. This is particularly useful while plotting date-time objects.

\[ reference \]
A logical flag determining whether the default graphical parameters for `panel.abline` should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The `panel.refline` function is a wrapper around `panel.abline` that calls it with `reference = TRUE`.

\[ expr \]
An expression considered as a function of \( x \), or a function, to be plotted as a curve.

\[ n \]
The number of points to use for drawing the curve.

\[ from, to \]
optional lower and upper x-limits of curve. If missing, limits of current panel are used

\[ curve.type \]
Type of curve ("p" for points, etc), passed to `llines`

\[ regular \]
A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).

\[ start, end \]
endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of `regular`, and cover 3% of the panel width and height.
x.units, y.units

Character vectors, replicated to be of length two. Specifies the (grid) units associated with start and end above. x.units and y.units are for the rug on the x-axis and y-axis respectively (and thus are associated with start and end values on the y and x scales respectively).

col, col.line, lty, lwd, alpha, border

Graphical parameters.

type

Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified type argument (perhaps meant for another function) does not affect the display.

fun

The function that will be applied to the subset of x values (or y if horizontal is FALSE) determined by the unique values of y(x).

horizontal

A logical flag. If FALSE, the plot is ‘transposed’ in the sense that the roles of x and y are switched; x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.

dmath

A vectorized function that produces density values given a numeric vector named x, e.g., dnorm.

args

A list giving additional arguments to be passed to dmath.

...

Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by col, col.line, and col.symbol, the last two overriding the first for lines and points respectively.

identifier

A character string that is prepended to the names of grobs that are created by this panel function.

Details

panel.abline adds a line of the form y = a + b * x, or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. panel.refline is similar, but uses the “reference.line” settings for the defaults.

panel.grid draws a reference grid.

panel.curve adds a curve, similar to what curve does with add = TRUE. Graphical parameters for the curve are obtained from the “add.line” setting.

panel.average treats one of x and y as a factor (according to the value of horizontal), calculates fun applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with panel.xploplot, and more commonly with panel.superpose to produce interaction plots.

panel.linejoin is an alias for panel.average. It is retained for back-compatibility, and may go away in future.

panel.mathdensity plots a (usually theoretical) probability density function. This can be useful in conjunction with histogram and densityplot to visually assess goodness of fit (note, however, that qqmath is more suitable for this).

panel.rug adds a rug representation of the (marginal) data to the panel, much like rug.

panel.lmline(x, y) is equivalent to panel.abline(lm(y ~ x)).

`Lattice, panel.axis, panel.identify identify, trellis.par.set`.

Examples

### Interaction Plot

```r
bwplot(yield ~ site, barley, groups = year,
  panel = function(x, y, groups, subscripts, ...) {
    panel.grid(h = -1, v = 0)
    panel.stripplot(x, y, ..., jitter.data = TRUE,
      groups = groups, subscripts = subscripts)
    panel.superpose(x, y, ..., panel.groups = panel.average,
      groups = groups, subscripts = subscripts)
  },
  auto.key =
  list(points = FALSE, lines = TRUE, columns = 2))
```

### Superposing a fitted normal density on a Histogram

```r
histogram(~ height | voice.part, data = singer, layout = c(2, 4),
  type = "density", border = "transparent", col.line = "grey60",
  xlab = "Height (inches)",
  ylab = "Density Histogram\n with Normal Fit",
  panel = function(x, ...) {
    panel.histogram(x, ...)
    panel.mathdensity(dmath = dnorm,
      args = list(mean=mean(x),sd=sd(x)), ...)
  })
```

---

**F_2_panel.loess**  
*Panel Function to Add a LOESS Smooth*

Description

A predefined panel function that can be used to add a LOESS smooth based on the provided data.

Usage

```r
panel.loess(x, y, span = 2/3, degree = 1,
  family = c("symmetric", "gaussian"),
  evaluation = 50,
  lwd, lty, col, col.line, type,
  horizontal = FALSE,
  ..., identifier = "loess")
```

Arguments

- `x, y`: Variables defining the data to be used.
- `lwd, lty, col, col.line`: Graphical parameters for the added line. `col.line` overrides `col`.
type      Ignored. The argument is present only to make sure that an explicitly specified
type argument (perhaps meant for another function) does not affect the display.
span, degree, family, evaluation
        Arguments to loess.smooth, for which panel.loess is essentially a wrapper.
horizontal     A logical flag controlling which variable is to be treated as the predictor (by de-
        fault \( x \)) and which as the response (by default \( y \)). If TRUE, the plot is ‘transposed’
in the sense that \( y \) becomes the predictor and \( x \) the response. (The name ‘horizontal’ may seem
        an odd choice for this argument, and originates from similar usage in bwplot).
...     Extra arguments, passed on to panel.lines.
identifier     A character string that is prepended to the names of grobs that are created by
        this panel function.

Value

The object returned by loess.smooth.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, loess.smooth, prepanel.loess

Description

Useful panel function with qqmath. Draws a line passing through the points (usually) determined
by the .25 and .75 quantiles of the sample and the theoretical distribution.

Usage

panel.qqmathline(x, y = x,
        distribution = qnorm,
        probs = c(0.25, 0.75),
        qtype = 7,
        groups = NULL,
        ...,
        identifier = "qqmathline")

Arguments

\( x \)     The original sample, possibly reduced to a fewer number of quantiles, as determined by the f.value argument to qqmath
\( y \)     an alias for \( x \) for backwards compatibility
distribution quantile function for reference theoretical distribution.
panel.smoothScatter

Lattice panel function analogous to smoothScatter

Description

This function allows the user to place smoothScatter plots in lattice graphics.

Usage

panel.smoothScatter(x, y = NULL,
    nbin = 64, cuts = 255,
    bandwidth,
    colramp,
    nrpoints = 100,
    transformation = function(x) x^0.25,
    pch = ".",
    cex = 1, col="black",
    range.x,
    ..., raster = FALSE,
    subscripts,
    identifier = "smoothScatter")

Arguments

x Numeric vector containing x-values or n by 2 matrix containing x and y values.

y Numeric vector containing y-values (optional). The length of x must be the same as that of y.

nbin Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.

cuts number of cuts defining the color gradient

probs numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.

qtype the type of quantile computation used in quantile

groups optional grouping variable. If non-null, a line will be drawn for each group.

... other arguments.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

prepanel.qqmathline, qqmath, quantile
bandwidth  Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function \texttt{bkde2D}.

colramp  Function accepting an integer \(n\) as an argument and returning \(n\) colors.

nrpoints  Numeric vector of length 1 giving number of points to be superimposed on the density image. The first \(nrpoints\) points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose \(nrpoints = \text{Inf}\).

transformation  Function that maps the density scale to the color scale.

pch, cex  graphical parameters for the \(nrpoints\) “outlying” points shown in the display

range.x  see \texttt{bkde2D} for details.

col  \texttt{points} color parameter

...  Further arguments that are passed on to \texttt{panel.levelplot}.

raster  logical; if \texttt{TRUE}, \texttt{panel.levelplot.raster} is used, making potentially smaller output files.

subscripts  ignored, but necessary for handling of \texttt{...} in certain situations. Likely to be removed in future.

identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

This replicates the display part of the \texttt{smoothScatter} function by replacing standard graphics calls by grid-compatible ones.

Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

Examples

```r
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, , c(2,4)] <- (-ddf[, , c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
   panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```
**F_2_panel.spline**

Panel Function to Add a Spline Smooth

**Description**

A predefined panel function that can be used to add a spline smooth based on the provided data.

**Usage**

```r
panel.spline(x, y, npoints = 101,
             lwd = plot.line$lwd,
             lty = plot.line$lty,
             col, col.line = plot.line$col,
             type,
             horizontal = FALSE, ..., 
             keep.data = FALSE,
             identifier = "spline")
```

**Arguments**

- **x, y** Variables defining the data to be used.
- **npoints** The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.
- **lwd, lty, col, col.line** Graphical parameters for the added line. `col.line` overrides `col`.
- **type** Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.
- **horizontal** A logical flag controlling which variable is to be treated as the predictor (by default `x`) and which as the response (by default `y`). If TRUE, the plot is 'transposed' in the sense that `y` becomes the predictor and `x` the response. (The name 'horizontal' may seem an odd choice for this argument, and originates from similar usage in `bwplot`).
- **keep.data** Passed on to `smooth.spline`. The default here (FALSE) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to TRUE if the return value of `panel.spline`, which is the fitted model as returned by `smooth.spline`, is to be used for subsequent computations.
- **...** Extra arguments, passed on to `smooth.spline` and `panel.lines` as appropriate.
- **identifier** A character string that is prepended to the names of grobs that are created by this panel function.

**Value**

The fitted model as returned by `smooth.spline`.

**Author(s)**

Lattice, smooth.spline, prepanel.spline

F_2_panel.superpose  Panel Function for Display Marked by groups

Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The x (and y where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

Usage

panel.superpose(x, y = NULL, subscripts, groups,
    panel.groups = "panel.xyplot",
    ..., 
    col, col.line, col.symbol,
    pch, cex, fill, font,
    fontface, fontfamily,
    lty, lwd, alpha,
    type = "p", grid = FALSE,
    distribute.type = FALSE)

panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
    col, col.line, col.symbol,
    pch, cex, fill, font,
    fontface, fontfamily,
    lty, lwd, alpha)

Arguments

x, y  Coordinates of the points to be displayed. Usually numeric.

panel.groups  The panel function to be used for each subgroup of points. Defaults to panel.xyplot.

To be able to distinguish between different levels of the originating group inside panel.groups, it will be supplied two special arguments called group.number and group.value which will hold the numeric code and factor level corresponding to the current level of groups. No special care needs to be taken when writing a panel.groups function if this feature is not used.

subscripts  An integer vector of subscripts giving indices of the x and y values in the original data source. See the corresponding entry in xyplot for details.

groups  A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of groups. The default graphical parameters are obtained from the "superpose.symbol" and "superpose.line" settings using trellis.par.get wherever appropriate.
type

Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the `panel.groups` function, which must know what to do with it. By default, `panel.groups` is `panel.xyplot`, whose help page describes the admissible values.

The functions `panel.superpose` and `panel.superpose.2` differ only in the default value of `distribute.type`, which controls the way the `type` argument is interpreted. If `distribute.type = FALSE`, then the interpretation is the same as for `panel.xyplot` for each of the unique groups. In other words, if `type` is a vector, all the individual components are honoured concurrently. If `distribute.type = TRUE`, `type` is replicated to be as long as the number of unique values in `groups`, and one component used for the points corresponding to each different group. Even in this case, it is possible to request multiple types per group, specifying `type` as a list, each component being the desired type vector for the corresponding group.

If `distribute.type = FALSE`, any occurrence of "g" in `type` causes a grid to be drawn, and all such occurrences are removed before `type` is passed on to `panel.groups`.

grid

Logical flag specifying whether a background reference grid should be drawn. See `panel.xyplot` for details.

col

A vector color specification. See Details.

col.line

A vector color specification. See Details.

col.symbol

A vector color specification. See Details.

pch

A vector plotting character specification. See Details.

cex

A vector size factor specification. See Details.

fill

A vector fill color specification. See Details.

font, fontface, fontfamily

A vector color specification. See Details.

lty

A vector color specification. See Details.

lwd

A vector color specification. See Details.

alpha

A vector alpha-transparency specification. See Details.

... Extra arguments. Passed down to `panel.superpose` from `panel.superpose.2`, and to `panel.groups` from `panel.superpose`.

distribute.type

logical controlling interpretation of the `type` argument.

Details

`panel.superpose` divides up the `x` (and optionally `y`) variable(s) by the unique values of `groups[subscripts]`, and plots each subset with different graphical parameters. The graphical parameters (`col.symbol`, `pch`, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When `panel.groups` is called for the `i`-th level of `groups`, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the `panel.groups` function. With the default `panel.groups`, the `col` argument is overridden by `col.line` and `col.symbol` for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, `col` will still be supplied as an argument to `panel.groups` functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the
"superpose.line" and "superpose.symbol" settings as appropriate. The alpha parameter takes it default from the "superpose.line" setting.

panel.superpose and panel.superpose.2 differ essentially in how type is interpreted by default. The default behaviour in panel.superpose is the opposite of that in S, which is the same as that of panel.superpose.2.

panel.superpose.plain is the same as panel.superpose, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in xyplot.ts.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org> (panel.superpose.2 originally contributed by Neil Klepeis)

See Also

Different functions when used as panel.groups gives different types of plots, for example panel.xyplot, panel.dotplot and panel.average (This can be used to produce interaction plots).

See Lattice for an overview of the package, and xyplot for common arguments (in particular, the discussion of the extended formula interface and the groups argument).

Panel Function to create Violin Plots

This is a panel function that can create a violin plot. It is typically used in a high-level call to bwplot.

Usage

```r
panel.violin(x, y, box.ratio = 1, box.width, horizontal = TRUE, alpha, border, lty, lwd, col, varwidth = FALSE, bw, adjust, kernel, window, width, n = 50, from, to, cut, na.rm, ..., identifier = "violin")
```

Arguments

- `x, y` numeric vector or factor. Violin plots are drawn for each unique value of `y` if `horizontal` is TRUE (FALSE)
- `box.ratio` ratio of the thickness of each violin and inter violin space
- `box.width` thickness of the violins in absolute units; overrides `box.ratio`. Useful for specifying thickness when the categorical variable is not a factor, as use of `box.ratio` alone cannot achieve a thickness greater than 1.
horizontal  logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of \texttt{x} and \texttt{y} are switched. \texttt{x} is now the 'factor'. See documentation of \texttt{bwplot} for a fuller explanation.

\texttt{alpha, border, lty, lwd, col}

graphical parameters controlling the violin. Defaults are taken from the \texttt{plot.polygon} settings.

\texttt{varwidth}  logical. If FALSE, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by \texttt{box.ratio}). If TRUE, densities across violins will have comparable scale.

\texttt{bw, adjust, kernel, window, width, n, from, to, cut, na.rm}

arguments to \texttt{density}, passed on as appropriate

\texttt{...}

arguments passed on to \texttt{density}.

\texttt{identifier}  A character string that is prepended to the names of grobs that are created by this panel function.

\textbf{Details}

Creates Violin plot of \texttt{x} for every level of \texttt{y}. Note that most arguments controlling the display can be supplied to the high-level (typically \texttt{bwplot}) call directly.

\textbf{Author(s)}

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

\textbf{See Also}

\texttt{bwplot, density}

\textbf{Examples}

\begin{verbatim}
bwplot(voice.part ~ height, singer,
panel = function(..., box.ratio) {
    panel.violin(..., col = "transparent",
        varwidth = FALSE, box.ratio = box.ratio)
    panel.bwplot(..., fill = NULL, box.ratio = .1)
})
\end{verbatim}

\textbf{Description}

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.
Usage

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
    xlim, ylim, zlim,
    screen = list(z = 40, x = -60),
    R.mat = diag(4),
    aspect = c(1, 1), panel.aspect = 1,
    ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
    groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)

Arguments

x, y  
x and y values, numeric or factor
horizontal  
logical, applicable when one of the variables is to be treated as categorical (factor or shingle).
horizontal.axis  
logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
nlevels  
number of levels of such a categorical variable.
origin, stack  
for barcharts or the type="h" plot type
breaks, equal.widths, type, nint  
details of histogram calculations. type has a different meaning in prepanel.default.xyplot (see panel.xyplot)
groups, subscripts  
See xyplot. Whenever appropriate, calculations are done separately for each group and then combined.
weights  
numeric vector of weights for the density calculations. If this is specified, it is subsetted by subscripts to match it to x.
perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom  
see panel.cloud
f.value, distribution, tails.n  
see panel.qqmath
darg  
list of arguments passed to density
z  
see panel.parallel and panel.pairs
qtype  
type of quantile
...  
other arguments, usually ignored

Value

A list with components xlim, ylim, dx and dy, and possibly xat and yat, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for xyplot.
F_3_prepanel.functions

Useful Prepanel Function for Lattice

Description

These are predefined prepanel functions available in Lattice.

Usage

prepanel.lmline(x, y, ...)
preadpanel.qqmathline(x, y = x, distribution = qnorm,
                      probs = c(0.25, 0.75), qtype = 7,
                      groups, subscripts,
                      ...)
preadpanel.loess(x, y, span, degree, family, evaluation,
                   horizontal = FALSE, ...)
preadpanel.spline(x, y, npoints = 101,
                     horizontal = FALSE, ..., keep.data = FALSE)

Arguments

x, y x and y values, numeric or factor
distribution quantile function for theoretical distribution. This is automatically passed in
          when this is used as a prepanel function in qqmath.
qtype type of quantile
probs numeric vector of length two, representing probabilities. If used with
       aspect="xy", the aspect ratio will be chosen to make the line passing through
       the corresponding quantile pairs as close to 45 degrees as possible.
span, degree, family, evaluation
  Arguments controlling the underlying loess smooth.
horizontal, npoints
  See documentation for corresponding panel function.
keep.data Ignored. Present to capture argument of the same name in smooth.spline.
groups, subscripts
  See xyplot. Whenever appropriate, calculations are done separately for each
  group and then combined.
... Other arguments. These are passed on to other functions if appropriate (in par-
          ticular, smooth.spline), and ignored otherwise.
Details

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, prepanel.lmline computes the dx and dy such that it reflects the slope of the linear regression line; for prepanel.qqmathline, this is the slope of the line passing through the quantile pairs specified by probs. For prepanel.loess and prepanel.spline, dx and dy reflect the piecewise slopes of the nonlinear smooth.

Value

usually a list with components xlim, ylim, dx and dy, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under xyplot. There are also several prepanel functions that serve as the default for high level functions, see prepanel.default.xyplot

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, xyplot, banking, panel.loess, panel.spline.

Description

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The xscale.components and yscale.components arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the axis argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

Usage

xscale.components.default(lim,
   packet.number = 0,
   packet.list = NULL,
   top = TRUE,
   ...
) 
yscale.components.default(lim,
   packet.number = 0,
   packet.list = NULL,
   right = TRUE,
   ...
) 
axis.default(side = c("top", "bottom", "left", "right"),
   scales, components, as.table,
   labels = c("default", "yes", "no"),
   ticks = c("default", "yes", "no"),

G_axis.default  Default axis annotation utilities
Arguments

lim the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.

packet.number which packet (counted according to the packet order, described in \texttt{print.trellis}) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.

packet.list list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)

top, right the value of the top and right components of the result, as appropriate. See below for interpretation.

side on which side the axis is to be drawn. The usual partial matching rules apply.

scales the appropriate component of the scales argument supplied to the high level function, suitably standardized.

components list, similar to those produced by \texttt{xscale.components.default} and \texttt{yscale.components.default}.

as.table the as.table argument in the high level function.

labels whether labels are to be drawn. By default, the rules determined by scales are used.

ticks whether labels are to be drawn. By default, the rules determined by scales are used.

... many other arguments may be supplied, and are passed on to other internal functions.

prefix A character string identifying the plot being drawn (see \texttt{print.trellis}). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.

Details

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

Value

\texttt{xscale.components.default} and \texttt{yscale.components.default} return a list of the form suitable as the components argument of \texttt{axis.default}. Valid components in the return value of \texttt{xscale.components.default} are:

num.limit A numeric limit for the box.
bottom A list with two elements, ticks and labels. ticks must be a list with components at and tck which give the location and lengths of tick marks. tck can be a vector, and will be recycled to be as long as at. labels must be a list with components at, labels, and check.overlap. at and labels give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. check.overlap is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.

top This can be a logical flag; if TRUE, top is treated as being the same as bottom; if FALSE, axis annotation for the top axis is omitted. Alternatively, top can be a list like bottom.

Valid components in the return value of yscale.components.default are left and right. Their interpretations are analogous to (respectively) the bottom and top components described above.

G_banking

Banking

Description

Calculates banking slope
Usage

banking(dx, dy)

Arguments

dx, dy vector of consecutive x, y differences.

Details

banking is the banking function used when aspect = "xy" in high level Trellis functions. It is usually not very meaningful except with xyplot. It considers the absolute slopes (based on dx and dy) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs’ website (see Lattice), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying lattice.options("banking").

## with and without banking

plot <- xyplot(sunspot.year ~ 1700:1988, xlab = "", type = "l",
               scales = list(x = list(alternating = 2)),
               main = "Yearly Sunspots")
print(plot, position = c(0, .3, 1, .9), more = TRUE)
print(update(plot, aspect = "xy", main = "", xlab = "Year"),
      position = c(0, 0, 1, .3))

## cut-and-stack plot (see also xyplot.ts)

xyplot(sunspot.year ~ time(sunspot.year) | equal.count(time(sunspot.year)),
       xlab = "", type = "l", aspect = "xy", strip = FALSE,
       scales = list(x = list(alternating = 2, relation = "sliced")),
       as.table = TRUE, main = "Yearly Sunspots")
G_latticeParseFormula  Parse Trellis formula

Description

this function is used by high level Lattice functions like xyplot to parse the formula argument and evaluate various components of the data.

Usage

latticeParseFormula(model, data, dimension = 2,
subset = TRUE, groups = NULL,
multiple, outer,
subscripts,
drop)

Arguments

model the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the dimension argument. The 2d formulas are of the form $y \sim x \mid g_1 \times \ldots \times g_n$, and the 3d formulas are of the form $z \sim x \times y \mid g_1 \times \ldots \times g_n$. In the first form, $y$ may be omitted. The conditioning variables $g_1, \ldots, g_n$ can be omitted in either case.
data the environment/dataset where the variables in the formula are evaluated.
dimension dimension of the model, see above
subset index for choosing a subset of the data frame
groups the grouping variable, if present
multiple, outer logicals, determining how a '+' in the y and x components of the formula are processed. See xyplot for details
subscripts logical, whether subscripts are to be calculated
drop logical or list, similar to the drop.unused.levels argument in xyplot, indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

Value

Returns a list with several components, including left, right, left.name, right.name, condition for 2-D, and left, right.x, right.y, left.name, right.x.name, right.y.name, condition for 3-D. Other possible components are groups, subscr.

Saikat DebRoy, Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

xyplot, Lattice
Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

Usage

packet.panel.default(layout, condlevels, page, row, column, skip, all.pages.skip = TRUE)

Arguments

layout
the layout argument in high level functions, suitably standardized.

condlevels
a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels

page, row, column
the location of the panel in the coordinate system of pages, rows and columns.

skip
the skip argument in high level functions

all.pages.skip
whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is p, then the i-th conditioning variable will have level condlevels[[i]][p[i]].

  ## returns a function that when used as the 'packet.panel'
  ## argument in print.trellis plots page number 'n' only
  function(layout, page, ...) {
    stopifnot(layout[3] == 1)
    packet.panel.default(layout = layout, page = n, ...)
  }
}
data(mtcars)
HP <- equal.count(mtcars$hp, 6)
p <-
  xyplot(mpg ~ disp | HP * factor(cyl),
         mtcars, layout = c(0, 6, 1))
print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))
```

G_panel.axis

Panel Function for Drawing Axis Ticks and Labels

Description

panel.axis is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. current.panel.limits can be used to retrieve a panel’s x and y limits.

Usage

```r
panel.axis(side = c("bottom", "left", "top", "right"),
  at, labels = TRUE,
  draw.labels = TRUE,
  check.overlap = FALSE,
  outside = FALSE,
  ticks = TRUE,
  half = !outside,
  which.half,
  tck = as.numeric(ticks),
  rot = if (is.logical(labels)) 0 else c(90, 0),
  text.col, text.alpha, text.cex, text.font,
  text.fontfamily, text.fontface, text.lineheight,
  line.col, line.lty, line.lwd, line.alpha)
```

```r
current.panel.limits(unit = "native")
```
Arguments

side
A character string indicating which side axes are to be drawn on. Partial specification is allowed.

at
Numeric vector giving location of labels. Can be missing, in which case they are computed from the native coordinates of the active viewport.

labels
The labels to go along with at, as a character vector or a vector of expressions. This only makes sense provided at is explicitly specified, as otherwise the provided labels may not match the computed at values. Alternatively, labels can be a logical flag: If TRUE, the labels are derived from at, otherwise, labels are empty.

draw.labels
A logical indicating whether labels are to be drawn.

check.overlap
A logical, whether to check for overlapping of labels. This also has the effect of removing at values that are ‘too close’ to the limits.

outside
A logical flag, indicating whether to draw the labels outside the panel or inside. Note that outside=TRUE will only have a visible effect if clipping is disabled for the viewport (panel).

ticks
Logical flag, whether to draw the tickmarks.

half
Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in splom.

which.half
Character string, either "lower" or "upper", indicating which half is to be used for tick locations if half = TRUE. Defaults to whichever is suitable for splom.

tck
A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.

rot
Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.

text.col
Color for the axis label text. See gpar for more details on this and the other graphical parameters listed below.

text.alpha
Alpha-transparency value for the axis label text.

text.cex
Size multiplier for the axis label text.

text.font, text.fontfamily, text.fontface
Font for the axis label text.

text.lineheight
Line height for the axis label text.

unit
Which grid unit the values should be in.

Details

panel.axis can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in panel.pairs for splom, as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots ‘after the fact’ by adding axes.
2826

**G_panel.number**

Value

current.panel.limits returns a list with components xlim and ylim, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by unit, by default "native".

**G_panel.number** Accessing Auxiliary Information During Plotting

Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the panel, strip and axis functions. Note that this information is not available to the prepanel function, which is executed prior to the actual plotting.

Usage

current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)
trellis.currentLayout(which = c("packet", "panel"), prefix)

Arguments

which
whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

prefix
A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See trellis.focus.
G_Rows

Value

trellis.currentLayout returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. current.row and current.column return integer indices specifying which row and column in the layout are currently active. panel.number returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). packet.number gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. which.packet returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called panel.number and packet.number that were made available to panel and strip. If you have written such functions, it should be enough to replace instances of panel.number and packet.number by the corresponding function calls. You should also remove panel.number and packet.number from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G_utilities.3d Utility functions for 3-D plots

Description
These are (related to) the default panel functions for cloud and wireframe.

Usage

ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)

Arguments

x
x can be a numeric matrix with 3 rows for ltransform3dto3d

screen
list, as described in panel.cloud

R.mat
4x4 transformation matrix in homogeneous coordinates

dist
controls transformation to account for perspective viewing

Details

ltransform3dMatrix and ltransform3dto3d are utility functions to help in computation of projections. These functions are used inside the panel functions for cloud and wireframe. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the screen argument in cloud and wireframe and a R.mat, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying R.mat followed by the rotations in screen. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

**H_barley**  

Yield data from a Minnesota barley trial

### Description

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

### Usage

barley

### Format

A data frame with 120 observations on the following 4 variables.

- **yield**: Yield (averaged across three blocks) in bushels/acre.
- **year**: Factor with levels 1932, 1931
- **site**: Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

### Details

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

### Author(s)

Documentation contributed by Kevin Wright.

)

H_ethanol

Engine exhaust fumes from burning ethanol

Description

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

Usage

ethanol

Format

A data frame with 88 observations on the following 3 variables.

NOx  Concentration of nitrogen oxides (NO and NO2) in micrograms/J.
C    Compression ratio of the engine.
E    Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.
## Constructing panel functions on the fly

```r
EE <- equal.count(ethanol$E, number=9, overlap=1/4)
xyplot(NOx ~ C | EE, data = ethanol,
prepanel = function(x, y) prepanel.loess(x, y, span = 1),
xlab = "Compression ratio", ylab = "NOx (micrograms/J)",
panel = function(x, y) {
  panel.grid(h=-1, v= 2)
  panel.xyplot(x, y)
  panel.loess(x,y, span=1)
},
aspect = "xy")
```

# Wireframe loess surface fit. See Figure 4.61 from Cleveland.
```r
require(stats)
with(ethanol, {
  eth.lo <- loess(NOx ~ C * E, span = 1/3, parametric = "C",
                 drop.square = "C", family="symmetric")
  eth.marginal <- list(C = seq(min(C), max(C), length.out = 25),
                        E = seq(min(E), max(E), length.out = 25))
  eth.grid <- expand.grid(eth.marginal)
  eth.fit <- predict(eth.lo, eth.grid)
  wireframe(eth.fit ~ eth.grid$C * eth.grid$E,
            shade=TRUE,
            screen = list(z = 40, x = -60, y=0),
            distance = .1,
            xlab = "C", ylab = "E", zlab = "NOx")
})
```

### Melanoma skin cancer incidence

**Description**

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**

`melanoma`
**H_singer**

**Format**
A data frame with 37 observations on the following 2 variables.

- **year**  Years 1936 to 1972.
- **incidence**  Rate of melanoma cancer per 100,000 population.

**Note**
This dataset is not related to the `melanoma` dataset in the `boot` package with the same name.
The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per million, but this is not consistent with data found at the National Cancer Institute (https://www.cancer.gov/).

**Author(s)**
Documentation contributed by Kevin Wright.

**Source**

**References**

**Examples**

```r
# Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
data = melanoma,
aspect = "xy",
panel = function(x, y)

**H_singer**  
*Heights of New York Choral Society singers*

**Description**
Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**
singer
Format

A data frame with 235 observations on the following 2 variables.

**height** Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

  panel.qqmath(x, ...)
},
xlab = "Unit Normal Quantile",
ylab="Height (inches)"
)
```

Description

These datasets record mortality rates across all ages in the USA by cause of death, sex, and rural/urban status, 2011–2013. The two datasets represent the national aggregate rates and the region-wise rates for each administrative region under the Department of Health and Human Services (HHS).
H_USMortality

Usage

USMortality
USRegionalMortality

Format

USRegionalMortality is a data frame with 400 observations on the following 6 variables.

Region A factor specifying HHS Region. See details.
Status A factor with levels Rural and Urban
Sex A factor with levels Female and Male
Cause Cause of death. A factor with levels Alzheimers, Cancer, Cerebrovascular diseases, Diabetes, Flu and pneumonia, Heart disease, Lower respiratory, Nephritis, Suicide, and Unintentional injuries
Rate Age-adjusted death rate per 100,000 population
SE Standard error for the rate

USMortality is a data frame with 40 observations, containing the same variables with the exception of Region.

Details

The region-wise data give estimated rates separately for each of 10 HHS regions. The location of the regional offices and their coverage area, available from https://www.hhs.gov/about/agencies/iea/regional-offices/index.html, is given below.

HHS Region 01 - Boston: Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont
HHS Region 02 - New York: New Jersey, New York, Puerto Rico, and the Virgin Islands
HHS Region 03 - Philadelphia: Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia
HHS Region 04 - Atlanta: Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee
HHS Region 05 - Chicago: Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin
HHS Region 06 - Dallas: Arkansas, Louisiana, New Mexico, Oklahoma, and Texas
HHS Region 07 - Kansas City: Iowa, Kansas, Missouri, and Nebraska
HHS Region 08 - Denver: Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming
HHS Region 09 - San Francisco: Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and Republic of Palau
HHS Region 10 - Seattle: Alaska, Idaho, Oregon, and Washington

References

Examples

```r
dotplot(reorder(Cause, Rate) ~ Rate | Status,
data = USMortality, groups = Sex,
par.settings = simpleTheme(pch = 16), auto.key = list(columns = 2),
scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
dotplot(reorder(Cause, Rate):Sex ~ Rate | Status,
data = USRegionalMortality, groups = Sex,
scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
```

I_lset

**Interface to modify Trellis Settings - Defunct**

Description

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

Usage

```r
I_lset(theme = col.whitebg())
```

Arguments

- **theme**
  
  a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

Chapter 24

The mgcv package

anova.gam  Approximate hypothesis tests related to GAM fits

Description

Performs hypothesis tests relating to one or more fitted \texttt{gam} objects. For a single fitted \texttt{gam} object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to \texttt{drop1} rather than \texttt{anova.lm} (i.e. it’s like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table or GLRT test: this latter approach should not be use to test the significance of terms which can be penalized to zero. Models to be compared should be fitted to the same data using the same smoothing parameter selection method.

Usage

\begin{verbatim}
## S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
       freq = FALSE)
## S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3),...)
\end{verbatim}

Arguments

- \texttt{object,...} fitted model objects of class \texttt{gam} as produced by \texttt{gam}().
- \texttt{x} an \texttt{anova.gam} object produced by a single model call to \texttt{anova.gam}().
- \texttt{dispersion} a value for the dispersion parameter: not normally used.
- \texttt{test} what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp". Reset to "Chisq" for extended and general families unless NULL.
- \texttt{freq} whether to use frequentist or Bayesian approximations for parametric term p-values. See \texttt{summary.gam} for details.
- \texttt{digits} number of digits to use when printing output.
Details

If more than one fitted model is provided then \texttt{anova.glm} is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom (when possible this is a smoothing parameter uncertainty corrected version). For extended and general families this is set so that a GLRT test is used. The p-values resulting from the multi-model case are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to \texttt{anova.gam}, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notionl null model.

If only one model is provided then the significance of each model term is assessed using Wald like tests, conditional on the smoothing parameter estimates: see \texttt{summary.gam} and Wood (2013a,b) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but it is available in package \texttt{RLRsim}).

In the single model case \texttt{print.anova.gam} is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (freq=TRUE), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the \texttt{paraPen} argument will not be good.

Value

In the multi-model case \texttt{anova.gam} produces output identical to \texttt{anova.glm}, which it in fact uses.

In the single model case an object of class \texttt{anova.gam} is produced, which is in fact an object returned from \texttt{summary.gam}.

\texttt{print.anova.gam} simply produces tabulated output.

WARNING

If models 'a' and 'b' differ only in terms with no un-penalized components (such as random effects) then p values from \texttt{anova(a,b)} are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using 'paraPen': use freq=TRUE to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to \texttt{drop1}, not \texttt{anova.lm}.
bam

Description

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM (the extended families listed in family.mgcv can also be used). The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like gam, except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data (see Wood, Goude and Shaw, 2015). The advantage of bam is much lower memory footprint than gam, but it can also be much faster, for large datasets. bam can also compute on a cluster set up by the parallel package.

An alternative fitting approach (Wood et al. 2017, Li and Wood, 2019) is provided by the discrete=TRUE method. In this case a method based on discretization of covariate values and C code level parallelization (controlled by the nthreads argument instead of the cluster argument) is used. This extends both the data set and model size that are practical.
Usage

`bam(formula, family = gaussian(), data = list(), weights = NULL, subset = NULL, na.action = na.omit, offset = NULL, method = "fREML", control = list(), select = FALSE, scale = 0, gamma = 1, knots = NULL, sp = NULL, min.sp = NULL, paraPen = NULL, chunk.size = 10000, rho = 0, AR.start = NULL, discrete = FALSE, cluster = NULL, nthreads = 1, gc.level = 0, use.chol = FALSE, samfrac = 1, coef = NULL, drop.unused.levels = TRUE, G = NULL, fit = TRUE, drop.intercept = NULL, ...)`

Arguments

- **formula**: A GAM formula (see `formula.gam` and also `gam.models`). This is exactly like the formula for a GLM except that smooth terms, `s` and `te` can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).

- **family**: This is a family object specifying the distribution and link to use in fitting etc. See `glm` and `family` for more details. The extended families listed in `family.mgcv` can also be used.

- **data**: A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`: typically the environment from which `gam` is called.

- **weights**: prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. `weights <- weights/mean(weights)`).

- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.

- **na.action**: a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.

- **offset**: Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in `formula` (this used to conform to the behaviour of `lm` and `glm`).

- **method**: The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows’ Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation.

- **control**: A list of fit control parameters to replace defaults returned by `gam.control`. Any control parameters not supplied stay at their default values.

- **select**: Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See `gamma` to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.

- **scale**: If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for
Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.

**gamma**
Increase above 1 to force smoother fits. gamma is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so \( \log(n)/2 \) is BIC like). \( n/\text{gamma} \) can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.

**knots**
this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See tprs for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.

**sp**
A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then length(sp) must correspond to the number of underlying smoothing parameters. Note that discrete=TRUE may result in re-ordering of variables in tensor product smooths for improved efficiency, and sp must be supplied in re-ordered order.

**min.sp**
Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters full.sp, in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. length(min.sp) should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).

**paraPen**
optimal list specifying any penalties to be applied to parametric model terms. gam.models explains more.

**chunk.size**
The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to 4*p if chunk.size < 4*p where p is the number of coefficients.

**rho**
An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in std.rsd if non zero. Also usable with other models when discrete=TRUE, in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.

**AR.start**
logical variable of same length as data, TRUE at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If NULL then there are no breaks in AR1 correlation.

**discrete**
with method="REML" it is possible to discretize covariates for storage and efficiency reasons. If discrete is TRUE, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins.

**cluster**
bam can compute the computationally dominant QR decomposition in parallel using parLapply from the parallel package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.

**nthreads**
Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If NA set to max(1,length(cluster)). See details.
gc.level
to keep the memory footprint down, it can help to call the garbage collector often, but this takes a substantial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between. Not as much of a problem as it used to be.

use.chol
By default bam uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.

samfrac
For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. samfrac is the sampling fraction to use. 0.1 is often reasonable.

coeff
initial values for model coefficients

drop.unused.levels
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

G
if not NULL then this should be the object returned by a previous call to bam with fit=FALSE. Causes all other arguments to be ignored except sp, chunk.size, gamma, nthreads, cluster, rho, gc.level, samfrac, use.chol, method and scale (if >0).

fit
if FALSE then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the G argument to bam.

drop.intercept
Set to TRUE to force the model to really not have the a constant in the parametric model part, even with factor variables present.

... further arguments for passing on e.g. to gam.fit (such as mustart).

Details
When discrete=FALSE, bam operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using predict.gam. For each block the factor R, from the QR decomposition of the whole model matrix is updated, along with Q'y, and the sum of squares of y. At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudodata, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified via the asymptotic multivariate normality of Q'z where z is the IRLS pseudodata.

For full method details see Wood, Goude and Shaw (2015).

Note that POI is not as stable as the default nested iteration used with gam, but that for very large, information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are typically much less costly in the multi-dimensional case.
If cluster is provided as a cluster set up using `makeCluster` (or `makeForkCluster`) from the `parallel` package, then the rate limiting QR decomposition of the model matrix is performed in parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine it is usually best to set the cluster size to the number of physical cores, which is often less than what is reported by `detectCores`. Using more than the number of physical cores can result in no speed up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

When `discrete=TRUE` the covariate data are first discretized. Discretization takes place on a smooth by smooth basis, or in the case of tensor product smooths (or any smooth that can be represented as such, such as random effects), separately for each marginal smooth. The required spline bases are then evaluated at the discrete values, and stored, along with index vectors indicating which original observation they relate to. Fitting is by a version of performance oriented iteration/PQL using REML smoothing parameter selection on each iterative working model (as for the default method). The iteration is based on the derivatives of the REML score, without computing the score itself, allowing the expensive computations to be reduced to one parallel block Cholesky decomposition per iteration (plus two basic operations of equal cost, but easily parallelized). Unlike standard POI/PQL, only one step of the smoothing parameter update for the working model is taken at each step (rather than iterating to the optimal set of smoothing parameters for each working model). At each step a weighted model matrix crossproduct of the model matrix is required - this is efficiently computed from the pre-computed basis functions evaluated at the discretized covariate values. Efficient computation with tensor product terms means that some terms within a tensor product may be re-ordered for maximum efficiency. See Wood et al (2017) and Li and Wood (2019) for full details.

When `discrete=TRUE` parallel computation is controlled using the `nthreads` argument. For this method no cluster computation is used, and the `parallel` package is not required. Note that actual speed up from parallelization depends on the BLAS installed and your hardware. With the (R default) reference BLAS using several threads can make a substantial difference, but with a single threaded tuned BLAS, such as openblas, the effect is less marked (since cache use is typically optimized for one thread, and is then sub optimal for several). However the tuned BLAS is usually much faster than using the reference BLAS, however many threads you use. If you have a multi-threaded BLAS installed then you should leave `nthreads` at 1, since calling a multi-threaded BLAS from multiple threads usually slows things down: the only exception to this is that you might choose to form discrete matrix cross products (the main cost in the fitting routine) in a multi-threaded way, but use single threaded code for other computations: this can be achieved by e.g. `nthreads=c(2,1)`, which would use 2 threads for discrete inner products, and 1 for most code calling BLAS. Not that the basic reason that multi-threaded performance is often disappointing is that most computers are heavily memory bandwidth limited, not flop rate limited. It is hard to get data to one core fast enough, let alone trying to get data simultaneously to several cores.

`discrete=TRUE` will often produce identical results to the methods without discretization, since covariates often only take a modest number of discrete values anyway, so no approximation at all is involved in the discretization process. Even when some approximation is involved, the differences are often very small as the algorithms discretize marginally whenever possible. For example each margin of a tensor product smooth is discretized separately, rather than discretizing onto a grid of covariate values (for an equivalent isotropic smooth we would have to discretize onto a grid). The marginal approach allows quite fine scale discretization and hence very low approximation error. Note that when using the smooth id mechanism to link smoothing parameters, the discrete method cannot force the linked bases to be identical, so some differences to the non discrete methods will be noticeable.

The extended families given in `family.mgcv` can also be used. The extra parameters of these are estimated by maximizing the penalized likelihood, rather than the restricted marginal likelihood as
in `gam`. So estimates may differ slightly from those returned by `gam`. Estimation is accomplished by a Newton iteration to find the extra parameters (e.g. the theta parameter of the negative binomial or the degrees of freedom and scale of the scaled t) maximizing the log likelihood given the model coefficients at each iteration of the fitting procedure.

**Value**

An object of class "gam" as described in `gamObject`.

**WARNINGS**

The routine may be slower than optimal if the default "tp" basis is used.

Unless `discrete=TRUE`, you must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than 'gam' for the same dataset.

With `discrete=TRUE`, te terms are efficiently computed, but t2 are not.

**Examples**

```r
library(mgcv)
## See help("mgcv-parallel") for using bam in parallel

## Sample sizes are small for fast run times.
set.seed(3)
dat <- gamSim(1,n=25000,dist="normal",scale=20)
bs <- "cr";k <- 12
b <- bam(y ~ s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k)+
s(x3,bs=bs),data=dat)
summary(b)
plot(b,pages=1,rug=FALSE)  ## plot smooths, but not rug
```
bam.update

Update a strictly additive bam model for new data.

Description

Gaussian with identity link models fitted by `bam` can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

Usage

bam.update(b, data, chunk.size=10000)

Arguments

- **b**: A gam object fitted by `bam` and representing a strictly additive model (i.e. gaussian errors, identity link).
- **data**: Extra data to augment the original data used to obtain b. Must include a weights column if the original fit was weighted and a AR.start column if AR.start was non NULL in original fit.
- **chunk.size**: Size of subsets of data to process in one go when getting fitted values.
bam.update updates the QR decomposition of the (weighted) model matrix of the GAM represented by \( b \) to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the same AR1 model for the residuals as that employed in the original model fit (see rho parameter of \( \texttt{bam} \)).

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

**Value**

An object of class "gam" as described in \( \texttt{gamObject} \).

**WARNINGS**

AIC computation does not currently take account of AR model, if used.

**bandchol**

Choleski decomposition of a band diagonal matrix

**Description**

Computes Choleski decomposition of a (symmetric positive definite) band-diagonal matrix, A.

**Usage**

`bandchol(B)`

**Arguments**

B  
An n by k matrix containing the diagonals of the matrix A to be decomposed. First row is leading diagonal, next is first sub-diagonal, etc. sub-diagonals are zero padded at the end. Alternatively gives A directly, i.e. a square matrix with 2k-1 non zero diagonals (those from the lower triangle are not accessed).

**Details**

Calls `dpbtrf` from LAPACK. The point of this is that it has $O(k^2n)$ computational cost, rather than the $O(n^3)$ required by dense matrix methods.

**Value**

Let R be the factor such that t(R)%*%R = A. R is upper triangular and if the rows of B contained the diagonals of A on entry, then what is returned is an n by k matrix containing the diagonals of R, packed as B was packed on entry. If B was square on entry, then R is returned directly. See examples.

**References**

Examples

```r
require(mgcv)
## simulate a banded diagonal matrix
n <- 7; set.seed(8)
A <- matrix(0, n, n)
sdiag(A) <- runif(n); sdiag(A, 1) <- runif(n - 1)
sdiag(A, 2) <- runif(n - 2)
A <- crossprod(A)

## full matrix form...
bandchol(A)
chol(A) ## for comparison

## compact storage form...
B <- matrix(0, 3, n)
B[1, ] <- sdiag(A); B[2, 1:(n-1)] <- sdiag(A, 1)
B[3, 1:(n-2)] <- sdiag(A, 2)
bandchol(B)
```

betar

**GAM beta regression family**

### Description

Family for use with `gam` or `bam`, implementing regression for beta distributed data on (0,1). A linear predictor controls the mean, \( \mu \) of the beta distribution, while the variance is then \( \mu(1 - \mu)/(1 + \phi) \), with parameter \( \phi \) being estimated during fitting, alongside the smoothing parameters.

### Usage

```r
betar(theta = NULL, link = "logit", eps = .Machine$double.eps*100)
```

### Arguments

- **theta**: the extra parameter (\( \phi \) above).
- **link**: The link function: one of "logit", "probit", "cloglog" and "cauchit".
- **eps**: the response variable will be truncated to the interval \([\text{eps}, 1-\text{eps}]\) if there are values outside this range. This truncation is not entirely benign, but too small a value of \( \text{eps} \) will cause stability problems if there are zeroes or ones in the response.

### Details

These models are useful for proportions data which cannot be modelled as binomial. Note the assumption that data are in (0,1), despite the fact that for some parameter values 0 and 1 are perfectly legitimate observations. The restriction is needed to keep the log likelihood bounded for all parameter values. Any data exactly at 0 or 1 are reset to be just above 0 or just below 1 using the `eps` argument (in fact any observation <\text{eps} is reset to \text{eps} and any observation >1-\text{eps} is reset to 1-\text{eps}). Note the effect of this resetting. If \( \mu\phi > 1 \) then impossible 0s are replaced with highly improbable \text{eps} values. If the inequality is reversed then 0s with infinite probability density are replaced with \text{eps} values having high finite probability density. The equivalent condition for 1s is
Clearly all types of resetting are somewhat unsatisfactory, and care is needed if data contain 0s or 1s (often it makes sense to manually reset the 0s and 1s in a manner that somehow reflects the sampling setup).

### Value

An object of class `extended.family`.

### WARNINGS

Do read the details section if your data contain 0s and or 1s.

### Author(s)

Natalya Pya (nat.pya@gmail.com) and Simon Wood (s.wood@r-project.org)

### Examples

```r
library(mgcv)
## Simulate some beta data...
set.seed(3); n<-400
dat <- gamSim(1,n=n)
mu <- binomial()$linkinv(dat$f/4-2)
phi <- .5
a <- mu*phi;b <- phi - a;
dat$y <- rbeta(n,a,b)

bm <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=betar(link="logit"),data=dat)

bm
plot(bm,pages=1)
```

### blas.thread.test

#### BLAS thread safety

**Description**

Most BLAS implementations are thread safe, but some versions of OpenBLAS, for example, are not. This routine is a diagnostic helper function, which you will never need if you don’t set `nthreads>1`, and even then are unlikely to need.

**Usage**

```r
blas.thread.test(n=1000,nt=4)
```

**Arguments**

- **n**: Number of iterations to run of parallel BLAS calling code.
- **nt**: Number of parallel threads to use
Details

While single threaded OpenBLAS 0.2.20 was thread safe, versions 0.3.0-0.3.6 are not, and from version 0.3.7 thread safety of the single threaded OpenBLAS requires making it with the option USE_LOCKING=1. The reference BLAS is thread safe, as are MKL and ATLAS. This routine repeatedly calls the BLAS from multi-threaded code and is sufficient to detect the problem in single threaded OpenBLAS 0.3.x.

A multi-threaded BLAS is often no faster than a single-threaded BLAS, while judicious use of threading in the code calling the BLAS can still deliver a modest speed improvement. For this reason it is often better to use a single threaded BLAS and the codethreads options to bam or gam. For bam(...,discrete=TRUE) using several threads can be a substantial benefit, especially with the reference BLAS.

The MKL BLAS is multithreaded by default. Under linux setting environment variable MKL_NUM_THREADS=1 before starting R gives single threaded operation.

Simon N. Wood <simon.wood@r-project.org>

Description

mgcv works largely because many people have reported bugs over the years. If you find something that looks like a bug, please report it, so that the package can be improved. mgcv does not have a large development budget, so it is a big help if bug reports follow the following guidelines.

The ideal report consists of an email to <simon.wood@r-project.org> with a subject line including mgcv somewhere, containing

1. The results of running sessionInfo in the R session where the problem occurs. This provides platform details, R and package version numbers, etc.
3. Short cut and paste-able code that produces the problem, including the code for loading/generating the data (using standard R functions like load, read.table etc).
4. Any required data files. If you send real data it will only be used for the purposes of debugging.

Of course if you have dug deeper and have an idea of what is causing the problem, that is also helpful to know, as is any suggested code fix. (Don’t send a fixed package .tar.gz file, however - I can’t use this).

choldrop

Deletion and rank one Cholesky factor update

Description

Given a Cholesky factor, \( R \), of a matrix, \( A \), choldrop finds the Cholesky factor of \( A[-k,-k] \), where \( k \) is an integer. cholup finds the factor of \( A + uu^T \) (update) or \( A - uu^T \) (downdate).

Usage

choldrop(R, k)
cholup(R, u, up)

Arguments

- \( R \) : Cholesky factor of a matrix, \( A \).
- \( k \) : row and column of \( A \) to drop.
- \( u \) : vector defining rank one update.
- \( up \) : if TRUE compute update, otherwise downdate.

Details

First consider choldrop. If \( R \) is upper triangular then \( \text{t}(R[-k,-k]) \times \% \times \text{t}(R[-k]) = A[-k,-k] \), but \( R[-k,-k] \) has elements on the first sub-diagonal, from its \( k \)th column onwards. To get from this to a triangular Cholesky factor of \( A[-k,-k] \) we can apply a sequence of Givens rotations from the left to eliminate the sub-diagonal elements. The routine does this. If \( R \) is a lower triangular factor then Givens rotations from the right are needed to remove the extra elements. If \( n \) is the dimension of \( R \) then the update has \( O(n^2) \) computational cost.

cholup (which assumes \( R \) is upper triangular) updates based on the observation that \( R^T R + uu^T = [u, R^T]^T[u, R^T] = [u, R^T]Q^T Q[u, R^T]^T \), and therefore we can construct \( Q \) so that \( Q[u, R^T]^T = [0, R_1^T]^T \), where \( R_1 \) is the modified factor. \( Q \) is constructed from a sequence of Givens rotations in order to zero the elements of \( u \). Downdating is similar except that hyperbolic rotations have to be used in place of Givens rotations — see Golub and van Loan (2013, section 6.5.4) for details. Downdating only works if \( A - uu^T \) is positive definite. Again the computational cost is \( O(n^2) \).

Note that the updates are vector oriented, and are hence not susceptible to speed up by use of an optimized BLAS. The updates are set up to be relatively Cache friendly, in that in the upper triangular case successive Givens rotations are stored for sequential application column-wise, rather than being applied row-wise as soon as they are computed. Even so, the upper triangular update is slightly slower than the lower triangular update.

choose.k

Basis dimension choice for smooths

Description

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size, \( k \). When setting up models in the mgcv package, using s or te terms in a model formula, \( k \) must be chosen: the defaults are essentially arbitrary.

In practice \( k-1 \) (or \( k \)) sets the upper limit on the degrees of freedom associated with an s smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For te smooths the upper limit of the degrees of freedom is given by the product of the \( k \) values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the fx=TRUE option, in which case it is unpenalized.

So, exact choice of \( k \) is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.
choose.k

As with all model assumptions, it is useful to be able to check the choice of k informally. If the effective degrees of freedom for a model term are estimated to be much less than k-1 then this is unlikely to be very worthwhile, but as the EDF approach k-1, checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased k to see if there is pattern in the residuals that could potentially be explained by increasing k. Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect k and refit the original model. If there are no statistically important changes as a result of doing this, then k was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when k is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

gam.check runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which k is too low. Grossly too small k will also be visible from partial residuals available with plot.gam.

One scenario that can cause confusion is this: a model is fitted with k=10 for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with k=20 and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with k=20 contains a larger subspace of functions with EDF 8.7 than did the function space with k=10: one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

Examples

```r
## Simulate some data ....
library(mgcv)
set.seed(1)
dat <- gamSim(1,n=400,scale=2)

## fit a GAM with quite low 'k'
b<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),data=dat)
plot(b,pages=1,residuals=TRUE) ## hint of a problem in s(x2)

## the following suggests a problem with s(x2)
gam.check(b)

## Another approach (see below for more obvious method)....
## check for residual pattern, removeable by increasing 'k'
## typically 'k', below, should be substantially larger than
## the original, 'k' but certainly less than n/2.
## Note use of cheap "cs" shrinkage smoothers, and gamma=1.4
## to reduce chance of overfitting...
```
rsd <- residuals(b)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
rm(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
rm(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## 'k' too low
rm(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## refit...
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=20)+s(x3,k=6),data=dat)
gam.check(b) ## better

## similar example with multi-dimensional smooth
b1 <- gam(y~s(x0)+s(x1,x2,k=15)+s(x3),data=dat)
rsd <- residuals(b1)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,x2,k=100,bs="ts"),gamma=1.4,data=dat) ## 'k' too low
rsd <- residuals(b1)
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b1) ## shows same problem

## and a 'te' example
b2 <- gam(y~s(x0)+te(x1,x2,k=4)+s(x3),data=dat)
rsd <- residuals(b2)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~te(x1,x2,k=10,bs="cs"),gamma=1.4,data=dat) ## 'k' too low
rsd <- residuals(b2)
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b2) ## shows same problem

## same approach works with other families in the original model
data <- gamSim(1,n=400,scale=.25,dist="poisson")
bp<-gam(y~s(x0,k=5)+s(x1,k=5)+s(x2,k=5)+s(x3,k=5),
       data=dat,family=poisson,method="ML")
gam.check(bp)

rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
rm(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## 'k' too low
rm(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

tm(dat)

## More obvious, but more expensive tactic... Just increase
## suspicious k until fit is stable.
set.seed(0)
data <- gamSim(1,n=400,scale=2)
## fit a GAM with quite low 'k'
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
data=dat,method="REML")
b
## edf for 3rd smooth is highest as proportion of k -- increase k
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=12)+s(x3,k=6),
data=dat,method="REML")
b
## edf substantially up, -ve REML substantially down
```r
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
       data=dat,method="REML")
b
## slight edf increase and ~ve REML change
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
       data=dat,method="REML")
b
## definitely stabilized (but really k around 20 would have been fine)
```

cnorm

---

**GAM censored normal family for log-normal AFT and Tobit models**

**Description**

Family for use with `gam` or `bam`, implementing regression for censored normal data. If `y` is the response with mean `μ` and standard deviation `w^{-1/2} \exp(\theta)`, then `w^{1/2}(y - μ) \exp(-θ)` follows an `N(0, 1)` distribution. That is

\[
y \sim N(μ, e^{θ}w^{-1}).
\]

`θ` is a single scalar for all observations. Observations may be left, interval or right censored or uncensored.

Useful for log-normal accelerated failure time (AFT) models, Tobit regression, and crudely rounded data, for example.

**Usage**

`cnorm(theta=NULL,link="identity")`

**Arguments**

- **theta**: log standard deviation parameter. If supplied and positive then taken as a fixed value of standard deviation (not its log). If supplied and negative taken as negative of initial value for standard deviation (not its log).
- **link**: The link function: "identity", "log" or "sqrt".

**Details**

If the family is used with a vector response, then it assumed that there is no censoring, and a regular Gaussian regression results. If there is censoring then the response should be supplied as a two column matrix. The first column is always numeric. Entries in the second column are as follows.

- If an entry is identical to the corresponding first column entry, then it is an uncensored observation.
- If an entry is numeric and different to the first column entry then there is interval censoring. The first column entry is the lower interval limit and the second column entry is the upper interval limit. `y` is only known to be between these limits.
- If the second column entry is `-Inf` then the observation is left censored at the value of the entry in the first column. It is only known that `y` is less than or equal to the first column value.
- If the second column entry is `Inf` then the observation is right censored at the value of the entry in the first column. It is only known that `y` is greater than or equal to the first column value.
Any mixture of censored and uncensored data is allowed, but be aware that data consisting only of right and/or left censored data contain very little information.

**Value**

An object of class extended.family.

**columb**

*Reduced version of Columbus OH crime data*

**Description**

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

**Usage**

```r
data(columb)
data(columb.polys)
```

**Format**

- *columb* is a 49 row data frame with the following columns:
  - **area**: land area of district
  - **home.value**: housing value in 1000USD.
  - **income**: household income in 1000USD.
  - **crime**: residential burglaries and auto thefts per 1000 households.
  - **open.space**: measure of open space in district.
  - **district**: code identifying district, and matching `names(columb.polys)`.

- *columb.polys* contains the polygons defining the areas in the format described below.

**Details**

The data frame *columb* relates to the districts whose boundaries are coded in *columb.polys*. *columb.polys[[i]]* is a 2 column matrix, containing the vertices of the polygons defining the boundary of the *i*th district. *columb.polys[[2]]* has an artificial hole inserted to illustrate how holes in districts can be specified. Different polygons defining the boundary of a district are separated by NA rows in *columb.polys[[1]]*, and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). `names(columb.polys)` matches `columb$district` (order unimportant).
Source

The data are adapted from the Columbus example in the spdep package, where the original source is given as:

## see ?mrf help files

---

### Description

Produces summary measures of concurvity between gam components.

### Usage

```r
concurvity(b, full=TRUE)
```

### Arguments

- `b` An object inheriting from class "gam".
- `full` If `TRUE` then concurvity of each term with the whole of the rest of the model is considered. If `FALSE` then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered.

### Details

Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term, f, in the model can be decomposed into a part, g, that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term’s own space. If g makes up a large part of f then there is a concurvity problem. The indices used are all based on the square of $||g||/||f||$, that is the ratio of the squared Euclidean norms of the vectors of f and g evaluated at the observed covariate values.

The three measures are as follows

- **Worst** This is the largest value that the square of $||g||/||f||$ could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.
This just returns the value of the square of $||g||/||f||$ according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.

This is the squared F-norm of the basis for $g$ divided by the F-norm of the basis for $f$. It is a measure of the extent to which the $f$ basis can be explained by the $g$ basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.

Value

If full=TRUE a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If full=FALSE a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

## fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")

## assess concurvity between each term and `rest of model'...
concurvity(b)

## ... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)
**Description**

The `cox.ph` family implements the Cox Proportional Hazards model with Peto’s correction for ties, optional stratification, and estimation by penalized partial likelihood maximization, for use with `gam`. In the model formula, event time is the response. Under stratification the response has two columns: time and a numeric index for stratum. The `weights` vector provides the censoring information (0 for censoring, 1 for event). `cox.ph` deals with the case in which each subject has one event/censoring time and one row of covariate values. When each subject has several time dependent covariates see `cox.pht`.

See example below for conditional logistic regression.

**Usage**

```r
cox.ph(link="identity")
```

**Arguments**

- `link` currently (and possibly for ever) only "identity" supported.

**Details**

Used with `gam` to fit Cox Proportional Hazards models to survival data. The model formula will have event/censoring times on the left hand side and the linear predictor specification on the right hand side. Censoring information is provided by the `weights` argument to `gam`, with 1 indicating an event and 0 indicating censoring.

Stratification is possible, allowing for different baseline hazards in different strata. In that case the response has two columns: the first is event/censoring time and the second is a numeric stratum index. See below for an example.

Prediction from the fitted model object (using the `predict` method) with `type="response"` will predict on the survivor function scale. This requires evaluation times to be provided as well as covariates (see example). Also see example code below for extracting the cumulative baseline hazard/survival directly. The fitted.values stored in the model object are survival function estimates for each subject at their event/censoring time.

`deviance`, `martingale`, `score`, or ` schoenfeld` residuals can be extracted. See Klein and Moeschberger (2003) for descriptions. The score residuals are returned as a matrix of the same dimension as the model matrix, with a "terms" attribute, which is a list indicating which model matrix columns belong to which model terms. The score residuals are scaled. For parametric terms this is by the standard deviation of associated model coefficient. For smooth terms the sub matrix of score residuals for the term is postmultiplied by the transposed Cholesky factor of the covariance matrix for the term’s coefficients. This is a transformation that makes the coefficients approximately independent, as required to make plots of the score residuals against event time interpretable for checking the proportional hazards assumption (see Klein and Moeschberger, 2003, p376). Penalization causes drift in the score residuals, which is also removed, to allow the residuals to be approximately interpreted as unpenalized score residuals. Schoenfeld and score residuals are computed by strata. See the examples for simple PH assumption checks by plotting score residuals, and Klein and Moeschberger (2003, section 11.4) for details. Note that high correlation between terms can undermine these checks.

Estimation of model coefficients is by maximising the log-partial likelihood penalized by the smoothing penalties. See e.g. Hastie and Tibshirani, 1990, section 8.3. for the partial likelihood used (with Peto’s approximation for ties), but note that optimization of the partial likelihood does
The percentage deviance explained reported for Cox PH models is based on the sum of squares of the deviance residuals, as the model deviance, and the sum of squares of the deviance residuals when the covariate effects are set to zero, as the null deviance. The same baseline hazard estimate is used for both.

This family deals efficiently with the case in which each subject has one event/censoring time and one row of covariate values. For studies in which there are multiple time varying covariate measures for each subject then the equivalent Poisson model should be fitted to suitable pseudodata using bam(..., discrete=TRUE). See `cox.pht`.

**Value**

An object inheriting from class `general.family`.

```

## conditional logistic regression models are often estimated using the
## cox proportional hazards partial likelihood with a strata for each
## case-control group. A dummy vector of times is created (all equal).
## The following compares to 'clogit' for a simple case. Note that
## the gam log likelihood is not exact if there is more than one case
## per stratum, corresponding to clogit's approximate method.

```r
library(survival); library(mgcv)
infert$dumt <- rep(1, nrow(infert))
```
The \texttt{cox.ph} family only allows one set of covariate values per subject. If each subject has several time varying covariate measurements then it is still possible to fit a proportional hazards regression model, via an equivalent Poisson model. The recipe is provided by Whitehead (1980) and is equally valid in the smooth additive case. Its drawback is that the equivalent Poisson dataset can be quite large.

The trick is to generate an artificial Poisson observation for each subject in the risk set at each non-censored event time. The corresponding covariate values for each subject are whatever they are at the event time, while the Poisson response is zero for all subjects except those experiencing the event at that time (this corresponds to Peto’s correction for ties). The linear predictor for the model must include an intercept for each event time (the cumulative sum of the exponential of these is the Breslow estimate of the baseline hazard).

Below is some example code employing this trick for the \texttt{pbcseq} data from the \texttt{survival} package. It uses \texttt{bam} for fitting with the \texttt{discrete=TRUE} option for efficiency: there is some approximation involved in doing this, and the exact equivalent to what is done in \texttt{cox.ph} is rather obtained by using \texttt{gam} with \texttt{method="REML"} (taking many times the computational time for the example below). An alternative fits the model as a conditional logistic model using stratified Cox PH with event times as strata (see example). This would be identical in the unpenalized case, but smoothing parameter estimates can differ.

The function \texttt{tdpois} in the example code uses crude piecewise constant interpolation for the covariates, in which the covariate value at an event time is taken to be whatever it was the previous time that it was measured. Obviously more sophisticated interpolation schemes might be preferable.

cSplineDes

---

### cSplineDes

**Evaluate cyclic B spline basis**

**Description**

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.

**Usage**

`cSplineDes(x, knots, ord = 4, derivs=0)`

**Arguments**

- `x` covariate values for smooth.
- `knots` The knot locations: the range of these must include all the data.
- `ord` order of the basis. 4 is a cubic spline basis. Must be >1.
- `derivs` order of derivative of the spline to evaluate, between 0 and ord-1. Recycled to length of `x`.

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with `length(x)` rows and `length(knots)-1` columns.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**

- `cyclic.p.spline`
Examples

```r
require(mgcv)
## create some x's and knots...
 n <- 200
 x <- 0:(n-1)/(n-1); k <- 0:5/5
 X <- cSplineDes(x,k) # cyclic spline design matrix
## plot evaluated basis functions...
 plot(x,X[,1],type="l"); for (i in 2:5) lines(x,X[,i],col=i)
## check that the ends match up....
 ee <- X[1,]-X[n,]
 tol <- .Machine$double.eps^.75
 if (all.equal(ee,ee*0,tolerance=tol)!=TRUE)
   stop("cyclic spline ends don't match!")
## similar with uneven data spacing...
 x <- sort(runif(n)) + 1 # sorting just makes end checking easy
 k <- seq(min(x),max(x),length=8) # create knots
 X <- cSplineDes(x,k) # get cyclic spline model matrix
 plot(x,X[,1],type="l"); for (i in 2:ncol(X)) lines(x,X[,i],col=i)
 ee <- X[1,]-X[n,]; ee # do ends match??
 tol <- .Machine$double.eps^.75
 if (all.equal(ee,ee*0,tolerance=tol)!=TRUE)
   stop("cyclic spline ends don't match!")
```

---

**dDeta**

**Obtaining derivative w.r.t. linear predictor**

**Description**

INTERNAL function. Distribution families provide derivatives of the deviance and link w.r.t. \( \mu = \text{inv}_\text{link}(\eta) \). This routine converts these to the required derivatives of the deviance w.r.t. \( \eta \), the linear predictor.

**Usage**

```r
dDeta(y, mu, wt, theta, fam, deriv = 0)
```

**Arguments**

- `y` vector of observations.
- `mu` if \( \eta \) is the linear predictor, \( \mu = \text{inv}_\text{link}(\eta) \). In a traditional GAM \( \mu = E(y) \).
- `wt` vector of weights.
- `theta` vector of family parameters that are not regression coefficients (e.g. scale parameters).
- `fam` the family object.
- `deriv` the order of derivative of the smoothing parameter score required.

**Value**

A list of derivatives.
Author(s)

Simon N. Wood <simon.wood@r-project.org>.

---

**dpnorm**

*Stable evaluation of difference between normal c.d.f.s*

**Description**

Evaluates the difference between two $N(0, 1)$ cumulative distribution functions avoiding cancellation error.

**Usage**

```
dpnorm(x0, x1)
```

**Arguments**

- `x0`: vector of lower values at which to evaluate standard normal distribution function.
- `x1`: vector of upper values at which to evaluate standard normal distribution function.

**Details**

Equivalent to `pnorm(x1) - pnorm(x0)`, but stable when `x0` and `x1` values are very close, or in the upper tail of the standard normal.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```r
require(mgcv)
x <- seq(-10, 10, length=10000)
eps <- 1e-10
y0 <- pnorm(x+eps)-pnorm(x) ## cancellation prone
y1 <- dpnorm(x, x+eps) ## stable
## illustrate stable computation in black, and
## cancellation prone in red...
par(mfrow=c(1,2),mar=c(4,4,1,1))
plot(log(y1),log(y0),type="l")
lines(log(y1[x>0]),log(y0[x>0]),col=2)
plot(x,log(y1),type="l")
lines(x,log(y0),col=2)
```
Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for vis.gam and plot.gam.

Usage

```r
exclude.too.far(g1, g2, d1, d2, dist)
```

Arguments

- `g1`: co-ordinates of grid relative to first axis.
- `g2`: co-ordinates of grid relative to second axis.
- `d1`: co-ordinates of data relative to first axis.
- `d2`: co-ordinates of data relative to second axis.
- `dist`: how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and `dist` is a distance within this unit square.

Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in `g1` and `g2` lies exactly in the unit square (i.e. on [0,1] by [0,1]). These scalings are applied to `g1`, `g2`, `d1` and `d2`. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than `dist` the corresponding entry in the returned array is set to TRUE (otherwise to FALSE). The distance calculations are performed in compiled code for speed without storage overheads.

Value

A logical array with TRUE indicating a node in the grid defined by `g1`, `g2` that is ‘too far’ from any datum.

extract.lme.cov

Extract the data covariance matrix from an lme object

Description

This is a service routine for gamm. Extracts the estimated covariance matrix of the data from an lme object, allowing the user control about which levels of random effects to include in this calculation. extract.lme.cov forms the full matrix explicitly: extract.lme.cov2 tries to be more economical than this.

Usage

    extract.lme.cov(b,data=NULL,start.level=1)
    extract.lme.cov2(b,data=NULL,start.level=1)

Arguments

b 
  A fitted model object returned by a call to lme

data 
  The data frame/ model frame that was supplied to lme, but with any rows removed by the na.action dropped. Uses the data stored in the model object if not supplied.

start.level 
  The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.

Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extracts that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The extract.lme.cov calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. extract.lme.cov2 is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.
**extract.lme.cov**

**gamm** uses **extract.lme.cov2**.

**extract.lme.cov** does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. **extract.lme.cov2** does deal with this situation.

**Value**

For **extract.lme.cov** an estimated covariance matrix.

For **extract.lme.cov2** a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

```
Factor smooth interactions in GAMs

Description

The interaction of one or more factors with a smooth effect, produces a separate smooth for each factor level. These smooths can have different smoothing parameters, or all have the same smoothing parameter. There are several ways to set them up.

Factor by variables. If the by variables for a smooth (specified using s, te, ti or t2) is a factor, then a separate smooth is produced for each factor level. If the factor is ordered, then no smooth is produced for its first level: this is useful for setting up models which have a reference level smooth and then difference to reference smooths for each factor level except the first (which is the reference). Giving the smooth an id forces the same smoothing parameter to be used for all levels of the factor. For example s(x, by=fac, id=1) would produce a separate smooth of x for each level of fac, with each smooth having the same smoothing parameter. See gam.models for more.

Sum to zero smooth interactions bs="sz" These factor smooth interactions are specified using s(...,bs="sz"). There may be several factors supplied, and a smooth is produced for each combination of factor levels. The smooths are constructed to exclude the ‘main effect’ smooth, or the effects of individual smooths produced for lower order combinations of factor levels. For example, with a single factor, the smooths for the different factor levels are so constrained that the sum over all factor levels of equivalent spline coefficients are all zero. This allows the meaningful and identifiable construction of models with a main effect smooth plus smooths for the difference between each factor level and the main effect. Such a construction is often more natural than the by variable with ordered factors construction. See smooth.construct.sz.smooth.spec.

Random wiggly curves bs="fs" This approach produces a smooth curve for each level of a single factor, treating the curves as entirely random. This means that in principle a model can be constructed with a main effect plus factor level smooth deviations from that effect. However the model is not forced to make the main effect do as much of the work as possible, in the way that the "sz" approach does. This approach can be very efficient with gamm as it exploits the nested estimation available in lme. See smooth.construct.fs.smooth.spec.

family.mgcv

**Distribution families in mgcv**

**Description**

As well as the standard families documented in family (see also glm) which can be used with functions gam, bam and gamm, mgcv also supplies some extra families, most of which are currently only usable with gam, although some can also be used with bam. These are described here.

**Details**

The following families are in the exponential family given the value of a single parameter. They are usable with all modelling functions.

- **Tweedie** An exponential family distribution for which the variance of the response is given by the mean response to the power \( p \). \( p \) is in \((1,2)\) and must be supplied. Alternatively, see tw to estimate \( p \) (gam/bam only).
- **negbin** The negative binomial. Alternatively see nb to estimate the \( \theta \) parameter of the negative binomial (gam/bam only).

The following families are for regression type models dependent on a single linear predictor, and with a log likelihood which is a sum of independent terms, each corresponding to a single response observation. Usable with gam, with smoothing parameter estimation by "REML" or "ML" (the latter does not integrate the unpenalized and parameteric effects out of the marginal likelihood optimized for the smoothing parameters). Also usable with bam.

- **betar** for proportions data on \((0,1)\) when the binomial is not appropriate.
- `cnorm` censored normal distribution, for log normal accelerated failure time models, Tobit regression and rounded data, for example.
- `nb` for negative binomial data when the `theta` parameter is to be estimated.
- `ocat` for ordered categorical data.
- `scat` scaled t for heavy tailed data that would otherwise be modelled as Gaussian.
- `tw` for Tweedie distributed data, when the power parameter relating the variance to the mean is to be estimated.
- `zip` for zero inflated Poisson data, when the zero inflation rate depends simply on the Poisson mean.

The following families implement more general model classes. Usable only with `gam` and only with REML or NCV smoothing parameter estimation.
- `cox.ph` the Cox Proportional Hazards model for survival data (no NCV).
- `gammals` a gamma location-scale model, where the mean and standard deviation are modelled with separate linear predictors.
- `gaulss` a Gaussian location-scale model where the mean and the standard deviation are both modelled using smooth linear predictors.
- `gev1ss` a generalized extreme value (GEV) model where the location, scale and shape parameters are each modelled using a linear predictor.
- `gumb1ss` a Gumbel location-scale model (2 linear predictors).
- `shash` Sinh-arcsinh location scale and shape model family (4 linear predictors).
- `ziplss` a ‘two-stage’ zero inflated Poisson model, in which ‘potential-presence’ is modelled with one linear predictor, and Poisson mean abundance given potential presence is modelled with a second linear predictor.
- `mvn` multivariate normal additive models (no NCV).
- `multinom` multinomial logistic regression, for unordered categorical responses.

**FFdes**  
*Level 5 fractional factorial designs*

**Description**

Computes level 5 fractional factorial designs for up to 120 factors using the algorithm of Sanchez and Sanchez (2005), and optionally central composite designs.

**Usage**

`FFdes(size=5, ccd=FALSE)`
**Arguments**

- **size**: number of factors up to 120.
- **ccd**: if TRUE, adds points along each axis at the same distance from the origin as the points in the fractional factorial design, to create the outer points of a central composite design. Add central points to complete.

**Details**

Basically a translation of the code provided in the appendix of Sanchez and Sanchez (2005).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

**Examples**

```r
require(mgcv)
plot(rbind(0,FFdes(2,TRUE)),xlab="x",ylab="y",
     col=c(2,1,1,1,4,4,4,4),pch=19,main="CCD")
FFdes(5)
FFdes(5,TRUE)
```

**Description**

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.

**Usage**

```r
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)
```

**Arguments**

- **fam**: A family.
Details

Consider the first 3 function first.

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions dvar, d2var, d3var, d2link, d3link, d4link and for RE/ML 1s, then these functions simply return the family unmodified: this allows non-standard links to be used with gam when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then d4link and d3var can be dummy, as they are ignored. Similarly 1s is only needed for RE/ML.

The dvar function is a function of a mean vector, mu, and returns a vector of corresponding first derivatives of the family variance function. The d2link function is also a function of a vector of mean values, mu: it returns a vector of second derivatives of the link, evaluated at mu. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a dvar and d2var, function if your family only requires links that occur in one of the standard families.

The second two functions are useful for investigating the distribution of residuals and are used by qq.gam. If possible the functions add quantile (qf) or random deviate (rd) generating functions to the family. If a family already has qf or rd functions then it is left unmodified. qf functions are only available for some families, and for quasi families neither type of function is available.

Value

A family object with extra component functions dvar, d2var, d2link, d3link, d4link, 1s, and possibly qf and rd, depending on which functions are called. fix.family.var also adds a variable scale set to negative to indicate that family has a free scale parameter.

gam.fit3, qq.gam
Usage

fixDependence(X1, X2, tol = .Machine$double.eps^*.5, rank.def=0, strict=FALSE)

Arguments

X1  A matrix.
X2  A matrix, the columns of which may be partially linearly dependent on the
columns of X1.
tol  The tolerance to use when assessing linear dependence.
rank.def  If the degree of rank deficiency in X2, given X1, is known, then it can be supplied
here, and tol is then ignored. Unused unless positive and not greater than the
number of columns in X2.
strict  if TRUE then only columns individually dependent on X1 are detected, if FALSE
then enough columns to make the reduced X2 full rank and independent of X1
are detected.

Details

The algorithm uses a simple approach based on QR decomposition: see Wood (2017, section 5.6.3)
for details.

Value

A vector of the columns of X2 which are linearly dependent on columns of X1 (or which need to
be deleted to achieve independence and full rank if strict==FALSE). NULL if the two matrices are
independent.

X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
fixDependence(X1,X2, strict=TRUE)
**Description**

Description of `gam` formula (see Details), and how to extract it from a fitted `gam` object.

**Usage**

```r
## S3 method for class 'gam'
formula(x,...)
```

**Arguments**

- **x**: fitted model objects of class `gam` (see `gamObject`) as produced by `gam()`.
- **...**: un-used in this case

**Details**

`gam` will accept a formula or, with some families, a list of formulae. Other `mgcv` modelling functions will not accept a list. The list form provides a mechanism for specifying several linear predictors, and allows these to share terms: see below.

The formulae supplied to `gam` are exactly like those supplied to `glm` except that smooth terms, `s`, `te`, `ti` and `t2` can be added to the right hand side (and `. ` is not supported in `gam` formulae).

Smooth terms are specified by expressions of the form:

$s(x_1, x_2, \ldots, k=12, fx=FALSE, bs="tp", by=z, id=1)$

where $x_1$, $x_2$, etc. are the covariates which the smooth is a function of, and $k$ is the dimension of the basis used to represent the smooth term. If $k$ is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for $k$, but if not informal checking is easy: see `choose.k` and `gam.check`.

`fx` is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by $k$ (almost always $k-1$). `bs` indicates the basis to use for the smooth: the built in options are described in `smooth.terms`, and user defined smooths can be added (see `user.defined.smooth`). If `bs` is not supplied then the default "tp" (`tprs`) basis is used. `by` can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x, by=z))` would specify a model $E(y) = f(x)z$ where $f(\cdot)$ is a smooth function. The `by` option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for ‘varying coefficient models’: see `gam.models`. `id` is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

`te(x, z, bs=c("tp", "tp"), m=c(2,3), k=c(5,10))`

which would specify a tensor product smooth of the two covariates $x$ and $z$ constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. `te` provides further information. `ti` terms are a variant designed to be used as interaction terms when the main effects (and any lower order interactions) are present. `t2` produces tensor product smooths that are the natural low rank analogue of smoothing spline anova models.
s, te, ti and t2 terms accept an sp argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If sp is supplied then it over-rides whatever is in the sp argument to gam, if it is not supplied then it defaults to all negative, but does not over-ride the sp argument to gam.

Formulae can involve nested or “overlapping” terms such as
\[ y = s(x) + s(z) + s(x, z) \quad \text{or} \quad y = s(x, z) + s(z, v) \]
but nested models should really be set up using ti terms: see gam.side for further details and examples.

Smooth terms in a gam formula will accept matrix arguments as covariates (and corresponding by variable), in which case a ‘summation convention’ is invoked. Consider the example of
\[ s(X, Z, \text{by}=L) \]
where \( X, Z \) and \( L \) are \( n \) by \( m \) matrices. Let \( F \) be the \( n \) by \( m \) matrix that results from evaluating the smooth at the values in \( X \) and \( Z \). Then the contribution to the linear predictor from the term will be rowSums(\( F*L \)) (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see linear.functional.terms for more information and examples (including functional linear models/signal regression).

Note that gam allows any term in the model formula to be penalized (possibly by multiple penalties), via the paraPen argument. See gam.models for details and example code.

When several formulae are provided in a list, then they can be used to specify multiple linear predictors for families for which this makes sense (e.g. mvn). The first formula in the list must include a response variable, but later formulae need not (depending on the requirements of the family). Let the linear predictors be indexed, \( 1 \) to \( d \) where \( d \) is the number of linear predictors, and the indexing is in the order in which the formulae appear in the list. It is possible to supply extra formulae specifying that several linear predictors should share some terms. To do this a formula is supplied in which the response is replaced by numbers specifying the indices of the linear predictors which will share the terms specified on the r.h.s. For example \( 1+3\sim s(x)+z-1 \) specifies that linear predictors 1 and 3 will share the terms \( s(x) \) and \( z \) (but we don’t want an extra intercept, as this would usually be unidentifiable). Note that it is possible that a linear predictor only includes shared terms: it must still have its own formula, but the r.h.s. would simply be \(-1\) (e.g. \( y \sim -1 \) or \( \sim -1 \)). See multinom for an example.

Value

Returns the model formula, x$formula. Provided so that anova methods print an appropriate description of the model.

WARNING

A gam formula should not refer to variables using e.g. dat["x"].

gam
Description

This is a service routine for `gamm`. Given, $V$, an estimated covariance matrix obtained using `extract.lme.cov2` this routine forms a matrix square root of $X^T V^{-1} X$ as efficiently as possible, given the structure of $V$ (usually sparse).

Usage

`formXtViX(V, X)`

Arguments

- `V`: A data covariance matrix list returned from `extract.lme.cov2`
- `X`: A model matrix.

Details

The covariance matrix returned by `extract.lme.cov2` may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

Value

A matrix, $R$ such that `crossprod(R)` gives $X^T V^{-1} X$.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

For `lme` see:

For details of how GAMMs are set up for estimation using `lme` see:

[https://www.maths.ed.ac.uk/~swood34/](https://www.maths.ed.ac.uk/~swood34/)

`gamm, extract.lme.cov2`
Examples

```r
require(mgcv)
library(nlme)
data(ergoStool)
b <- lme(effort ~ Type, data=ergoStool, random=~1|Subject)
V1 <- extract.lme.cov(b, ergoStool)
V2 <- extract.lme.cov2(b, ergoStool)
X <- model.matrix(b, data=ergoStool)
crossprod(formXtViX(V2, X))
t(X)
```

---

**fs.test**

**FELSPLINE test function**

Description

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

Usage

```r
fs.test(x,y,r0=.1, r=.5, l=3, b=1, exclude=TRUE)
fs.boundary(r0=.1, r=.5, l=3, n.theta=20)
```

Arguments

- `x,y` Points at which to evaluate the test function.
- `r0` The test domain is a sort of bent sausage. This is the radius of the inner bend.
- `r` The radius of the curve at the centre of the sausage.
- `l` The length of an arm of the sausage.
- `b` The rate at which the function increases per unit increase in distance along the centre line of the sausage.
- `exclude` Should exterior points be set to NA?
- `n.theta` How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve.

Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

Value

`fs.test` returns function evaluations, or NAs for points outside the boundary. `fs.boundary` returns a list of `x,y` points to be jointed up in order to define/draw the boundary.

Author(s)

Simon N. Wood <simon.wood@r-project.org>
References

Examples

```r
require(mgcv)
# plot the function, and its boundary...
fsb <- fs.boundary()
m<-300;n<-150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsb$x,fsb$y,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```

full.score

GCV/UBRE score for use within nlm

Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters.

This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the the outer method is "nlm.fd" (see `gam` argument optimizer).

Usage

```r
full.score(sp,G,family,control,gamma,...)
```

Arguments

- `sp` The logs of the smoothing parameters
- `G` a list returned by `mgcv:::gam.setup`
- `family` The family object for the GAM.
- `control` a list returned be `gam.control`
- `gamma` the degrees of freedom inflation factor (usually 1).
- `...` other arguments, typically for passing on to `gam.fit`.

Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by `gam.fit`.

Author(s)

Simon N. Wood <simon.wood@r-project.org>
**Description**

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM and a variety of other models estimated by a quadratically penalised likelihood type approach (see `family.mgcv`). The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Confidence/credible intervals are readily available for any quantity predicted using a fitted model.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML/NCV or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate), and users can add smooths. Linear functionals of smooths can also be included in models. For an overview of the smooths available see `smooth.terms`. For more on specifying models see `gam.models`, `random.effects` and `linear.functional.terms`. For more on model selection see `gam.selection`. Do read `gam.check` and `choose.k`.

See package `gam`, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see `bam`, for mixed GAM see `gamm` and `random.effects`.

**Usage**

```r
gam(formula,family=gaussian(),data=list(),weights=NULL,subset=NULL,
    na.action,offset=NULL,method="GCV.Cp",
    optimizer=c("outer","newton"),control=list(),scale=0,
    select=FALSE,knots=NULL,sp=NULL,min.sp=NULL,H=NULL,gamma=1,
    fit=TRUE,paraPen=NULL,G=NULL,in.out,drop.unused.levels=TRUE,
    drop.intercept=NULL,nei=NULL,discrete=FALSE,...)
```

**Arguments**

- **formula** A GAM formula, or a list of formulae (see `formula.gam` and also `gam.models`). These are exactly like the formula for a GLM except that smooth terms, s, te, ti and t2, can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).

- **family** This is a family object specifying the distribution and link to use in fitting etc (see `glm` and `family`). See `family.mgcv` for a full list of what is available, which goes well beyond exponential family. Note that quasi families actually result in the use of extended quasi-likelihood if method is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6).

- **data** A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`: typically the environment from which `gam` is called.

- **weights** prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to re-weight the contributions of each datum without
changing the overall magnitude of the log likelihood, then you should normalize
the weights (e.g. `weights <- weights/mean(weights)`).

**subset**

An optional vector specifying a subset of observations to be used in the fitting
process.

**na.action**

A function which indicates what should happen when the data contain 'NA's.
The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is
unset. The 'factory-fresh' default is 'na.omit'.

**offset**

Can be used to supply a model offset for use in fitting. Note that this offset
will always be completely ignored when predicting, unlike an offset included in
`formula` (this used to conform to the behaviour of `lm` and `glm`).

**control**

A list of fit control parameters to replace defaults returned by `gam.control`.
Values not set assume default values.

**method**

The smoothing parameter estimation method. "GCV.Cp" to use GCV for
unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale.
"GACV.Cp" is equivalent, but using GACV in place of GCV. "NCV" for neigh-
bourhood cross-validation using the neighbourhood structure specified be nei.
"REML" for REML estimation, including of unknown scale, "P-REML" for REML
estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are sim-
ilar, but using maximum likelihood in place of REML. Beyond the exponential
family "REML" is the default, and the only other options are "ML" or "NCV".

**optimizer**

An array specifying the numerical optimization method to use to optimize the
smoothing parameter estimation criterion (given by `method`). "perf" (depre-
cated) for performance iteration. "outer" for the more stable direct approach.
"outer" can use several alternative optimizers, specified in the second element
of `optimizer`: "newton" (default), "bfgs", "optim", "nlm" and "nlm.fd" (the
latter is based entirely on finite differenced derivatives and is very slow). "efs"

**scale**

If this is positive then it is taken as the known scale parameter. Negative signals
that the scale parameter is unknown. 0 signals that the scale parameter is 1 for
Poisson and binomial and unknown otherwise. Note that (RE)ML methods can
only work with scale parameter 1 for the Poisson and binomial cases.

**select**

If this is TRUE then `gam` can add an extra penalty to each term so that it can be
penalized to zero. This means that the smoothing parameter estimation that is
part of fitting can completely remove terms from the model. If the corresponding
smoothing parameter is estimated as zero then the extra penalty has no effect.
Use `gamma` to increase level of penalization.

**knots**

This is an optional list containing user specified knot values to be used for basis
construction. For most bases the user simply supplies the knots to be used,
which must match up with the k value supplied (note that the number of knots is
not always just k). See `tprs` for what happens in the "tp"/"ts" case. Different
terms can use different numbers of knots, unless they share a covariate.

**sp**

A vector of smoothing parameters can be provided here. Smoothing parameters
must be supplied in the order that the smooth terms appear in the model formula.
Negative elements indicate that the parameter should be estimated, and hence a
mixture of fixed and estimated parameters is possible. If smooths share smooth-
ing parameters then `length(sp)` must correspond to the number of underlying
smoothing parameters.

**min.sp**

Lower bounds can be supplied for the smoothing parameters. Note that if this
option is used then the smoothing parameters `full.sp`, in the returned object,
will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. \texttt{length(min.sp)} should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).

A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.

\texttt{gamma}

Increase this beyond 1 to produce smoother models. \texttt{gamma} multiplies the effective degrees of freedom in the GCV or UBRE/AIC. \texttt{code/gamma} can be viewed as an effective sample size in the GCV score, and this also enables it to be used with REML/ML. Ignored with P-RE/ML or the \texttt{efs} optimizer.

\texttt{fit}

If this argument is \texttt{TRUE} then \texttt{gam} sets up the model and fits it, but if it is \texttt{FALSE} then the model is set up and an object \texttt{G} containing what would be required to fit is returned. See argument \texttt{G}.

\texttt{paraPen}

optional list specifying any penalties to be applied to parametric model terms. \texttt{gam.models} explains more.

\texttt{G}

Usually \texttt{NULL}, but may contain the object returned by a previous call to \texttt{gam} with \texttt{fit=FALSE}, in which case all other arguments are ignored except for \texttt{sp, gamma, in.out, scale, control, method optimizer and fit}.

\texttt{in.out}

optional list for initializing outer iteration. If supplied then this must contain two elements: \texttt{sp} should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); \texttt{scale} is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the the initial value of the scale parameter, if this is to be estimated by RE/ML.

\texttt{drop.unused.levels}

by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

\texttt{drop.intercept}

Set to \texttt{TRUE} to force the model to really not have the a constant in the parametric model part, even with factor variables present. Can be vector when \texttt{formula} is a list.

\texttt{nei}

A list specifying the neighbourhood structure for NCV. \texttt{k} is the vector of indices to be dropped for each neighbourhood and \texttt{m} gives the end of each neighbourhood. So \texttt{nei$k[(nei$m[j-1]+1):nei$m[j]]} gives the points dropped for the neighbourhood \texttt{j}. \texttt{i} is the vector of indices of points to predict, with corresponding endpoints \texttt{mi}. So \texttt{nei$i[(nei$mi[j-1]+1):nei$mi[j]]} indexes the points to predict for neighbourhood \texttt{j}. If \texttt{nei==NULL} (or \texttt{k} or \texttt{m} are missing) then leave-one-out cross validation is obtained.

\texttt{discrete}

experimental option for setting up models for use with discrete methods employed in \texttt{bam}. Do not modify.

\texttt{...}

further arguments for passing on e.g. to \texttt{gam.fit} (such as \texttt{mustart}).

Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional
parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = \alpha + f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables $y_i \sim \text{Poi}$, and $f_1$ and $f_2$ are smooth functions of covariates $x_1$ and $x_2$. The log is an example of a link function. Note that to be identifiable the model requires constraints on the smooth functions. By default these are imposed automatically and require that the function sums to zero over the observed covariate values (the presence of a metric by variable is the only case which usually suppresses this).

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex over-fitting estimates of $f_1$ and $f_2$. For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggliness’. To control the trade-off between penalizing wigginess and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The mgcv implementation of gam represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

gam in mgcv solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where $D$ is the deviance, $n$ the number of data, $s$ the scale parameter and $DoF$ the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when $s$ is known.

Alternatives are GACV, NCV or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice. The main computational challenge solved by the mgcv package is to optimize the smoothness selection criteria efficiently and reliably.

Broadly gam works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (/design matrix) and a set of penalty matrices for the smooth terms. The linear identifiability constraints are also obtained at this point. The model is fit using gam.fit, gam.fit3 or variants, which are modifications of glm.fit. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Re-weighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is possible in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS step a working penalized linear model is estimated, and the smoothing parameter estimation can be performed for each such working model. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. This option is available in bam and gamm but is deprecated for gam (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and gam.fit3 or one of its variants is used in place of gam.fit. gam uses the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see smooth.terms for an overview and smooth.construct for how to add
smooth classes). The choice of the basis dimension \((k\) in the \(s\), \(te\), \(ti\) and \(t2\) terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by \(k=1\) or occasionally \(k\)). Of course the \(k\) should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that \texttt{gam} assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end \texttt{gam} allows the non smooth model components to be penalized via argument \texttt{paraPen} and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in \texttt{linear.functional.terms}. \texttt{link\{family.mgcv\}} details what is available beyond GLMs and the exponential family.

Details of the default underlying fitting methods are given in Wood (2011 and 2004). Some alternative methods are discussed in Wood (2000 and 2006).

\texttt{gam()} is not a clone of Trevor Hastie’s original (as supplied in S-PLUS or package \texttt{gam}). The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no \texttt{lo} smooths, but instead (a) \texttt{s} terms can have more than one argument, implying an isotropic smooth and (b) \texttt{te}, \texttt{ti} or \texttt{t2} smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. (vii) Models beyond the exponential family are available. See package \texttt{gam}, for GAMs via the original Hastie and Tibshirani approach.

\textbf{Value}

If \texttt{fit=FALSE} the function returns a list \(G\) of items needed to fit a GAM, but doesn’t actually fit it. Otherwise the function returns an object of class "gam" as described in \texttt{gamObject}.

\textbf{WARNINGS}

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See \texttt{choose.k} and \texttt{gam.check}.

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

gam.check

Some diagnostics for a fitted gam model

Description

Takes a fitted gam object produced by gam() and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate. Care should be taken in interpreting the results when applied to gam objects returned by gamm.

Usage

```
gam.check(b, old.style=FALSE,
    type=c("deviance","pearson","response"),
    k.sample=5000,k.rep=200,
    rep=0, level=.9, r1.col=2, rep.col="gray80", ...)
```

Arguments

b  a fitted gam object as produced by gam().
old.style  If you want old fashioned plots, exactly as in Wood, 2006, set to TRUE.
type  type of residuals, see residuals.gam, used in all plots.
k.sample  Above this k testing uses a random sub-sample of data.
Checking a fitted `gam` is like checking a fitted `glm`, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. `choose.k` provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the $k$-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The $p$-value is computed by simulation: the residuals are randomly re-shuffled $k$.rep times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than $k$.sample data, the tests are based of $k$.sample randomly sampled data. Low $p$-values may indicate that the basis dimension, $k$, has been set too low, especially if the reported edf is close to $k'$, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated $p$-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA $p$-value.

Doubling a suspect $k$ and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course $p$-values can be low for reasons other than a too low $k$. See `choose.k` for fuller discussion.

The QQ plot produced is usually created by a call to `qq.gam`, and plots deviance residuals against approximate theoretical quantiles of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using `qq.gam`. Note that residuals for models fitted to binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

Take care when interpreting results from applying this function to a model fitted using `gamm`. In this case the returned `gam` object is based on the working model used for estimation, and will treat all the random effects as part of the error. This means that the residuals extracted from the `gam` object are not standardized for the family used or for the random effects or correlation structure. Usually
it is necessary to produce your own residual checks based on consideration of the model structure you have used.

**Value**

A vector of reference quantiles for the residual distribution, if these can be computed.

**See Also**

choose.k, gam.magic

**Examples**

```r
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
gam.check(b,pch=19,cex=.3)
```

---

**Description**

This is an internal function of package mgcv which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see `gam` arguments `method` and `optimizer`.

**Usage**

```r
gam.control(nthreads=1,ncv.threads=1,irls.reg=0.0,epsilon = 1e-07, maxit = 200,
mgcv.tol=1e-7,mgcv.half=15, trace = FALSE,
rank.tol=.Machine$double.eps^0.5,nlm=list(),
optim=list(),newton=list(),outerPIsteps=0,
idLinksBases=TRUE,scalePenalty=TRUE,efs.lspmax=15,
efs.tol=.1,keepData=FALSE,scale.est="fletcher",
edge.correct=FALSE)
```
Arguments

nthreads Some parts of some smoothing parameter selection methods (e.g. REML) can use some parallelization in the C code if your R installation supports openMP, and nthreads is set to more than 1. Note that it is usually better to use the number of physical cores here, rather than the number of hyper-threading cores.

ncv.threads The computations for neighbourhood cross-validation (NCV) typically scale better than the rest of the GAM computations and are worth parallelizing. ncv.threads allows you to set the number of threads to use separately.

irls.reg For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and irls.reg is the size of the penalty.

epsilon This is used for judging conversion of the GLM IRLS loop in gam.fit or gam.fit3.

maxit Maximum number of IRLS iterations to perform.

mgcv.tol The convergence tolerance parameter to use in GCV/UBRE optimization.

mgcv.half If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.

trace Set this to TRUE to turn on diagnostic output.

rank.tol The tolerance used to estimate the rank of the fitting problem.

nlm list of control parameters to pass to nlm if this is used for outer estimation of smoothing parameters (not default). See details.

optim list of control parameters to pass to optim if this is used for outer estimation of smoothing parameters (not default). See details.

newton list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.

outerPIsteps The number of performance iteration steps used to initialize outer iteration.

idLinksBases If smooth terms have their smoothing parameters linked via the id mechanism (see s), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set scalePenalty to FALSE as well in this case).

scalePenalty gamm is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accommodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set idLinksBases to FALSE.

efs.lspmax maximum log smoothing parameters to allow under extended Fellner Schall smoothing parameter optimization.

efs.tol change in REML to count as negligible when testing for EFS convergence. If the step is small and the last 3 steps led to a REML change smaller than this, then stop.
### Details

Outer iteration using `newton` is controlled by the list `newton` with the following elements:

- **conv.tol** (default 1e-6) is the relative convergence tolerance;
- **maxNstep** is the maximum length allowed for an element of the Newton search direction (default 5);
- **maxSstep** is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2);
- **maxHalf** is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements:

- **ndigit** is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`;
- **gradtol** is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to `10*epsilon`;
- **stepmax** is the maximum allowable log smoothing parameter step - defaults to 2;
- **steptol** is the minimum allowable step length - defaults to 1e-4;
- **iterlim** is the maximum number of optimization steps allowed - defaults to 200;
- **check.analyticals** indicates whether the built in exact derivative calculations should be checked numerically - defaults to `FALSE`. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value 1e7.

GAM convergence and performance issues

Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The fitting methods used by `gam` opt for certainty of convergence over speed of fit. `bam` opts for speed.

`gam` uses a nested iteration method (see `gam.outer`), in which each trial set of smoothing parameters proposed by an outer Newton algorithm require an inner Newton algorithm (penalized iteratively re-weighted least squares, PIRLS) to find the corresponding best fit model coefficients. Implicit differentiation is used to find the derivatives of the coefficients with respect to log smoothing parameters, so that the derivatives of the smoothness selection criterion can be obtained, as required by the outer iteration. This approach is less expensive than it at first appears, since excellent starting values for the inner iteration are available as soon as the smoothing parameters start to converge. See Wood (2011) and Wood, Pya and Saefken (2016).

`bam` uses an alternative approach similar to ‘performance iteration’ or ‘PQL’. A single PIRLS iteration is run to find the model coefficients. At each step this requires the estimation of a working penalized linear model. Smoothing parameter selection is applied directly to this working model at each step (as if it were a Gaussian additive model). This approach is more straightforward to code and in principle less costly than the nested approach. However it is not guaranteed to converge, since the smoothness selection criterion is changing at each iteration. It is sometimes possible for the algorithm to cycle around a small set of smoothing parameter, coefficient combinations without ever converging. `bam` includes some checks to limit this behaviour, and the further checks in the algorithm used by `bam(..., discrete=TRUE)` actually guarantee convergence in some cases, but in general guarantees are not possible. See Wood, Goude and Shaw (2015) and Wood et al. (2017).

`gam` when used with ‘general’ families (such as `multinom` or `cox.ph`) can also use a potentially faster scheme based on the extended Fellner-Schall method (Wood and Fasiolo, 2017). This also operates with a single iteration and is not guaranteed to converge, theoretically.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the “`bfgs`” method option in `gam` argument `optimizer`; this can be faster than the default. (ii) Try using `bam` (iii) For large datasets it may be worth changing the smoothing basis to use `bs=“cr”` (see `s` for details) for 1-d smooths, and to use `te` smooths in place of `s` smooths for smooths of more than one variable. This is because the default thin plate regression spline basis "`tp`" is costly to set up for large datasets.

If you have convergence problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in `gam.control`, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of `gam`: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.
Please report convergence problems, especially if you there is no obvious pathology in the data/model that suggests convergence should fail.

gam.fit

GAM P-IRLS estimation with GCV/UBRE smoothness estimation

Description

This is an internal function of package mgcv. It is a modification of the function glm.fit, designed to be called from gam when performance iteration is selected (not the default). The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine magic. For further information on usage see code for gam. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see gam.control). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

Usage

gam.fit(G, start = NULL, etastart = NULL, mustart = NULL, family = gaussian(), control = gam.control(), gamma=1, fixedSteps=(control$maxit+1),...)

Arguments

G
An object of the type returned by `gam` when `fit=FALSE`.

start
Initial values for the model coefficients.

etastart
Initial values for the linear predictor.

mustart
Initial values for the expected response.

family
The family object, specifying the distribution and link to use.

control
Control option list as returned by `gam.control`.

gamma
Parameter which can be increased to up the cost of each effective degree of freedom in the GCV or AIC/UBRE objective.

fixedSteps
How many steps to take: useful when only using this routine to get rough starting values for other methods.

... Other arguments: ignored.

Value

A list of fit information.

Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them.
by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for `gam`.

**Usage**

```r
gam.fit3(x, y, sp, Eb, UrS=list(),
    weights = rep(1, nobs), start = NULL, etastart = NULL,
    mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
    Mp = -1, family = gaussian(), control = gam.control(),
    intercept = TRUE, deriv=2, gamma=1, scale=1,
    printWarn = TRUE, scoreType="REML", null.coef=rep(0,ncol(x)),
    pearson.extra=0, dev.extra=0, n.true=-1, Sl=NULL, nei=NULL,...)
```

**Arguments**

- `x` The model matrix for the GAM (or any penalized GLM).
- `y` The response variable.
- `sp` The log smoothing parameters.
- `Eb` A balanced version of the total penalty matrix: used for numerical rank determination.
- `UrS` List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.
- `weights` prior weights for fitting.
- `start` optional starting parameter guesses.
- `etastart` optional starting values for the linear predictor.
- `mustart` optional starting values for the mean.
- `offset` the model offset.
- `U1` An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.
- `Mp` The dimension of the total penalty null space — required for ML smoothness estimation only.
- `family` the family - actually this routine would never be called with `gaussian()`.
- `control` control list as returned from `glm.control`
- `intercept` does the model have an intercept, TRUE or FALSE
- `deriv` Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.
- `gamma` The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.
- `scale` The scale parameter - needed for the UBRE/AIC score.
- `printWarn` Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.
- `scoreType` specifies smoothing parameter selection criterion to use.
null.coef coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.

pearson.extra Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.

dev.extra Extra component to add to deviance for REML/ML type smoothness selection criteria.

n.true Number of data to assume in smoothness selection criteria. <=0 indicates that it should be the number of rows of X.

S1 A smooth list suitable for passing to gam.fit5.

nei List specifying neighbourhood structure if NCV used. See gam.

... Other arguments: ignored.

Details

This routine is basically glm.fit with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed ‘outer’ iteration.

Note that use of non-standard families with this routine requires modification of the families as described in fix.family.link.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

The routine has been modified from glm.fit in R 2.0.1, written by the R core (see glm.fit for further credits).

**Description**

INTERNAL function for post-processing the output of `gam.fit5`.

**Usage**

`gam.fit5.post.proc(object, Sl, L, lsp0, S, off, gamma)`

**Arguments**

- `object`: output of `gam.fit5`.
- `Sl`: penalty object, output of `Sl.setup`.
- `L`: matrix mapping the working smoothing parameters.
- `lsp0`: log smoothing parameters.
- `S`: penalty matrix.
- `off`: vector of offsets.
- `gamma`: parameter for increasing model smoothness in fitting.

**Value**

A list containing:

- `R`: unpivoted Choleski of estimated expected hessian of log-likelihood.
- `Vb`: the Bayesian covariance matrix of the model parameters.
- `Ve`: "frequentist" alternative to `Vb`.
- `Vc`: corrected covariance matrix.
- `F`: matrix of effective degrees of freedom (EDF).
- `edf`: `diag(F)`.
- `edf2`: `diag(2F-FF)`.

Simple posterior simulation with gam fits

Description

GAM coefficients can be simulated directly from the Gaussian approximation to the posterior for the coefficients, or using a simple Metropolis Hastings sampler. See also \texttt{ginla}.

Usage

\begin{verbatim}
gam.mh(b, ns=10000, burn=1000, t.df=40, rw.scale=.25, thin=1)
\end{verbatim}

Arguments

- \texttt{b}: a fitted model object from \texttt{gam}, \texttt{bam} fits are not supported.
- \texttt{ns}: the number of samples to generate.
- \texttt{burn}: the length of any initial burn in period to discard (in addition to codens).
- \texttt{t.df}: degrees of freedom for static multivariate t proposal. Lower for heavier tailed proposals.
- \texttt{rw.scale}: Factor by which to scale posterior covariance matrix when generating random walk proposals. Negative or non finite to skip the random walk step.
- \texttt{thin}: retain only every \texttt{thin} samples.

Details

Posterior simulation is particularly useful for making inferences about non-linear functions of the model coefficients. Simulate random draws from the posterior, compute the function for each draw, and you have a draw from the posterior for the function. In many cases the Gaussian approximation to the posterior of the model coefficients is accurate, and samples generated from it can be treated as samples from the posterior for the coefficients. See example code below. This approach is computationally very efficient.

In other cases the Gaussian approximation can become poor. A typical example is in a spatial model with a log or logit link when there is a large area of observations containing only zeroes. In this case the linear predictor is poorly identified and the Gaussian approximation can become useless (an example is provided below). In that case it can sometimes be useful to simulate from the posterior using a Metropolis Hastings sampler. A simple approach alternates fixed proposals, based on the Gaussian approximation to the posterior, with random walk proposals, based on a shrunken version of the approximate posterior covariance matrix. \texttt{gam.mh} implements this. The fixed proposal often promotes rapid mixing, while the random walk component ensures that the chain does not become stuck in regions for which the fixed Gaussian proposal density is much lower than the posterior density.

The function reports the acceptance rate of the two types of step. If the random walk acceptance probability is higher than a quarter then \texttt{rw.step} should probably be increased. Similarly if the acceptance rate is too low, it should be decreased. The random walk steps can be turned off altogether (see above), but it is important to check the chains for stuck sections if this is done.

Value

A list containing the retained simulated coefficients in matrix \texttt{bs} and two entries for the acceptance probabilities.

gam.models

Specifying generalized additive models

Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let $y_i$ denote an independent random variable with mean $\mu_i$ and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = X_i\beta + f_1(x_{i1}, x_{i2}) + f_2(x_{i3}) + L_i f_3(x_{i4}) + \ldots$$

where $g$ is a known smooth monotonic ‘link’ function, $X_i\beta$ is the parametric part of the linear predictor, the $x_j$ are predictor variables, the $f_j$ are smooth functions and $L_i$ is some linear functional of $f_3$. There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. gam always applies such constraints unless there is a by variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for gam. Specification of the distribution and link function is done using the family argument to gam and works in the same way as for glm. This page therefore concentrates on the model formula for gam.
Models with simple smooth terms

Consider the example model.

\[ g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i}) \]

where the response variables \( y_i \) has expectation \( \mu_i \) and \( g \) is a link function.

The \texttt{gam} formula for this would be

\[ y \sim x1 + x2 + s(x3) + s(x4,x5). \]

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in \texttt{s} and \texttt{te}, and further discussion of basis dimension choice can be found in \texttt{choose.k}. For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

\[ y \sim x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE). \]

The above assumes that \( x_4 \) and \( x_5 \) are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see \texttt{te}).

\[ y \sim x1 + x2 + s(x3) + te(x4, x5) \]

would generate a tensor product smooth of \( x_4 \) and \( x_5 \). By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

\[ y \sim x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE). \]

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

Nested terms/functional ANOVA

Sometimes it is interesting to specify smooth models with a main effects + interaction structure such as

\[ E(y_i) = f_1(x_i) + f_2(z_i) + f_3(x_i, z_i) \]

or

\[ E(y_i) = f_1(x_i) + f_2(z_i) + f_3(v_i) + f_4(x_i, z_i) + f_5(z_i, v_i) + f_6(x_i, z_i, v_i) \]

for example. Such models should be set up using \texttt{ti} terms in the model formula. For example:

\[ y \sim ti(x) + ti(z) + ti(x, z), \]

\[ y \sim ti(x) + ti(z) + ti(v) + ti(x, z) + ti(x, v) + ti(z, v) + ti(x, z, v). \]

The \texttt{ti} terms produce interactions with the component main effects excluded appropriately. (There is in fact no need to use \texttt{ti} terms for the main effects here, \texttt{s} terms could also be used.)

gam allows nesting (or ‘overlap’) of \texttt{te} and \texttt{s} smooths, and automatically generates side conditions to make such models identifiable, but the resulting models are much less stable and interpretable than those constructed using \texttt{ti} terms.

‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The \texttt{s} and \texttt{te} terms used to specify smooths accept an argument \texttt{by}, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a \texttt{by} variable is numeric, then its \texttt{i}th element multiples the \texttt{i}th row of the model matrix corresponding to the smooth term concerned.
Factor smooth interactions (see also `factor.smooth.interaction`). If a by variable is a `factor` then it generates an indicator vector for each level of the factor, unless it is an `ordered` factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter). `ordered` by variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see b3 example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor by variables.

As an example, consider the model

\[ E(y_i) = \beta_0 + f(x_i)z_i \]

where \( f \) is a smooth function, and \( z_i \) is a numeric variable. The appropriate formula is:

\[ y \sim s(x, by=z) \]

- the `by` argument ensures that the smooth function gets multiplied by covariate \( z \). Note that when using factor by variables, centering constraints are applied to the smooths, which usually means that the `by` variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor by variables.

by variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a `by` variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the `by` variable is a constant vector, or, (ii) for a matrix by variable, \( L \), if \( L %*% rep(1, ncol(L)) \) is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute “always.apply”.

**Linking smooths with ‘id’**

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to `s` or `te` terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that \( E(y_i) \equiv \mu_i \) and

\[ g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i}) \]

but that \( f_1 \) and \( f_3 \) should have the same smoothing parameters (and \( x_2 \) and \( x_3 \) are on different scales). Then the `gam` formula

\[ y \sim s(x_1, id=1) + te(x_2, x_3) + s(x_4, id=1) \]

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor by variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `id` s are not supported by `gamm`.

**Linear functional terms**

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic
regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in mgcv using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any by variable matrix must be of the same dimension. Consider, for example the term
\[
s(X,Z, by=L)
\]
where X, Z and L are \(n \times p\) matrices. Let \(f\) denote the thin plate regression spline specified. The resulting contribution to the \(i^{th}\) element of the linear predictor is
\[
\sum_{j=1}^{p} L_{ij} f(X_{ij}, Z_{ij})
\]
If no \(L\) is supplied then all its elements are taken as 1. In R code terms, let \(F\) denote the \(n \times p\) matrix obtained by evaluating the smooth at the values in X and Z. Then the contribution of the term to the linear predictor is \(\text{rowSums}(L*F)\) (note that it’s element by element multiplication here!).

The summation convention applies to \(te\) terms as well as \(s\) terms. More details and examples are provided in \texttt{linear.functional.terms}. 

Random effects

Random effects can be added to \texttt{gam} models using \texttt{s(...,bs=”re”)} terms (see \texttt{smooth.construct.re.smooth.spec}), or the \texttt{paraPen} argument to \texttt{gam} covered below. See \texttt{gam.vcomp}, \texttt{random.effects} and \texttt{smooth.construct.re.smooth.spec} for further details. An alternative is to use the approach of \texttt{gamm}.

Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, by variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, \texttt{gam} also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix \(X\), and want to penalize the corresponding coefficients, \(\beta\) with two penalties \(\beta^T S_1 \beta\) and \(\beta^T S_2 \beta\). Then something like the following would be appropriate:
\[
\text{gam}(y \sim X - 1, \text{paraPen}=\text{list}(X=\text{list}(S1,S2)))
\]
The \texttt{paraPen} argument should be a list with elements having names corresponding to the terms being penalized. Each element of \texttt{paraPen} is itself a list, with optional elements \(L\), \texttt{rank} and \texttt{sp}: all other elements must be penalty matrices. If present, \texttt{rank} is a vector giving the rank of each penalty matrix (if absent this is determined numerically). \(L\) is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties; taken as the identity if not supplied. \(sp\) is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of \texttt{paraPen} is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated
scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’
example below.

P-values for penalized parametric terms should be treated with caution. If you must have them,
then use the option freq=TRUE in \texttt{anova.gam} and \texttt{summary.gam}, which will tend to give reasonable
results for random effects implemented this way, but not for terms with a rank deficient penalty (or
penalties with a wide eigen-spectrum).

**gam.outer**

Minimize GCV or UBRE score of a GAM using ‘outer’ iteration

---

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using `newton` (default), `bfgs`, `optim` or `nlm`. Exact (first and second) derivatives of the score can be used by fitting with `gam.fit3`. This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for `gam`.
Usage

```r
gam.outer(lsp, fscale, family, control, method, optimizer, 
          criterion, scale, gamma, G, start=NULL, nei=NULL, ...)```

Arguments

- `lsp`: The log smoothing parameters.
- `fscale`: Typical scale of the GCV or UBRE/AIC score.
- `family`: the model family.
- `control`: control argument to pass to `gam.fit` if pure finite differencing is being used.
- `method`: method argument to `gam` defining the smoothness criterion to use (but depending on whether or not scale known).
- `optimizer`: The argument to `gam` defining the numerical optimization method to use.
- `criterion`: Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".
- `scale`: Supplied scale parameter. Positive indicates known.
- `gamma`: The degree of freedom inflation factor for the GCV/UBRE/AIC score.
- `G`: List produced by `mgcvs::gam.setup`, containing most of what's needed to actually fit a GAM.
- `start`: starting parameter values.
- `nei`: List specifying neighbourhood structure if NCV used. See `gam`.
- `...`: other arguments, typically for passing on to `gam.fit3` (ultimately).

Details

See Wood (2008) for full details on ‘outer iteration’.

Finding stable orthogonal re-parameterization of the square root penalty.

Description

INTERNAL function for finding an orthogonal re-parameterization which avoids "dominant machine zero leakage" between components of the square root penalty.

Usage

gam.reparam(rS, lsp, deriv)

Arguments

rS     list of the square root penalties: last entry is root of fixed penalty, if fixed.penalty==TRUE (i.e. length(rS)>length(sp)). The assumption here is that rS[i] are in a null space of total penalty already; see e.g. totalPenaltySpace and mini.roots.

lsp    vector of log smoothing parameters.

 deriv if deriv==1 also the first derivative of the log-determinant of the penalty matrix is returned, if deriv>1 also the second derivative is returned.

Value

A list containing

- S: the total penalty matrix similarity transformed for stability.
- rS: the component square roots, transformed in the same way.
- Qs: the orthogonal transformation matrix S = t(Qs)%*%S0%*%Qs, where S0 is the untransformed total penalty implied by sp and rS on input.
- det: log|S|.
- det1: dlog|S|/dlog(sp) if deriv>0.
- det2: hessian of log|S| wrt log(sp) if deriv>1.

Scale parameter estimation in GAMs

Description

Scale parameter estimation in `gam` depends on the type of family. For extended families then the RE/ML estimate is used. For conventional exponential families, estimated by the default outer iteration, the scale estimator can be controlled using argument `scale.est` in `gam.control`. The options are "fletcher" (default), "pearson" or "deviance". The Pearson estimator is the (weighted) sum of squares of the Pearson residuals, divided by the effective residual degrees of freedom. The Fletcher (2012) estimator is an improved version of the Pearson estimator. The deviance estimator simply substitutes deviance residuals for Pearson residuals.

Usually the Pearson estimator is recommended for GLMs, since it is asymptotically unbiased. However, it can also be unstable at finite sample sizes, if a few Pearson residuals are very large. For example, a very low Poisson mean with a non zero count can give a huge Pearson residual, even though the deviance residual is much more modest. The Fletcher (2012) estimator is designed to reduce these problems.

For performance iteration the Pearson estimator is always used.

`gamm` uses the estimate of the scale parameter from the underlying call to `lme`. `bam` uses the REML estimator if the method is "fREML". Otherwise the estimator is a Pearson estimator.

Generalized Additive Model Selection

Description

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.
Smoothness selection criteria

Given a model structure specified by a gam model formula, \texttt{gam()} attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows’ Cp (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The \texttt{method} argument to \texttt{gam} selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these ‘flat’ regions can be separated from regions of lower score by a small ‘lip’. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see \texttt{gam} arguments \texttt{method} and \texttt{optimizer}) and see if the estimates change, or try changing some or all of the smoothing parameters ‘manually’ (argument \texttt{sp} of \texttt{gam}, or \texttt{sp} arguments to \texttt{s} or \texttt{te}).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as ‘completely smooth’ and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby ‘selected out’ of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes \texttt{cs.smooth} and \texttt{tprs.smooth} (specified by \texttt{"cs"} and \texttt{"ts"} respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively ‘completely smooth’ according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the ‘completely smooth’ functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The \texttt{select} argument to \texttt{gam} turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposing the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as
the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

**Interactive term selection**

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated theta parameter is a special case: the GCV score is not informative, because of the theta estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by summary.gam, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

**Caveats/platitudes**

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn’t fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with ‘everything in’ and hoping that automatic selection will find the right structure is not often successful.

gam.side

**Identifiability side conditions for a GAM**

Description

GAM formulae with repeated variables may only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from `mgcv:::gam.setup` and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

Usage

gam.side(sm,Xp,tol=.Machine$double.eps*.5,with.pen=FALSE)

Arguments

- **sm** A list of smooth objects as returned by `smooth.construct`
- **Xp** The model matrix for the strictly parametric model components.
- **tol** The tolerance to use when assessing linear dependence of smooths.
- **with.pen** Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints.
Details

Models such as \( y = s(x) + s(z) + s(x, z) \) can be estimated by \texttt{gam}, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using \texttt{fixDependence}. This makes the routine rather general, and not dependent on any particular basis.

\texttt{Xp} is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute "del.index", listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

WARNINGS

Much better statistical stability will be obtained by using models like \( y = s(x) + s(z) + ti(x, z) \) or \( y = ti(x) + ti(z) + ti(x, z) \) rather than \( y = s(x) + s(z) + s(x, z) \), since the former are designed not to require further constraint.

gam.vcomp

Report gam smoothness estimates as variance components

Description

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

Usage

gam.vcomp(x,rescale=TRUE,conf.lev=.95)

Arguments

x

a fitted model object of class gam as produced by gam()

rescale

the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if TRUE this rescaling is reversed, so that the variance components are on the original scale.

conf.lev

when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at.

Details

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term’s coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth’s coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for gam models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by gam in which random effects have been incorporated.
Value

Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

For models in which there are more smoothing parameters than actually estimated (e.g. if some were fixed, or smoothing parameters are linked) then a list is returned. The vc element is as above, the all element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

Objective functions for GAM smoothing parameter estimation

Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by optim or nlm. Not normally called directly, but rather service routines for gam.outer.

Usage

gam2objective(lsp, args, ...)
gam2derivative(lsp, args, ...)

Arguments

lsp The log smoothing parameters.
args List of arguments required to call gam.fit3.
... Other arguments for passing to gam.fit3.

Details

gam2objective and gam2derivative are functions suitable for calling by optim, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.
gam4objective is an equivalent to gam2objective, suitable for optimization by nlm - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.
The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

gamlss.etamu

Transform derivatives wrt mu to derivatives wrt linear predictor

Description

Mainly intended for internal use in specifying location scale models. Let \( g(\mu) = lp \), where \( lp \) is the linear predictor, and \( g \) is the link function. Assume that we have calculated the derivatives of the log-likelihood wrt \( \mu \). This function uses the chain rule to calculate the derivatives of the log-likelihood wrt \( lp \). See \texttt{trind.generator} for array packing conventions.

Usage

\[
gamlss.etamu(l1, l2, l3 = \text{NULL}, l4 = \text{NULL}, ig1, g2, g3 = \text{NULL},
g4 = \text{NULL}, i2, i3 = \text{NULL}, i4 = \text{NULL}, \text{deriv} = 0)
\]

Arguments

- \( l1 \): array of 1st order derivatives of log-likelihood wrt mu.
- \( l2 \): array of 2nd order derivatives of log-likelihood wrt mu.
- \( l3 \): array of 3rd order derivatives of log-likelihood wrt mu.
- \( l4 \): array of 4th order derivatives of log-likelihood wrt mu.
- \( ig1 \): reciprocal of the first derivative of the link function wrt the linear predictor.
- \( g2 \): array containing the 2nd order derivative of the link function wrt the linear predictor.
- \( g3 \): array containing the 3rd order derivative of the link function wrt the linear predictor.
- \( g4 \): array containing the 4th order derivative of the link function wrt the linear predictor.
- \( i2 \): two-dimensional index array, such that \( l2[, i2[i,j]] \) contains the partial wrt. params indexed by \( i,j \) with no restriction on the index values (except that they are in 1,...,ncol(l1)).
- \( i3 \): third-dimensional index array, such that \( l3[, i3[i,j,k]] \) contains the partial wrt. params indexed by \( i,j,k \).
- \( i4 \): third-dimensional index array, such that \( l4[, i4[i,j,k,l]] \) contains the partial wrt. params indexed by \( i,j,k,l \).
- \( \text{deriv} \): if \( \text{deriv}==0 \) only first and second order derivatives will be calculated. If \( \text{deriv}==1 \) the function goes up to 3rd order, and if \( \text{deriv}==2 \) it provides also 4th order derivatives.

Value

A list where the arrays \( l1, l2, l3, l4 \) contain the derivatives (up to order four) of the log-likelihood wrt the linear predictor.

trind.generator

gamlss.gH  Calculating derivatives of log-likelihood wrt regression coefficients

Description

Mainly intended for internal use with location scale model families. Given the derivatives of the
log-likelihood wrt the linear predictor, this function obtains the derivatives and Hessian wrt the
regression coefficients and derivatives of the Hessian w.r.t. the smoothing parameters. For input
derivative array packing conventions see trind.generator.

Usage

gamlss.gH(X, jj, l1, l2, i2, l3 = 0, i3 = 0, l4 = 0, i4 = 0, d1b = 0,
d2b = 0, deriv = 0, fh = NULL, D = NULL, sandwich = FALSE)

Arguments

X  matrix containing the model matrices of all the linear predictors.
jj  list of index vectors such that X[,jj[[i]]] is the model matrix of the i-th linear
predictor.
l1  array of 1st order derivatives of each element of the log-likelihood wrt each
parameter.
l2  array of 2nd order derivatives of each element of the log-likelihood wrt each
parameter.
i2  two-dimensional index array, such that l2[,i2[i,j]] contains the partial w.r.t.
params indexed by i,j with no restriction on the index values (except that they
are in 1,...,ncol(l1)).
l3  array of 3rd order derivatives of each element of the log-likelihood wrt each
parameter.
i3  third-dimensional index array, such that l3[,i3[i,j,k]] contains the partial
w.r.t. params indexed by i,j,k.
l4  array of 4th order derivatives of each element of the log-likelihood wrt each
parameter.
i4  third-dimensional index array, such that l4[,i4[i,j,k,l]] contains the partial
w.r.t. params indexed by i,j,k,l.
d1b  first derivatives of the regression coefficients wrt the smoothing parameters.
d2b  second derivatives of the regression coefficients wrt the smoothing parameters.
deriv  if deriv==0 only first and second order derivatives will be calculated. If
deriv==1 the function return also the diagonal of the first derivative of the
Hessian, if deriv==2 it return the full 3rd order derivative and if deriv==3 it
provides also 4th order derivatives.
fh  eigen-decomposition or Cholesky factor of the penalized Hessian.
D  diagonal matrix, used to provide some scaling.
sandwich  set to TRUE to return sandwich estimator 'filling', as opposed to the Hessian, in
12.
**Value**

A list containing `lb` - the grad vector w.r.t. coefs; `lbb` - the Hessian matrix w.r.t. coefs; `d1H` - either a list of the derivatives of the Hessian w.r.t. the smoothing parameters, or a single matrix whose columns are the leading diagonals of these derivative matrices; `trHid2H` - the trace of the inverse Hessian multiplied by the second derivative of the Hessian w.r.t. all combinations of smoothing parameters.

**gamm**  
*Generalized Additive Mixed Models*

**Description**

Fits the specified generalized additive mixed model (GAMM) to data, by a call to `lme` in the normal errors identity link case, or by a call to `gammPQL` (a modification of `gPQL` from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than `gam`, and not quite as numerically robust. To use `lme4` in place of `nlme` as the underlying fitting engine, see `gamm4` from package `gamm4`. Smooths are specified as in a call to `gam` as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for `lme` are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of `gam` and `lme`.

**Usage**

```r
gamm(formula, random=NULL, correlation=NULL, family=gaussian(), data=list(), weights=NULL, subset=NULL, na.action=knots=NULL, control=list(niterEM=0, optimMethod="L-BFGS-B", returnObject=TRUE), niterPQL=20, verbosePQL=TRUE, method="ML", drop.unused.levels=TRUE, mustart=NULL, etastart=NULL, ...)```

**Arguments**

- **formula**  
  A GAM formula (see also `formula.gam` and `gam.models`). This is like the formula for a `glm` except that smooth terms (s, te etc.) can be added to the right hand side of the formula. Note that ids for smooths and fixed smoothing parameters are not supported. Any offset should be specified in the formula.
### gamm

**random**
The (optional) random effects structure as specified in a call to `lme`: only the list form is allowed, to facilitate manipulation of the random effects structure within `gamm` in order to deal with smooth terms. See example below.

**correlation**
An optional `corStruct` object (see `corClasses`) as used to define correlation structures in `lme`. Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of `lme`). This is a GEE approach to correlation in the generalized case. See examples below.

**family**
A family as used in a call to `glm` or `gam`. The default gaussian with identity link causes `gamm` to fit by a direct call to `lme` provided there is no offset term, otherwise `gammPQL` is used.

**data**
A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`, typically the environment from which `gamm` is called.

**weights**
In the generalized case, weights with the same meaning as `glm` weights. An `lme` type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for `lme` for details of how to use such an argument).

**subset**
an optional vector specifying a subset of observations to be used in the fitting process.

**na.action**
a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.

**knots**
this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.

**control**
A list of fit control parameters for `lme` to replace the defaults returned by `lmeControl`. Note the setting for the number of EM iterations used by `lme`: smooths are set up using custom `pdMat` classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include `niterEM=0`, as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The `optimMethod` option is only used if your version of R does not have the `nlminb` optimizer function.

**niterPQL**
Maximum number of PQL iterations (if any).

**verbosePQL**
Should PQL report its progress as it goes along?

**method**
Which of “ML” or “REML” to use in the Gaussian additive mixed model case when `lme` is called directly. Ignored in the generalized case (or if the model has an offset), in which case `gammPQL` is used.

**drop.unused.levels**
by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

**mustart**
starting values for mean if PQL used.

**etastart**
starting values for linear predictor if PQL used (over-rides `mustart` if supplied).

... further arguments for passing on e.g. to `lme`
Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as lme. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in glmmPQL by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the nlme library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using lme or gammPQL in gamm can be found in Wood (2004 ,2006a,b). In addition gamm obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in gam, although adaptive smoothing bases are not available. Prediction from the returned gam object is straightforward using predict.gam, but this will set the random effects to zero. If you want to predict with random effects set to their predicted values then you can adapt the prediction code given in the examples below.

In the event of lme convergence failures, consider modifying options(mgcv.vc.logrange): reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See notExp2 for more information on this option. Failing that, you can try increasing the niterEM option in control: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of gamm works best with R 2.2.0 or above and nlme, 3.1-62 and above, since these use an improved optimizer.

Value

Returns a list with two items:

- **gam**: an object of class gam, less information relating to GCV/UBRE model selection. At present this contains enough information to use predict, summary and print methods and vis.gam, but not to use e.g. the anova method function to compare models. This is based on the working model when using gammPQL.
- **lme**: the fitted model object returned by lme or gammPQL. Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to lme and gammPQL are constructed.

WARNINGS

gamm has a somewhat different argument list to gam, gam arguments such as gamma supplied to gamm will just be ignored.

gamm performs poorly with binary data, since it uses PQL. It is better to use gam with s(...,bs="re") terms, or gamm4.
gamm assumes that you know what you are doing! For example, unlike \texttt{glmmPQL} from \texttt{MASS} it will return the complete \texttt{lme} object from the working model at convergence of the PQL iteration, including the 'log likelihood', even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000's of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument \texttt{random}.

\texttt{gamm} is not as numerically stable as \texttt{gam}: an \texttt{lme} call will occasionally fail. See details section for suggestions, or try the 'gamm4' package.

\texttt{gamm} is usually much slower than \texttt{gam}, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see \texttt{memory.limit}).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the \texttt{gam} object part of the returned object is not complete in the sense of having all the elements defined in \texttt{gamObject} and does not inherit from \texttt{glm}: hence e.g. multi-model \texttt{anova} calls will not work. It is also based on the working model when PQL is used.

The parameterization used for the smoothing parameters in \texttt{gamm}, bounds them above and below by an effective infinity and effective zero. See \texttt{notExp2} for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

**gammals**

*Gamma location-scale model family*

### Description

The **gammals** family implements gamma location scale additive models in which the log of the mean and the log of the scale parameter (see details) can depend on additive smooth predictors. Useable only with **gam**, the linear predictors are specified via a list of formulae.

### Usage

```r
gammals(link=list("identity","log"),b=-7)
```
Arguments

- **link**
  - A two item list specifying the link for the mean and the standard deviation. See details for meaning which may not be intuitive.

- **b**
  - The minimum log scale parameter.

Details

Used with `gam` to fit gamma location - scale models parameterized in terms of the log mean and the log scale parameter (the response variance is the squared mean multiplied by the scale parameter). Note that identity links mean that the linear predictors give the log mean and log scale directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument **b**: if $\eta$ is the linear predictor for the log scale parameter, $\phi$, then $\log \phi = b + \log(1 + e^\eta)$.

`gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the log mean on the right hand side. The second is one sided, specifying the linear predictor for the log scale on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean (on original, not log, scale), and the second column is the log scale. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response". The first column is on the original data scale when type="response" and on the log mean scale of the linear predictor when type="link". The second column when type="response" is again the log scale parameter, but is on the linear predictor when type="link".

The null deviance reported for this family computed by setting the fitted values to the mean response, but using the model estimated scale.

Value

An object inheriting from class `general.family`.

Examples

```r
library(mgcv)
## simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 * 
(10 * x)^3 * (1 - x)^10
f3 <- function(x) 0 * x
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- exp((f0(x0)+f2(x2))/5)
th <- exp(f1(x1)/2-2)
y <- rgamma(n, shape=1/th, scale=mu*th)
b1 <- gam(list(y-s(x0)+s(x2),-s(x1)+s(x3)), family=gammls)
plot(b1, pages=1)
```
summary(b1)
gam.check(b1)
plot(mu,fitted(b1)[,1]);abline(0,1,col=2)
plot(log(th),fitted(b1)[,2]);abline(0,1,col=2)

---

gamObject  Fitted gam object

Description
A fitted GAM object returned by function gam and of class "gam" inheriting from classes "glm" and "lm". Method functions anova, logLik, influence, plot, predict, print, residuals and summary exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

Value
A gam object has the following elements:

- **aic**: AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE.
- **assign**: Array whose elements indicate which model term (listed in pterms) each parameter relates to: applies only to non-smooth terms.
- **boundary**: did parameters end up at boundary of parameter space?
- **call**: the matched call (allows update to be used with gam objects, for example).
- **cmX**: column means of the model matrix (with elements corresponding to smooths set to zero) — useful for componentwise CI calculation.
- **coefficients**: the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.
- **control**: the gam control list used in the fit.
- **converged**: indicates whether or not the iterative fitting method converged.
- **data**: the original supplied data argument (for class "glm" compatibility). Only included if gam control argument element keepData is set to TRUE (default is FALSE).
- **db.drho**: matrix of first derivatives of model coefficients w.r.t. log smoothing parameters.
- **deviance**: model deviance (not penalized deviance).
- **df.null**: null degrees of freedom.
- **df.residual**: effective residual degrees of freedom of the model.
- **edf**: estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.
- **edf1**: similar, but using alternative estimate of EDF. Useful for testing.
edf2

if estimation is by ML or REML then an edf that accounts for smoothing parameter uncertainty can be computed, this is it. edf1 is a heuristic upper bound for edf2.

family

family object specifying distribution and link used.

tfitted.values

fitted model predictions of expected value for each datum.

formula

the model formula.

full.sp

full array of smoothing parameters multiplying penalties (excluding any contribution from \texttt{min.sp} argument to \texttt{gam}). May be larger than \texttt{sp} if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the \texttt{sp} argument of \texttt{gam}.

F

Degrees of freedom matrix. This may be removed at some point, and should probably not be used.

gcv.ubre

The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.

hat

array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.

iter

number of iterations of P-IRLS taken to get convergence.

linear.predictors

fitted model prediction of link function of expected value for each datum.

method

One of “GCV”, “UBRE”, “REML”, “P-REML”, “ML”, “P-ML”, “PQL”, “lme.ML” or “lme.REML”, depending on the fitting criterion used.

mgcv.conv

A list of convergence diagnostics relating to the “magic” parts of smoothing parameter estimation - this will not be very meaningful for pure “outer” estimation of smoothing parameters. The items are: full.rank, The apparent rank of the problem given the model matrix and constraints; rank, The numerical rank of the problem; fully.converged, TRUE if multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; hess.pos.def Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; iter How many iterations were required to find the smoothing parameters? score.calls, and how many times did the GCV/UBRE score have to be evaluated?; rms.grad, root mean square of the gradient of the GCV/UBRE score at convergence.

min.edf

Minimum possible degrees of freedom for whole model.

model

model frame containing all variables needed in original model fit.

na.action

The \texttt{na.action} used in fitting.

nsdf

number of parametric, non-smooth, model terms including the intercept.

null.deviance

deviance for single parameter model.

offset

model offset.

optimizer

optimizer argument to \texttt{gam}, or “magic” if it’s a pure additive model.

outer.info

If ‘outer’ iteration has been used to fit the model (see \texttt{gam} argument optimizer) then this is present and contains whatever was returned by the optimization routine used (currently \texttt{nlm} or \texttt{optim}).

paraPen

If the \texttt{paraPen} argument to \texttt{gam} was used then this provides information on the parametric penalties. NULL otherwise.

pred.formula

one sided formula containing variables needed for prediction, used by \texttt{predict.gam}
prior.weights  prior weights on observations.
pterms terms object for strictly parametric part of model.
R Factor R from QR decomposition of weighted model matrix, unpivoted to be in
   same column order as model matrix (so need not be upper triangular).
rank apparent rank of fitted model.
reml.scale The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness
   estimation.
residuals the working residuals for the fitted model.
rV If present, rV%*%t(rV)*sig2 gives the estimated Bayesian covariance matrix.
scale when present, the scale (as sig2)
scale.estimated TRUE if the scale parameter was estimated, FALSE otherwise.
sig2 estimated or supplied variance/scale parameter.
smooth list of smooth objects, containing the basis information for each term in the
   model formula in the order in which they appear. These smooth objects are
   what gets returned by the smooth.construct objects.
sp estimated smoothing parameters for the model. These are the underlying
   smoothing parameters, subject to optimization. For the full set of smoothing
   parameters multiplying the penalties see full.sp. Divide the scale parameter
   by the smoothing parameters to get, variance components, but note that this is
   not valid for smooths that have used rescaling to improve conditioning.
terms terms object of model model frame.
var.summary A named list of summary information on the predictor variables. If a paramet-
   ric variable is a matrix, then the summary is a one row matrix, containing the
   observed data value closest to the column median, for each matrix column. If
   the variable is a factor then summary is the modal factor level, returned as a
   factor, with levels corresponding to those of the data. For numerics and ma-
   trix arguments of smooths, the summary is the mean, nearest observed value to
   median and maximum, as a numeric vector. Used by vis.gam, in particular.
Ve frequentist estimated covariance matrix for the parameter estimators. Particularly
   useful for testing whether terms are zero. Not so useful for CI’s as smooths
   are usually biased.
Vp estimated covariance matrix for the parameters. This is a Bayesian posterior
   covariance matrix that results from adopting a particular Bayesian model of
   the smoothing process. Particularly useful for creating credible/confidence intervals.
Vc Under ML or REML smoothing parameter estimation it is possible to correct the
   covariance matrix Vp for smoothing parameter uncertainty. This is the corrected
   version.
weights final weights used in IRLS iteration.
y response data.

WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow
smoothing parameter estimation etc.

gamSim

Simulate example data for GAMs

Description
Function used to simulate data sets to illustrate the use of gam and gamm. Mostly used in help files to keep down the length of the example code sections.

Usage
gamSim(eg=1,n=400,dist="normal",scale=2,verbose=TRUE)

Arguments
eg numeric value specifying the example required.
n number of data to simulate.
dist character string which may be used to specify the distribution of the response.
scale Used to set noise level.
verbose Should information about simulation type be printed?

Details
See the source code for exactly what is simulated in each case.
1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

Value
Depends on eg, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.
The gaulss family implements Gaussian location-scale additive models in which the mean and the logb of the standard deviation (see details) can depend on additive smooth predictors. Useable only with \texttt{gam}, the linear predictors are specified via a list of formulae.

### Usage

\begin{verbatim}
gaulss(link=list("identity","logb"),b=0.01)
\end{verbatim}

### Arguments

- **link**: two item list specifying the link for the mean and the standard deviation. See details.
- **b**: The minimum standard deviation, for the "logb" link.

### Details

Used with \texttt{gam} to fit Gaussian location-scale models. \texttt{gam} is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the mean on the right hand side. The second is one sided, specifying the linear predictor for the standard deviation on the right hand side.

Link functions "identity", "inverse", "log" and "sqrt" are available for the mean. For the standard deviation only the "logb" link is implemented: \( \eta = \log(\sigma - b) \) and \( \sigma = b + \exp(\eta) \). This link is designed to avoid singularities in the likelihood caused by the standard deviation tending to zero. Note that internally the family is parameterized in terms of the \( \tau = \sigma^{-1} \), i.e. the standard deviation of the precision, so the link and inverse link are coded to reflect this, however the relationships between the linear predictor and the standard deviation are as given above.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the inverse of the standard deviation. Predictions using \texttt{predict.gam} will also produce 2 column matrices for type "link" and "response". The second column when type="response" is again on the reciprocal standard deviation scale (i.e. the square root precision scale). The second column when type="link" is \( \log(\sigma - b) \). Also \texttt{plot.gam} will plot smooths relating to \( \sigma \) on the \( \log(\sigma - b) \) scale (so high values correspond to high standard deviation and low values to low standard deviation). Similarly the smoothing penalties are applied on the (log) standard deviation scale, not the log precision scale.
The null deviance reported for this family is the sum of squares of the difference between the response and the mean response divided by the standard deviation of the response according to the model. The deviance is the sum of squares of residuals divided by model standard deviations.

**Value**

An object inheriting from class `general.family`.

**References**

**Examples**

```r
library(mgcv);library(MASS)
b <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
data=mcycle,family=gaulss())
summary(b)
plot(b,pages=1,scale=0)
```

---

### get.var

Get named variable or evaluate expression from list or data.frame

**Description**

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then NULL is returned. The routine is useful for processing gam formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

**Usage**

```r
get.var(txt,data,vecMat=TRUE)
```

**Arguments**

- `txt`: a text string which is either the name of a variable in `data` or when parsed is an expression that can be evaluated in `data`. It can also be neither in which case the function returns NULL.
- `data`: A data frame or list.
- `vecMat`: Should matrices be coerced to numeric vectors?

**Value**

The evaluated variable or NULL. May be coerced to a numeric vector if it's a matrix.

```
$location

Description

The gevlss family implements Generalized Extreme Value location scale additive models in which
the location, scale and shape parameters depend on additive smooth predictors. Usable only with
``gam``, the linear predictors are specified via a list of formulae.

Usage

```
gevlss(link=list("identity","identity","logit"))
```

Arguments

```
link three item list specifying the link for the location scale and shape parameters.
See details.
```

Details

Used with `gam` to fit Generalized Extreme Value location scale and shape models. `gam` is called with
a list containing 3 formulae: the first specifies the response on the left hand side and the structure
of the linear predictor for the location parameter on the right hand side. The second is one sided,
specifying the linear predictor for the log scale parameter on the right hand side. The third is one
sided specifying the linear predictor for the shape parameter.

Link functions "identity" and "log" are available for the location (mu) parameter. There is
no choice of link for the log scale parameter ($\rho = \log \sigma$). The shape parameter (xi) defaults to a
modified logit link restricting its range to (-1,.5), the upper limit is required to ensure finite variance,
while the lower limit ensures consistency of the MLE (Smith, 1985).

The fitted values for this family will be a three column matrix. The first column is the location
parameter, the second column is the log scale parameter, the third column is the shape parameter.
This family does not produce a null deviance. Note that the distribution for \( \xi = 0 \) is approximated
by setting \( \xi \) to a small number.
The derivative system code for this family is mostly auto-generated, and the family is still somewhat experimental.

The GEV distribution is rather challenging numerically, and for small datasets or poorly fitting models improved numerical robustness may be obtained by using the extended Fellner-Schall method of Wood and Fasiolo (2017) for smoothing parameter estimation. See examples.

Value

An object inheriting from class `general.family`.

b <- gam(list(y~s(x2),~s(x0),~s(x1)),family=gevlss,data=data,optimizer="efs")

## plot and look at residuals...

plot(b,pages=1,scale=0)

summary(b)
```
par(mfrow=c(2,2))
mu <- fitted(b)[,1]; rho <- fitted(b)[,2]
xi <- fitted(b)[,3]
## Get the predicted expected response...
fv <- mu + exp(rho)*(gamma(1-xi)-1)/xi
rsd <- residuals(b)
plot(fv,rsd);qqnorm(rsd)
plot(fv,residuals(b,"pearson"))
plot(fv,residuals(b,"response"))

ginla

GAM Integrated Nested Laplace Approximation Newton Enhanced

Description

Apply Integrated Nested Laplace Approximation (INLA, Rue et al. 2009) to models estimable by `gam` or `bam`, using the INLA variant described in Wood (2019). Produces marginal posterior densities for each coefficient, selected coefficients or linear transformations of the coefficient vector.

Usage

```r
ginla(G, A=NULL, nk=16, nb=100, J=1, interactive=FALSE, int=0, approx=0)
```

Arguments

- **G**: A pre-fit gam object, as produced by `gam(...,fit=FALSE)` or `bam(..., discrete=TRUE, fit=FALSE).
- **A**: Either a matrix of transforms of the coefficients that are of interest, or an array of indices of the parameters of interest. If NULL then distributions are produced for all coefficients.
- **nk**: Number of values of each coefficient at which to evaluate its log marginal posterior density. These points are then spline interpolated.
- **nb**: Number of points at which to evaluate posterior density of coefficients for returning as a gridded function.
- **J**: How many determinant updating steps to take in the log determinant approximation step. Not recommended to increase this.
- **interactive**: If this is >0 or TRUE then every approximate posterior is plotted in red, overlaid on the simple Gaussian approximate posterior. If 2 then waits for user to press return between each plot. Useful for judging whether anything is gained by using INLA approach.
- **int**: 0 to skip integration and just use the posterior modal smoothing parameter. >0 for integration using the CCD approach proposed in Rue et al. (2009).
- **approx**: 0 for full approximation; 1 to update Hessian, but use approximate modes; 2 as 1 and assume constant Hessian. See details.
Details

Let $\beta$, $\theta$, and $y$ denote the model coefficients, hyperparameters/smoothing parameters and response data, respectively. In principle, INLA employs Laplace approximations for $\pi(\beta_i|\theta,y)$ and $\pi(\theta|y)$ and then obtains the marginal posterior distribution $\pi(\beta_i|y)$ by intergrating the approximations to $\pi(\beta_i|\theta,y)\pi(\theta|y)$ w.r.t $\theta$ (marginals for the hyperparameters can also be produced). In practice the Laplace approximation for $\pi(\beta_i|\theta,y)$ is too expensive to compute for each $\beta_i$ and must itself be approximated. To this end, there are two quantities that have to be computed: the posterior mode $\beta^*|\beta_i$ and the determinant of the Hessian of the joint log density $\log \pi(\beta,\theta,y)$ w.r.t. $\beta$ at the mode. Rue et al. (2009) originally approximated the posterior conditional mode by the conditional mode implied by a simple Gaussian approximation to the posterior $\pi(\beta|y)$. They then approximated the log determinant of the Hessian as a function of $\beta_i$ using a first order Taylor expansion, which is cheap to compute for the sparse model representation that they use, but not when using the dense low rank basis expansions used by gam. They also offer a more expensive alternative approximation based on computing the log determinant with respect only to those elements of $\beta$ with sufficiently high correlation with $\beta_i$ according to the simple Gaussian posterior approximation: efficiency again seems to rest on sparsity. Wood (2018) suggests computing the required posterior modes exactly, and basing the log determinant approximation on a BFGS update of the Hessian at the unconditional model. The latter is efficient with or without sparsity, whereas the former is a 'for free' improvement. Both steps are efficient because it is cheap to obtain the Cholesky factor of $H$ - see choldrop. This is the approach taken by this routine.

The approx argument allows two further approximations to speed up computations. For approx==1 the exact posterior conditional modes are not used, but instead the conditional modes implied by the simple Gaussian posterior approximation. For approx==2 the same approximation is used for the modes and the Hessian is assumed constant. The latter is quite fast as no log joint density gradient evaluations are required.

Note that for many models the INLA estimates are very close to the usual Gaussian approximation to the posterior, the interactive argument is useful for investigating this issue.

bam models are only supported with the discrete=TRUE option. The discrete=FALSE approach would be too inefficient. AR1 models are not supported (related arguments are simply ignored).

Value

A list with elements beta and density, both of which are matrices. Each row relates to one coefficient (or linear coefficient combination) of interest. Both matrices have nb columns. If int!=0 then a further element reml gives the integration weights used in the CCD integration, with the central point weight given first.

WARNINGS

This routine is still somewhat experimental, so details are liable to change. Also currently not all steps are optimally efficient.

The routine is written for relatively expert users.

ginla is not designed to deal with rank deficient models.

```

gumbels

### Gumbel location-scale model family

#### Description

The gumbels family implements Gumbel location scale additive models in which the location and scale parameters (see details) can depend on additive smooth predictors. Useable only with `gam`, the linear predictors are specified via a list of formulae.

#### Usage

```r
gumbels(link=list("identity","log"),b=-7)
```

#### Arguments

- `link` two item list specifying the link for the location $\mu$ and log scale parameter $\beta$. See details for meaning, which may not be intuitive.
- `b` The minimum log scale parameter.

#### Details

Let $z = (y - \mu)e^{-\beta}$, then the log Gumbel density is $l = -\beta - z - e^{-z}$. The expected value of a Gumbel r.v. is $\mu + \gamma e^\beta$ where $\gamma$ is Euler's constant (about 0.57721566). The corresponding variance is $\pi^2 e^{2\beta}/6$. 
gumbls is used with \texttt{gam} to fit Gumbel location - scale models parameterized in terms of location parameter $\mu$ and the log scale parameter $\beta$. Note that identity link for the scale parameter means that the corresponding linear predictor gives $\beta$ directly. By default the log link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument $b$: if $\eta$ is the linear predictor for the log scale parameter, $\beta$, then $\beta = b + \log(1 + e^\eta)$.

\texttt{gam} is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for location parameter, $\mu$, on the right hand side. The second is one sided, specifying the linear predictor for the log scale, $\beta$, on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the log scale parameter, $\beta$. Predictions using \texttt{predict.gam} will also produce 2 column matrices for type "link" and "response". The first column is on the original data scale when type="response" and on the log mean scale of the linear predictor when type="link". The second column when type="response" is again the log scale parameter, but is on the linear predictor when type="link".

\textbf{Value}

An object inheriting from class \texttt{general.family}.

\textbf{References}

\textbf{Examples}

```r
library(mgcv)
## simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1-x))^6 + 10 * 
     (10 * x)^3 * (1-x)^10
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- f0(x0) + f1(x1)
beta <- exp(f2(x2)/5)
y <- mu - beta*log(-log(runif(n))) ## Gumbel quantile function

b <- gam(list(y~s(x0)+s(x1),~s(x2)+s(x3)),family=gumbls)
plot(b,pages=1,scale=0)
summary(b)
gam.check(b)
```
Description

Smooth terms are generally only identifiable up to an additive constant. In consequence sum-to-zero identifiability constraints are imposed on most smooth terms. The exceptions are terms with by variables which cause the smooth to be identifiable without constraint (that doesn’t include factor by variables), and random effect terms. Alternatively smooths can be set up to pass through zero at a user specified point.

Details

By default each smooth term is subject to the sum-to-zero constraint

$$\sum_i f(x_i) = 0.$$ 

The constraint is imposed by reparameterization. The sum-to-zero constraint causes the term to be orthogonal to the intercept: alternative constraints lead to wider confidence bands for the constrained smooth terms.

No constraint is used for random effect terms, since the penalty (random effect covariance matrix) anyway ensures identifiability in this case. Also if a by variable means that the smooth is anyway identifiable, then no extra constraint is imposed. Constraints are imposed for factor by variables, so that the main effect of the factor must usually be explicitly added to the model (the example below is an exception).

Occasionally it is desirable to substitute the constraint that a particular smooth curve should pass through zero at a particular point: the pc argument to s, te, ti and t2 allows this: if specified then such constraints are always applied.

Author(s)

Simon N. Wood (s.wood@r-project.org)

Examples

```r
## Example of three groups, each with a different smooth dependence on x
## but each starting at the same value...
require(mgcv)
set.seed(53)
n <- 100;x <- runif(3*n);z <- runif(3*n)
fac <- factor(rep(c("a","b","c"),each=100))
y <- c(sin(x[1:100]*4),exp(3*x[101:200])/10-.1,exp(-10*(x[201:300]-.5))/(1+exp(-10*(x[201:300]-.5)))-0.9933071) + z*(1-z)*5 + rnorm(100)*.4
## 'pc' used to constrain smooths to 0 at x=0...
b <- gam(y~s(x,by=fac,pc=0)+s(z))
plot(b,pages=1)
```

Description

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as 'inside' if they are interior to an odd number of polygons.
Usage

`in.out(bnd,x)`

Arguments

- **bnd**: A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed. Alternatively can be a lists where `bnd[[i]][[1]], bnd[[i]][[2]]` defines the `i`th boundary loop.

- **x**: A two column matrix. Each row is a point to test for inclusion in the region defined by `bnd`. Can also be a 2-vector, defining a single point.

Details

The algorithm works by counting boundary crossings (using compiled C code).

Value

A logical vector of length `nrow(x)`. TRUE if the corresponding row of `x` is inside the boundary and FALSE otherwise.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

https://www.maths.ed.ac.uk/~swood34/

Examples

```r
library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd,type="n")
polygon(bnd)
x <- seq(7.9,8.7,length=20)
y <- seq(13.7,14.3,length=20)
gr <- as.matrix(expand.grid(x,y))
inside <- in.out(bnd,gr)
points(gr,col=as.numeric(inside)+1)
```

influence.gam

*Extract the diagonal of the influence/hat matrix for a GAM*

Description

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted `gam` object.

Usage

```r
## S3 method for class 'gam'
influence(model,...)
```
Arguments

model: fitted model objects of class gam as produced by gam().

Details

Simply extracts hat array from fitted model. (More may follow!)

Value

An array (see above).

Author(s)

Simon N. Wood <simon.wood@r-project.org>

See Also

gam

Description

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

Usage

initial.sp(X,S,off,expensive=FALSE,XX=FALSE)

Arguments

X: is the model matrix.
S: is a list of penalty matrices. S[[i]] is the ith penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of S[[i]] occupies element off[i],off[i] of the ith penalty matrix. Each S[[i]] must be positive semi-definite.
off: is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving S[[i]].
expensive: if TRUE then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.
XX: if TRUE then X contains X^T X, rather than X.
inSide

Details

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1. Usually only called by magic and gam.

Value

An array of initial smoothing parameter estimates.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

See Also

magic, gam.outer, gam.

Description

Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

Usage

inSide(bnd,x,y)

Arguments

bnd This should have two equal length columns with names matching whatever is supplied in x and y. This may contain several sections of boundary separated by NA. Alternatively bnd may be a list, each element of which contains 2 columns named as above. See below for details.

x x co-ordinates of points to be tested.

y y co-ordinates of points to be tested.

Details

Segments of boundary are separated by NAs, or are in separate list elements. The boundary co-ordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).

The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner ‘islands’ completely enclosed in the outer loop.

The routine calls compiled C code and operates by an exhaustive search for each point in x, y.
The function returns a logical array of the same dimension as x and y. TRUE indicates that the corresponding x, y point lies inside the boundary.

------

### interpret.gam

Interpret a GAM formula

**Description**

This is an internal function of package mgcv. It is a service routine for gam which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

**Usage**

```r
interpret.gam(gf, extra.special = NULL)
```

**Arguments**

- `gf` A GAM formula as supplied to `gam` or `gamm`, or a list of such formulae, as supplied for some `gam` families.
- `extra.special` Name of any extra special in formula in addition to s, te, ti and t2.
Value

An object of class split.gam.formula with the following items:

- **pf**: A model formula for the strictly parametric part of the model.
- **pfok**: TRUE if there is a pf formula.
- **smooth.spec**: A list of class xx.smooth.spec objects where xx depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)
- **full.formula**: An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.
- **fake.formula**: A formula suitable for use in evaluating a model frame.
- **response**: Name of the response variable.

gam, gamm

Description

Facilities to auto-generate model specification code and associated data to simulate with GAMs in JAGS (or BUGS). This is useful for inference about models with complex random effects structure best coded in JAGS. It is a very inefficient approach to making inferences about standard GAMs. The idea is that jagam generates template JAGS code, and associated data, for the smooth part of the model. This template is then directly edited to include other stochastic components. After simulation with the resulting model, facilities are provided for plotting and prediction with the model smooth components.

Usage

```r
jagam(formula, family=gaussian, data=list(), file, weights=NULL, na.action, offset=NULL, knots=NULL, sp=NULL, drop.unused.levels=TRUE, control=gam.control(), centred=TRUE, sp.prior = "gamma", diagonalize=FALSE)

sim2jam(sam, pregam, edf.type=2, burnin=0)
```
Arguments

formula
A GAM formula (see formula.gam and also gam.models). This is exactly like
the formula for a GLM except that smooth terms, s, te, ti and t2 can be added
to the right hand side to specify that the linear predictor depends on smooth
functions of predictors (or linear functionals of these).

family
This is a family object specifying the distribution and link function to use. See
glm and family for more details. Currently only gaussian, poisson, binomial
and Gamma families are supported, but the user can easily modify the assumed
distribution in the JAGS code.

data
A data frame or list containing the model response variable and covari-
ates required by the formula. By default the variables are taken from
environment(formula): typically the environment from which jagam is
called.

file
Name of the file to which JAGS model specification code should be written. See
setwd for setting and querying the current working directory.

weights
prior weights on the data.

na.action
a function which indicates what should happen when the data contain ‘NA’s.
The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is
unset. The “factory-fresh” default is ‘na.omit’.

offset
Can be used to supply a model offset for use in fitting. Note that this offset
will always be completely ignored when predicting, unlike an offset included in
formula: this conforms to the behaviour of lm and glm.

control
A list of fit control parameters to replace defaults returned by gam.control.
Any control parameters not supplied stay at their default values. little effect on
jagam.

knots
this is an optional list containing user specified knot values to be used for basis
construction. For most bases the user simply supplies the knots to be used,
which must match up with the k value supplied (note that the number of knots is
not always just k). See tprs for what happens in the "tp"/"ts" case. Different
terms can use different numbers of knots, unless they share a covariate.

sp
A vector of smoothing parameters can be provided here. Smoothing parameters
must be supplied in the order that the smooth terms appear in the model formula
(without forgetting null space penalties). Negative elements indicate that the
parameter should be estimated, and hence a mixture of fixed and estimated pa-
rameters is possible. If smooths share smoothing parameters then length(sp)
must correspond to the number of underlying smoothing parameters.

don.unused.levels
by default unused levels are dropped from factors before fitting. For some
smooths involving factor variables you might want to turn this off. Only do
so if you know what you are doing.

centred
Should centring constraints be applied to the smooths, as is usual with GAMS?
Only set this to FALSE if you know exactly what you are doing. If FALSE there
is a (usually global) intercept for each smooth.

sp.prior
"gamma" or "log.uniform" prior for the smoothing parameters? Do check that
the default parameters are appropriate for your model in the JAGS code.

diagonalize
Should smooths be re-parameterized to have i.i.d. Gaussian priors (where pos-
sible)? For Gaussian data this allows efficient conjugate samplers to be used,
and it can also work well with GLMs if the JAGS "glm" module is loaded, but
otherwise it is often better to update smoothers blockwise, and not do this.
jagam

jags sample object, containing at least fields b (coefficients) and rho (log smoothing parameters). May also contain field mu containing monitored expected response.

standard mgcv GAM setup data, as returned in jagam return list.

Since EDF is not uniquely defined and may be affected by the stochastic structure added to the JAGS model file, 3 options are offered. See details.

the amount of burn in to discard from the simulation chains. Limited to .9 of the chain length.

Details

Smooths are easily incorporated into JAGS models using multivariate normal priors on the smooth coefficients. The smoothing parameters and smoothing penalty matrices directly specify the prior multivariate normal precision matrix. Normally a smoothing penalty does not correspond to a full rank precision matrix, implying an improper prior inappropriate for Gibbs sampling. To rectify this problem the null space penalties suggested in Marra and Wood (2011) are added to the usual penalties.

In an additive modelling context it is usual to centre the smooths, to avoid the identifiability issues associated with having an intercept for each smooth term (in addition to a global intercept). Under Gibbs sampling with JAGS it is technically possible to omit this centring, since we anyway force propriety on the priors, and this propriety implies formal model identifiability. However, in most situations this formal identifiability is rather artificial and does not imply statistically meaningful identifiability. Rather it serves only to massively inflate confidence intervals, since the multiple intercept terms are not identifiable from the data, but only from the prior. By default then, jagam imposes standard GAM identifiability constraints on all smooths. The centred argument does allow you to turn this off, but it is not recommended. If you do set centred=FALSE then chain convergence and mixing checks should be particularly stringent.

The final technical issue for model setup is the setting of initial conditions for the coefficients and smoothing parameters. The approach taken is to take the default initial smoothing parameter values used elsewhere by mgcv, and to take a single PIRLS fitting step with these smoothing parameters in order to obtain starting values for the smooth coefficients. In the setting of fully conjugate updating the initial values of the coefficients are not critical, and good results are obtained without supplying them. But in the usual setting in which slice sampling is required for at least some of the updates then very poor results can sometimes be obtained without initial values, as the sampler simply fails to find the region of the posterior mode.

The sim2jam function takes the partial gam object (pregam) from jagam along with simulation output in standard rjags form and creates a reduced version of a gam object, suitable for plotting and prediction of the model’s smooth components. sim2gam computes effective degrees of freedom for each smooth, but it should be noted that there are several possibilities for doing this in the context of a model with a complex random effects structure. The simplest approach (edf.type=0) is to compute the degrees of freedom that the smooth would have had if it had been part of an unweighted Gaussian additive model. One might choose to use this option if the model has been modified so that the response distribution and/or link are not those that were specified to jagam. The second option is (edf.type=1) uses the edf that would have been computed by gam had it produced these estimates - in the context in which the JAGS model modifications have all been about modifying the random effects structure, this is equivalent to simply setting all the random effects to zero for the effective degrees of freedom calculation. The default option (edf.type=2) is to base the EDF on the sample covariance matrix, Vp, of the model coefficients. If the simulation output (sim) includes a mu field, then this will be used to form the weight matrix W in \( X'WXX = (X)'WXX \), where the EDF is computed from rowSums(Vp*XWX)*scale. If mu is not supplied then it is estimated from the the model matrix X and the mean of the simulated coefficients, but the resulting W may not be
strictly compatible with the $V_p$ matrix in this case. In the situation in which the fitted model is very different in structure from the regression model of the template produced by $\text{jagam}$ then the default option may make no sense, and indeed it may be best to use option 0.

**Value**

For $\text{jagam}$ a three item list containing

- `pregam`: standard mgcv GAM setup data.
- `jags.data`: list of arguments to be supplied to JAGS containing information referenced in model specification.
- `jags.ini`: initialization data for smooth coefficients and smoothing parameters.

For $\text{sim2jam}$ an object of class "jam": a partial version of an mgcv `gamObject`, suitable for plotting and predicting.

**WARNINGS**

Gibb’s sampling is a very slow inferential method for standard GAMs. It is only likely to be worthwhile when complex random effects structures are required above what is possible with direct GAMM methods.

Check that the parameters of the priors on the parameters are fit for your purpose.

## End(Not run)

---

### Description

Takes a fitted `gam` object produced by `gam()` and runs diagnostic tests of whether the basis dimension choices are adequate.

### Usage

```r
k.check(b, subsample=5000, n.rep=400)
```

### Arguments

- `b`: a fitted `gam` object as produced by `gam()`.
- `subsample`: above this number of data, testing uses a random sub-sample of data of this size.
- `n.rep`: how many re-shuffles to do to get p-value for $k$ testing.

### Details

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the $k$-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled $n_{rep}$ times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `subsample` data, the tests are based of `subsample` randomly sampled data. Low p-values may indicate that the basis dimension, $k$, has been set too low, especially if the reported edf is close to $k'$, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect $k$ and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low $k$. See `choose.k` for fuller discussion.

### Value

A matrix containing the output of the tests described above.

ldetS

Getting log generalized determinant of penalty matrices

Description
INTERNAL function calculating the log generalized determinant of penalty matrix S stored block-wise in an Sl list (which is the output of Sl.setup).

Usage
ldetS(Sl, rho, fixed, np, root = FALSE, repara = TRUE, nt = 1, deriv=2, sparse=FALSE)

Arguments
Sl the output of Sl.setup.
rho the log smoothing parameters.
fixed an array indicating whether the smoothing parameters are fixed (or free).
np number of coefficients.
root indicates whether or not to return the matrix square root, E, of the total penalty S_tot.
repara if TRUE multi-term blocks will be re-parameterized using gam.reparam, and a re-parameterization object supplied in the returned object.
nt number of parallel threads to use.
deriv order of derivative to use
sparse should E be sparse?
Value

A list containing:

- `1detS`: the log-determinant of S.
- `1detS1`: the gradient of the log-determinant of S.
- `1detS2`: the Hessian of the log-determinant of S.
- `Sl`: with modified rS terms, if needed and rho added to each block
- `rp`: a re-parameterization list.
- `rp`: E a total penalty square root such that \( t(E) \times E = S_{tot} \) (if root==TRUE).

Author(s)

ldTweedie

Log Tweedie density evaluation

Description

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter, phi, and p, or w.r.t. rho=\( \log(\phi) \) and theta where \( p = \frac{(a+b\times\exp(theta))}{(1+\exp(theta))} \).

Usage

```r
ldTweedie(y, mu=y, p=1.5, phi=1, rho=NA, theta=NA, a=1.001, b=1.999, all.derivs=FALSE)
```

Arguments

- `y`: values at which to evaluate density.
- `mu`: corresponding means (either of same length as y or a single value).
- `p`: the variance of y is proportional to its mean to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.
- `phi`: The scale parameter. Variance of y is phi*mu^p.
- `rho`: optional log scale parameter. Over-rides phi if theta also supplied.
- `theta`: parameter such that \( p = \frac{(a+b\times\exp(theta))}{(1+\exp(theta))} \). Over-rides p if rho also supplied.
- `a`: lower limit parameter (>1) used in definition of p from theta.
- `b`: upper limit parameter (<2) used in definition of p from theta.
- `all.derivs`: if TRUE then derivatives w.r.t. mu are also returned. Only available with rho and phi parameterization.
Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1.

ldTweedie is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on p the calculation of Tweedie densities is less straightforward. If you really need this case then the tweedie package is the place to start.

The rho, theta parameterization is useful for optimization of p and phi, in order to keep p bounded well away from 1 and 2, and phi positive. The derivatives near p=1 tend to infinity. Note that if p and phi (or theta and rho) both contain only a single unique value, then the underlying code is able to use buffering to avoid repeated calls to expensive log gamma, di-gamma and tri-gamma functions (mu can still be a vector of different values). This is much faster than is possible when these parameters are vectors with different values.

Value

A matrix with 6 columns, or 10 if all.derivs=TRUE. The first is the log density of y (log probability if p=1). The second and third are the first and second derivatives of the log density w.r.t. phi. 4th and 5th columns are first and second derivative w.r.t. p, final column is second derivative w.r.t. phi and p.

If rho and theta were supplied then derivatives are w.r.t. these. In this case, and if all.derivs=TRUE then the 7th column is the derivative w.r.t. mu, the 8th is the 2nd derivative w.r.t. mu, the 9th is the mixed derivative w.r.t. theta and mu and the 10th is the mixed derivative w.r.t. rho and mu.

linear.functional.terms

Linear functionals of a smooth in GAMs

Description

`gam` allows the response variable to depend on linear functionals of smooth terms. Specifically dependancies of the form

\[ g(\mu_i) = \ldots + \sum_j L_{ij} f(x_{ij}) + \ldots \]

are allowed, where the \( x_{ij} \) are covariate values and the \( L_{ij} \) are fixed weights. i.e. the response can depend on the weighted sum of the same smooth evaluated at different covariate values. This allows, for example, for the response to depend on the derivatives or integrals of a smooth (approximated by finite differencing or quadrature, respectively). It also allows dependence on predictor functions (sometimes called 'signal regression').

The mechanism by which this is achieved is to supply matrices of covariate values to the model smooth terms specified by `s` or `te` terms in the model formula. Each column of the covariate matrix gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of evaluated smooth values be \( F \) (\( F \) will have the same dimension as the covariate matrices). In the absense of a by variable then these columns are simply summed and added to the linear predictor. i.e. the contribution of the term to the linear predictor is `rowSums(F)`. If a by variable is present then it must be a matrix, \( L \), of the same dimension as \( F \) (and the covariate matrices), and it contains the weights \( L_{ij} \) in the summation given above. So in this case the contribution to the linear predictor is `rowSums(L*F)`.

Note that if a \( L_1 \) (i.e. `rowSums(L)`) is a constant vector, or there is no by variable then the smooth will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also that for centred smooths it can be worth replacing the constant term in the model with `rowSums(L)` in order to ensure that predictions are automatically on the right scale.

`predict.gam` can accept matrix predictors for prediction with such terms, in which case its `newdata` argument will need to be a list. However when predicting from the model it is not necessary to provide matrix covariate and by variable values. For example to simply examine the underlying smooth function one would use vectors of covariate values and vector by variables, with the by variable and equivalent of \( L_1 \), above, set to vectors of ones.

The mechanism is usable with random effect smooths which take factor arguments, by using a trick to create a 2D array of factors. Simply create a factor vector containing the columns of the factor matrix stacked end to end (column major order). Then reset the dimensions of this vector to create the appropriate 2D array: the first dimension should be the number of response data and the second the number of columns of the required factor matrix. You can not use `matrix` or `data.matrix` to set up the required matrix of factor levels. See example below.

**Description**

Function to extract the log-likelihood for a fitted `gam` model (note that the models are usually fitted by penalized likelihood maximization). Used by `AIC`. See details for more information on AIC computation.

**Usage**

```r
## S3 method for class 'gam'
logLik(object,...)
```

**Arguments**

- `object` fitted model objects of class `gam` as produced by `gam()`.
- `...` un-used in this case

**Details**

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that `AIC` functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). See e.g. Wood, Pya and Saefken (2016) for a derivation of an appropriate AIC.

For `gaussian` family models the MLE of the scale parameter is used. For other families with a scale parameter the estimated scale parameter is used. This is usually not exactly the MLE, and is not the simple deviance based estimator used with `glm` models. This is because the simple deviance based estimator can be badly biased in some cases, for example when a Tweedie distribution is employed with low count data.

There are two possible AIC’s that might be considered for use with GAMs. Marginal AIC is based on the marginal likelihood of the GAM, that is the likelihood based on treating penalized (e.g. spline) coefficients as random and integrating them out. The degrees of freedom is then the number of smoothing/variance parameters + the number of fixed effects. The problem with Marginal AIC is that marginal likelihood underestimates variance components/oversmooths, so that the approach favours simpler models excessively (substituting REML does not work, because REML is not comparable between models with different unpenalized/fixed components). Conditional AIC uses the likelihood of all the model coefficients, evaluated at the penalized MLE. The degrees of freedom to use then is the effective degrees of freedom for the model. However, Greven and Kneib (2010) show that the neglect of smoothing parameter uncertainty can lead to this conditional AIC being excessively likely to select larger models. Wood, Pya and Saefken (2016) propose a simple correction to the effective degrees of freedom to fix this problem. mgcv applies this correction whenever possible: that is when using ML or REML smoothing parameter selection with `gam` or `bam`. The correction is not computable when using the Extended Fellner Schall or BFGS optimizer (since the correction requires an estimate of the covariance matrix of the log smoothing parameters).

**Value**

Standard `logLik` object: see `logLik`.

ls.size

Size of list elements

Description

Produces a named array giving the size, in bytes, of the elements of a list.

Usage

ls.size(x)

Arguments

x

A list.

Value

A numeric vector giving the size in bytes of each element of the list x. The elements of the array have the same names as the elements of the list. If x is not a list then its size in bytes is returned, un-named.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

https://www.maths.ed.ac.uk/~swood34/

Examples

library(mgcv)
b <- list(M=matrix(runif(100),10,10),quote=
"The world is ruled by idiots because only an idiot would want to rule the world.",
fam=binomial())
ls.size(b)
Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton’s method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

Usage

```r
magic(y, X, sp, S, off, L = NULL, lsp0 = NULL, rank = NULL, H = NULL, C = NULL,
       w = NULL, gamma = 1, scale = 1, gcv = TRUE, ridge.parameter = NULL,
       control = list(tol = 1e-6, step.half = 25, rank.tol =
                     .Machine$double.eps^0.5), extra.rss = 0, n.score = length(y), nthreads = 1)
```

Arguments

- `y`: is the response data vector.
- `X`: is the model matrix (more columns than rows are allowed).
- `sp`: is the array of smoothing parameters. The vector `L%*%log(sp) + lsp0` contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in `S` (if `L` is taken as the identity if `NULL`). Any `sp` values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value.
- `S`: is a list of penalty matrices. `S[[i]]` is the `i`th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of `S[[i]]` occupies element `off[i]` of the `i`th penalty matrix. Each `S[[i]]` must be positive semi-definite. Set to `list()` if there are no smoothing parameters to be estimated.
- `off`: is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving `S[[i]]`.
- `L`: is a matrix mapping `log(sp)` to the log smoothing parameters that actually multiply the penalties defined by the elements of `S`. Taken as the identity, if `NULL`. See above under `sp`.
- `lsp0`: If `L` is not `NULL` this is a vector of constants in the linear transformation from `log(sp)` to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the `S[[i]]` are given by `L%*%log(sp) + lsp0`. Taken as 0 if `NULL`.
- `rank`: is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.
H is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.

C is the optional matrix specifying any linear equality constraints on the fitting problem. If b is the parameter vector then the parameters are forced to satisfy Cb = 0.

w the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of y, specifically \( V^{-1}_y = w'w \). If w is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of y. See below for an example using this.

gamma is an inflation factor for the model degrees of freedom in the GCV or UBRE score.

scale is the scale parameter for use with UBRE.

gcv should be set to TRUE if GCV is to be used, FALSE for UBRE.

ridge.parameter It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.

control is a list of iteration control constants with the following elements:

tol The tolerance to use in judging convergence.

step.half If a trial step fails then the method tries halving it up to a maximum of step.half times.

rank.tol is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than \( \text{rank\_tol} \) multiplied by the largest singular value of the problem is set to zero.

extra.rss is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with n.score, this is useful for certain methods for dealing with very large data sets.

n.score number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.

nthreads magic can make use of multiple threads if this is set to >1.

Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

\[
\text{minimise } \| W(Xb - y) \|^2 + b' H b + \sum_{i=1}^{m} \theta_i S_i b
\]

possibly subject to constraints Cb = 0. X is a design matrix, b a parameter vector, y a data vector, W a weight matrix, S_i a positive semi-definite matrix of coefficients defining the ith penalty with associated smoothing parameter \( \theta_i \), H is the positive semi-definite offset penalty matrix and C a matrix of coefficients defining any linear equality constraints on the problem. X need not be of full column rank.

The \( \theta_i \) are chosen to minimize either the GCV score:
\[ V_g = \frac{n\|W(y - Ay)\|^2}{\|\text{tr}(I - \gamma A)\|^2} \]

or the UBRE score:

\[ V_u = \|W(y - Ay)\|^2/n - 2\phi \text{tr}(I - \gamma A)/n + \phi \]

where \( \gamma \) is gamma the inflation factor for degrees of freedom (usually set to 1) and \( \phi \) is scale, the scale parameter. \( A \) is the hat matrix (influence matrix) for the fitting problem (i.e. the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through \( A \).

The method operates by Newton or steepest descent updates of the logs of the \( \theta_i \). A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small \( \theta_i \), it’s important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a \( \log(\theta_i) \) change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal \( b \) parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

**Value**

The function returns a list with the following items:

- **b** The best fit parameters given the estimated smoothing parameters.
- **scale** the estimated (GCV) or supplied (UBRE) scale parameter.
- **score** the minimized GCV or UBRE score.
- **sp** an array of the estimated smoothing parameters.
- **sp.full** an array of the smoothing parameters that actually multiply the elements of \( S \) (same as sp if \( L \) was NULL). This is \( \exp(L\%*\%\log(sp)) \).
- **rV** a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters \( b \) is given by \( rV\%*\%t(rV)\%*\%scale \).
- **gcv.info** is a list of information about the performance of the method with the following elements:
  - **full.rank** The apparent rank of the problem: number of parameters less number of equality constraints.
  - **rank** The estimated actual rank of the problem (at the final iteration of the method).
  - **fully.converged** is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it converged by failing to decrease the score along the search direction.
**hess.pos.def** is TRUE if the hessian of the UBRE or GCV score was positive definite at convergence.

**iter** is the number of Newton/Steepest descent iterations taken.

**score.calls** is the number of times that the GCV/UBRE score had to be evaluated.

**rms.grad** is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.

**R** The factor R from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to :math:`X`. So it may not be upper triangular.

Note that some further useful quantities can be obtained using **magic.post.proc**.

## Use 'magic' for a standard additive model fit ...
library(mgcv)
set.seed(1):n <- 200:sig <- 1
dat <- gamSim(1,n=n, scale=sig)
k <- 30
## set up additive model
G <- gam(y~s(x0,k=k)+s(x1,k=k)+s(x2,k=k)+s(x3,k=k), fit=FALSE, data=dat)
## fit using magic (and gam default tolerance)
mgfit <- magic(G$y, G$X, G$sp, G$S, G$off, rank=G$rank,
control=list(tol=1e-7, step.half=15))
## and fit using gam as consistency check
b <- gam(G=G)
mgfit$b; b$sp # compare smoothing parameter estimates
edf <- magic.post.proc(G$X, mgfit, G$w)$edf # get e.d.f. per param
range(edf-b$edf) # compare

## p>n example... fit model to first 100 data only, so more
## params than data...
mgfit <- magic(G$y[1:100], G$X[1:100,], G$sp, G$S, G$off, rank=G$rank)
edf <- magic.post.proc(G$X[1:100,], mgfit, G$w[1:100])$edf

## constrain first two smooths to have identical smoothing parameters
L <- diag(3); L <- rbind(L[1,], L)
mgfit <- magic(G$y, G$X, rep(-1,3), G$S, G$off, L=L, rank=G$rank, C=G$C)
```

Now a correlated data example ... 
library(nlme)
## simulate truth
set.seed(1);n<-400;sig<-2
x <- 0:(n-1)/(n-1)
f <- 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
## produce scaled covariance matrix for AR1 errors...
V <- corMatrix(Initialize(corAR1(.6),data.frame(x=x)))
Cv <- chol(V) # t(Cv)%*%Cv=V
## Simulate AR1 errors ...
e <- t(Cv)%*%rnorm(n,0,sig) # so cov(e) = V * sig^2
## Observe truth + AR1 errors
y <- f + e
## GAM ignoring correlation
par(mfrow=c(1,2))
b <- gam(y~s(x,k=20))
plot(b);lines(x,f-mean(f),col=2);title("Ignoring correlation")
## Fit smooth, taking account of known* correlation...
w <- solve(t(Cv)) # V'(-1) = w'w
## Use 'gam' to set up model for fitting...
G <- gam(y~s(x,k=20),fit=FALSE)
## fit using magic, with weight *matrix*
mgfit <- magic(G$y,G$X,G$sp,G$S,G$off,rank=G$rank,C=G$C,w=w)
## Modify previous gam object using new fit, for plotting...
mg.stuff <- magic.post.proc(G$X,mgfit,w)
b$edf <- mg.stuff$edf;b$Vp <- mg.stuff$Vb
b$coefficients <- mgfit$b
plot(b);lines(x,f-mean(f),col=2);title("Known correlation")

---

magic.post.proc

**Auxilliary information from magic fit**

**Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

**Usage**

magic.post.proc(X,object,w=NULL)

**Arguments**

- `X`
  - is the model matrix.
- `object`
  - is the list returned by magic after fitting the model with model matrix X.
- `w`
  - is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to magic, if one was.). If w is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If w is a matrix then t(w)%*%w should typically give the inverse of the covariance matrix of the response data supplied to magic.
Details

object contains rV (V, say), and scale (\(\phi\), say) which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is \(VV'\phi\). The vector of estimated degrees of freedom for each parameter is the leading diagonal of \(VV'X'WX'\) where \(W\) is either the weight matrix \(w\) or the matrix \(\text{diag}(w)\). The hat/influence matrix is given by \(WXVV'X'\).

The frequentist parameter estimator covariance matrix is \(VV'X'WXVV'\phi\): it is sometimes useful for testing terms for equality to zero.

Value

A list with three items:

- \(V_b\) the Bayesian covariance matrix of the model parameters.
- \(V_e\) the frequentist covariance matrix for the parameter estimators.
- \(\text{hat}\) the leading diagonal of the hat (influence) matrix.
- \(\text{edf}\) the array giving the estimated degrees of freedom associated with each parameter.

**mgcv.FAQ**

**Frequently Asked Questions for package mgcv**

**Description**

This page provides answers to some of the questions that get asked most often about mgcv

**FAQ list**

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the `summary.gam` Alternatively, simple random effects can be fitted with `gam`, which makes comparison straightforward. Package `gamm4` is an alternative, which allows AIC type model selection for generalized models.

2. **How do I get the equation of an estimated smooth?** This slightly misses the point of semi-parametric modelling: the idea is that we estimate the form of the function from data without assuming that it has a particular simple functional form. Of course for practical computation the functions do have underlying mathematical representations, but they are not very helpful, when written down. If you do need the functional forms then see chapter 5 of Wood (2017). However for most purposes it is better to use `predict.gam` to evaluate the function for whatever argument values you need. If derivatives are required then the simplest approach is to use finite differencing (which also allows SEs etc to be calculated).
3. **Some of my smooths are estimated to be straight lines and their confidence intervals vanish at some point in the middle. What is wrong?** Nothing. Smooths are subject to sum-to-zero identifiability constraints. If a smooth is estimated to be a straight line then it consequently has one degree of freedom, and there is no choice about where it passes through zero — so the CI must vanish at that point.

4. **How do I test whether a smooth is significantly different from a straight line.** See `tprs` and the example therein.

5. **An example from an mgcv helpfile gives an error - is this a bug?** It might be, but first please check that the version of mgcv you have loaded into R corresponds to the version from which the helpfile came. Many such problems are caused by trying to run code only supported in a later mgcv version in an earlier version. Another possibility is that you have an object loaded whose name clashes with an mgcv function (for example you are trying to use the mgcv `multinom` function, but have another object called `multinom` loaded.)

6. **Some code from Wood (2006) causes an error: why?** The book was written using mgcv version 1.3. To allow for REML estimation of smoothing parameters in versions 1.5, some changes had to be made to the syntax. In particular the function `gam.method` no longer exists. The smoothness selection method (GCV, REML etc) is now controlled by the `method` argument to `gam` while the optimizer is selected using the `optimizer` argument. See `gam` for details.

7. **Why is a model object saved under a previous mgcv version not usable with the current mgcv version?** I’m sorry about this issue, I know it’s really annoying. Here’s my defence. Each mgcv version is run through an extensive test suite before release, to ensure that it gives the same results as before, unless there are good statistical reasons why not (e.g. improvements to p-value approximation, fixing of an error). However it is sometimes necessary to modify the internal structure of model objects in a way that makes an old style object unusable with a newer version. For example, bug fixes or new R features sometimes require changes in the way that things are computed which in turn require modification of the object structure. Similarly improvements, such as the ability to compute smoothing parameters by RE/ML require object level changes. The only fix to this problem is to access the old object using the original mgcv version (available on CRAN), or to recompute the fit using the current mgcv version.

8. **When using `gamm` or `gamm4`, the reported AIC is different for the gam object and the lme or lmer object. Why is this?** There are several reasons for this. The most important is that the models being used are actually different in the two representations. When treating the GAM as a mixed model, you are implicitly assuming that if you gathered a replicate dataset, the smooths in your model would look completely different to the smooths from the original model, except for having the same degree of smoothness. Technically you would expect the smooths to be drawn afresh from their distribution under the random effects model. When viewing the gam from the usual penalized regression perspective, you would expect smooths to look broadly similar under replication of the data. i.e. you are really using Bayesian model for the smooths, rather than a random effects model (it’s just that the frequentist random effects and Bayesian computations happen to coincide for computing the estimates). As a result of the different assumptions about the data generating process, AIC model comparisons can give rather different answers depending on the model adopted. Which you use should depend on which model you really think is appropriate. In addition the computations of the AICs are different. The mixed model AIC uses the marginal likelihood and the corresponding number of model parameters. The gam model uses the penalized likelihood and the effective degrees of freedom.

9. **What does ’mgcv’ stand for?** ’Mixed GAM Computation Vehicle’, is my current best effort (let me know if you can do better). Originally it stood for ‘Multiple GCV’, which has long since ceased to be usefully descriptive, (and I can’t really change ’mgcv’ now without causing disruption). On a bad inbox day ’Mad GAM Computing Vulture’.
10. **My new method is failing to beat mgcv, what can I do?** If speed is the problem, then make sure that you use the slowest basis possible (“tp”) with a large sample size, and experiment with different optimizers to find one that is slow for your problem. For prediction error/MSE, then leaving the smoothing basis dimensions at their arbitrary defaults, when these are inappropriate for the problem setting, is a good way of reducing performance. Similarly, using p-splines in place of derivative penalty based splines will often shave a little more from the performance here. Unlike REML/ML, prediction error based smoothness selection criteria such as Mallows Cp and GCV often produce a small proportion of severe overfits, so careful choice of smoothness selection method can help further. In particular GCV etc. usually result in worse confidence interval and p-value performance than ML or REML. If all this fails, try using a really odd simulation setup for which mgcv is clearly not suited: for example poor performance is almost guaranteed for small noisy datasets with large numbers of predictors.

**mgcv.package**

Mixed GAM Computation Vehicle with GCV/AIC/REML smoothness estimation and GAMMs by REML/PQL

**Description**

mgcv provides functions for generalized additive modelling (gam and bam) and generalized additive mixed modelling (gamm, and random.effects). The term GAM is taken to include any model dependent on unknown smooth functions of predictors and estimated by quadratically penalized (possibly quasi-) likelihood maximization. Available distributions are covered in family.mgcv and available smooths in smooth.terms.

Particular features of the package are facilities for automatic smoothness selection (Wood, 2004, 2011), and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available. In addition to the main modelling functions, jagam provided facilities to ease the set up of models for use with JAGS, while ginla provides marginal inference via a version of Integrated Nested Laplace Approximation.

**Details**

mgcv provides generalized additive modelling functions gam, predict.gam and plot.gam, which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other
functions such as `summary.gam` and `anova.gam` are also provided, for extracting information from a fitted `gamObject`.

Use of `gam` is much like use of `glm`, except that within a `gam` model formula, isotropic smooths of any number of predictors can be specified using `s` terms, while scale invariant smooths of any number of predictors can be specified using `te`, `ti` or `t2` terms. `smooth_terms` provides an overview of the built in smooth classes, and `random.effects` should be referred to for an overview of random effects terms (see also `mrf` for Markov random fields). Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE or (RE)ML. See `gam`, `gam.models`, `linear.functional.terms` and `gam.selection` for some discussion of model specification and selection. For detailed control of fitting see `gam.convergence`, `gam` arguments method and optimizer and `gam.control`. For checking and visualization see `gam.check`, `choose.k`, `vis.gam` and `plot.gam`. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see `smooth.construct`, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals (see Marra and Wood, 2012). The Bayesian covariance matrix for the model coefficients is returned in `Vp` of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas (see Wood, 2013a,b). Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

For large datasets (that is large n) see `bam` which is a version of `gam` with a much reduced memory footprint.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`. See also `mgcv.FAQ`.

### mgcv.parallel

*Parallel computation in mgcv.*

**Description**

mgcv can make some use of multiple cores or a cluster.

- **bam** can use an openMP based parallelization approach alongside discretisation of covariates to achieve substantial speed ups. This is selected using the `discrete=TRUE` option to `bam`, with the number of threads controlled via the `nthreads` argument. This is the approach that scales best. See example below.

Alternatively, function **bam** can use the facilities provided in the **parallel** package. See examples below. Note that most multi-core machines are memory bandwidth limited, so parallel speed up tends to be rather variable.

- Function **gam** can use parallel threads on a (shared memory) multi-core machine via openMP (where this is supported). To do this, set the desired number of threads by setting `nthreads` to the number of cores to use, in the `control` argument of `gam`. Note that, for the most part, only the dominant $O(np^2)$ steps are parallelized (n is number of data, p number of parameters). For additive Gaussian models estimated by GCV, the speed up can be disappointing as these employ an $O(p^3)$ SVD step that can also have substantial cost in practice.

- **magic** can also use multiple cores, but the same comments apply as for the GCV Gaussian additive model.

If `control$nthreads` is set to more than the number of cores detected, then only the number of detected cores is used. Note that using virtual cores usually gives very little speed up, and can even slow computations slightly. For example, many Intel processors reporting 4 cores actually have 2 physical cores, each with 2 virtual cores, so using 2 threads gives a marked increase in speed, while using 4 threads makes little extra difference.

Note that on Intel and similar processors the maximum performance is usually achieved by disabling Hyper-Threading in BIOS, and then setting the number of threads to the number of physical cores used. This prevents the operating system scheduler from sending 2 floating point intensive threads
to the same physical core, where they have to share a floating point unit (and cache) and therefore slow each other down. The scheduler tends to do this under the manager - worker multi-threading approach used in mgcv, since the manager thread looks very busy up to the point at which the workers are set to work, and at the point of scheduling the scheduler has no way of knowing that the manager thread actually has nothing more to do until the workers are finished. If you are working on a many cored platform where you can not disable hyper-threading then it may be worth setting the number of threads to one less than the number of physical cores, to reduce the frequency of such scheduling problems.

mgcv’s work splitting always makes the simple assumption that all your cores are equal, and you are not sharing them with other floating point intensive threads.

In addition to hyper-threading several features may lead to apparently poor scaling. The first is that many CPUs have a Turbo mode, whereby a few cores can be run at higher frequency, provided the overall power used by the CPU does not exceed design limits, however it is not possible for all cores on the CPU to run at this frequency. So as you add threads eventually the CPU frequency has to be reduced below the Turbo frequency, with the result that you don’t get the expected speed up from adding cores. Secondly, most modern CPUs have their frequency set dynamically according to load. You may need to set the system power management policy to favour high performance in order to maximize the chance that all threads run at the speed you were hoping for (you can turn off dynamic power control in BIOS, but then you turn off the possibility of Turbo also).

Because the computational burden in mgcv is all in the linear algebra, then parallel computation may provide reduced or no benefit with a tuned BLAS. This is particularly the case if you are using a multi threaded BLAS, but a BLAS that is tuned to make efficient use of a particular cache size may also experience loss of performance if threads have to share the cache.

mini.roots

### mini.roots

**Obtain square roots of penalty matrices**

---

**Description**

INTERNAL function to obtain square roots, \( B[i] \), of the penalty matrices \( S[i] \)'s having as few columns as possible.

**Usage**

```r
mini.roots(S, off, np, rank = NULL)
```

**Arguments**

- **S**: a list of penalty matrices, in packed form.
- **off**: a vector where the i-th element is the offset for the i-th matrix. The elements in columns 1:off[i] of \( B[i] \) will be equal to zero.
- **np**: total number of parameters.
- **rank**: here rank[i] is optional supplied rank of \( S[i] \). Set rank[i] < 1, or rank=NULL to estimate.

**Value**

A list of matrix square roots such that \( S[i] = B[i] %*% t(B[i]) \).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.
Description

If there are missing values in the response or covariates of a GAM then the default is simply to use only the ‘complete cases’. If there are many missing covariates, this can get rather wasteful. One possibility is then to use imputation. Another is to substitute a simple random effects model in which the by variable mechanism is used to set \( s(x) \) to zero for any missing \( x \), while a Gaussian random effect is then substituted for the ‘missing’ \( s(x) \). See the example for details of how this works, and `gam.models` for the necessary background on by variables.

Examples

```r
## The example takes a couple of minutes to run...

require(mgcv)
par(mfrow=c(4,4),mar=c(4,4,1,1))
for (sim in c(1,7)) { # cycle over uncorrelated and correlated covariates
  n <- 350;set.seed(2)
  # simulate data but randomly drop 300 covariate measurements
  # leaving only 50 complete cases...
  dat <- gamSim(sim,n=n,scale=3) # 1 or 7
  drop <- sample(1:n,300) # to
  for (i in 2:5) dat[drop[1:75+(i-2)*75],i] <- NA
  # process data.frame producing binary indicators of missingness,
  # mx0, mx1 etc. For each missing value create a level of a factor
  # idx0, idx1, etc. So idx0 has as many levels as x0 has missing
  # values. Replace the NA’s in each variable by the mean of the
  # non missing for that variable...

  dname <- names(dat)[2:5]
  dat1 <- dat
  for (i in 1:4) {
    by.name <- paste("m",dname[i],sep="")
    dat1[[by.name]] <- is.na(dat1[[dname[i]]])
    dat1[[dname[i]]][dat1[[by.name]]] <- mean(dat1[[dname[i]]],na.rm=TRUE)
    lev <- rep(1,n);lev[dat1[[by.name]]] <- 1:sum(dat1[[by.name]])
    id.name <- paste("id",dname[i],sep="")
    dat1[[id.name]] <- factor(lev)
    dat1[[by.name]] <- as.numeric(dat1[[by.name]])
  }
  # Fit a gam, in which any missing value contributes zero
  # to the linear predictor from its smooth, but each
```
model.matrix.gam

## missing has its own random effect, with the random effect
## variances being specific to the variable. e.g.
## for s(x0,by=ordered(!mx0)), declaring the 'by' as an ordered
## factor ensures that the smooth is centred, but multiplied
## by zero when mx0 is one (indicating a missing x0). This means
## that any value (within range) can be put in place of the
## NA for x0. s(idx0,bs="re",by=mx0) produces a separate Gaussian
## random effect for each missing value of x0 (in place of s(x0),
## effectively). The 'by' variable simply sets the random effect to
## zero when x0 is non-missing, so that we can set idx0 to any
## existing level for these cases.

b <- bam(y~s(x0,by=ordered(!mx0))+s(x1,by=ordered(!mx1))+
        s(x2,by=ordered(!mx2))+s(x3,by=ordered(!mx3))+
        s(idx0,bs="re",by=mx0)+s(idx1,bs="re",by=mx1)+
        s(idx2,bs="re",by=mx2)+s(idx3,bs="re",by=mx3),
        ,data=dat1,discrete=TRUE)

for (i in 1:4) plot(b,select=i) # plot the smooth effects from b

## fit the model to the 'complete case' data...

b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="REML")
plot(b2) # plot the complete case results

---

model.matrix.gam  
Extract model matrix from GAM fit

Description

Obtains the model matrix from a fitted gam object.

Usage

## S3 method for class 'gam'
model.matrix(object, ...)

Arguments

object                  fitted model object of class gam as produced by gam().
...
other arguments, passed to predict.gam.

Details

Calls predict.gam with no newdata argument and type="lpmatrix" in order to obtain the model
matrix of object.

Value

A model matrix.
Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

See Also

gam

Examples

```r
require(mgcv)
n <- 15
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=6),knots=list(x=seq(0,1,length=6)))
model.matrix(mod)
```

Description

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the `gam`, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

Usage

```r
mono.con(x, up=TRUE, lower=NA, upper=NA)
```

Arguments

- **x**
  - The array of knot locations.
- **up**
  - If `TRUE` then the constraints imply increase, if `FALSE` then decrease.
- **lower**
  - This specifies the lower bound on the spline unless it is `NA` in which case no lower bound is imposed.
- **upper**
  - This specifies the upper bound on the spline unless it is `NA` in which case no upper bound is imposed.

Details

Consider the natural cubic spline passing through the points \( \{x_i, p_i : i = 1 \ldots n\} \). Then it is possible to find a relatively small set of linear constraints on \( \mathbf{p} \) sufficient to ensure monotonicity (and bounds if required): \( \mathbf{A} \mathbf{p} \geq \mathbf{b} \). Details are given in Wood (1994).
mroot

Value

a list containing constraint matrix A and constraint vector b.

**mroot**  
Smallest square root of matrix

Description

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleski decomposition or singular value decomposition to do this.

Usage

mroot(A, rank=NULL, method="chol")

Arguments

A  
The positive semi-definite matrix, a square root of which is to be found.
rank  
if the rank of the matrix A is known then it should be supplied. NULL or <1 imply that it should be estimated.
method  
"chol" to use pivoted choloeski decompositon, which is fast but tends to over-estimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank.

Details

The function uses SVD, or a pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

Value

A matrix, B with as many columns as the rank of A, and such that $A = BB'$.
multinom

Author(s)

Simon N. Wood <simon.wood@r-project.org>

Examples

```r
require(mgcv)
set.seed(0)
a <- matrix(runif(24),6,4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
svd.err <- max(abs(A-B%*%t(B)));svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

Description

Family for use with `gam`, implementing regression for categorical response data. Categories must be coded 0 to K, where K is a positive integer. `gam` should be called with a list of K formulae, one for each category except category zero (extra formulae for shared terms may also be supplied: see `formula.gam`). The first formula also specifies the response variable.

Usage

```r
multinom(K=1)
```

Arguments

- `K` There are K+1 categories and K linear predictors.

Details

The model has K linear predictors, \( \eta_j \), each dependent on smooth functions of predictor variables, in the usual way. If response variable, \( y \), contains the class labels 0,...,K then the likelihood for \( y>0 \) is \( \exp(\eta_y)/(1 + \sum_j \exp(\eta_j)) \). If \( y=0 \) the likelihood is \( 1/(1 + \sum_j \exp(\eta_j)) \). In the two class case this is just a binary logistic regression model. The implementation uses the approach to GAMLSS models described in Wood, Pya and Saefken (2016).

The residuals returned for this model are simply the square root of -2 times the deviance for each observation, with a positive sign if the observed y is the most probable class for this observation, and a negative sign otherwise.

Use `predict` with `type="response"` to get the predicted probabilities in each category.

Note that the model is not completely invariant to category relabelling, even if all linear predictors have the same form. Realistically this model is unlikely to be suitable for problems with large numbers of categories. Missing categories are not supported.
Value

An object of class `general.family`.

Examples

```r
library(mgcv)
set.seed(6)
## simulate some data from a three class model
n <- 1000
f1 <- function(x) sin(3*pi*x)*exp(-x)
f2 <- function(x) x^3
f3 <- function(x) .5*exp(-x^2)-.2
f4 <- function(x) 1
x1 <- runif(n);x2 <- runif(n)
eta1 <- 2*(f1(x1) + f2(x2))-.5
eta2 <- 2*(f3(x1) + f4(x2))-1
p <- exp(cbind(0,eta1,eta2))
p <- p/rowSums(p) ## prob. of each category
cp <- t(apply(p,1,cumsum)) ## cumulative prob.
## simulate multinomial response with these probabilities
y <- apply(cp,1,function(x) min(which(x>runif(1))))-1
## plot simulated data...
plot(x1,x2,col=y+3)
## now fit the model...
b <- gam(list(y~s(x1)+s(x2),~s(x1)+s(x2)),family=multinom(K=2))
plot(b,pages=1)
gam.check(b)
## now a simple classification plot...
expand.grid(x1=seq(0,1,length=40),x2=seq(0,1,length=40)) -> gr
pp <- predict(b,newdata=gr,type="response")
pc <- apply(pp,1,function(x) which(max(x)==x)[1])-1
plot(gr,col=pc+c,pch=19)
## example sharing a smoother between linear predictors
## ?formula.gam gives more details.
b <- gam(list(y~s(x1),~s(x1),1+2~s(x2)-1),family=multinom(K=2))
plot(b,pages=1)
```
mvn

Multivariate normal additive models

Description

Family for use with gam implementing smooth multivariate Gaussian regression. The means for each dimension are given by a separate linear predictor, which may contain smooth components. Extra linear predictors may also be specified giving terms which are shared between components (see formula.gam). The Choleski factor of the response precision matrix is estimated as part of fitting.

Usage

mvn(d=2)

Arguments

d

The dimension of the response (>1).

Details

The response is d dimensional multivariate normal, where the covariance matrix is estimated, and the means for each dimension have separate linear predictors. Model specification is via a list of gam like formulae - one for each dimension. See example.

Currently the family ignores any prior weights, and is implemented using first derivative information sufficient for BFGS estimation of smoothing parameters. "response" residuals give raw residuals, while "deviance" residuals are standardized to be approximately independent standard normal if all is well.

Value

An object of class general.family.

```

negbin

GAM negative binomial families

Description

The `gam` modelling function is designed to be able to use the `negbin` family (a modification of MASS library `negative.binomial` family by Venables and Ripley), or the `nb` function designed for integrated estimation of parameter theta. \( \theta \) is the parameter such that \( \text{var}(y) = \mu + \mu^2/\theta \), where \( \mu = E(y) \).

Two approaches to estimating theta are available (with `gam` only):

- With `negbin` then if ‘performance iteration’ is used for smoothing parameter estimation (see `gam`), then smoothing parameters are chosen by GCV and \( \theta \) is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection with the `nb` family then \( \theta \) is estimated alongside the smoothing parameters by ML or REML.

To use the first option, set the optimizer argument of `gam` to "perf" (it can sometimes fail to converge).

Usage

```r
negbin(theta = stop("'theta' must be specified"), link = "log")
```

```r
nb(theta = NULL, link = "log")
```
Arguments

theta Either i) a single value known value of theta or ii) two values of theta specifying
the endpoints of an interval over which to search for theta (this is an option only
for negbin, and is deprecated). For nb then a positive supplied theta is treated
as a fixed known parameter, otherwise it is estimated (the absolute value of a
negative theta is taken as a starting value).

link The link function: one of "log", "identity" or "sqrt"

Details

nb allows estimation of the theta parameter alongside the model smoothing parameters, but is only
usable with gam or bam (not gamm).

For negbin, if a single value of theta is supplied then it is always taken as the known fixed value
and this is useable with bam and gamm. If theta is two numbers (theta[2]>theta[1]) then they
are taken as specifying the range of values over which to search for the optimal theta. This option
is deprecated and should only be used with performance iteration estimation (see gam argument
optimizer), in which case the method of estimation is to choose $\hat{\theta}$ so that the GCV (Pearson)
estimate of the scale parameter is one (since the scale parameter is one for the negative binomial).
In this case $\theta$ estimation is nested within the IRLS loop used for GAM fitting. After each call
to fit an iteratively weighted additive model to the IRLS pseudodata, the $\theta$ estimate is updated.
This is done by conditioning on all components of the current GCV/Pearson estimator of the scale
parameter except $\theta$ and then searching for the $\hat{\theta}$ which equates this conditional estimator to one.
The search is a simple bisection search after an initial crude line search to bracket one. The search
will terminate at the upper boundary of the search region is a Poisson fit would have yielded an
estimated scale parameter <1.

Value

For negbin an object inheriting from class family, with additional elements

- dvar the function giving the first derivative of the variance function w.r.t. mu.
- d2var the function giving the second derivative of the variance function w.r.t. mu.
- getTheta A function for retrieving the value(s) of theta. This also useful for retriving the
estimate of theta after fitting (see example).

For nb an object inheriting from class extended.family.

WARNINGS

gamm does not support theta estimation

The negative binomial functions from the MASS library are no longer supported.

new.name(Obtain a name for a new variable that is not already in use)

Description

gamm works by transforming a GAMM into something that can be estimated by lme, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

Usage

new.name(proposed,old.names)

Arguments

  proposed a suggested name
  old.names An array of names that must not be duplicated

Value

A name that is not in old.names.
Description

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter \( a \) should be non-negative then we use \( a = \exp(b) \) and optimize with respect to the unconstrained parameter \( b \). This often works well, but it does imply a rather limited working range for \( b \): using 8 byte doubles, for example, if \( b \)'s magnitude gets much above 700 then \( a \) overflows or underflows. This can cause problems for numerical optimization methods.

\( \text{notExp} \) is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than \( \exp \). It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

\( \text{notLog} \) is the inverse function of \( \text{notExp} \).

The major use of these functions was originally to provide more robust \( \text{pdMat} \) classes for \( \text{lme} \) for use by \( \text{gamm} \). Currently the \( \text{notExp2} \) and \( \text{notLog2} \) functions are used in their place, as a result of changes to the \( \text{nlme} \) optimization routines.

Usage

\[
\text{notExp}(x) \\
\text{notLog}(x)
\]

Arguments

\( x \) Argument array of real numbers (\( \text{notExp} \)) or positive real numbers (\( \text{notLog} \)).

Value

An array of function values evaluated at the supplied argument values.

plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!

notExp2

Alternative to log parameterization for variance components

Description

notLog2 and notExp2 are alternatives to log and exp or notLog and notExp for re-parameterization
of variance parameters. They are used by the pdTens and pdIdnot classes which in turn implement
smooths for gamm.

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2
is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument
changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain posi-
tive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes
a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the
notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without
failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML
criterion are not invalidated by the trick, unless parameter estimates end up close to the effective
zero or effective infinity: but if this is the case then the asymptotics would also have been invalid
for a conventional monotonic parameterization.
This reparameterization was made necessary by some modifications to the underlying optimization method in lme introduced in nlme 3.1-62. It is possible that future releases will return to the notExp parameterization.

Note that you can reset 'effective zero' and 'effective infinity': see below.

Usage

\[
\text{notExp2}(x, d = \text{.Options$mgcv.vc.logrange}, b = 1/d) \\
\text{notLog2}(x, d = \text{.Options$mgcv.vc.logrange}, b = 1/d)
\]

Arguments

- \(x\): Argument array of real numbers (notExp) or positive real numbers (notLog).
- \(d\): the range of notExp2 runs from \(\exp(-d)\) to \(\exp(d)\). To change the range used by gamm reset mgcv.vc.logrange using options.
- \(b\): determines the period of the cycle of notExp2.

Value

An array of function values evaluated at the supplied argument values.

```
null.space.dimension  The basis of the space of un-penalized functions for a TPRS

Description

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. null.space.dimension finds the dimension of this space, \( M \), given the number of covariates that the smoother is a function of, \( d \), and the order of the smoothing penalty, \( m \). If \( m \) does not satisfy \( 2m > d + 1 \) then the smallest possible dimension for the null space is found given \( d \) and the requirement that the smooth should be visually smooth.

Usage

null.space.dimension(d,m)

Arguments

d 

is a positive integer - the number of variables of which the t.p.s. is a function.

m 

a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

Details

Thin plate splines are only visually smooth if the order of the wiggliness penalty, \( m \), satisfies \( 2m > d + 1 \). If \( 2m < d + 1 \) then this routine finds the smallest \( m \) giving visual smoothness for the given \( d \), otherwise the supplied \( m \) is used. The null space dimension is given by:

\[
M = \frac{(m + d - 1)!}{(d!)(m - 1)!}
\]

which is the value returned.

Value

An integer (array), the null space dimension \( M \).

tprs

Examples

require(mgcv)
null.space.dimension(2,0)
Description

Family for use with `gam` or `bam`, implementing regression for ordered categorical data. A linear predictor provides the expected value of a latent variable following a logistic distribution. The probability of this latent variable lying between certain cut-points provides the probability of the ordered categorical variable being of the corresponding category. The cut-points are estimated along side the model smoothing parameters (using the same criterion). The observed categories are coded 1, 2, 3, ... up to the number of categories.

Usage

```r
ocat(theta=NULL, link="identity", R=NULL)
```

Arguments

- `theta`: cut point parameter vector (dimension R-2). If supplied and all positive, then taken to be the cut point increments (first cut point is fixed at -1). If any are negative then absolute values are taken as starting values for cutpoint increments.
- `link`: The link function: only "identity" allowed at present (possibly for ever).
- `R`: the number of categories.

Details

Such cumulative threshold models are only identifiable up to an intercept, or one of the cut points. Rather than remove the intercept, `ocat` simply sets the first cut point to -1. Use `predict.gam` with type="response" to get the predicted probabilities in each category.

Value

An object of class `extended.family`.

**one.se.rule**

The one standard error rule for smoother models

**Description**

The ‘one standard error rule’ (see e.g. Hastie, Tibshirani and Friedman, 2009) is a way of producing smoother models than those directly estimated by automatic smoothing parameter selection methods. In the single smoothing parameter case, we select the largest smoothing parameter within one standard error of the optimum of the smoothing parameter selection criterion. This approach can be generalized to multiple smoothing parameters estimated by REML or ML.

**Details**

Under REML or ML smoothing parameter selection an asymptotic distributional approximation is available for the log smoothing parameters. Let \( \rho \) denote the log smoothing parameters that we want to increase to obtain a smoother model. The large sample distribution of the estimator of \( \rho \) is \( N(\rho, V) \) where \( V \) is the matrix returned by `sp.vcov`. Drop any elements of \( \rho \) that are already at ‘effective infinity’, along with the corresponding rows and columns of \( V \). The standard errors of the log smoothing parameters can be obtained from the leading diagonal of \( V \). Let the vector of these be \( d \). Now suppose that we want to increase the estimated log smoothing parameters by an amount \( \alpha d \). We choose \( \alpha \) so that \( \alpha d^T V^{-1} d = \sqrt{2p} \), where \( p \) is the dimension of \( d \) and \( 2p \) the variance of a chi-squared r.v. with \( p \) degrees of freedom.

The idea is that we increase the log smoothing parameters in proportion to their standard deviation, until the RE/ML is increased by 1 standard deviation according to its asymptotic distribution.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>
**pcls**

**Penalized Constrained Least Squares Fitting**

**Description**

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

**Usage**

```r
pcls(M)
```

**Arguments**

- `M` is the single list argument to pcls. It should have the following elements:
  - `y` The response data vector.
  - `w` A vector of weights for the data (often proportional to the reciprocal of the variance).
  - `X` The design matrix for the problem, note that `ncol(M$X)` must give the number of model parameters, while `nrow(M$X)` should give the number of data.
  - `C` Matrix containing any linear equality constraints on the problem (e.g. `Cp = c`). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector `c`, it is defined implicitly by the initial parameter estimates `p`.

**Examples**

```r
require(mgcv)
set.seed(2) ## simulate some data...
dat <- gamSim(1,n=400,dist="normal",scale=2)
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="REML")
b ## only the first 3 smoothing parameters are candidates for
## increasing here...
V <- sp.vcov(b)[1:3,1:3] ## the approx cov matrix of sps
d <- diag(V)^.5 ## sp se.
## compute the log smoothing parameter step...
d <- sqrt(2*length(d))/d
sp <- b$sp ## extract original sp estimates
sp[1:3] <- sp[1:3]*exp(d) ## apply the step
## refit with the increased smoothing parameters...
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="REML",sp=sp)
b;b1 ## compare fits
```
A list of penalty matrices. \( S[[i]] \) is the smallest contiguous matrix including all the non-zero elements of the \( i \)th penalty matrix. The first parameter it penalizes is given by \( \text{off}[i]+1 \) (starting counting at 1).

Offset values locating the elements of \( M S \) in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)

An array of smoothing parameter estimates.

An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.

Matrix for the inequality constraints \( A_{in}p > b_{in} \).

Vector in the inequality constraints.

This solves the problem:

\[
\text{minimise } \| W^{1/2}(Xp - y) \|^2 + \sum_{i=1}^{m} \lambda_i p'S_i p
\]

subject to constraints \( Cp = c \) and \( A_{in}p > b_{in} \), w.r.t. \( p \) given the smoothing parameters \( \lambda_i \). \( X \) is a design matrix, \( p \) a parameter vector, \( y \) a data vector, \( W \) a diagonal weight matrix, \( S_i \) a positive semi-definite matrix of coefficients defining the \( i \)th penalty and \( C \) a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the \( \lambda_i \). Note that \( X \) must be of full column rank, at least when projected into the null space of any equality constraints. \( A_{in} \) is a matrix of coefficients defining the inequality constraints, while \( b_{in} \) is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e. \( X'X \) is not formed explicitly. See Gill et al. 1981.

The function returns an array containing the estimated parameter vector.

Overflow proof pdMat class for multiples of the identity matrix

Description
This set of functions is a modification of the pdMat class pdIdent from library nlme. The modification is to replace the log parameterization used in pdMat with a notLog2 parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the pdTens class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the pdTens class it is easy to do so.

Usage

```
pdIdnot(value = numeric(0), form = NULL, nam = NULL, data = sys.frame(sys.parent()))
```

Arguments

- `value`: Initialization values for parameters. Not normally used.
- `form`: A one sided formula specifying the random effects structure.
- `nam`: a names argument, not normally used with this class.
- `data`: data frame in which to evaluate formula.

Details

The following functions are provided: Dim.pdIdnot, coef.pdIdnot, corMatrix.pdIdnot, logDet.pdIdnot, pdConstruct.pdIdnot, pdFactor.pdIdnot, pdMatrix.pdIdnot, solve.pdIdnot, summary.pdIdnot. (e.g. mgcv:::coef.pdIdnot to access.)

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is initialised with estimates of the scaled covariance matrix itself.

Value

A class pdIdnot object, or related quantities. See the nlme documentation for further details.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

The nlme source code.
https://www.maths.ed.ac.uk/~swood34/
This set of functions implements an \texttt{n1me} library \texttt{pdMat} class to allow tensor product smooths to be estimated by \texttt{lme} as called by \texttt{gamm}. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It’s not possible to transform the problem to make the required random effects covariance matrix look like one of the standard \texttt{pdMat} classes: hence the need for the \texttt{pdTens} class. A \texttt{notLog2} parameterization ensures that the parameters are positive.

These functions (\texttt{pdTens}, \texttt{pdConstruct.pdTens}, \texttt{pdFactor.pdTens}, \texttt{pdMatrix.pdTens}, \texttt{coef.pdTens} and \texttt{summary.pdTens}) would not normally be called directly.

**Usage**

\begin{verbatim}
pdTens(value = numeric(0), form = NULL, nam = NULL, data = sys.frame(sys.parent()))
\end{verbatim}

**Arguments**

- **value**: Initialization values for parameters. Not normally used.
- **form**: A one sided formula specifying the random effects structure. The formula should have an attribute \texttt{S} which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects.
- **nam**: A names argument, not normally used with this class.
- **data**: Data frame in which to evaluate formula.

**Details**

If using this class directly note that it is worthwhile scaling the \texttt{S} matrices to be of ‘moderate size’, for example by dividing each matrix by its largest singular value: this avoids problems with \texttt{lme} defaults (\texttt{smooth.construct.tensor.smooth.spec} does this automatically).

This appears to be the minimum set of functions required to implement a new \texttt{pdMat} class. Note that while the \texttt{pdFactor} and \texttt{pdMatrix} functions return the inverse of the scaled random effect covariance matrix or its factor, the \texttt{pdConstruct} function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes intialized with its inverse.
pen.edf

Value

A class pdTens object, or its coefficients or the matrix it represents or the factor of that matrix. pdFactor returns the factor as a vector (packed column-wise) (pdMatrix always returns a matrix).

t2 gamm

Examples

# see gamm

---

pen.edf Extract the effective degrees of freedom associated with each penalty in a gam fit

Description

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for t2 terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. te terms).

Usage

pen.edf(x)

Arguments

x an object inheriting from gam

Details

Useful for models containing t2 terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

Value

A vector of EDFs, named with labels identifying which penalty each EDF relates to.
Author(s)

Simon N. Wood <simon.wood@r-project.org>

t2

Examples

```r
require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400,scale=2) ## simulate data
## following `t2' smooth basically separates smooth
## of x0,x1 into main effects + interaction....

b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
data=dat,method="ML")
pen.edf(b)

## label "rr" indicates interaction edf (range space times range space)
## label "nr" (null space for x0 times range space for x1) is main
## effect for x1.
## label "rn" is main effect for x0
## clearly interaction is negligible

## second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)
+s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)

## In this case the EDF is negligible for all terms in the t2 smooth
## apart from the 'main effects' (r2 and 2r). To understand the labels
## consider the following 2 examples....
## "r1" relates to the interaction of the range space of the first
## marginal smooth and the first basis function of the null
## space of the second marginal smooth
## "2r" relates to the interaction of the second basis function of
## the null space of the first marginal smooth with the range
## space of the second marginal smooth.
```

place.knots

Automatically place a set of knots evenly through covariate values

Description

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

Usage

```r
place.knots(x,nk)
```
Arguments

- x: array of covariate values (need not be sorted).
- nk: integer indicating the required number of knots.

Details

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

Value

An array of knot locations.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

smooth.construct.cc.smooth.spec

Examples

```r
require(mgcv)
x<-runif(30)
place.knots(x,7)
rm(x)
```

Description

Takes a fitted `gam` object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

Usage

```r
## S3 method for class 'gam'
plot(x, residuals=FALSE, rug=NULL, se=TRUE, pages=0, select=NULL, scale=-1,
     n=100, n2=40, n3=3, pers=FALSE, theta=30, phi=30, jit=FALSE, xlab=NULL,
     ylab=NULL, main=NULL, ylim=NULL, xlim=NULL, too.far=0.1,
     all.terms=FALSE, shade=FALSE, shade.col="gray80", shift=0,
     trans=I, seWithMean=FALSE, unconditional=FALSE, by.resids=FALSE,
     scheme=0,...)
```
Arguments

x

a fitted gam object as produced by gam().

residuals

If TRUE then partial residuals are added to plots of 1-D smooths. If FALSE then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If TRUE then the residuals are the working residuals from the IRLS iteration weighted by the (square root) IRLS weights, in order that they have constant variance if the model is correct. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals).

rug

When TRUE the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth. The default of NULL sets rug to TRUE when the dataset size is <= 10000 and FALSE otherwise.

se

when TRUE (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlayed on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also shade, below.

pages

(default 0) the number of pages over which to spread the output. For example, if pages=1 then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.

select

Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set select=2.

scale

set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if ylim supplied.

n

number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.

n2

Square root of number of points used to grid estimates of 2-d functions for contouring.

n3

Square root of number of panels to use when displaying 3 or 4 dimensional functions.

pers

Set to TRUE if you want perspective plots for 2-d terms.

theta

One of the perspective plot angles.

phi

The other perspective plot angle.

jit

Set to TRUE if you want rug plots for 1-d terms to be jittered.

xlab

If supplied then this will be used as the x label for all plots.

ylab

If supplied then this will be used as the y label for all plots.

main

Used as title (or z axis label) for plots if supplied.

ylim

If supplied then this pair of numbers are used as the y limits for each plot.

xlim

If supplied then this pair of numbers are used as the x limits for each plot.

too.far

If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before
deciding what to exclude, and too.far is a distance within the unit square. Setting to zero can make plotting faster for large datasets, but care then needed with interpretation of plots.

**all.terms** if set to TRUE then the partial effects of parametric model components are also plotted, via a call to `termplot`. Only terms of order 1 can be plotted in this way. Also see warnings.

**shade** Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using `termplot`).

**shade.col** define the color used for shading confidence bands.

**shift** constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with `trans`.

**trans** monotonic function to apply to each smooth (after any shift), before plotting. Monotonicity is not checked, but default plot limits assume it. `shift` and `trans` are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.

**seWithMean** if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. If seWithMean=2 then the intervals include the uncertainty in the mean of the fixed effects (but not in the mean of any un-centred smooths or random effects). Marra and Wood (2012) suggests that TRUE results in better coverage performance, and this is also suggested by simulation.

**unconditional** if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used to compute uncertainty bands, if available. Otherwise the bands treat the smoothing parameters as fixed.

**by.resids** Should partial residuals be plotted for terms with by variables? Usually the answer is no, they would be meaningless.

**scheme** Integer or integer vector selecting a plotting scheme for each plot. See details.

*other graphics parameters to pass on to plotting commands. See details for smooth plot specific options.*

**Details**

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by `termplot`.

For smooth terms `plot.gam` actually calls plot method functions depending on the class of the smooth. Currently `random.effects`, Markov random fields (`mrf`), `Spherical.Spline` and `factor.smooth.interaction` terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled `s(cov, edf)` where cov is the covariate name, and edf the estimated (or user defined for regression splines) degrees of freedom of the smooth. `scheme == 0` produces a smooth curve with dashed curves indicating 2 standard error bounds. `scheme == 1` illustrates the error bounds using a shaded region.

For scheme==0, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like `s(var1, var2, edf)`, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When se=TRUE, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If se is a positive number then contour plots are at plus or minus se multiplied by the s.e. Contour levels are chosen to try and
ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths scheme==1 produces a perspective plot, while scheme==2 produces a heatmap, with overlaid contours and scheme==3 a greyscale heatmap (contour.col controls the contour colour).

Smooths of 3 and 4 variables are displayed as tiled heatmaps with overlaid contours. In the 3 variable case the third variable is discretized and a contour plot of the first 2 variables is produced for each discrete value. The panels in the lower and upper rows are labelled with the corresponding third variable value. The lowest value is bottom left, and highest at top right. For 4 variables, two of the variables are coarsely discretized and a square array of image plots is produced for each combination of the discrete values. The first two arguments of the smooth are the ones used for the image/contour plots, unless a tensor product term has 2D marginals, in which case the first 2D marginal is image/contour plotted. n3 controls the number of panels. See also vis.gam.

Fine control of plots for parametric terms can be obtained by calling termplot directly, taking care to use its terms argument.

Note that, if seWithMean=TRUE, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka’s (1988) results presented in Marra and Wood (2012). There are two possible variants of this approach. In the default variant the extra uncertainty is in the mean of all other terms in the model (fixed and random, including uncentred smooths). Alternatively, if seWithMean=2 then only the uncertainty in parametric fixed effects is included in the extra uncertainty (this latter option actually tends to lead to wider intervals when the model contains random effects).

Several smooth plots methods using image will accept an hcolors argument, which can be anything documented in heat.colors (in which case something like hcolors=rainbow(50) is appropriate), or the grey function (in which case something like hcolors=grey(0:50/50) is needed). Another option is contour.col which will set the contour colour for some plots. These options are useful for producing grey scale pictures instead of colour.

Sometimes you may want a small change to a default plot, and the arguments to plot.gam just won’t let you do it. In this case, the quickest option is sometimes to clone the smooth.construct and Predict.matrix methods for the smooth concerned, modifying only the returned smoother class (e.g. to foo.smooth). Then copy the plot method function for the original class (e.g. mgcv:::plot.mgcv.smooth), modify the source code to plot exactly as you want and rename the plot method function (e.g. plot.foo.smooth). You can then use the cloned smooth in models (e.g. s(x,bs="foo")), and it will automatically plot using the modified plotting function.

**Value**

The functions main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

**WARNING**

Note that the behaviour of this function is not identical to plot.gam() in S-PLUS.

Plotting can be slow for models fitted to large datasets. Set rug=FALSE to improve matters. If it’s still too slow set too.far=0, but then take care not to overinterpret smooths away from supporting data.
Plots of 2-D smooths with standard error contours shown can not easily be customized. `all.terms` uses `termplot` which looks for the original data in the environment of the fitted model object formula. Since `gam` resets this environment to avoid large saved model objects containing data in hidden environments, this can fail.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>
Henric Nilsson <henric.nilsson@statisticon.se> donated the code for the shade option.

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

**polys.plot**

_ Plot geographic regions defined as polygons_

### Description

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

### Usage

```r
polys.plot(pc,z=NULL,scheme="heat",lab="",...)
```

### Arguments

- **pc**
  - A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several
polygons, then each of these must be separated by an NA row in the matrix. See mrf for an example.

z

A vector of values associated with each area (item) of pc. If the vector elements have names then these are used to match elements of z to areas defined in pc. Otherwise pc and z are assumed to be in the same order. If z is NULL then polygons are not filled.

scheme

One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of z.

lab

label for plot.

... other arguments to pass to plot (currently only if z is NULL).

Details

Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing mrf smooths.

Value

Simply produces a plot.

Author(s)

Simon Wood <simon.wood@r-project.org>

See Also

mrf and columb.polys.

Examples

```r
## see also ?mrf for use of z
require(mgcv)
data(columb.polys)
polys.plot(columb.polys)
```

Description

In most cases essentially a wrapper for predict.gam for prediction from a model fitted by bam. Can compute on a parallel cluster. For models fitted using discrete methods with discrete=TRUE then discrete prediction methods are used instead.

Takes a fitted bam object produced by bam and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R.
Usage

```r
## S3 method for class 'bam'
predict(object, newdata, type = "link", se.fit = FALSE, terms = NULL,
exclude = NULL, block.size = 500000, newdata.guaranteed = FALSE,
na.action = na.pass, cluster = NULL, discrete = TRUE, n.threads = 1,
gc.level = 0, ...)
```

Arguments

- **object**: a fitted `bam` object as produced by `bam`.
- **newdata**: A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If `newdata` is provided then it should contain all the variables needed for prediction: a warning is generated if not.
- **type**: When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. type="iterms" is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).
- **se.fit**: when this is TRUE (not default) standard error estimates are returned for each prediction.
- **terms**: if type="terms" or type="iterms" then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any terms not named in this array will be set to zero. If NULL then all terms are included. "(Intercept)" is the intercept term.
- **exclude**: if type="terms" or type="iterms" then terms (smooth or parametric) named in this array will not be returned. Otherwise any terms named in this array will be set to zero. If NULL then no terms are excluded. To avoid supplying covariate values for excluded smooth terms, set `newdata.guaranteed=TRUE`, but note that this skips all checks of `newdata`.
- **block.size**: maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.
- **newdata.guaranteed**: Set to TRUE to turn off all checking of `newdata` except for sanity of factor levels: this can speed things up for large prediction tasks, but `newdata` must be complete, with no NA values for predictors required in the model.
- **na.action**: what to do about NA values in `newdata`. With the default `na.pass`, any row of `newdata` containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). `na.exclude` or `na.omit` result in the dropping of `newdata` rows, if they contain any NA values for required predictors. If `newdata` is missing then NA handling is determined from `object$na.action`. 

predict.bam can compute in parallel using `parLapply` from the `parallel` package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for `bam`.

if `TRUE` then discrete prediction methods used with model fitted by discrete methods. `FALSE` for regular prediction. See details.

if `se.fit=TRUE` and discrete prediction is used then parallel computation can be used to speed up se calculation. This specifies number of threads to use.

increase from 0 to up the level of garbage collection if default does not give enough.

other arguments.

Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters $V_p$ in the fitted `bam` object.

To facilitate plotting with `termplot`, if `object` possesses an attribute "para.only" and type="terms" then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to `bam` as an argument is always ignored when predicting, unlike offsets specified in the `bam` model formula.

See the examples in `predict.gam` for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

When `discrete=TRUE` the prediction data in `newdata` is discretized in the same way as is done when using discrete fitting methods with `bam`. However the discretization grids are not currently identical to those used during fitting. Instead, discretization is done afresh for the prediction data. This means that if you are predicting for a relatively small set of prediction data, or on a regular grid, then the results may in fact be identical to those obtained without discretization. The disadvantage to this approach is that if you make predictions with a large data frame, and then split it into smaller data frames to make the predictions again, the results may differ slightly, because of slightly different discretization errors.

Value

If `type="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is `TRUE` then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether type is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples in `predict.gam`. 
predict.gam

Prediction from fitted GAM model

Description

Takes a fitted gam object produced by gam() and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

Usage

## S3 method for class 'gam'
predict(object, newdata, type="link", se.fit=FALSE, terms=NULL,
   exclude=NULL, block.size=NULL, newdata.guaranteed=FALSE,
   na.action=na.pass, unconditional=FALSE, iterms.type= NULL,...)
**predict.gam**

**Arguments**

- **object**: A fitted `gam` object as produced by `gam()`.
- **newdata**: A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If `newdata` is provided then it should contain all the variables needed for prediction: a warning is generated if not. See details for use with `link(linear.functional.terms)`.
- **type**: When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When `type="terms"` each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. `type="iters"` is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When `type="response"` predictions on the scale of the response are returned (possibly with approximate standard errors). When `type="lmatrix"` then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case `se.fit` is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).
- **se.fit**: when this is TRUE (not default) standard error estimates are returned for each prediction.
- **terms**: if `type="terms"` or `type="iters"` then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any terms not named in this array will be set to zero. If NULL then all terms are included.
- **exclude**: if `type="terms"` or `type="iters"` then terms (smooth or parametric) named in this array will not be returned. Otherwise any terms named in this array will be set to zero. If NULL then no terms are excluded. Note that this is the term names as it appears in the model summary, see example. You can avoid providing the covariates for excluded smooth terms by setting `newdata.guaranteed=TRUE`, which will avoid all checks on `newdata` (covariates for parametric terms can not be skipped).
- **block.size**: maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this. If NULL then block size is 1000 if new data supplied, and the number of rows in the model frame otherwise.
- **newdata.guaranteed**: Set to TRUE to turn off all checking of `newdata` except for sanity of factor levels: this can speed things up for large prediction tasks, but `newdata` must be complete, with no NA values for predictors required in the model.
- **na.action**: what to do about NA values in `newdata`. With the default `na.pass`, any row of `newdata` containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). `na.exclude` or `na.omit` result in the dropping of `newdata` rows, if they contain any NA values for required predictors. If `newdata` is missing then NA handling is determined from `object$na.action`.
- **unconditional**: if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used, when available, otherwise the covariance matrix conditional on the estimated smoothing parameters is used.
if type="iterms" then standard errors can either include the uncertainty in the overall mean (default, with fixed and random effects included) or the uncertainty in the mean of the non-smooth fixed effects only (iterms.type=2).

... other arguments.

Details

The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters \( \Psi \) in the fitted gam object.

When predicting from models with linear.functional.terms then there are two possibilities. If the summation convention is to be used in prediction, as it was in fitting, then newdata should be a list, with named matrix arguments corresponding to any variables that were matrices in fitting. Alternatively one might choose to simply evaluate the constituent smooths at particular values in which case arguments that were matrices can be replaced by vectors (and newdata can be a dataframe). See linear.functional.terms for example code.

To facilitate plotting with termplot, if object possesses an attribute "para.only" and type="terms" then only parametric terms of order 1 are returned (i.e. those that termplot can handle).

Note that, in common with other prediction functions, any offset supplied to gam as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the lpmatrix for obtaining credible regions for quantities derived from the model.

Value

If type="lpmatrix" then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if se.fit is TRUE then a 2 item list is returned with items (both arrays) fit and se.fit containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether type is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

newdata can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples.

Note that the behaviour of this function is not identical to predict.gam() in Splus. type="terms" does not exactly match what predict.lm does for parametric model components.

  lines(x.mesh,df+2*df.sd,lty=2);lines(x.mesh,df-2*df.sd,lty=2)
}
In practice this method is often called via the wrapper function `PredictMat`.

Usage

```r
Predict.matrix(object, data)
Predict.matrix2(object, data)
```

Arguments

- **object**: is a smooth object produced by a `smooth.construct` method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate `Predict.matrix` function to produce a prediction matrix for new covariate values. Further details are given in `smooth.construct`.

- **data**: A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for `smooth.construct` and `smooth.construct2`.

Details

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for `smooth.construct` for details.

Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`. If the smooth class is one which generates offsets the corresponding offset is returned as attribute "offset" of the matrix.

Predict.matrix.cr.smooth

Predict matrix method functions

Description

The various built in smooth classes for use with gam have associate Predict.matrix method functions to enable prediction from the fitted model.

Usage

## S3 method for class 'cr.smooth'
Predict.matrix(object, data)
## S3 method for class 'cs.smooth'
Predict.matrix(object, data)
## S3 method for class 'cyclic.smooth'
Predict.matrix(object, data)
## S3 method for class 'pspline.smooth'
Predict.matrix(object, data)
## S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
## S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
## S3 method for class 'ts.smooth'
Predict.matrix(object, data)
## S3 method for class 't2.smooth'
Predict.matrix(object, data)

Arguments

object a smooth object, usually generated by a smooth.construct method having processed a smooth specification object generated by an s or te term in a gam formula.

data A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for smooth.construct and smooth.construct2.

Details

The Predict matrix function is not normally called directly, but is rather used internally by predict.gam etc. to predict from a fitted gam model. See Predict.matrix for more details, or the specific smooth.construct pages for details on a particular smooth class.

Value

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

Author(s)

Simon N. Wood <simon.wood@r-project.org>
Predict.matrix.soap.film

Prediction matrix for soap film smooth

Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the \texttt{Predict.matrix} method function required by \texttt{gam}.

Usage

\begin{verbatim}
## S3 method for class 'soap.film'
Predict.matrix(object, data)
## S3 method for class 'sw'
Predict.matrix(object, data)
## S3 method for class 'sf'
Predict.matrix(object, data)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{object} A class "soap.film", "sf" or "sw" object.
  \item \texttt{data} A list list or data frame containing the arguments of the smooth at which predictions are required.
\end{itemize}

Details

The smooth object will be largely what is returned from \texttt{smooth.construct.so.smooth.spec}, although elements \texttt{X} and \texttt{S} are not needed, and need not be present, of course.

Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

points(x, y, pch=".")
contour(xm, yn, matrix(fv.gam, m, n), levels=seq(-5, 5, by=.25), add=TRUE)

print.gam

---

### Description

The default print method for a gam object.

### Usage

```r
## S3 method for class 'gam'
print(x, ...)
```

### Arguments

- `x, ...`: fitted model objects of class gam as produced by `gam()`.

### Details

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See `gamObject` (or `names(x)`) for a listing of what the object contains. `summary.gam` provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBER(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REM). If rank deficiency of the model was detected then the apparent rank is reported, along with the length of the coefficient vector (rank in absense of rank deficiency). Rank deficiency occurs when not all coefficients are identifiable given the data. Although the fitting routines (except `gamm`) deal gracefully with rank deficiency, interpretation of rank deficient models may be difficult.
**psum.chisq**

_Evaluate the c.d.f. of a weighted sum of chi-squared deviates_

**Description**

Evaluates the c.d.f. of a weighted sum of chi-squared random variables by the method of Davies (1973, 1980). That is it computes

\[ P(q < \sum_{i=1}^{r} \lambda_i X_i + \sigma Z) \]

where \( X_j \) is a chi-squared random variable with \( \text{df}[j] \) (integer) degrees of freedom and non-centrality parameter \( \text{nc}[j] \), while \( Z \) is a standard normal deviate.

**Usage**

```r
psum.chisq(q, lb, df=rep(1, length(lb)), nc=rep(0, length(lb)), sigz=0,
lower.tail=FALSE, tol=2e-5, nlim=100000, trace=FALSE)
```

**Arguments**

- `q` is the vector of quantile values at which to evaluate.
- `lb` contains \( \lambda_i \), the weight for deviate i. Weights can be positive and/or negative.
- `df` is the integer vector of chi-squared degrees of freedom.
- `nc` is the vector of non-centrality parameters for the chi-squared deviates.
- `sigz` is the multiplier for the standard normal deviate. Non-positive to exclude this term.
- `lower.tail` indicates whether lower of upper tail probabilities are required.
- `tol` is the numerical tolerance to work to.
- `nlim` is the maximum number of integration steps to allow.
- `trace` can be set to TRUE to return some trace information and a fault code as attributes.

`gam`, `summary.gam`
Details

This calls a C translation of the original Algol60 code from Davies (1980), which numerically inverts the characteristic function of the distribution (see Davies, 1973). Some modifications have been made to remove goto statements and global variables, to use a slightly more efficient sorting of lb and to use R functions for log(1+x). In addition the integral and associated error are accumulated in single terms, rather than each being split into 2, since only their sums are ever used. If q is a vector then psum.chisq calls the algorithm separately for each q[i].

If the Davies algorithm returns an error then an attempt will be made to use the approximation of Liu et al (2009) and a warning will be issued. If that is not possible then an NA is returned. A warning will also be issued if the algorithm detects that round off errors may be significant.

If trace is set to TRUE then the result will have two attributes. "ifault" is 0 for no problem, 1 if the desired accuracy can not be obtained, 2 if round-off error may be significant, 3 if invalid parameters have been supplied or 4 if integration parameters can not be located. "trace" is a 7 element vector: 1. absolute value sum; 2. total number of integration terms; 3. number of integrations; 4. integration interval in main integration; 5. truncation point in initial integration; 6. sd of convergence factor term; 7. number of cycles to locate integration parameters. See Davies (1980) for more details.

Note that for vector q these attributes relate to the final element of q.

df <- c(2,1,1,1) ## degrees of freedom
nc <- c(1,1.5,4,1) ## non-centrality parameter
q <- c(1,6,20) ## quantiles to evaluate

psum.chisq(q,lb,df,nc)

## same by simulation...
psc.sim <- function(q,lb,df=lb*0+1,nc=df*0,ns=10000) {
  r <- length(lb); p <- q
  X <- rowSums(rep(lb,each=ns) *
    matrix(rchisq(r*ns,rep(df,each=ns),rep(nc,each=ns)),ns,r))
  apply(matrix(q,1,function(q) mean(X>q)),1)
}

psum.chisq(q,lb,df,nc)
psc.sim(q,lb,df,nc,100000)
```
Description

Takes a fitted gam object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

Usage

```
qq.gam(object, rep=0, level=.9, s.rep=10,
       type=c("deviance","pearson","response"),
       pch=".", rl.col=2, rep.col="gray80", ...)```

Arguments

- `object` a fitted `gam` object as produced by `gam()` (or a `glm` object).
- `rep` How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.
- `level` If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated.
- `s.rep` how many times to randomize uniform quantiles to data under direct computation.
- `type` what sort of residuals should be plotted? See `residuals.gam`.
- `pch` plot character to use. 19 is good.
- `rl.col` color for the reference line on the plot.
- `rep.col` color for reference bands or replicate reference plots.
- `...` extra graphics parameters to pass to plotting functions.

Details

QQ-plots of the the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the
quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficients and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended).

Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

### Random effects in GAMs

**Description**

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. `gamm` and `gamm4` from the `gamm4` package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with `gam` by making use of `s(..., bs="re")` terms in a model: see `smooth.construct.re.smooth.spec`, for full details. The basic idea is that, e.g., `s(x,z,g,bs="re")` generates an i.i.d. Gaussian random effect with model matrix given by `model.matrix(~x:z:g-1)` — in principle such terms can take any number of arguments. This simple approach is sufficient for implementing a wide range of commonly used random effect structures. For example if `g` is a factor then `s(g,bs="re")` produces a random coefficient for each level of `g`, with the random coefficients all modelled as i.i.d. normal. If `g` is a factor and `x` is numeric, then `s(x,g,bs="re")` produces an i.i.d. normal random slope relating the response to `x` for each level of `g`. If `h` is another factor then `s(h,g,bs="re")`
produces the usual i.i.d. normal g - h interaction. Note that a rather useful approximate test for zero random effect is also implemented for such terms based on Wood (2013). If the precision matrix is known to within a multiplicative constant, then this can be supplied via the xt argument of s. See smooth.construct.re.smooth.spec for details and example. Some models require differences between different levels of the same random effect: these can be implemented as described in linear.functional.terms.

Alternatively, but less straightforwardly, the paraPen argument to gam can be used: see gam.models. If smoothing parameter estimation is by ML or REML (e.g. gam(...,method="REML") then this approach is a completely conventional likelihood based treatment of random effects.

gam can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However gam is often faster and more reliable than gamm or gamm4, when the number of random effects is modest.

To facilitate the use of random effects with gam, gam.vcomp is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see summary.gam and anova.gam.

---

**residuals.gam**

**Generalized Additive Model residuals**

**Description**

Returns residuals for a fitted gam model object. Pearson, deviance, working and response residuals are available.

**Usage**

```r
## S3 method for class 'gam'
residuals(object, type = "deviance", ...)
```

**Arguments**

- **object**  
a gam fitted model object.
- **type**  
the type of residuals wanted. Usually one of "deviance", "pearson", "scaled.pearson", "working", or "response".
- **...**  
other arguments.
Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter); \( ((y - \mu) / \sqrt{V(\mu)}) \), where \( y \) is data \( \mu \) is model fitted value and \( V \) is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

Families can supply their own residual function, which is used in place of the standard function if present, (e.g. \texttt{cox.ph}).

Value

A vector of residuals.

\texttt{gam}

\begin{itemize}
  \item \texttt{rig(n,mean,scale)}
\end{itemize}

Description

Generates inverse Gaussian random deviates.

Usage

\begin{itemize}
  \item \texttt{rig(n,mean,scale)}
\end{itemize}

Arguments

\begin{itemize}
  \item \texttt{n} the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required.
  \item \texttt{mean} vector of mean values.
  \item \texttt{scale} vector of scale parameter values (lambda, see below)
\end{itemize}

Details

If \( x \) if the returned vector, then \( E(x) = \text{mean} \) while \( \text{var}(x) = \text{scale} \times \text{mean}^3 \). For density and distribution functions see the \texttt{statmod} package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that \texttt{scale} here is the scale parameter in the GLM sense, which is the reciprocal of the usual ‘lambda’ parameter.
Value
A vector of inverse Gaussian random deviates.

Author(s)
Simon N. Wood <simon.wood@r-project.org>

References
https://www.maths.ed.ac.uk/~swood34/

Examples
```
require(mgcv)
set.seed(7)
## An inverse.gaussian GAM example, by modify 'gamSim' output...
dat <- gamSim(1,n=400,dist="normal",scale=1)
dat$f <- dat$f/4  ## true linear predictor
ey <- exp(dat$f); scale <- .5  ## mean and GLM scale parameter
## simulate inverse Gaussian response...
dat$y <- rig(ey,mean=Ey, scale=.2)
big <- gam(y~ s(x0)+ s(x1)+s(x2)+s(x3),family=inverse.gaussian(link=log),
data=dat,method="REML")
plot(big,pages=1)
gam.check(big)
summary(big)
```

Description
Generate from or evaluate multivariate normal or t densities.

Usage
```
rmvn(n,mu,V)
r.mvt(n,mu,V,df)
dmvn(x,mu,V,R=NULL)
d.mvt(x,mu,V,df,R=NULL)
```

Arguments
```
n number of simulated vectors required.
mu the mean of the vectors: either a single vector of length p=ncol(V) or an n by p
matrix.
V A positive semi definite covariance matrix.
df The degrees of freedom for a t distribution.
x A vector or matrix to evaluate the log density of.
R An optional Cholesky factor of V (not pivoted).
```
Details

Uses a ‘square root’ of V to transform standard normal deviates to multivariate normal with the correct covariance matrix.

Value

An n row matrix, with each row being a draw from a multivariate normal or t density with covariance matrix V and mean vector mu. Alternatively each row may have a different mean vector if mu is a vector.

For density functions, a vector of log densities.

colMeans(z) ## observed mu
dmvn(z,mu,V)

Rrank

Find rank of upper triangular matrix

Description

Finds rank of upper triangular matrix R, by estimating condition number of upper rank by rank block, and reducing rank until this is acceptably low. Assumes R has been computed by a method that uses pivoting, usually pivoted QR or Choleski.

Usage

Rrank(R,tol=.Machine$double.eps^.9)

Arguments

R
An upper triangular matrix, obtained by pivoted QR or pivoted Choleski.

tol
the tolerance to use for judging rank.

Details

The method is based on Cline et al. (1979) as described in Golub and van Loan (1996).
**rTweedie**

**Generate Tweedie random deviates**

Description

Generates Tweedie random deviates, for powers between 1 and 2.

Usage

`rTweedie(mu, p=1.5, phi=1)`

Arguments

- `mu` vector of expected values for the deviates to be generated. One deviate generated for each element of `mu`.
- `p` the variance of a deviate is proportional to its mean, `mu` to the power `p`. `p` must be between 1 and 2. 1 is Poisson like (exactly Poisson if `phi=1`), 2 is gamma.
- `phi` The scale parameter. Variance of the deviates is given by `phi*mu^p`.

Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution, with mean `mu*(2-p)/(2-p)*phi`). The Gamma random variables that are summed have shape parameter `(2-p)/(p-1)` and scale parameter `phi*(p-1)*mu*(p-1)` (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of `rtweedie` from the `tweedie` package.

Value

A vector of random deviates from a Tweedie distribution, expected value vector `mu`, variance vector `phi*mu^p`.

s

Defining smooths in GAM formulae

Description
Function used in definition of smooth terms within gam model formulae. The function does not
evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

Usage
s(..., k=-1,fx=FALSE,bs="tp",m=NA,by=NA,xt=NULL,id=NULL,sp=NULL,pc=NULL)

Arguments
...
a list of variables that are the covariates that this smooth is a function of. Transformations whose form
depends on the values of the data are best avoided here: e.g. s(log(x)) is fine, but s(I(x/sd(x))) is not (see predict.gam).

k
the dimension of the basis used to represent the smooth term. The default depends on the number of
variables that the smooth is a function of. k should not be less than the dimension of the null space of the penalty
for the term (see null.space.dimension), but will be reset if it is. See choose.k for further
information.

fx
indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized
regression spline (FALSE).
bs

a two letter character string indicating the (penalized) smoothing basis to use.
(eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see
smooth.terms for an over view of what is available.

m

The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with
2nd derivatives when using default t.p.r.s basis). NA signals autoinitialization.
Only some smooth classes use this. The "ps" class can use a 2 item array giving
the basis and penalty order separately.

by

a numeric or factor variable of the same dimension as each covariate. In the
numeric vector case the elements multiply the smooth, evaluated at the corre-
sponding covariate values (a ‘varying coefficient model’ results). For the num-
meric by variable case the resulting smooth is not usually subject to a centering
constraint (so the by variable should not be added as an additional main ef-
fect). In the factor by variable case a replicate of the smooth is produced for
each factor level (these smooths will be centered, so the factor usually needs to
be added as a main effect as well). See gam.models for further details. A by
variable may also be a matrix if covariates are matrices: in this case implements
linear functional of a smooth (see gam.models and linear.functional.terms
for details).

xt

Any extra information required to set up a particular basis. Used e.g. to set large
data set handling behaviour for "tp" basis. If xt$sumConv exists and is FALSE
then the summation convention for matrix arguments is turned off.

id

A label or integer identifying this term in order to link its smoothing parameters
to others of the same type. If two or more terms have the same id then they
will have the same smoothing parameters, and, by default, the same bases (first
occurrence defines basis type, but data from all terms used in basis construction).
An id with a factor by variable causes the smooths at each factor level to have
the same smoothing parameter.

sp

any supplied smoothing parameters for this term. Must be an array of the
same length as the number of penalties for this smooth. Positive or zero ele-
ments are taken as fixed smoothing parameters. Negative elements signal auto-
initialization. Over-rides values supplied in sp argument to gam. Ignored by
gamm.

pc

If not NULL, signals a point constraint: the smooth should pass through zero at
the point given here (as a vector or list with names corresponding to the smooth
names). Never ignored if supplied. See identifiability.

Details

The function does not evaluate the variable arguments. To use this function to specify use of your
own smooths, note the relationships between the inputs and the output object and see the example
in smooth.construct.

Value

A class xx.smooth.spec object, where xx is a basis identifying code given by the bs argument
of s. These smooth.spec objects define smooths and are turned into bases and penalties by
smooth.construct method functions.

The returned object contains the following items:

term

An array of text strings giving the names of the covariates that the term is a function of.
bs.dim The dimension of the basis used to represent the smooth.
fixed TRUE if the term is to be treated as a pure regression spline (with fixed
degrees of freedom); FALSE if it is to be treated as a penalized regression spline
dim The dimension of the smoother - i.e. the number of covariates that it is a function
of.
p.order The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.
by is the name of any by variable as text ("NA" for none).
label A suitable text label for this smooth term.
xt The object passed in as argument xt.
id An identifying label or number for the smooth, linking it to other smooths. De-
defaults to NULL for no linkage.
sp array of smoothing parameters for the term (negative for auto-estimation). De-
defaults to NULL.

Examples
# example utilising `by` variables
library(mgcv)
set.seed(0)
n<-200;sig2<-4
x1 <- runif(n, 0, 1);x2 <- runif(n, 0, 1);x3 <- runif(n, 0, 1)
fac<-c(rep(1,n/2),rep(2,n/2)) # create factor
fac.1<-rep(0,n)+(fac==1);fac.2<-1-fac.1 # and dummy variables
fac<-as.factor(fac)
f1 <- exp(2 * x1) - 3.75887
f2 <- 0.2 * x1^11 * (10 * (1 - x1))^6 + 10 * (10 * x1)^3 * (1 - x1)^10
f<-f1*fac.1+f2*fac.2+x2
e <- rnorm(n, 0, sqrt(abs(sig2)))
y <- f + e
# NOTE: smooths will be centered, so need to include fac in model....
b<-gam(y~fac+s(x1,by=fac)+x2)
plot(b,pages=1)
Description

Family for use with glm or gam, implementing regression for the heavy tailed response variables, y, using a scaled t model. The idea is that \((y - \mu)/\sigma \sim t_\nu\) where \(\mu\) is determined by a linear predictor, while \(\sigma\) and \(\nu\) are parameters to be estimated alongside the smoothing parameters.

Usage

scat(theta = NULL, link = "identity", min.df = 3)

Arguments

theta the parameters to be estimated \(\nu = b + \exp(\theta_1)\) (where ‘b’ is min.df) and \(\sigma = \exp(\theta_2)\). If supplied and both positive, then taken to be fixed values of \(\nu\) and \(\sigma\). If any negative, then absolute values taken as starting values.

link The link function: one of "identity", "log" or "inverse".

min.df minimum degrees of freedom. Should not be set to 2 or less as this implies infinite response variance.

Details

Useful in place of Gaussian, when data are heavy tailed. min.df can be modified, but lower values can occasionally lead to convergence problems in smoothing parameter estimation. In any case min.df should be >2, since only then does a t random variable have finite variance.

Value

An object of class extended.family.

sdig

Extract or modify diagonals of a matrix

Description

Extracts or modifies sub- or super- diagonals of a matrix.

Usage

sdig(A,k=0)
sdig(A,k=0) <- value

Arguments

A  a matrix
k  sub- (negative) or super- (positive) diagonal of a matrix. 0 is the leading diagonal.
value single value, or vector of the same length as the diagonal.

Value

A vector containing the requested diagonal, or a matrix with the requested diagonal replaced by value.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

Examples

require(mgcv)
A <- matrix(1:35,7,5)
A
sdig(A,1) ## first super diagonal
sdig(A,-1) ## first sub diagonal

sdig(A) <- 1 ## leading diagonal set to 1
sdig(A,3) <- c(-1,-2) ## set 3rd super diagonal
The shash family implements the four-parameter sinh-arcsinh (shash) distribution of Jones and Pewsey (2009). The location, scale, skewness and kurtosis of the density can depend on additive smooth predictors. Useable only with gam, the linear predictors are specified via a list of formulae. It is worth carefully considering whether the data are sufficient to support estimation of such a flexible model before using it.

Usage

shash(link = list("identity", "logeb", "identity", "identity"),
      b = 1e-2, phiPen = 1e-3)

Arguments

link vector of four characters indicating the link function for location, scale, skewness and kurtosis parameters.

b positive parameter of the logeb link function, see Details.

phiPen positive multiplier of a ridge penalty on kurtosis parameter. Do not touch it unless you know what you are doing, see Details.

Details

The density function of the shash family is

\[ p(y|\mu, \sigma, \epsilon, \delta) = C(z) \exp\left\{-\frac{S(z)^2}{2}\right\}\left\{2\pi(1+z^2)^{1/2}\right\}^{-1/2}/\sigma, \]

where \( C(z) = \left\{1 + S(z)^2\right\}^{1/2}, S(z) = \sinh\{\delta \sinh^{-1}(z) - \epsilon\} \) and \( z = (y - \mu)/(\sigma\delta) \). Here \( \mu \) and \( \sigma > 0 \) control, respectively, location and scale, \( \epsilon \) determines skewness, while \( \delta > 0 \) controls tailweight. shash can model skewness to either side, depending on the sign of \( \epsilon \). Also, shash can have tails that are lighter (\( \delta > 1 \)) or heavier (\( 0 < \delta < 1 \)) than a normal. For fitting purposes, here we are using \( \tau = \log(\sigma) \) and \( \phi = \log(\delta) \).

The density is based on the expression given on the second line of section 4.1 and equation (2) of Jones and Pewsey (2009), and uses the simple reparameterization given in section 4.3.

The link function used for \( \tau \) is logeb with is \( \eta = \log\{\exp(\tau) - b\} \) so that the inverse link is \( \tau = \log(\sigma) = \log\{\exp(\eta) + b\} \). The point is that we are don’t allow \( \sigma \) to become smaller than a small constant \( b \). The likelihood includes a ridge penalty \( -\phi\text{Pen} \times \phi^2 \), which shrinks \( \phi \) toward zero. When sufficient data is available the ridge penalty does not change the fit much, but it is useful to include it when fitting the model to small data sets, to avoid \( \phi \) diverging to +infinity (a problem already identified by Jones and Pewsey (2009)).

Value

An object inheriting from class general.family.

Examples

```r
require(mgcv)

si <- function(theta,y,x,z,opt=TRUE,k=10,fx=FALSE) {
  ## Fit single index model using gam call, given theta (defines alpha).
  ## Return ML if opt==TRUE and fitted gam with theta added otherwise.
  ## Suitable for calling from 'optim' to find optimal theta/alpha.
  alpha <- c(1,theta)  ## constrained alpha defined using free theta
  kk <- sqrt(sum(alpha^2))
  alpha <- alpha/kk  ## so now ||alpha||=1
  a <- x%*%alpha  ## argument of smooth
  b <- gam(y~s(a,fx=fx,k=k)+s(z),family=poisson,method="ML")  ## fit model
  if (opt) return(b$gcv.ubre) else {
    b$alpha <- alpha  ## add alpha
    J <- outer(alpha,-theta/kk^2)  ## compute Jacobian
    for (j in 1:length(theta)) J[j+1,j] <- J[j+1,j] + 1/kk
    b$J <- J  ## dalpha_i/dtheta_j
    return(b)
  }
}
```

## simulate some data from a single index model...

```r
set.seed(1)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 * (10 * x)^3 * (1 - x)^10
n <- 200;m <- 3
x <- matrix(runif(n*m),n,m)  ## the covariates for the single index part
z <- runif(n)  ## another covariate
alpha <- c(1,-1,.5); alpha <- alpha/sqrt(sum(alpha^2))
eta <- as.numeric(f2((x%*%alpha+.41)/1.4)+1+z^2*2)/4
mu <- exp(eta)
y <- rpois(n,mu)  ## Poi response
```

## now fit to the simulated data...

```r
th0 <- c(-.8,.4)  ## close to truth for speed
## get initial theta, using no penalization...
f0 <- nlm(si,th0,y=y,x=x,z=z,fx=TRUE,k=5)
## now get theta/alpha with smoothing parameter selection...
f1 <- nlm(si,f0$estimate,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <- f1$estimate
```

## Alternative using 'optim'...

```r
th0 <- rep(0,m-1)
## get initial theta, using no penalization...
f0 <- optim(th0,si,y=y,x=x,z=z,fx=TRUE,k=5)
## now get theta/alpha with smoothing parameter selection...
f1 <- optim(f0$par,si,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <- f1$par
```
## extract and examine fitted model...

```r
b <- si(theta.est,y,x,z,opt=FALSE) ## extract best fit model
plot(b,pages=1)
b
b$alpha
```

## get sd for alpha...

```r
Vt <- b$J%*%solve(f1$hessian,t(b$J))
diag(Vt)^.5
```

### Sl.inirep

**Re-parametrizing model matrix X**

**Description**

INTERNAL routine to apply initial SI re-parameterization to model matrix X, or, if inverse==TRUE, to apply inverse re-parametrization to parameter vector or covariance matrix.

**Usage**

```r
Sl.inirep(Sl,X,l,r,nt=1)
Sl.initial.repara(Sl, X, inverse = FALSE, both.sides = TRUE, cov = TRUE, nt = 1)
```

**Arguments**

- **Sl**: the output of `Sl.setup`.
- **X**: the model matrix.
- **l**: if non-zero apply transform (positive) or inverse transform from left. 1 or -1 of transform, 2 or -2 for transpose.
- **r**: if non-zero apply transform (positive) or inverse transform from right. 1 or -1 of transform, 2 or -2 for transpose.
- **inverse**: if TRUE an inverse re-parametrization is performed.
- **both.sides**: if `inverse==TRUE` and `both.sides==FALSE` then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If `both.sides==FALSE`, X is a vector and `inverse==FALSE` then X is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix).
- **cov**: boolean indicating whether X is a covariance matrix.
- **nt**: number of parallel threads to be used.

**Value**

A re-parametrized version of X.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.
**Sl.repara**

Applying re-parameterization from log-determinant of penalty matrix to model matrix.

**Description**

INTERNAL routine to apply re-parameterization from log-determinant of penalty matrix, \( \det S \) to model matrix, \( X \), blockwise.

**Usage**

```r
Sl.repara(rp, X, inverse = FALSE, both.sides = TRUE)
```

**Arguments**

- **rp**: reparametrization.
- **X**: if \( X \) is a matrix it is assumed to be a model matrix whereas if \( X \) is a vector it is assumed to be a parameter vector.
- **inverse**: if TRUE an inverse re-parametrization is performed.
- **both.sides**: if inverse==TRUE and both.sides==FALSE then the re-parametrization only applied to rhs, as appropriate for a choleski factor. If both.sides==FALSE, \( X \) is a vector and inverse==FALSE then \( X \) is taken as a coefficient vector (so re-parametrization is inverse of that for the model matrix).

**Value**

A re-parametrized version of \( X \).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

**Sl.setup**

Setting up a list representing a block diagonal penalty matrix

**Description**

INTERNAL function for setting up a list representing a block diagonal penalty matrix from the object produced by \( \text{gam.setup} \).

**Usage**

```r
Sl.setup(G, cholesky=FALSE, no.repara=FALSE, sparse=FALSE)
```

**Arguments**

- **G**: the output of \( \text{gam.setup} \).
- **cholesky**: re-parameterize using Cholesky only.
- **no.repara**: set to TRUE to turn off all initial reparameterization.
- **sparse**: sparse setup?
Value

A list with an element for each block. For block, b, $S[[b]]$ is a list with the following elements

- `repara`: should re-parameterization be applied to model matrix, etc? Usually `FALSE` if non-linear in coefficients.
- `start, stop`: such that `start:stop` are the indexes of the parameters of this block.
- `S`: a list of penalty matrices for the block ($\text{dim} = \text{stop}-\text{start}+1$) If `length(S)==1` then this will be an identity penalty. Otherwise it is a multiple penalty, and an rS list of square root penalty matrices will be added. S (if `repara==\text{TRUE}`) and rS (always) will be projected into range space of total penalty matrix.
- `rS`: square root of penalty matrices if multiple penalties are used.
- `D`: a reparameterization matrix for the block. Applies to cols/params in `start:stop`. If numeric then $X[,start:stop] %*% \text{diag}(D)$ is re-parametrization of $X[,start:stop]$, and $b.\text{orig} = D %*% b.\text{repara}$ (where $b.\text{orig}$ is the original parameter vector). If matrix then $X[,start:stop] %*% D$ is re-parametrization of $X[,start:stop]$ and $b.\text{orig} = D %*% b.\text{repara}$ (where $b.\text{orig}$ is the original parameter vector).

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

---

**slanczos**

*Compute truncated eigen decomposition of a symmetric matrix*

Description

Uses Lanczos iteration to find the truncated eigen-decomposition of a symmetric matrix.

Usage

```r
slanczos(A, k=10, kl=-1, tol=.Machine$double.eps^.5, nt=1)
```

Arguments

- `A`: A symmetric matrix.
- `k`: Must be non-negative. If `k1` is negative, then the `k` largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If `k` is non-negative then the `k` highest eigenvalues are found together with their eigenvectors and the `k` lowest eigenvalues with eigenvectors are also returned.
- `kl`: If `k1` is non-negative then the `k1` lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the `k` highest eigenvalues + vectors). negative `k1` signals that the `k` largest magnitude eigenvalues should be returned, with eigenvectors.
- `tol`: tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by `tol` (or the machine precision!).
- `nt`: number of threads to use for leading order iterative multiplication of `A` by vector. May show no speed improvement on two processor machine.
Details

If $k_1$ is non-negative, returns the highest $k$ and lowest $k_1$ eigenvalues, with their corresponding eigenvectors. If $k_1$ is negative, returns the largest magnitude $k$ eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of $A$, as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small $k$ and $k_1$ the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner triadiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

Value

A list with elements values (array of eigenvalues); vectors (matrix with eigenvectors in its columns); iter (number of iterations required).

range(er$values-um$values[ind]); range(abs(er$vectors)-abs(um$vectors[,ind]))
```
smooth.construct

Description

Smooth terms in a GAM formula are turned into smooth specification objects of class \texttt{xx.smooth.spec} during processing of the formula. Each of these objects is converted to a smooth object using an appropriate \texttt{smooth.construct} function. New smooth classes can be added by writing a new \texttt{smooth.construct} method function and a corresponding \texttt{Predict.matrix} method function (see example code below).

In practice, \texttt{smooth.construct} is usually called via \texttt{smooth.construct2} and the wrapper function \texttt{smoothCon}, in order to handle by variables and centering constraints (see the \texttt{smoothCon} documentation if you need to handle these things directly, for a user defined smooth class).

Usage

\begin{verbatim}
smooth.construct(object, data, knots)
smooth.construct2(object, data, knots)
\end{verbatim}

Arguments

\begin{description}
\item[object] is a smooth specification object, generated by an \texttt{s} or \texttt{te} term in a GAM formula. Objects generated by \texttt{s} terms have class \texttt{xx.smooth.spec} where \texttt{xx} is given by the \texttt{bs} argument of \texttt{s} (this convention allows the user to add their own smoothers). If \texttt{object} is not class \texttt{tensor.smooth.spec} it will have the following elements:
\item[term] The names of the covariates for this smooth, in an array.
\item[bs.dim] Argument \texttt{k} of the \texttt{s} term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for \texttt{cc} terms). \texttt{bs.dim<0} indicates that the constructor should set this to the default value.
\item[fixed] TRUE if the term is to be unpenalized, otherwise FALSE.
\item[dim] the number covariates of which this smooth is a function.
\item[p.order] the order of the smoothness penalty or \texttt{NA} for autoselection of this. This is argument \texttt{m} of the \texttt{s} term that generated \texttt{object}.
\item[by] the name of any by variable to multiply this term as supplied as an argument to \texttt{s}. "\texttt{NA}" if there is no such term.
\item[label] A suitable label for use with this term.
\item[xt] An object containing information that may be needed for basis setup (used, e.g. by \texttt{"tp"} smooths to pass optional information on big dataset handling).
\item[id] Any identity associated with this term — used for linking bases and smoothing parameters. \texttt{NULL} by default, indicating no linkage.
\item[sp] Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless \texttt{NULL} (default), over-rides \texttt{sp} argument to \texttt{gam}.
\end{description}

If \texttt{object} is of class \texttt{tensor.smooth.spec} then it was generated by a \texttt{te} term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

\begin{description}
\item[margin] is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.
\item[term] is the array of names of the covariates that are arguments of the smooth.
by is the name of any by variable, or "NA".

fx is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

label A suitable label for use with this term.

dim is the number of covariates of which this smooth is a function.

mp TRUE if multiple penalties are to be used.

np TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

id Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

sp Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides sp argument to gam.

data For smooth.construct a data frame or list containing the evaluation of the elements of object$log$term, with names given by object$log$term. The last entry will be the by variable, if object$log$by is not "NA". For smooth.construct2 data need only be an object within which object$log$term can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

knots an optional data frame or list containing the knots relating to object$log$term. If it is NULL then the knot locations are generated automatically. The structure of knots should be as for data, depending on whether smooth.construct or smooth.construct2 is used.

Details

There are built in methods for objects with the following classes: tp.smooth.spec (thin plate regression splines; see tprs); ts.smooth.spec (thin plate regression splines with shrinkage-to-zero); cr.smooth.spec (cubic regression splines: see cubic.regression.spline; cs.smooth.spec (cubic regression splines with shrinkage-to-zero); cc.smooth.spec (cyclic cubic regression splines); ps.smooth.spec (Eilers and Marx (1986) style P-splines: see p.spline); cp.smooth.spec (cyclic P-splines); ad.smooth.spec (adaptive smooths of 1 or 2 variables: see adaptive.smooth); re.smooth.spec (simple random effect terms); mrf.smooth.spec (Markov random field smoothers for smoothing over discrete districts); tensor.smooth.spec (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default mgcv.smooth method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for mgcv:::plot.sos.smooth, mgcv:::plot.random.effect, mgcv:::plot.mgcv.smooth for example code.

Value

The input argument object, assigned a new class to indicate what type of smooth it is and with at least the following items added:

X The model matrix from this term. This may have an "offset" attribute: a vector of length nrow(X) containing any contribution of the smooth to the model offset term. by variables do not need to be dealt with here, but if they are then an item by.done must be added to the object.
A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.

An array giving the ranks of the penalties.

The dimension of the penalty null space (before centering).

The following items may be added:

The matrix defining any identifiability constraints on the term, for use when fitting. If this is NULL then smoothCon will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied C has an attribute "always.apply" then it is never ignored, even if any by variables of a smooth imply that no constraint is actually needed. Code for creating C should check whether the specification object already contains a zero row matrix, and leave this unchanged if it is (since this signifies no constraint should be produced).

An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.

if this is non-NULL then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because gamm requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.

the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is null then smoothCon will set it to the basis dimension. smoothCon will reduce this by the number of constraints.

0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 is it can be used but not plotted. Set to 1 if NULL.

Set to FALSE if this smooth should not be plotted by plot.gam. Set to TRUE if NULL.

Set to FALSE to ensure that the smooth is never subject to side constraints as a result of nesting.

smooths may depend on fewer ‘underlying’ smoothing parameters than there are elements of S. In this case L is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the S[[i]]. L=NULL signifies that there is one smoothing parameter per S[[i]].

Usually the returned object will also include extra information required to define the basis, and used by Predict.matrix methods to make predictions using the basis. See the Details section for links to the information included for the built in smooth classes.

tensor.smooth returned objects will additionally have each element of the margin list updated in the same way. tensor.smooths also have a list, XP, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.
**WARNING**

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

smooth.construct.ad.smooth.spec

Adaptive smooths in GAMs

Description

`gam` can use adaptive smooths of one or two variables, specified via terms like `s(...,bs="ad",...)`. (`gamm` can not use such terms — check out package `AdaptFit` if this is a
The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the \( k \) argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the \( m \) argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables \( k \) is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making \( k \) a two element vector. Similarly, in the two dimensional case \( m \) is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then \( m \) specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument \( xt \) with a character vector \( xt.bs \) specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting \( m=10 \) for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

Usage

```r
## S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- `object` a smooth specification object, usually generated by a term `s(...,bs="ad",...)`
- `data` a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots` a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`

Details

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

Value

An object of class "pspline.smooth" in the 1D case or "tensor.smooth" in the 2D case.

smooth.construct.bs.smooth.spec

Penalized B-splines in GAMs

Description

gam can use smoothing splines based on univariate B-spline bases with derivative based penalties, specified via terms like s(x,bs="bs",m=c(3,2)). m[1] controls the spline order, with m[1]=3 being a cubic spline, m[1]=2 being quadratic, and so on. The integrated square of the m[2]th derivative is used as the penalty. So m=c(3,2) is a conventional cubic spline. Any further elements of m, after the first 2, define the order of derivative in further penalties. If m is supplied as a single number, then it is taken to be m[1] and m[2]=m[1]-1, which is only a conventional smoothing spline in the m=3, cubic spline case. Notice that the definition of the spline order in terms of m[1] is intuitive, but differs to that used with the tprs and p.spline bases. See details for options for controlling the interval over which the penalty is evaluated (which can matter if it is necessary to extrapolate).

Usage

## S3 method for class 'bs.smooth.spec'
smooth.construct(object, data, knots)

## S3 method for class 'Bspline.smooth'
Predict.matrix(object, data)

Arguments

object       a smooth specification object, usually generated by a term s(x,bs="bs",...)
data         a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots        a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.

Details

The basis and penalty are sparse (although sparse matrices are not used to represent them). m[2]>m[1] will generate an error, since in that case the penalty would be based on an undefined derivative of the basis, which makes no sense. The terms can have multiple penalties of different orders, for example s(x,bs="bs",m=c(3,2,1,0)) specifies a cubic basis with 3 penalties: a conventional cubic spline penalty, an integrated square of first derivative penalty, and an integrated square of function value penalty.
The default basis dimension, $k$, is the larger of 10 and $m[1]$. $m[1]$ is the lower limit on basis dimension. If knots are supplied, then the number of supplied knots should be $k + m[1] + 1$, and the range of the middle $k-m[1]+1$ knots should include all the covariate values. Alternatively, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (making this range too wide mean that there is no information about some basis coefficients, because the corresponding basis functions have a span that includes no data). Unlike P-splines, splines with derivative based penalties can have uneven knot spacing, without a problem.

Another option is to supply 4 knots. Then the outer 2 define the interval over which the penalty is to be evaluated, while the inner 2 define an interval within which all but the outermost 2 knots should lie. Normally the outer 2 knots would be the interval over which predictions might be required, while the inner 2 knots define the interval within which the data lie. This option allows the penalty to apply over a wider interval than the data, while still placing most of the basis functions where the data are. This is useful in situations in which it is necessary to extrapolate slightly with a smooth. Only applying the penalty over the interval containing the data amounts to a model in which the function could be less smooth outside the interval than within it, and leads to very wide extrapolation confidence intervals. However the alternative of evaluating the penalty over the whole real line amounts to asserting certainty that the function has some derivative zeroed away from the data, which is equally unreasonable. It is preferable to build a model in which the same smoothness assumptions apply over both data and extrapolation intervals, but not over the whole real line. See example code for practical illustration.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior $k-m[1]+1$ knots — the interval over which the penalty is evaluated). Such extrapolation is not allowed in basis construction, but is when predicting.

It is possible to set a deriv flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it.

Value

An object of class "Bspline.smooth". See smooth.construct, for the elements that this object will contain.

WARNING

$m[1]$ directly controls the spline order here, which is intuitively sensible, but different to other bases.

smooth.construct.cr.smooth.spec

Penalized Cubic regression splines in GAMs

Description

gam can use univariate penalized cubic regression spline smooths, specified via terms like
s(x,bs="cr"). s(x,bs="cs") specifies a penalized cubic regression spline which has had its
penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing
parameter goes to infinity a normal cubic spline tends to a straight line.) s(x,bs="cc") specifies a
cyclic penalized cubic regression spline smooth.

'Cardinal' spline bases are used: Wood (2017) sections 5.3.1 and 5.3.2 gives full details. These
bases have very low setup costs. For a given basis dimension, k, they typically perform a little less
well then thin plate regression splines, but a little better than p-splines. See te to use these bases in
tensor product smooths of several variables.

Default k is 10.

Usage

## S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)

## S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)

## S3 method for class 'cc.smooth.spec'
smooth.construct(object, data, knots)

Arguments

object a smooth specification object, usually generated by a term
s(...,bs="cr"),...,s(...,bs="cs"),... or s(...,bs="cc"),...

data a list containing just the data (including any by variable) required by this term,
with names corresponding to object$term (and object$by). The by variable
is the last element.
knots a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details.

Details

The constructor is not normally called directly, but is rather used internally by gam. To use for basis setup it is recommended to use smooth.construct2.

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of \( x \) then there would be a knot at every 10th (ordered) \( x \) value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

Value

An object of class "cr.smooth" "cs.smooth" or "cyclic.smooth". In addition to the usual elements of a smooth class documented under smooth.construct, this object will contain:

- \( \text{xp} \) giving the knot locations used to generate the basis.
- \( \text{F} \) For class "cr.smooth" and "cs.smooth" objects \( t(F) \) transforms function values at the knots to second derivatives at the knots.
- \( \text{BD} \) class "cyclic.smooth" objects include matrix \( BD \) which transforms function values at the knots to second derivatives at the knots.

### smooth.construct.ds.smooth.spec

**Low rank Duchon 1977 splines**

**Description**

Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like `s(x,z,bs="ds",m=c(1,.5)` in a `gam` model formula. In the notation of Duchon (1977) `m` is given by `m[1]` (default value 2), while `s` is given by `m[2]` (default value 0).

Duchon’s (1977) construction generalizes the usual thin plate spline penalty as follows. The usual TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial mth order derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the fourier frequencies, raised to the power 2s. s is a user selected constant taking integer values divided by 2. If d is the number of arguments of the smooth, then it is required that `-d/2 < s < d/2`. To obtain continuous functions we further require that `m + s > d/2`. If `s=0` then the usual thin plate spline is recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003) to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is used here. For large datasets the same subsampling approach as is used in the `tprs` case is employed here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin plate splines, while still yielding continuous functions. For example, we can set `m = 1` and `s = d/2 - .5` in order to use first derivative penalization for any `d` (which has the advantage that the dimension of the null space of unpenalized functions is only `d+1`).

**Usage**

```r
## S3 method for class 'ds.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'duchon.spline'
Predict.matrix(object, data)
```
Arguments

object  a smooth specification object, usually generated by a term 
$s(...,bs="ds",...)$.

data  a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.

knots  a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL

Details

The default basis dimension for this class is $k=M+k.def$ where $M$ is the null space dimension (dimension of unpenalized function space) and $k.def$ is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choose, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by gam. To use for basis setup it is recommended to use smooth.construct2.

For these classes the specification object will contain information on how to handle large datasets in their xt field. The default is to randomly subsample 2000 ‘knots’ from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the xt argument to s. This is supplied as a list with elements max.knots and seed containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R’s RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, $k$. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds max.knots. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, $k$. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

Value

An object of class "duchon.spline". In addition to the usual elements of a smooth class documented under smooth.construct, this object will contain:

shift  A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.

Xu  A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

UZ  The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.
null.space.dimension
The dimension of the space of functions that have zero wiggliness according to
the wiggliness penalty for this term.

Usage

## S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'fs.interaction'
Predict.matrix(object, data)

Arguments

object
For the smooth.construct method a smooth specification object, usually generated by a term \( s(x,...,bs="fs",:) \). May have a gamm attribute: see details. For the predict.Matrix method an object of class "fs.interaction" produced by the smooth.construct method.

data
a list containing just the data (including any by variable) required by this term, with names corresponding to object$term.

knots
a list containing any knots supplied for smooth basis setup.

Details

This class produces a smooth for each level of a single factor variable. Within a \texttt{gam} formula this is done with something like \( s(x,\text{fac},bs="fs") \), which is almost equivalent to \( s(x,by=\text{fac},id=1) \) (with the \texttt{gam} argument select=TRUE). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with \texttt{gam}, where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) \texttt{gam} only allows one conditioning factor for smooths, so \( s(x)+s(z,\text{fac},bs="fs")+s(v,\text{fac},bs="fs") \) is OK, but \( s(x)+s(z,\text{fac1},bs="fs")+s(v,\text{fac2},bs="fs") \) is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction. To facilitate this the constructor is called from \texttt{gam} with an attribute "gamm" attached to the smooth specification object. The result differs from that resulting from the case where this is not done.

Note that \texttt{gamm4} from the \texttt{gamm4} package suffers from none of the restrictions that apply to \texttt{gam}, and "fs" terms can be used without side-effects. Constructor is still called with a smooth specification object having a "gamm" attribute.

Any singly penalized basis can be used to smooth at each factor level. The default is "tp", but alternatives can be supplied in the \texttt{xt} argument of \texttt{s} (e.g. \( s(x,\text{fac},bs="fs",xt="cr") \) or \( s(x,\text{fac},bs="fs",xt=\text{list(bs="cr")}) \)). The \texttt{k} argument to \( s(\ldots,bs="fs") \) refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently \texttt{gamm} (or \texttt{gamm4}) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down \texttt{k}.

The plot method for this class has two schemes. \texttt{scheme==0} is in colour, while \texttt{scheme==1} is black and white.

Value

An object of class "fs.interaction" or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves. The contents of an "fs.interaction" object will depend on whether or not \texttt{smooth.construct} was called with an object with attribute \texttt{gamm}: see below.

smooth.construct.gp.smooth.spec

Low rank Gaussian process smooths

Description
Gaussian process/kriging models based on simple covariance functions can be written in a very
similar form to thin plate and Duchon spline models (e.g. Handcock, Meier, Nychka, 1994), and
low rank versions produced by the eigen approximation method of Wood (2003). Kammann and
Wand (2003) suggest a particularly simple form of the Matern covariance function with only a
single smoothing parameter to estimate, and this class implements this and other similar models.
Usually invoked by an \texttt{s(...,bs="gp")} term in a \texttt{gam} formula. Argument \texttt{m} selects the covariance function, sets the range parameter and any power parameter. If \texttt{m} is not supplied then it defaults to \texttt{NA} and the covariance function suggested by Kammann and Wand (2003) along with their suggested range parameter is used. Otherwise \texttt{abs(m[1])} between 1 and 5 selects the correlation function from respectively, spherical, power exponential, and Matern with kappa = 1.5, 2.5 or 3.5. The sign of \texttt{m[1]} determines whether a linear trend in the covariates is added to the Gaussian process (positive), or not (negative). The latter ensures stationarity. \texttt{m[2]}, if present, specifies the range parameter, with non-positive or absent indicating that the Kammann and Wand estimate should be used. \texttt{m[3]} can be used to specify the power for the power exponential which otherwise defaults to 1.

**Usage**

```r
## S3 method for class 'gp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'gp.smooth'
Predict.matrix(object, data)
```

**Arguments**

- **object**: a smooth specification object, usually generated by a term \texttt{s(...,bs="ms",...)}.
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to \texttt{object$term} and \texttt{object$by}. The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be \texttt{NULL}

**Details**

Let $\rho > 0$ be the range parameter, $0 < \kappa \leq 2$ and $d$ denote the distance between two points. Then the correlation functions indexed by \texttt{m[1]} are:

1. $1 - 1.5d/\rho + 0.5(d/\rho)^3$ if $d \leq \rho$ and 0 otherwise.
2. $\exp(-(d/\rho)^\kappa)$.
3. $\exp(-(d/\rho)(1 + d/\rho))$.
4. $\exp(-(d/\rho)(1 + d/\rho + (d/\rho)^2/3))$.
5. $\exp(-(d/\rho)(1 + d/\rho + 2(d/\rho)^2/5 + (d/\rho)^3/15))$.

See Fahrmeir et al. (2013) section 8.1.6, for example. Note that setting $r$ to too small a value will lead to unpleasant results, as most points become all but independent (especially for the spherical model. Note: Wood 2017, Figure 5.20 right is based on a buggy implementation).

The default basis dimension for this class is $k = M \times k.\text{def}$ where $M$ is the null space dimension (dimension of unpenalized function space) and $k.\text{def}$ is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by \texttt{gam}. To use for basis setup it is recommended to use \texttt{smooth.construct2}.
For these classes the specification object will contain information on how to handle large datasets in their xt field. The default is to randomly subsample 2000 ‘knots’ from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the xt argument to s. This is supplied as a list with elements max.knots and seed containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R’s RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, k. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds max.knots. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, k. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

Value

An object of class “gp.smooth”. In addition to the usual elements of a smooth class documented under smooth.construct, this object will contain:

shift A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.

Xu A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

UZ The matrix mapping the smoother parameters back to the parameters of a full GP smooth.

null.space.dimension The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

gp.defn the type, range parameter and power parameter defining the correlation function.

smooth.construct.mrf.smooth.spec

Markov Random Field Smooths

Description

For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for mgcv. See details for how to deal with regions with missing data.

Usage

```r
## S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'mrf.smooth'
Predict.matrix(object, data)
```

Arguments

- **object**
  - For the smooth.construct method a smooth specification object, usually generated by a term `s(x,...,bs="mrf",xt=list(polys=foo))`. `x` is a factor variable giving labels for geographic districts, and the `xt` argument is obligatory: see details. For the Predict.Matrix method an object of class "mrf.smooth" produced by the smooth.construct method.

- **data**
  - a list containing just the data (including any by variable) required by this term, with names corresponding to object$term (and object$by). The by variable is the last element.
knots

If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).

Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the xt argument to s. This must contain at least one of the elements polys, nb or penalty.

polys contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. names(polys) must correspond to the levels of the argument of the smooth, in any order (i.e. it gives the area labels). polys[[i]] is a 2 column matrix the rows of which specify the vertices of the polygon(s) defining the boundary of the ith area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any polys[[i]] should not be a hole. An example of the structure is provided by columb.polys (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix. Plotting of the smooth is not possible without a polys object. If polys is the only element of xt provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one or more vertices.

nb is a named list defining the neighbourhood structure. names(nb) must correspond to the levels of the covariate of the smooth (i.e. the area labels), but can be in any order. nb[[i]] is a numeric vector indexing the neighbours of the ith area (and should not include i). All indices are relative to nb itself, but can be translated using names(nb). See example code. As an alternative each nb[[i]] can be an array of the names of the neighbours, but these will be converted to the arrays of numeric indices internally. If no penalty is provided then it is computed automatically from this list. The ith row of the penalty matrix will be zero everywhere, except in the ith column, which will contain the number of neighbours of the ith geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

penalty if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite. Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2017) Section 5.4.2. See Wood (2017, section 5.8.1).

Note that smooths of this class have a built in plot method, and that the utility function in.out can be useful for working with discrete area data. The plot method has two schemes, scheme==0 is colour, scheme==1 is grey scale.

The situation in which there are areas with no data requires special handling. You should set drop.unused.levels=FALSE in the model fitting function, gam, bam or gamm, having first ensured that any fixed effect factors do not contain unobserved levels. Also make sure that the basis dimension is set to ensure that the total number of coefficients is less than the number of observations.

Value

An object of class "mrf.smooth" or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in data.

       data=columb,method="REML")
b1 ## fit unchanged
plot(b1) ## but now there is no information with which to plot the mrf
**Description**

`gam` can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like `s(x,bs="ps")`. These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like `s(x,bs="cp",...)`. These bases can be used in tensor product smooths (see `te`).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed (but see also `d.spline`). This often provides a useful way of 'taming' an otherwise poorly behave smooth. However, in regular use, splines with derivative based penalties (e.g. "tp" or "cr" bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

**Usage**

```r
## S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

- `object`: a smooth specification object, usually generated by a term `s(x,bs="ps",...)` or `s(x,bs="cp",...)`
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`. See details for further information.

**Details**

A smooth term of the form `s(x,bs="ps",m=c(2,3))` specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If `m` is a single number then it is taken as the basis order and penalty order. The default is the 'cubic spline like' `m=c(2,2)`.

The default basis dimension, `k`, is the larger of 10 and `m[1]+1` for a "ps" terms and the larger of 10 and `m[1]` for a "cp" term. `m[1]+1` and `m[1]` are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. `k+1`) for a "cp" smooth. For the "ps" basis the number of supplied knots should be `k + m[1]`+ 2, and the range of the middle `k-m[1]` knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don’t make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions
Smoothed basis representations have a span that includes no data!), Note that P-splines don’t make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior $k-m[1]$ knots). Such extrapolation is not allowed in basis construction, but is when predicting.

For the "ps" basis it is possible to set flags in the smooth specification object, requesting setup according to the SCOP-spline monotonic smoother construction of Pya and Wood (2015). As yet this is not supported by any modelling functions in mgcv (see package scam). Similarly it is possible to set a deriv flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it. See examples below.

Value

An object of class "pspline.smooth" or "cp.smooth". See smooth.construct, for the elements that this object will contain.

```r
sspec$mono <- -1
sm1 <- smoothCon(sspec,dat)[[1]]
sm1$deriv <- 1
Xd1 <- PredictMat(sm1,dat)
plot(x,sm1$X%*%b,type="l",ylab="f(x)"
plot(x,Xd1%*%b,type="l",ylab="f'(x)"
```

## Now with sum to zero constraints as well...
```r
sspec$mono <- 1
sm <- smoothCon(sspec,dat,absorb.cons=TRUE)[[1]]
sm$deriv <- 1
Xd <- PredictMat(sm,dat)
b <- b[-1] # dropping first param
plot(x,sm$X%*%b,type="l",ylab="f(x)"
plot(x,Xd%*%b,type="l",ylab="f'(x)"
```

## Example using montonic constraints via the SCOP-spline

**Simple random effects in GAMs**
**Description**

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x, bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

**Usage**

```r
## S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'random.effect'
Predict.matrix(object, data)
```

**Arguments**

- `object`: For the `smooth.construct` method a smooth specification object, usually generated by a term `s(x,...,bs="re",.)`. For the `predict.Matrix` method an object of class "random.effect" produced by the `smooth.construct` method.
- `data`: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots`: generically a list containing any knots supplied for basis setup — unused at present.

**Details**

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x,z,bs="re")`. This will result in the model matrix component corresponding to `~x:z-1` being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x,bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x,v,w,bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

Some models require differences between the coefficients corresponding to different levels of the same random effect. See `linear.functional.terms` for how to implement this.

If the random effect precision matrix is of the form $\sum_{j} \lambda_j S_j$ for known matrices $S_j$ and unknown parameters $\lambda_j$, then a list containing the $S_j$ can be supplied in the `xt` argument of `s`. In this case an array `rank` should also be supplied in `xt` giving the ranks of the $S_j$ matrices. See simple example below.

Note that smooth `id`s are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when
gamm4 or gamm may be better alternatives. Note also that gam will not support models with more coefficients than data.

The situation in which factor variable random effects intentionally have unobserved levels requires special handling. You should set drop.unused.levels=FALSE in the model fitting function, gam, bam or gamm, having first ensured that any fixed effect factors do not contain unobserved levels.

The implementation is designed so that supplying random effect factor levels to predict.gam that were not levels of the factor when fitting, will result in the corresponding random effect (or interactions involving it) being set to zero (with zero standard error) for prediction. See random.effects for an example. This is achieved by the Predict.matrix method zeroing any rows of the prediction matrix involving factors that are NA. predict.gam will set any factor observation to NA if it is a level not present in the fit data.

Value

An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

Description

Sets up basis functions and wiggliness penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The so version sets up the full smooth. The sf version sets up just the boundary interpolating soap film, while the sw version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with gamm and gamm4. To use these to simply set up a basis, then call via the wrapper smooth.construct2 or smoothCon.

Usage

## S3 method for class 'so.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sw.smooth.spec'
smooth.construct(object, data, knots)

Arguments

- **object**
  A smooth specification object as produced by a s(.,...,bs="so",xt=list(bnd=bnd,...)) term in a gam formula. Note that the xt argument to s *must* be supplied, and should be a list, containing at least a boundary specification list (see details). xt may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the k argument of s, either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops.

- **data**
  A list or data frame containing the arguments of the smooth.

- **knots**
  list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the *interior* basis dimension (i.e. it is *not* supplied via argument k of s).

Details

For soap film smoothers the following *must* be supplied:

- k the basis dimension for each boundary loop smooth.
- xt$bnd the boundary specification for the smooth.
• knots the locations of the interior knots for the smooth.

When used in a GAM then k and xt are supplied via s while knots are supplied in the knots argument of gam.

The bnd element of the xt list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number of boundary loops. Each boundary loop list may also contain a column f giving known boundary conditions on a loop.

The bndSpec element of xt, if non-NULL, should contain

• bs the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument m must be supplied.
• knot.space set to "even" to get even knot spacing with the "cc" basis.
• m 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints get awkward).

Note that the function locator provides a simple means for defining boundaries graphically, using something like bnd <- as.data.frame(locator(type="l")), after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don’t want to smooth across, but doesn’t follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element nmax (default 200) of the list supplied as argument xt of s in a gam formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth \( f(x, y) \) is defined as the solution of

\[
 f_{xx} + f_{yy} = g
\]

subject to the condition that \( f = s \), on the boundary curve, where s is a smooth function (usually a cyclic penalized regression spline). The function g is defined as the solution of

\[
 g_{xx} + g_{yy} = 0
\]

where \( g = 0 \) on the boundary curve and \( g(x_k, y_k) = c_k \) at the ‘knots’ of the surface; the \( c_k \) are model coefficients.

In the simplest case, estimation of the coefficients of \( f \) (boundary coefficients plus \( c_k \)'s) is by minimization of

\[
 ||z - f||^2 + \lambda_s J_s(s) + \lambda_f J_f(f)
\]

where \( J_s \) is usually some cubic spline type wiggliness penalty on the boundary smooth and \( J_f \) is the integral of \( (f_{xx} + f_{yy})^2 \) over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The \( \lambda \)'s are smoothing parameters, selectable by GCV, REML, AIC, etc. z represents noisy observations of f.
Value

A list with all the elements of object plus

sd A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix.

X The model matrix: this will have an "offset" attribute, if there are any known boundary conditions.

S List of smoothing penalty matrices (in smallest non-zero submatrix form).

irng A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.

In addition there are all the elements usually added by smooth.construct methods.

WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

smooth.construct.sos.smooth.spec

Splines on the sphere

Description

gam can use isotropic smooths on the sphere, via terms like s(1a,1o,bs="sos",m=2,k=100). There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees) and the second longitude (in degrees). m (default 0) is an integer in the range -1 to 4 determining
the order of the penalty used. For \( m > 0 \), \((m+2)/2\) is the penalty order, with \( m = 2 \) equivalent to the usual second derivative penalty. \( m = 0 \) signals to use the 2nd order spline on the sphere, computed by Wendelberger’s (1981) method. \( m = -1 \) results in a Duchon spline being used (with \( m = 2 \) and \( s = 1/2 \)), following an unpublished suggestion of Jean Duchon.

\( k \) (default 50) is the basis dimension.

**Usage**

```r
## S3 method for class 'sos.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sos.smooth'
Predict.matrix(object, data)
```

**Arguments**

- `object` a smooth specification object, usually generated by a term `s(..., bs="sos",...).
- `data` a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots` a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`.

**Details**

For \( m > 0 \), the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of \( A \) — the \( A \) given in the 1981 paper is correct). For \( m = 0 \) (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For \( m = -1 \) a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a “normal” thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon. \( m = -2 \) is the same but with first derivative penalization.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. `theta`, `phi` give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. lat, lon gridlines are also plotted.

`scheme==1` is as `scheme==0`, but in black and white, without the image plot. `scheme>1` calls the default plotting method with `scheme` decremented by 2.

**Value**

An object of class "sos.smooth". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:
Xu  A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

UZ  The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.

Author(s)

smooth.construct.sz.smooth.spec

Constrained factor smooth interactions in GAMs

Description

Factor smooth interactions constructed to exclude main effects (and lower order factor smooth interactions). A smooth is constructed for each combination of the supplied factor levels. By appropriate application of sum to zero contrasts to equivalent smooth coefficients across factor levels, the required exclusion of lower order effects is achieved.

See factor.smooth for alternative factor smooth interactions.

Usage

```r
## S3 method for class 'sz.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sz.interaction'
Predict.matrix(object, data)
```

Arguments

- `object` For the smooth.construct method a smooth specification object, usually generated by a term `s(x,.,bs="sz",.)`. For the predict.Matrix method an object of class "sz.interaction" produced by the smooth.construct method.
- `data` a list containing just the data (including any by variable) required by this term, with names corresponding to object$term.
- `knots` a list containing any knots supplied for smooth basis setup.
smooth.construct.sz.smooth.spec

Details

This class produces a smooth for each combination of the levels of the supplied factor variables. `s(fac, x, bs="sz")` produces a smooth of `x` for each level of `fac`, for example. The smooths are constrained to represent deviations from the main effect smooth, so that models such as

\[ g(\mu_i) = f(x_i) + f_k(i)(x_i) \]

can be estimated in an identifiable manner, where \( k(i) \) indicates the level of some factor that applies for the \( i \)th observation. Identifiability in this case is ensured by constraining the coefficients of the splines representing the \( f_k \). In particular if \( \beta_{ki} \) is the \( i \)th coefficient of \( f_k \) then the constraints are \( \sum_k \beta_{ki} = 0 \).

Such sum to zero constraints are implemented using sum to zero contrasts: identity matrices with an extra row of -1s appended. Consider the case of a single factor first. The model matrix corresponding to a smooth per factor level is the row tensor product (see `tensor.prod.model.matrix`) of the model matrix for the factor, and the model matrix for the smooth. The contrast matrix is then the Kronecker product of the sum to zero contrast for the factor, and an identity matrix of dimension determined by the number of coefficients of the smooth.

If there are multiple factors then the overall model matrix is the row Kronecker product of all the factor model matrices and the smooth, while the contrast is the Kronecker product of all the sum-to-zero contrasts for the factors and a final identity matrix. Notice that this construction means that the main effects (and any interactions) of the factors are included in the factor level dependent smooths. In other words the individual smooths are not each centered. This means that adding main effects or interactions of the factors will lead to a rank deficient model.

The terms can have a smoothing parameter per smooth, or a single smoothing parameter for all the smooths. The latter is specified by giving the smooth term an id. e.g. `s(fac, x, bs="sz", id=1)`.

The basis for the smooths can be selected by supplying a list as the `xt` argument to `s`, with a `bs` item. e.g. `s(fac, x, xt=list(bs="cr"))` selects the "cr" basis. The default is "tp".

The plot method for this class has two schemes. `scheme==0` is in colour, while `scheme==1` is black and white. Currently it only works for 1D smooths.

Value

An object of class "sz.interaction" or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves.

```

### Arguments

- **object**: a smooth specification object of class `t2.smooth.spec`, usually generated by a term like `t2(x,z)` in a `gam` model formula.
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`. See details for further information.
Details

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See `t2`, `te`, `smooth.construct` and `smooth.terms`. The construction employed here produces tensor smooths for which the smoothing penalties are non-overlapping portions of the identity matrix. This makes their estimation by mixed modelling software rather easy.

Value

An object of class "t2.smooth".

smooth.construct.tensor.smooth.spec

Tensor product smoothing constructor

Description

A special smooth.construct method function for creating tensor product smooths from any combination of single penalty marginal smooths.

Usage

```r
## S3 method for class 'tensor.smooth.spec'
smooth.construct(object, data, knots)
```
**Arguments**

- **object**
  a smooth specification object of class `tensor.smooth.spec`, usually generated by a term like `te(x,z)` in a `gam` model formula.

- **data**
  a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.

- **knots**
  a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`. See details for further information.

**Details**

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See `te`, `smooth.construct` and `smooth.terms`.

**Value**

An object of class "tensor.smooth". See `smooth.construct`, for the elements that this object will contain.

```r
## see ?gam
```
Description

*gam* can use isotropic smooths of any number of variables, specified via terms like `s(x,z,bs="tp",m=3)` (or just `s(x,z)` as this is the default basis). These terms are based on thin plate regression splines. `m` specifies the order of the derivatives in the thin plate spline penalty.

If `m` is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth: this is useful if you need to test whether a smooth could be replaced by a linear term, or construct models with odd nesting structures.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample `max.knots` unique data locations if there are more than `max.knots` such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). `max.knots` is 2000, by default. Both `seed` and `max.knots` can be modified using the `xt` argument to `s`. Alternatively the user can supply knots from which to construct a basis.

The “ts” smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

Usage

```r
## S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- `object` a smooth specification object, usually generated by a term `s(...,bs="tp",...)` or `s(...,bs="ts",...)`
- `data` a list containing just the data (including any by variable) required by this term, with names corresponding to `object$term` (and `object$by`). The by variable is the last element.
- `knots` a list containing any knots supplied for basis setup — in same order and with same names as `data`. Can be `NULL`

Details

The default basis dimension for this class is `k=M+k.def` where `M` is the null space dimension (dimension of unpenalized function space) and `k.def` is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choise, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).
The default is to set \( m \) (the order of derivative in the thin plate spline penalty) to the smallest value satisfying \( 2m > d+1 \) where \( d \) if the number of covariates of the term: this yields ‘visually smooth’ functions. In any case \( 2m > d \) must be satisfied.

The constructor is not normally called directly, but is rather used internally by \texttt{gam}. To use for basis setup it is recommended to use \texttt{smooth.construct2}.

For these classes the specification object will contain information on how to handle large datasets in their \texttt{xt} field. The default is to randomly subsample 2000 ‘knots’ from which to produce a tprs basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the \texttt{xt} argument to \texttt{s}. This is supplied as a list with elements \texttt{max.knots} and \texttt{seed} containing a number to use in place of 2000, and the random number seed to use (either can be missing).

For these bases \texttt{knots} has two uses. Firstly, as mentioned already, for large datasets the calculation of the \texttt{tp} basis can be time-consuming. The user can retain most of the advantages of the \texttt{t.p.r.s.} approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, \( k \). This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds \texttt{max.knots}. The second possibility is to avoid the eigen-decomposition used to find the \texttt{t.p.r.s.} basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, \( k \). For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

**Value**

An object of class "tprs.smooth" or "ts.smooth". In addition to the usual elements of a smooth class documented under \texttt{smooth.construct}, this object will contain:

- \texttt{shift} A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
- \( X_u \) A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
- \( U_Z \) The matrix mapping the \texttt{t.p.r.s.} parameters back to the parameters of a full thin plate spline.
- \texttt{null.space.dimension} The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

plot(x,X1[,1],ylim=range(X1),type="l")
for (i in 1:ncol(X1)) lines(x,X1[,i],col=i)
```

smooth.info  
Generic function to provide extra information about smooth specification

Description

Takes a smooth specification object and adds extra basis specific information to it before smooth constructor called. Default method returns supplied object unmodified.

Usage

```r
smooth.info(object)
```

Arguments

- `object` is a smooth specification object
smooth.terms

Details

Sometimes it is necessary to know something about a smoother before it is constructed, beyond what is in the initial smooth specification object. For example, some smooth terms could be set up as tensor product smooths and it is useful for \texttt{bam} to take advantage of this when discrete covariate methods are used. However, \texttt{bam} needs to know whether a smoother falls into this category before it is constructed in order to discretize its covariates marginally instead of jointly. Rather than \texttt{bam} having a hard coded list of such smooth classes it is preferable for the smooth specification object to report this themselves. \texttt{smooth.info} method functions are the means for achieving this. When interpreting a \texttt{gam} formula the \texttt{smooth.info} function is applied to each smooth specification object as soon as it is produced (in \texttt{interpret.gam} function).

Value

A smooth specification object, which may be modified in some way.

smooth.terms

Smooth terms in GAM

Description

Smooth terms are specified in a \texttt{gam} formula using \texttt{s}, \texttt{te}, \texttt{ti} and \texttt{t2} terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see \texttt{user.defined.smooth}). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by \texttt{s} terms, or as building blocks for tensor product smoothing via \texttt{te}, \texttt{ti} or \texttt{t2} terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the \texttt{mgcv} package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).
Note that smooths can be used rather flexibly in GAM models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in `linear.functional.terms`.

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** `bs="tp"`. These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See `tprs` for further details.

`bs="ts"` is as `"tp"` but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.

**Duchon splines** `bs="ds"`. These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See `Duchon.spline` for further details.

**Cubic regression splines** `bs="cr"`. These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see `cubic.regression.spline` and e.g. Wood (2006a).

`bs="cs"` specifies a shrinkage version of `"cr"`.

`bs="cc"` specifies a cyclic cubic regression splines (see `cyclic.cubic.spline`). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**Splines on the sphere** `bs="sos"`. These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See `Spherical.Spline` for details.

**B-splines** `bs="bs"` B-spline basis with integrated squared derivative penalties. The order of basis and penalty can be chosen separately, and several penalties of different orders can be applied. Somewhat like a derivative penalty version of P-splines. See `bspline` for details.

**P-splines** `bs="ps"`. These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

`bs="cp"` gives a cyclic version of a P-spline (see `cyclic.p.spline`).

**Random effects** `bs="re"`. These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See `smooth.construct.re.smooth.spec`.

**Markov Random Fields** `bs="mrf"`. These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See `mrf` for details and an example.
Gaussian process smooths bs="gp". Gaussian process models with a variety of simple correlation functions can be represented as smooths. See \texttt{gp.smooth} for details.

Soap film smooths bs="so" (actually not single penalized, but bs="sw" and bs="sf" allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See \texttt{soap} for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations. All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via \texttt{te}, \texttt{ti} or \texttt{t2} terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. \texttt{Wood (2006b)} and \texttt{Wood, Scheipl and Faraway (2012)}, give the general recipe for these constructions.

te te smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See \texttt{Wood (2006b)}.

ti ti smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable an interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predicto \( f_1(x) + f_2(z) + f_3(x, z) \), we might use model formula \( y = s(x) + s(z) + ti(x, z) \) or \( y = t_1(x) + t_1(z) + ti(x, z) \). A similar construction involving te terms instead will be much less statistically stable.

t2 t2 uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the \texttt{gamm4} package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See \texttt{Wood, Scheipl and Faraway (2012/13)}.

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see \texttt{te} for an example of this). Note that te terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

Adaptive smoothers bs="ad" Univariate and bivariate adaptive smooths are available (see \texttt{adaptive.smooth}). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by \texttt{gamm}.

Factor smooth interactions bs="sz" Smooth factor interactions (see \texttt{factor.smooth}) are often produced using by variables (see \texttt{gam.models}), but it is often desirable to include smooths which represent the deviations from some main effect smooth that apply for each level of a factor (or combination of factors). See \texttt{smooth.construct.sz.smooth.spec} for details.
Random factor smooth interactions bs="fs" A special smoother class (see smooth.construct.fs.smooth.spec) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The “fs” smoothers are set up to be efficient when used with gamm, and have penalties on each null space component (i.e. they are fully ‘random effects’).

smooth2random(object,vnames,type=1)
smooth2random

Arguments

object an mgcv smooth object.
vnames a vector of names to avoid as dummy variable names in the random effects form.
type 1 for lme, otherwise lmer.

Details

There is a duality between smooths and random effects which means that smooths can be estimated using mixed modelling software. This function converts standard mgcv smooth objects to forms suitable for estimation by lme, for example. A service routine for gamm exported for use by package developers. See examples for creating prediction matrices for new data, corresponding to the random and fixed effect matrices returned when type=2.

Value

A list.

rand a list of random effects, including grouping factors, and a fixed effects matrix. Grouping factors, model matrix and model matrix name attached as attributes, to each element. Alternatively, for type=2 a list of random effect model matrices, each corresponding to an i.i.d. Gaussian random effect with a single variance component.

trans.U A matrix, trans.U, that transforms coeffs, in order [rand1, rand2,... fix] back to original parameterization. If null, then not needed. If null then taken as identity.

Xf A matrix for the fixed effects, if any.

fixed TRUE/FALSE, indicating if term was unpenalized or not. If unpenalized then other stuff may not be returned (it’s not a random effect).

rind an index vector such that if br is the vector of random coefficients for the term, br[rind] is the coeffs in order for this term.

pen.ind index of which penalty penalizes each coefficient: 0 for unpenalized.

range(r$Xf-re$Xf[1:10,])
range(r$rand[[1]]-re$rand[[1]][1:10,])
Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

Usage

smoothCon(object, data, knots=NULL, absorb.cons=FALSE, scale.penalty=TRUE, n=nrow(data), dataX=NULL, null.space.penalty=FALSE, sparse.cons=0, diagonal.penalty=FALSE, apply.by=TRUE, modCon=0)
PredictMat(object, data, n=nrow(data))

Arguments

object is a smooth specification object or a smooth object.
data A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it’s a list then n must be supplied explicitly if data is a list.
knots An optional data frame supplying any knot locations to be supplied for basis construction.
absorb.cons Set to TRUE in order to have identifiability constraints absorbed into the basis.
scale.penalty should the penalty coefficient matrix be scaled to have approximately the same ‘size’ as the inner product of the terms model matrix with itself? This can improve the performance of gamm fitting.
n number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if data is a list.
dataX Sometimes the basis should be set up using data in data, but the model matrix should be constructed with another set of data provided in dataX — n is assumed to be the same for both. Facilitates smooth id’s.
null.space.penalty Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.
apply.by set to FALSE to have basis setup exactly as in default case, but to return add an additional matrix X0 to the return object, containing the model matrix without the by variable, if a by variable is present. Useful for bam discrete method setup.
sparse.cons If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with bam). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint.
diagonal.penalty If TRUE then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix diagRP in the returned object for use by PredictMat.
smoothCon

modCon

force modification of any smooth supplied constraints. 0 - do nothing. 1 - delete supplied constraints, replacing with automatically generated ones. 2 - set fit and predict constraint to predict constraint. 3 - set fit and predict constraint to fit constraint.

Details

These wrapper functions exist to allow smooths specified using smooth.construct and Predict.matrix method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine’s also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object by.done. If this does not exist then smoothCon will use the default code. Similarly if a user defined Predict.matrix method handles by variables internally then the returned matrix should have a "by.done" attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix C of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix C should have no rows. There is an option to use centering constraint that generate no, or limited infil, if the smoother has a sparse model matrix.

smoothCon returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. smoothCon modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by PredictMat.

The parameterization used by gam can be controlled via gam.control.

Value

From smoothCon a list of smooth objects returned by the appropriate smooth.construct method function. If constraints are to be absorbed then the objects will have attributes "qrc" and "nCons". "nCons" is the number of constraints. "qrc" is usually the qr decomposition of the constraint matrix (returned by qr), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

times <- seq(0,60,length=200)  # creat prediction times
## Get matrix mapping beta to spline prediction at 'times'
Xp <- PredictMat(sm,data.frame(times=times))  # prediction matrix
lines(times,Xp%*%beta)  # add smooth to plot

## Same again but using a penalized regression spline of
## rank 30....
sm <- smoothCon(s(times,k=30),data=mcycle,knots=NULL)[[1]]
E <- t(mroot(sm$S)[[1]])  # square root penalty
X <- rbind(sm$X,0.1*E)  # augmented model matrix
y <- c(mcycle$accel,rep(0,nrow(E)))  # augmented data
beta <- coef(lm(y~X-1))  # fit penalized regression spline
Xp <- PredictMat(sm,data.frame(times=times))  # prediction matrix
with(mcycle,plot(times,accel))  # plot data
lines(times,Xp%*%beta)  # overlay smooth
```

---

**sp.vcov**

Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit

**Description**

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated gam object, provided the fit was with a method that evaluated the required Hessian.

**Usage**

```r
sp.vcov(x, edge.correct=TRUE, reg=1e-3)
```

**Arguments**

- `x` a fitted model object of class `gam` as produced by `gam()`.
- `edge.correct` if the model was fitted with `edge.correct=TRUE` (see `gam.control`), then the returned covariance matrix will be for the edge corrected log smoothing parameters.
- `reg` regularizer for Hessian - default is equivalent to prior variance of 1000 on log smoothing parameters.

**Details**

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.
Value

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter esti-
mators, if this can be extracted, otherwise NULL. If the scale parameter has been (RE)ML estimated
(i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and
column relate to the log scale parameter. If edge.correct=TRUE and this was used in fitting then
the edge corrected smoothing parameters are in attribute 1sp of the returned matrix.

Experimental sparse smoothers

Description

These are experimental sparse smoothing functions, and should be left well alone!

Usage

spasm.construct(object, data)
spasm.sp(object, sp, w=rep(1, object$nobs), get.trH=TRUE, block=0, centre=FALSE)
spasm.smooth(object, X, residual=FALSE, block=0)

Arguments

object          sparse smooth object
data            data frame
sp              smoothing parameter value
w               optional weights
get.trH         Should (estimated) trace of sparse smoother matrix be returned
block  index of block, 0 for all blocks
centre  should sparse smooth be centred?
X  what to smooth
residual  apply residual operation?

WARNING

It is not recommended to use these yet

Description

There is no step.gam in package mgcv. The mgcv default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows’ Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

Shrinkage smoothers are smooths in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smooths (see s)

Null space penalization An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggliness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The select argument to gam causes this latter approach to be used. Unpenalized terms (e.g. s(x,fx=TRUE)) remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

Summary for a GAM fit

Description

Takes a fitted gam object produced by gam() and produces various useful summaries from it. (See
sink to divert output to a file.)

Usage

## S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, re.test=TRUE, ...)

## S3 method for class 'summary.gam'
print(x,digits = max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"),...)

summary.gam

Summary for a GAM fit
Arguments

object: a fitted `gam` object as produced by `gam()`.

x: a summary.gam object produced by `summary.gam()`.

dispersion: A known dispersion parameter. NULL to use estimate or default (e.g. 1 for Poisson).

freq: By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to TRUE then the frequentist covariance matrix of the parameters is used instead.

re.test: Should tests be performed for random effect terms (including any term with a zero dimensional null space)? For large models these tests can be computationally expensive.

digits: controls number of digits printed in output.

signif.stars: Should significance stars be printed alongside output.

...: other arguments.

Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix $A$ for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let $P_i$ be the matrix giving the parameters of the $i$th smooth when applied to the data (or pseudodata in the generalized case) and let $X$ be the design matrix of the model. Then $\text{tr}(XP_i)$ is the edf for the $i$th term. Clearly this definition causes the edf’s to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of $2A - AA$.

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka’s (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurrence).

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and
is otherwise rather similar to the results using the frequentist covariance matrix (freq=TRUE), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the paraPen argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting freq=TRUE is appropriate.

Value

summary.gam produces a list of summary information for a fitted gam object.

- **p.coeff** is an array of estimates of the strictly parametric model coefficients.
- **p.t** is an array of the p.coeff’s divided by their standard errors.
- **p.pv** is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.
- **m** The number of smooth terms in the model.
- **chi.sq** An array of test statistics for assessing the significance of model smooth terms. See details.
- **s.pv** An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.
- **se** array of standard error estimates for all parameter estimates.
- **r.sq** The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that r.sq does not include any offset in the one parameter model.
- **dev.expl** The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so dev.expl can be substantially lower than r.sq when an offset is present.
- **edf** array of estimated degrees of freedom for the model terms.
- **residual.df** estimated residual degrees of freedom.
- **n** number of data.
- **np** number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).
- **rank** apparent model rank.
- **method** The smoothing selection criterion used.
- **sp.criterion** The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.
- **scale** estimated (or given) scale parameter.
- **family** the family used.
- **formula** the original GAM formula.
- **dispersion** the scale parameter.
- **pTerms.df** the degrees of freedom associated with each parametric term (excluding the constant).
pTerms.chi.sq: a Wald statistic for testing the null hypothesis that the each parametric term is zero.

pTerms.pv: p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.

cov.unscaled: The estimated covariance matrix of the parameters (or estimators if \texttt{freq=TRUE}), divided by scale parameter.

cov.scaled: The estimated covariance matrix of the parameters (estimators if \texttt{freq=TRUE}).

p.table: significance table for parameters

s.table: significance table for smooths

p.Terms: significance table for parametric model terms

**WARNING**

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

**Examples**

```r
library(mgcv)
set.seed(0)

dat <- gamSim(1,n=200,scale=2) ## simulate data

b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
summary(b)
```

Now check the p-values by using a pure regression spline.....

```r
b.d <- round(summary(b)$edf)+1  ## get edf per smooth
b.d <- pmax(b.d,3)  # can't have basis dimension less than 3!
bc <- gam(y~s(x0,k=b.d[1],fx=TRUE)+s(x1,k=b.d[2],fx=TRUE)+
s(x2,k=b.d[3],fx=TRUE)+s(x3,k=b.d[4],fx=TRUE),data=dat)
plot(bc,pages=1)
summary(bc)
```

## Example where some p-values are less reliable...

```r
dat <- gamSim(6,n=200,scale=2)
b <- gam(y~s(x0,m=1)+s(x1)+s(x2)+s(x3)+s(fac,bs="re"),data=dat)
## Here s(x0,m=1) can be penalized to zero, so p-value approximation
## cruder than usual...
summary(b)
```

## p-value check - increase k to make this useful!

```r
k<-20;n <- 200;p <- rep(NA,k)
for (i in 1:k)
{ b<-gam(y~te(x,z),data=data.frame(y=rnorm(n),x=runif(n),z=runif(n)),
method="ML")
p[i]<-summary(b)$s.p[1]
}
plot(((1:k)-0.5)/k,sort(p))
abline(0,1,col=2)
ks.test(p, "punif")  ## how close to uniform are the p-values?
```

## A Gamma example, by modify 'gamSim' output...

```r
dat <- gamSim(1,n=400,dist="normal",scale=1)
dat$f <- dat$f/4  ## true linear predictor
Ey <- exp(dat$f)/4;scale <- .5  ## mean and GLM scale parameter
## Note that 'shape' and 'scale' in 'rgamma' are almost
## opposite terminology to that used with GLM/GAM...
dat$y <- rgamma(Ey,shape=1/scale, scale=scale)
bg <- gam(y~ s(x0)+ s(x1)+s(x2)+s(x3),family=Gamma(link=log),
data=dat,method="REML")
summary(bg)
```

---

### t2

**Define alternative tensor product smooths in GAM formulae**

**Description**

Alternative to `te` for defining tensor product smooths in a `gam` formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl (mgcv implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with `gamm4` from package `gamm4`.

**Usage**

```r
t2(..., k=NA,bs="cr",m=NA,d=NA,by=NA,xt=FALSE, id=NULL,sp=NULL,full=FALSE,ord=FALSE,pc=FALSE)
```
Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. $t2(\log(x), z)$ is fine, but $t2(I(x/sd(x)), z)$ is not (see predict.gam).

k the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See choose.k for further information.

bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See smooth.terms for details and full list. User defined bases can also be used here (see smooth.construct for an example). If only one basis code is given then this is used for all bases.

m The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different $m$ for each margin. For marginals that take vector $m$ (e.g. p.spline and Duchon.spline), then a list can be supplied, with a vector element for each margin. NA autoinitializes. $m$ is ignored by some bases (e.g. "cr").

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set $d=c(2,1)$. Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See gam.models for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see gam.models and linear.functional.terms for details).

xt Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

sp any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to gam. Ignored by gamm.

full If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.
ord  an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.

pc  If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See identifiability.

Details

Smoothes of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See pen.edf for some further information.

Note that there are two ways to construct the product. When full=FALSE then the null space bases are treated as a whole in each product, but when full=TRUE each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

Value

A class t2.smooth.spec object defining a tensor product smooth to be turned into a basis and penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

margin  A list of smooth.spec objects of the type returned by s, defining the basis from which the tensor product smooth is constructed.
term
by
fx
label
dim
mp
np
id
sp

An array of text strings giving the names of the covariates that the term is a function of.

is the name of any by variable as text ("NA" for none).

logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.

A suitable text label for this smooth term.

The dimension of the smoother - i.e. the number of covariates that it is a function of.

TRUE is multiple penalties are to be used (default).

TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).

the id argument supplied to te.

the sp argument supplied to te.

x<-runif(n)/20;z<-runif(n);
xs<-seq(0,1,length=30)/20;zs<-seq(0,1,length=30)
Define tensor product smooths or tensor product interactions in GAM formulae

Description

Functions used for the definition of tensor product smooths and interactions within gam model formulae. te produces a full tensor product smooth, while ti produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present.
The functions do not evaluate the smooth - they exist purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

Usage

```r
te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
     np=TRUE, xt=NULL, id=NULL, sp=NULL, pc=NULL)
```

```r
ti(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
     np=TRUE, xt=NULL, id=NULL, sp=NULL, mc=NULL, pc=NULL)
```

Arguments

- `...` a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `te(log(x), z)` is fine, but `te(I(x/sd(x)), z)` is not (see `predict.gam`).
- `k` the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See `choose.k` for further information.
- `bs` array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See `smooth.terms` for details and full list. User defined bases can also be used here (see `smooth.construct` for an example). If only one basis code is given then this is used for all bases.
- `m` The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different $m$ for each margin. For marginals that take vector $m$ (e.g. `p.spline` and `Duchon.spline`), then a list can be supplied, with a vector element for each margin. NA autoinitializes. $m$ is ignored by some bases (e.g. "cr").
- `d` array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set $d=c(2,1)$. Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.
- `by` a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case causes a replicate of the smooth to be produced for each factor level. See `gam.models` for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see `gam.models` and `linear.functional.terms` for details).
- `fx` indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
- `np` TRUE to use the ‘normal parameterization’ for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at ‘knots’, spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.
Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

Any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to gam. Ignored by gamm.

For ti smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or FALSE/TRUE values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that ‘ti’ only applies constraints to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work.

If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See identifiability.

Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in tensor.prod.model.matrix and tensor.prod.penalties, to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

\[ f_1(x) + f_2(z) + f_3(x, z) \]

This functional ANOVA decomposition is supported by ti terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the \(~ ti(x) + ti(z) + ti(x, z)\) would produce the above main effects + interaction structure. This is much better than attempting the same thing with sor te terms representing the interactions (although mgcv does not forbid it). Technically ti terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework). See Wood (2017, section 5.6.3).

The ‘normal parameterization’ (np=TRUE) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done
for marginals of a single variable. This parameterization can reduce numerical stability when used
with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set np=FALSE.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if
any marginals would not need centering. The constructor for tensor product smooths ensures that
this happens.

The function does not evaluate the variable arguments.

Value

A class tensor.smooth.spec object defining a tensor product smooth to be turned into a basis and
penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

margin A list of smooth.spec objects of the type returned by s, defining the basis from
which the tensor product smooth is constructed.

term An array of text strings giving the names of the covariates that the term is a
function of.

by is the name of any by variable as text ("NA" for none).

fx logical array with element for each penalty of the term (tensor product smooths
have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.

label A suitable text label for this smooth term.

dim The dimension of the smoother - i.e. the number of covariates that it is a function
of.

mp TRUE is multiple penalties are to be used (default).

np TRUE to re-parameterize 1-D marginal smooths in terms of function values (de-
fault).

id the id argument supplied to te.

sp the sp argument supplied to te.

inter TRUE if the term was generated by ti, FALSE otherwise.

mc the argument mc supplied to ti.

plot(b)
Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth (marginals and results can be sparse). The model matrix construction uses row Kronecker products.

Usage

tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
a %x% b

Arguments

X
a list of model matrices for the marginal bases of a smooth. Items can be class "matrix" or "dgCMatrix", but not a mixture of the two.

S
a list of penalties for the marginal bases of a smooth.

a
a matrix with the same number of rows as A.

b
a matrix with the same number of rows as B.

Details

If \(X[1], X[2], \ldots, X[m]\) are the model matrices of the marginal bases of a tensor product smooth then the \(i\)th row of the model matrix for the whole tensor product smooth is given by \(X[1][i,] %x% X[2][i,] %x% \ldots %x% X[m][i,]\), where \(\%x\%\) is the Kronecker product. Of course the routine operates column-wise, not row-wise!

\(A %x% B\) is the operator form of this ‘row Kronecker product’.

If \(S[1], S[2], \ldots, S[m]\) are the penalty matrices for the marginal bases, and \(I[1], I[2], \ldots, I[m]\) are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has \(m\) associate penalties of the form:

\(S[1] %x% I[2] %x% \ldots %x% I[m]\),
\(I[1] %x% S[2] %x% \ldots %x% I[m]\)

\(\ldots\)
\(I[1] %x% I[2] %x% \ldots %x% S[m]\).

Of course it’s important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

Value

Either a single model matrix for a tensor product smooth (of the same class as the marginals), or a list of penalty terms for a tensor product smooth.

**totalPenaltySpace**

Obtaining (orthogonal) basis for null space and range of the penalty matrix

**Description**

INTERNAL function to obtain (orthogonal) basis for the null space and range space of the penalty, and obtain actual null space dimension components are roughly rescaled to avoid any dominating.

**Usage**

totalPenaltySpace(S, H, off, p)

**Arguments**

S  
a list of penalty matrices, in packed form.
H  
the coefficient matrix of an user supplied fixed quadratic penalty on the parameters of the GAM.
off  
a vector where the i-th element is the offset for the i-th matrix.
p  
total number of parameters.

**Value**

A list of matrix square roots such that S[[i]]=B[i]%*%t(B[i]).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.
trichol  

Description

Computes Choleski decomposition of a (symmetric positive definite) tri-diagonal matrix stored as a leading diagonal and sub/super diagonal.

Usage

trichol(ld, sd)

Arguments

ld  leading diagonal of matrix
sd  sub-super diagonal of matrix

Details

Calls dpttrf from LAPACK. The point of this is that it has $O(n)$ computational cost, rather than the $O(n^3)$ required by dense matrix methods.

Value

A list with elements ld and sd. ld is the leading diagonal and sd is the super diagonal of bidiagonal matrix $B$ where $B^T B = T$ and $T$ is the original tridiagonal matrix.

trind.generator  Generates index arrays for upper triangular storage

Description
Generates index arrays for upper triangular storage up to order four. Useful when working with higher order derivatives, which generate symmetric arrays. Mainly intended for internal use.

Usage
trind.generator(K = 2, ifunc = FALSE, reverse = !ifunc)

Arguments
K  positive integer determining the size of the array.
ifunc  if TRUE index functions are returned in place of index arrays.
reverse  should the reverse indices be computed? Probably not if ifunc==TRUE.

Details
Suppose that m=1 and you fill an array using code like for(i in 1:K) for(j in i:K) for(k in j:K) for(l in k:K) {a[,m] <- something; m <- m+1 } and do this because actually the same "something" would be stored for any permutation of the indices i,j,k,l. Clearly in storage we have the restriction i>=k>=j=i, but for access we want no restriction on the indices. i4[i,j,k,l] produces the appropriate m for unrestricted indices. i3 and i2 do the same for 3d and 2d arrays. If ifunc==TRUE then i2, i3 and i4 are functions, so i4(i,j,k,l) returns appropriate m. For high K the function versions save storage, but are slower.

If computed, the reverse indices pick out the unique elements of a symmetric array stored redundantly. The indices refer to the location of the elements when the redundant array is accessed as its underlying vector. For example the reverse indices for a 3 by 3 symmetric matrix are 1,2,3,5,6,9.

Value
A list where the entries i1 to i4 are arrays in up to four dimensions, containing K indexes along each dimension. If ifunc==TRUE index functions are returned in place of index arrays. If reverse==TRUE reverse indices i1r to i4r are returned (always as arrays).

Author(s)
Simon N. Wood <simon.wood@r-project.org>. 
Examples

```r
library(mgcv)
A <- trind.generator(3, reverse=TRUE)

# All permutations of c(1, 2, 3) point to the same index (5)
A$i3[1, 2, 3]
A$i3[2, 1, 3]
A$i3[2, 3, 1]
A$i3[3, 1, 2]
A$i3[1, 3, 2]

## use reverse indices to pick out unique elements
## just for illustration...
A$i2; A$i2[A$i2r]
A$i3[A$i3r]

## same again using function indices...
A <- trind.generator(3, ifunc=TRUE)
A$i3(1, 2, 3)
A$i3(2, 1, 3)
A$i3(2, 3, 1)
A$i3(3, 1, 2)
A$i3(1, 3, 2)
```

Tweedie

**GAM Tweedie families**

Description

Tweedie families, designed for use with `gam` from the `mgcv` library. Restricted to variance function powers between 1 and 2. A useful alternative to `quasi` when a full likelihood is desirable. Tweedie is for use with fixed `p`. `tw` is for use when `p` is to be estimated during fitting. For fixed `p` between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power `p`.

`tw` is only useable with `gam` and `bam` but not `gamm`. Tweedie works with all three.

Usage

```r
Tweedie(p=1, link = power(0))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```

Arguments

- `p` the variance of an observation is proportional to its mean to the power `p`. `p` must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.
- `link` The link function: one of "log", "identity", "inverse", "sqrt", or a power link (Tweedie only).
- `theta` Related to the Tweedie power parameter by \( p = (a + b \exp(\theta))/(1 + \exp(\theta)) \). If this is supplied as a positive value then it is taken as the fixed value for `p`. If it is a negative values then its absolute value is taken as the initial value for `p`.
- `a` lower limit on `p` for optimization.
- `b` upper limit on `p` for optimization.
Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1, and is therefore highly multimodal. See \texttt{ldTweedie} for more on this behaviour.

Tweedie is based partly on the \texttt{poisson} family, and partly on \texttt{tweedie} from the \texttt{statmod} package. It includes extra components to work with all \texttt{mgcv} GAM fitting methods as well as an \texttt{aic} function.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. p and the scale parameter. Without restricting p to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over \texttt{quasi}. If you need this case then the \texttt{tweedie} package is the place to start.

Value

For Tweedie, an object inheriting from class \texttt{family}, with additional elements

\begin{itemize}
  \item \texttt{dvar} the function giving the first derivative of the variance function w.r.t. mu.
  \item \texttt{d2var} the function giving the second derivative of the variance function w.r.t. mu.
  \item \texttt{ls} A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter.
\end{itemize}

For \texttt{tw}, an object of class \texttt{extended.family}.

## Same by approximate REML ...
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=Tweedie(1.25, power(.1)), data=dat, method="REML")
plot(b1, pages=1)
print(b1)

## Estimate p as part of fitting
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=tw(), data=dat, method="REML")
plot(b2, pages=1)
print(b2)

rm(dat)

twlss

Tweedie location scale family

Description

Tweedie family in which the mean, power and scale parameters can all depend on smooth linear predictors. Restricted to estimation via the extended Fellner Schall method of Wood and Fasiolo (2017). Only usable with `gam`. Tweedie distributions are exponential family with variance given by \( \phi \mu^p \) where \( \phi \) is a scale parameter, \( p \) a parameter (here between 1 and 2) and \( \mu \) is the mean.

Usage

```r
twlss(link=list("log","identity","identity"), a=1.01, b=1.99)
```

Arguments

- **link** The link function list: currently no choice.
- **a** lower limit on the power parameter relating variance to mean.
- **b** upper limit on power parameter.

Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1, and is therefore highly multimodal. See `l1Tweedie` for more on this behaviour.
The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. $p$ and the scale parameter. Without restricting $p$ to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over quasi. If you need this case then the tweedie package is the place to start.

uniquecombs  

find the unique rows in a matrix

Description

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit need not be the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

Usage

uniquecombs(x, ordered = FALSE)

Arguments

x is an \texttt{R} matrix (numeric), or data frame.

ordered set to \texttt{TRUE} to have the rows of the returned object in the same order regardless of input ordering.

Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model.

When \texttt{x} has only one column then the routine uses \texttt{unique} and \texttt{match} to get the index. When there are multiple columns then it uses \texttt{paste0} to produce labels for each row, which should be unique if the row is unique. Then \texttt{unique} and \texttt{match} can be used as in the single column case. Obviously the pasting is inefficient, but still quicker for large \textit{n} than the \texttt{C} based code that used to be called by this routine, which had \textit{O}(\textit{nlog} (\textit{n})) cost. In principle a hash table based solution in \texttt{C} would be only \textit{O}(\textit{n}) and much quicker in the multicolumn case. \texttt{unique} and \texttt{duplicated}, can be used in place of this, if the full index is not needed. Relative performance is variable.

If \texttt{x} is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

Value

A matrix or data frame consisting of the unique rows of \texttt{x} (in arbitrary order).

The matrix or data frame has an "index" attribute. \texttt{index[i]} gives the row of the returned matrix that contains row \textit{i} of the original matrix.

WARNINGS

If a dataframe contains variables of a type other than numeric, logical, factor or character, which either have no \texttt{as.character} method, or whose \texttt{as.character} method is a many to one mapping, then the routine is likely to fail.

If the character representation of a dataframe variable (other than of class factor of character) contains * then in principle the method could fail (but with a warning).
vcov.gam

Extract parameter (estimator) covariance matrix from GAM fit

Description

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted gam object.

Usage

## S3 method for class 'gam'
vcov(object, sandwich=FALSE, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)

Arguments

- **object**: fitted model object of class gam as produced by gam().
- **sandwich**: compute sandwich estimate of covariance matrix. Currently expensive for discrete bam fits.
vis.gam

freq  TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters. The latter option includes the expected squared bias according to the Bayesian smoothing prior.

dispersion  a value for the dispersion parameter: not normally used.

unconditional  if TRUE (and freq==FALSE) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.

...  other arguments, currently ignored.

Details

Basically, just extracts object$Ve, object$Vp or object$Vc (if available) from a gamObject, unless sandwich==TRUE in which case the sandwich estimate is computed (with or without the squared bias component).

Value

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument freq.

diag(vcov(mod))
```

vis.gam  Visualization of GAM objects

Description

Produces perspective or contour plot views of gam model predictions, fixing all but the values in view to the values supplied in cond.
vis.gam

Usage

vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA,
        color="heat", contour.col=NULL, se=-1, type="link",
        plot.type="persp", zlim=NULL, nCol=50, lp=1, ...)

Arguments

x
  a gam object, produced by gam()

view
  an array containing the names of the two main effect terms to be displayed on
  the x and y dimensions of the plot. If omitted the first two suitable terms will be
  used. Note that variables coerced to factors in the model formula won’t work as
  view variables, and vis.gam can not detect that this has happened when setting
defaults.

cond
  a named list of the values to use for the other predictor terms (not in view). Var-
  iables omitted from this list will have the closest observed value to the median
  for continuous variables, or the most commonly occuring level for factors. Para-
  metric matrix variables have all the entries in each column set to the observed
  column entry closest to the column median.

n.grid
  The number of grid nodes in each direction used for calculating the plotted sur-
  face.

too.far
  plot grid nodes that are too far from the points defined by the variables given in
  view can be excluded from the plot. too.far determines what is too far. The
  grid is scaled into the unit square along with the view variables and then grid
  nodes more than too.far from the predictor variables are excluded.

col
  The colours for the facets of the plot. If this is NA then if se>0 the facets are
  transparent, otherwise the colour scheme specified in color is used. If col is
  not NA then it is used as the facet colour.

color
  the colour scheme to use for plots when se<=0. One of "topo", "heat", "cm",
  "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors
  used when se>0.

contour.col
  sets the colour of contours when using plot.type="contour". Default scheme
  used if NULL.

se
  if less than or equal to zero then only the predicted surface is plotted, but if
  greater than zero, then 3 surfaces are plotted, one at the predicted values minus
  se standard errors, one at the predicted values and one at the predicted values
  plus se standard errors.

type
  "link" to plot on linear predictor scale and "response" to plot on the response
  scale.

plot.type
  one of "contour" or "persp".

zlim
  a two item array giving the lower and upper limits for the z-axis scale. NULL to
  choose automatically.

nCol
  The number of colors to use in color schemes.

lp
  selects the linear predictor for models with more than one.

... other options to pass on to persp, image or contour. In particular
  ticktype="detailed" will add proper axes labelling to the plots.
Details

The x and y limits are determined by the ranges of the terms named in view. If se<=0 then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- se standard errors. Parts of the x-y plane too far from data can be excluded by setting too.far

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the default values used by vis.gam.

Value

Simply produces a plot.

WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a view variable. When setting default view variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

**XWXd**

Internal functions for discretized model matrix handling

**Description**

Routines for computing with discretized model matrices as described in Wood et al. (2017) and Li and Wood (2019).

**Usage**

```
XWXd(X,w,k,ks,ts,dt,v,qc,nthreads=1,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,lt=NULL,rt=NULL)
XWyd(X,w,y,k,ks,ts,dt,v,qc,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,lt=NULL)
Xbd(X,beta,k,ks,ts,dt,v,qc,drop=NULL,lt=NULL)
diagXVXd(X,V,k,ks,ts,dt,v,qc,drop=NULL,nthreads=1,lt=NULL,rt=NULL)
```

**Arguments**

- **X**: A list of the matrices containing the unique rows of model matrices for terms of a full model matrix, or the model matrices of the terms margins. If term subsetting arguments `lt` and `rt` are non-NULL then this requires an "lpip" attribute: see details. The elements of `X` may be sparse matrices of class "dgCMatrix", in which case the list requires attributes "r" and "off" defining reverse indices (see details).
- **w**: An n-vector of weights
- **y**: n-vector of data.
- **beta**: coefficient vector.
- **k**: A matrix whose columns are index n-vectors each selecting the rows of an `X[[i]]` required to create the full matrix.
- **ks**: The ith term has index vectors `ks[i,1]:ks[i,2]-1`. The corresponding full model matrices are summed over.
The element of $X$ at which each model term starts.

How many elements of $X$ contribute to each term.

$v[i]$ is Householder vector for $i$th term, if $qc[i]>0$.

if $qc[i]>0$ then term has a constraint.

number of threads to use

list of columns of model matrix/parameters to drop

Negative to ignore. Otherwise sum rows $\left(\text{ar.stop}[i-1]+1:\text{ar.stop}[i]\right)$ of the rows selected by $\text{ar.row}$ and weighted by $\text{ar.w}$ to get $i$th row of model matrix to use.

extract these rows...

weight by these weights, and sum up according to $\text{ar.stop}$. Used to implement AR models.

use only columns of $X$ corresponding to these model matrix terms (for left hand $X$ in $XWXd$). If NULL set to $\text{rt}$.

as $\text{lt}$ for right hand $X$. If NULL set to $\text{lt}$. If $\text{lt}$ and $\text{rt}$ are NULL use all columns.

Coefficient covariance matrix.

Details

These functions are really intended to be internal, but are exported so that they can be used in the initialization code of families without problem. They are primarily used by $\text{bam}$ to implement the methods given in the references. $XWXd$ produces $X^TWX$, $XWy$ produces $X^TWy$, $Xbd$ produces $X\beta$ and $\text{diag}XVX^T$ produces the diagonal of $XVX^T$.

The "lpip" attribute of $X$ is a list of the coefficient indices for each term. Required if subsetting via $\text{lt}$ and $\text{rt}$.

$X$ can be a list of sparse matrices of class "dgCMatrix", in which case reverse indices are needed, mapping stored matrix rows to rows in the full matrix (that is the reverse of $k$ which maps full matrix rows to the stored unique matrix rows). $r$ is the same dimension as $k$ while $\text{off}$ is a list with as many elements as $k$ has columns. $r$ and $\text{off}$ are supplied as attributes to $X$. For simplicity let $r$ and codeoff denote a single column and element corresponding to each other: then $\text{coder[\text{off}[j]:\text{off}[j+1]-1]}$ contains the rows of the full matrix corresponding to row $j$ of the stored matrix. The reverse indices are essential for efficient computation with sparse matrices. See the example code for how to create them efficiently from the forward index matrix, $k$.

GAM zero-inflated (hurdle) Poisson regression family

Description
Family for use with gam or bam, implementing regression for zero inflated Poisson data when the complimentary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

Usage
