Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See `te`, `smooth.construct` and `smooth.terms`.

Value

An object of class "tensor.smooth". See `smooth.construct`, for the elements that this object will contain.

```
Description

gam can use isotropic smooths of any number of variables, specified via terms like $s(x,z,bs="tp",m=3)$ (or just $s(x,z)$ as this is the default basis). These terms are based on thin plate regression splines. m specifies the order of the derivatives in the thin plate spline penalty.

If m is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth: this is useful if you need to test whether a smooth could be replaced by a linear term, or construct models with odd nesting structures.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample max.knots unique data locations if there are more than max.knots such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). max.knots is 2000, by default. Both seed and max.knots can be modified using the xt argument to s. Alternatively the user can supply knots from which to construct a basis.

The “ts” smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

Usage

```r
## S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

Arguments

- **object**: a smooth specification object, usually generated by a term $s(...,bs="tp",...)$ or $s(...,bs="ts",...)$
- **data**: a list containing just the data (including any by variable) required by this term, with names corresponding to object$term and object$by. The by variable is the last element.
- **knots**: a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL

Details

The default basis dimension for this class is $k=M+k.def$ where $M$ is the null space dimension (dimension of unpenalized function space) and $k.def$ is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choise, provided it is not so small that it forces oversmoothing (the smoother’s degrees of freedom are controlled primarily by its smoothing parameter).
The default is to set $m$ (the order of derivative in the thin plate spline penalty) to the smallest value satisfying $2m > d + 1$ where $d$ if the number of covariates of the term: this yields ‘visually smooth’ functions. In any case $2m > d$ must be satisfied.

The constructor is not normally called directly, but is rather used internally by \texttt{gam}. To use for basis setup it is recommended to use \texttt{smooth.construct2}.

For these classes the specification object will contain information on how to handle large datasets in their \texttt{xt} field. The default is to randomly subsample 2000 ‘knots’ from which to produce a tprs basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the \texttt{xt} argument to \texttt{s}. This is supplied as a list with elements \texttt{max.knots} and \texttt{seed} containing a number to use in place of 2000, and the random number seed to use (either can be missing).

For these bases \texttt{knots} has two uses. Firstly, as mentioned already, for large datasets the calculation of the \texttt{tp} basis can be time-consuming. The user can retain most of the advantages of the t.p.r.s. approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, $k$. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds \texttt{max.knots}. The second possibility is to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, $k$. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggliness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the peturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Value

An object of class \texttt{"tprs.smooth"} or \texttt{"ts.smooth"}. In addition to the usual elements of a smooth class documented under \texttt{smooth.construct}, this object will contain:

\begin{itemize}
  \item \texttt{shift} A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
  \item \texttt{Xu} A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
  \item \texttt{UZ} The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.
  \item \texttt{null.space.dimension} The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.
\end{itemize}

**smooth.info**

Generic function to provide extra information about smooth specification

---

**Description**

Takes a smooth specification object and adds extra basis specific information to it before smooth constructor called. Default method returns supplied object unmodified.

**Usage**

`smooth.info(object)`

**Arguments**

- `object` is a smooth specification object
smooth.terms

Details

Sometimes it is necessary to know something about a smoother before it is constructed, beyond what is in the initial smooth specification object. For example, some smooth terms could be set up as tensor product smooths and it is useful for bam to take advantage of this when discrete covariate methods are used. However, bam needs to know whether a smoother falls into this category before it is constructed in order to discretize its covariates marginally instead of jointly. Rather than bam having a hard coded list of such smooth classes it is preferable for the smooth specification object to report this themselves. smooth.info method functions are the means for achieving this. When interpreting a gam formula the smooth.info function is applied to each smooth specification object as soon as it is produced (in interpret.gam).

Value

A smooth specification object, which may be modified in some way.

smooth.terms Smooth terms in GAM

Description

Smooth terms are specified in a gam formula using s, te, ti and t2 terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see user.defined.smooth). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by s terms, or as building blocks for tensor product smoothing via te, ti or t2 terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the mgcv package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).
Note that smooths can be used rather flexibly in `gam` models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in `linear.functional.terms`.

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** bs="tp". These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See `tprs` for further details.

bs="ts" is as "tp" but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.

**Duchon splines** bs="ds". These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See `Duchon.spline` for further details.

**Cubic regression splines** bs="cr". These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see `cubic.regression.spline` and e.g. Wood (2017).

bs="cs" specifies a shrinkage version of "cr".

bs="cc" specifies a cyclic cubic regression splines (see `cyclic.cubic.spline`). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**Splines on the sphere** bs="sos". These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See `Spherical.Spline` for details.

**B-splines** bs="bs" B-spline basis with integrated squared derivative penalties. The order of basis and penalty can be chosen separately, and several penalties of different orders can be applied. Somewhat like a derivative penalty version of P-splines. See `b.spline` for details.

**P-splines** bs="ps". These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

bs="cp" gives a cyclic version of a P-spline (see `cyclic.p.spline`).

**Random effects** bs="re". These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See `smooth.construct.re.smooth.spec`.

**Markov Random Fields** bs="mrf". These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See `mrf` for details and an example.
**Gaussian process smooths** bs="gp". Gaussian process models with a variety of simple correlation functions can be represented as smooths. See `gp.smooth` for details.

**Soap film smooths** bs="so" (actually not single penalized, but bs="sw" and bs="sf" allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See `soap` for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations. All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via `te`, `ti` or `t2` terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions.

**te** te smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See Wood (2006).

**ti** ti smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable an interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predicto $f_1(x) + f_2(z) + f_3(x, z)$, we might use model formula $y = s(x) + s(z) + ti(x, z)$ or $y = ti(x) + ti(z) + ti(x, z)$. A similar construction involving te terms instead will be much less statistically stable.

**t2** t2 uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the gamm4 package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See Wood, Scheipl and Faraway (2012/13).

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see te for an example of this). Note that te terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

**Adaptive smoothers** bs="ad" Univariate and bivariate adaptive smooths are available (see `adaptive.smooth`). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by gamm.

**Factor smooth interactions** bs="sz" Smooth factor interactions (see `factor.smooth`) are often produced using by variables (see `gam.models`), but it is often desirable to include smooths which represent the deviations from some main effect smooth that apply for each level of a factor (or combination of factors). See `smooth.construct.sz.smooth.spec` for details.
Random factor smooth interactions \( \text{bs} = \text{"fs"} \) A special smoother class (see \text{smooth.construct.fs.smooth.spec}) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The “fs” smoothers are set up to be efficient when used with \text{gamm}, and have penalties on each null space component (i.e. they are fully ‘random effects’).

smooth2random \text{smooth2random}

Convert a smooth to a form suitable for estimating as random effect

Description
A generic function for converting mgcv smooth objects to forms suitable for estimation as random effects by e.g. \text{lme}. Exported mostly for use by other package developers.
smooth2random

Usage

smooth2random(object, vnames, type=1)

Arguments

object an mgcv smooth object.
vnames a vector of names to avoid as dummy variable names in the random effects form.
type 1 for lme, otherwise lmer.

Details

There is a duality between smooths and random effects which means that smooths can be estimated using mixed modelling software. This function converts standard mgcv smooth objects to forms suitable for estimation by lme, for example. A service routine for gamm exported for use by package developers. See examples for creating prediction matrices for new data, corresponding to the random and fixed effect matrices returned when type=2.

Value

A list.

rand a list of random effects, including grouping factors, and a fixed effects matrix. Grouping factors, model matrix and model matrix name attached as attributes, to each element. Alternatively, for type=2 a list of random effect model matrices, each corresponding to an i.i.d. Gaussian random effect with a single variance component.

trans.U A matrix, trans.U, that transforms coeffs, in order [rand1, rand2,... fix] back to original parameterization. If null, then not needed. If null then taken as identity.

Xf A matrix for the fixed effects, if any.

fixed TRUE/FALSE, indicating if term was unpenalized or not. If unpenalized then other stuff may not be returned (it’s not a random effect).

rind an index vector such that if br is the vector of random coefficients for the term, br[rind] is the coeffs in order for this term.

pen.ind index of which penalty penalizes each coefficient: 0 for unpenalized.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

rangep(r$r$rand[[1]]-re$rand[[1]][1:10,])
smoothCon
Prediction/Construction wrapper functions for GAM smooth terms

Description
Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

Usage
smoothCon(object, data, knots=NULL, absorb.cons=FALSE, scale.penalty=TRUE, n=nrow(data), dataX=NULL, null.space.penalty=FALSE, sparse.cons=0, diagonal.penalty=FALSE, apply.by=TRUE, modCon=0)
PredictMat(object, data, n=nrow(data))

Arguments
object is a smooth specification object or a smooth object.
data A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it's a list then n must be supplied.
knots An optional data frame supplying any knot locations to be supplied for basis construction.
absorb.cons Set to TRUE in order to have identifiability constraints absorbed into the basis.
scale.penalty should the penalty coefficient matrix be scaled to have approximately the same ‘size’ as the inner product of the terms model matrix with itself? This can improve the performance of gamm fitting.
n number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if data is a list.
dataX Sometimes the basis should be set up using data in data, but the model matrix should be constructed with another set of data provided in dataX — n is assumed to be the same for both. Facilitates smooth id’s.
null.space.penalty Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.
apply.by set to FALSE to have basis setup exactly as in default case, but to return add an additional matrix X0 to the return object, containing the model matrix without the by variable, if a by variable is present. Useful for bam discrete method setup.
sparse.cons If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with bam). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint.
smoothCon

If TRUE then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix diagRP in the returned object for use by PredictMat.

modCon  force modification of any smooth supplied constraints. 0 - do nothing. 1 - delete supplied constraints, replacing with automatically generated ones. 2 - set fit and predict constraint to predict constraint. 3 - set fit and predict constraint to fit constraint.

Details

These wrapper functions exist to allow smooths specified using smooth.construct and Predict.matrix method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine’s also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object by..done. If this does not exist then smoothCon will use the default code. Similarly if a user defined Predict.matrix method handles by variables internally then the returned matrix should have a "by..done" attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix C of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix C should have no rows. There is an option to use centering constraint that generate no, or limited infill, if the smother has a sparse model matrix. smoothCon returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. smoothCon modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by PredictMat.

The parameterization used by gam can be controlled via gam.control.

Value

From smoothCon a list of smooth objects returned by the appropriate smooth.construct method function. If constraints are to be absorbed then the objects will have attributes "qrc" and "nCons". "nCons" is the number of constraints. "qrc" is usually the qr decomposition of the constraint matrix (returned by qr), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

with(mcycle,plot(times,accel)) ## plot data
lines(times,Xp%*%beta) ## overlay smooth
```

Description

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated `gam` object, provided the fit was with a method that evaluated the required Hessian.

Usage

```r
sp.vcov(x,edge.correct=TRUE,reg=1e-3)
```

Arguments

- `x` a fitted model object of class `gam` as produced by `gam()`.
- `edge.correct` if the model was fitted with `edge.correct=TRUE` (see `gam.control`), then the returned covariance matrix will be for the edge corrected log smoothing parameters.
- `reg` regularizer for Hessian - default is equivalent to prior variance of 1000 on log smoothing parameters.

Details

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.
spasm.construct

Value

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise NULL. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter. If edge.correct=TRUE and this was used in fitting then the edge corrected smoothing parameters are in attribute 1sp of the returned matrix.

step.gam       Alternatives to step.gam

Description

There is no step.gam in package mgcv. The mgcv default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows’ Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

Shrinkage smoothers are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see s)

Null space penalization An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggliness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The select argument to gam causes this latter approach to be used. Unpenalized terms (e.g. s(x,fx=TRUE)) remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

**summary.gam**

Summary for a GAM fit

**Description**

Takes a fitted `gam` object produced by `gam()` and produces various useful summaries from it. (See `sink` to divert output to a file.)

**Usage**

```r
## S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, re.test=TRUE, ...)

## S3 method for class 'summary.gam'
print(x,digits = max(3,getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"),...)
```
Arguments

- **object**: A fitted `gam` object as produced by `gam()`.
- **x**: A `summary.gam` object produced by `summary.gam()`.
- **dispersion**: A known dispersion parameter. `NULL` to use estimate or default (e.g. 1 for Poisson).
- **freq**: By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to `TRUE` then the frequentist covariance matrix of the parameters is used instead.
- **re.test**: Should tests be performed for random effect terms (including any term with a zero dimensional null space)? For large models these tests can be computationally expensive.
- **digits**: controls number of digits printed in output.
- **signif.stars**: Should significance stars be printed alongside output.
- **...**: other arguments.

Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix $\mathbf{A}$ for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let $\mathbf{P}_i$ be the matrix giving the parameters of the $i$th smooth when applied to the data (or pseudodata in the generalized case) and let $\mathbf{X}$ be the design matrix of the model. Then $\text{tr}(\mathbf{X} \mathbf{P}_i)$ is the edf for the $i$th term. Clearly this definition causes the edf's to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of $2\mathbf{A} - \mathbf{A} \mathbf{A}$. `print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka’s (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates. In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurvity).

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and
is otherwise rather similar to the results using the frequentist covariance matrix (freq=TRUE), since the parametric terms themselves are usually unpenalized. Default P-values for parametric terms that are penalized using the paraPen argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting freq=TRUE is appropriate.

**Value**

`summary.gam` produces a list of summary information for a fitted `gam` object.

- `p.coeff` is an array of estimates of the strictly parametric model coefficients.
- `p.t` is an array of the `p.coeff`'s divided by their standard errors.
- `p.pv` is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.
- `m` The number of smooth terms in the model.
- `chi.sq` An array of test statistics for assessing the significance of model smooth terms. See details.
- `s.pv` An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.
- `se` array of standard error estimates for all parameter estimates.
- `r.sq` The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that `r.sq` does not include any offset in the one parameter model.
- `dev.expl` The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so `dev.expl` can be substantially lower than `r.sq` when an offset is present.
- `edf` array of estimated degrees of freedom for the model terms.
- `residual.df` estimated residual degrees of freedom.
- `n` number of data.
- `np` number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).
- `rank` apparent model rank.
- `method` The smoothing selection criterion used.
- `sp.criterion` The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.
- `scale` estimated (or given) scale parameter.
- `family` the family used.
- `formula` the original GAM formula.
- `dispersion` the scale parameter.
- `pTerms.df` the degrees of freedom associated with each parametric term (excluding the constant).
| **pTerms.chi.sq** | a Wald statistic for testing the null hypothesis that the each parametric term is zero. |
| **pTerms.pv** | p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not. |
| **cov.unscaled** | The estimated covariance matrix of the parameters (or estimators if `freq=TRUE`), divided by scale parameter. |
| **cov.scaled** | The estimated covariance matrix of the parameters (estimators if `freq=TRUE`). |
| **p.table** | significance table for parameters |
| **s.table** | significance table for smooths |
| **p.Terms** | significance table for parametric model terms |

**WARNING**

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

**t2**

---

**Define alternative tensor product smooths in GAM formulae**

### Description

Alternative to `te` for defining tensor product smooths in a `gam` formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl (mgcv implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with `gamm4` from package `gamm4`. 
Usage

t2(..., k=NA, bs="cr", m=NA, d=NA, by=NA, xt=NULL, id=NULL, sp=NULL, full=FALSE, ord=NULL, pc=NULL)

Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. t2(log(x), z) is fine, but t2(I(x/sd(x)), z) is not (see predict.gam).

k the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See choose.k for further information.

bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See smooth.terms for details and full list. User defined bases can also be used here (see smooth.construct for an example). If only one basis code is given then this is used for all bases.

m The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. p.spline and Duchon.spline), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set d=c(2,1). Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See gam.models for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see gam.models and linear.functional.terms for details).

xt Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

id A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

sp any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to gam. Ignored by gamm.
If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.

ord

an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.

pc

If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See identifiability.

Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See pen.edf for some further information.

Note that there are two ways to construct the product. When full=FALSE then the null space bases are treated as a whole in each product, but when full=TRUE each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.
Value

A class t2.smooth.spec object defining a tensor product smooth to be turned into a basis and penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

- **margin**: A list of smooth.spec objects of the type returned by `s`, defining the basis from which the tensor product smooth is constructed.
- **term**: An array of text strings giving the names of the covariates that the term is a function of.
- **by**: is the name of any by variable as text ("NA" for none).
- **fx**: logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.
- **label**: A suitable text label for this smooth term.
- **dim**: The dimension of the smoother - i.e. the number of covariates that it is a function of.
- **mp**: TRUE is multiple penalties are to be used (default).
- **np**: TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).
- **id**: the id argument supplied to `te`.
- **sp**: the sp argument supplied to `te`.

Define tensor product smooths or tensor product interactions in GAM formulae

Description

Functions used for the definition of tensor product smooths and interactions within gam model formulae. `te` produces a full tensor product smooth, while `ti` produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present.

The functions do not evaluate the smooth - they exist purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

Usage

```r
te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
   np=TRUE, xt=NULL, id=NULL, sp=NULL, pc=NULL)
ti(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
   np=TRUE, xt=NULL, id=NULL, sp=NULL, mc=NULL, pc=NULL)
```

Arguments

- `...`: a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `te(log(x), z)` is fine, but `te(I(x/sd(x)), z)` is not (see `predict.gam`).
- `k`: the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See `choose.k` for further information.
- `bs`: array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See `smooth.terms` for details and full list. User defined bases can also be used here (see `smooth.construct` for an example). If only one basis code is given then this is used for all bases.
- `m`: The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different `m` for each margin. For marginals that take vector `m` (e.g. `p.spline` and `Duchon.spline`), then a list can be supplied, with a vector element for each margin. NA autoinitializes. `m` is ignored by some bases (e.g. "cr").
- `d`: array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set `d=c(2,1)`. Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.
by a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See \texttt{gam.models} for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see \texttt{gam.models} and \texttt{linear.functional.terms} for details).

\textbf{fx} indicates whether the term is a fixed d.f. regression spline (\texttt{TRUE}) or a penalized regression spline (\texttt{FALSE}).

\textbf{np} \texttt{TRUE} to use the ‘normal parameterization’ for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at ‘knots’, spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.

\textbf{xt} Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

\textbf{id} A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).

\textbf{sp} any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to \texttt{gam}. Ignored by \texttt{gamm}.

\textbf{mc} For \texttt{ti} smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or \texttt{FALSE}/\texttt{TRUE} values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that ‘ti’ only applies constraints to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work.

\textbf{pc} If not \texttt{NULL}, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See \texttt{identifiability}.

**Details**

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in \texttt{tensor.prod.model.matrix} and \texttt{tensor.prod.penalties}, to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

\[ f_1(x) + f_2(z) + f_3(x, z) \]
This functional ANOVA decomposition is supported by \texttt{ti} terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the $\sim \texttt{ti}(x) + \texttt{ti}(z) + \texttt{ti}(x,z)$ would produce the above main effects + interaction structure. This is much better than attempting the same thing with \texttt{sr} or \texttt{te} terms representing the interactions (although mgcv does not forbid it). Technically \texttt{ti} terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework). See Wood (2017, section 5.6.3).

The 'normal parameterization' (\texttt{np=TRUE}) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability when used with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set \texttt{np=FALSE}.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

\textbf{Value}

A class \texttt{tensor.smooth.spec} object defining a tensor product smooth to be turned into a basis and penalties by the \texttt{smooth.construct.tensor.smooth.spec} function.

The returned object contains the following items:

\begin{itemize}
  \item \texttt{margin} \hspace{1cm} A list of \texttt{smooth.spec} objects of the type returned by \texttt{s}, defining the basis from which the tensor product smooth is constructed.
  \item \texttt{term} \hspace{1cm} An array of text strings giving the names of the covariates that the term is a function of.
  \item \texttt{by} \hspace{1cm} is the name of any by variable as text ("NA" for none).
  \item \texttt{fx} \hspace{1cm} logical array with element for each penalty of the term (tensor product smooths have multiple penalties). \texttt{TRUE} if the penalty is to be ignored, \texttt{FALSE}, otherwise.
  \item \texttt{label} \hspace{1cm} A suitable text label for this smooth term.
  \item \texttt{dim} \hspace{1cm} The dimension of the smoother - i.e. the number of covariates that it is a function of.
  \item \texttt{mp} \hspace{1cm} \texttt{TRUE} is multiple penalties are to be used (default).
  \item \texttt{np} \hspace{1cm} \texttt{TRUE} to re-parameterize 1-D marginal smooths in terms of function values (default).
  \item \texttt{id} \hspace{1cm} the \texttt{id} argument supplied to \texttt{te}.
  \item \texttt{sp} \hspace{1cm} the \texttt{sp} argument supplied to \texttt{te}.
  \item \texttt{inter} \hspace{1cm} \texttt{TRUE} if the term was generated by \texttt{ti}, \texttt{FALSE} otherwise.
  \item \texttt{mc} \hspace{1cm} the argument \texttt{mc} supplied to \texttt{ti}.
\end{itemize}

## tensor.prod.model.matrix

### Row Kronecker product/ tensor product smooth construction

**Description**

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth (marginals and results can be sparse). The model matrix construction uses row Kronecker products.

**Usage**

```
tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
```

**Arguments**

- `X`: a list of model matrices for the marginal bases of a smooth. Items can be class "matrix" or "dgCMatrix", but not a mixture of the two.
- `S`: a list of penalties for the marginal bases of a smooth.
- `a`: a matrix with the same number of rows as `A`.
- `b`: a matrix with the same number of rows as `B`.

**Details**

If `X[1], X[2], ..., X[m]` are the model matrices of the marginal bases of a tensor product smooth then the ith row of the model matrix for the whole tensor product smooth is given by `X[1][i,] %x% X[2][i,] %x% ... X[m][i,]`, where `%x%` is the Kronecker product. Of course the routine operates column-wise, not row-wise!

`A %x% B` is the operator form of this 'row Kronecker product'.

If `S[1], S[2], ..., S[m]` are the penalty matrices for the marginal bases, and `I[1], I[2], ..., I[m]` are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has m associate penalties of the form:

- `S[1] %x% I[2] %x% ... I[m],`
- `I[1] %x% S[2] %x% ... I[m],`
- `...`
- `I[1] %x% I[2] %x% ... S[m].`

Of course it's important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.
Value

Either a single model matrix for a tensor product smooth (of the same class as the marginals), or a
list of penalty terms for a tensor product smooth.

totalPenaltySpace

Obtaining (orthogonal) basis for null space and range of the penalty
matrix

Description

INTERNAL function to obtain (orthogonal) basis for the null space and range space of the penalty,
and obtain actual null space dimension components are roughly rescaled to avoid any dominating.

Usage

totalPenaltySpace(S, H, off, p)
**Arguments**

- **S**: a list of penalty matrices, in packed form.
- **H**: the coefficient matrix of an user supplied fixed quadratic penalty on the parameters of the GAM.
- **off**: a vector where the i-th element is the offset for the i-th matrix.
- **p**: total number of parameters.

**Value**

A list of matrix square roots such that \( S[[1]] = B[[1]] \%\% t(B[[1]]) \).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

---

**trichol**

*Choleski decomposition of a tri-diagonal matrix*

**Description**

Computes Choleski decomposition of a (symmetric positive definite) tri-diagonal matrix stored as a leading diagonal and sub/super diagonal.

**Usage**

`trichol(ld, sd)`

**Arguments**

- **ld**: leading diagonal of matrix
- **sd**: sub-super diagonal of matrix

**Details**

Calls `dpttrf` from LAPACK. The point of this is that it has \( O(n) \) computational cost, rather than the \( O(n^3) \) required by dense matrix methods.

**Value**

A list with elements `ld` and `sd`. `ld` is the leading diagonal and `sd` is the super diagonal of bidiagonal matrix `B` where `B^T B = T` and `T` is the original tridiagonal matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

trind.generator

Generates index arrays for upper triangular storage

Description

Generates index arrays for upper triangular storage up to order four. Useful when working with higher order derivatives, which generate symmetric arrays. Mainly intended for internal use.

Usage

trind.generator(K = 2, ifunc=FALSE, reverse= !ifunc)

Arguments

K
positive integer determining the size of the array.

ifunc
if TRUE index functions are returned in place of index arrays.

reverse
should the reverse indices be computed? Probably not if ifunc==TRUE.

Details

Suppose that m=1 and you fill an array using code like for(i in 1:K) for(j in i:K) for(k in j:K) for(l in k:K) {a[,m] <- something; m <- m+1} and do this because actually the same "something" would be stored for any permutation of the indices i,j,k,l. Clearly in storage we have the restriction l>=k>=j>=i, but for access we want no restriction on the indices. 14[i,j,k,l] produces the appropriate m for unrestricted indices. 13 and i2 do the same for 3d and 2d arrays. If ifunc==TRUE then 12, 13 and 14 are functions, so 14(i,j,k,1) returns appropriate m. For high K the function versions save storage, but are slower.

If computed, the reverse indices pick out the unique elements of a symmetric array stored redundantly. The indices refer to the location of the elements when the redundant array is accessed as its underlying vector. For example the reverse indices for a 3 by 3 symmetric matrix are 1,2,3,5,6,9.
Value

A list where the entries $i_1$ to $i_4$ are arrays in up to four dimensions, containing $K$ indexes along each dimension. If $\text{ifunc}==\text{TRUE}$ index functions are returned in place of index arrays. If $\text{reverse}==\text{TRUE}$ reverse indices $i_1r$ to $i_4r$ are returned (always as arrays).

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

Examples

```r
library(mgcv)
A <- trind.generator(3,reverse=TRUE)

# All permutations of c(1, 2, 3) point to the same index (5)
A$i3[1, 2, 3]
A$i3[2, 1, 3]
A$i3[2, 3, 1]
A$i3[3, 1, 2]
A$i3[1, 3, 2]

## use reverse indices to pick out unique elements
## just for illustration...
A$i2[A$i2[A$i2r]]
A$i3[A$i3r]

## same again using function indices...
A <- trind.generator(3,ifunc=TRUE)
A$i3(1, 2, 3)
A$i3(2, 1, 3)
A$i3(2, 3, 1)
A$i3(3, 1, 2)
A$i3(1, 3, 2)
```

Tweedie

GAM Tweedie families

Description

Tweedie families, designed for use with `gam` from the mgcv library. Restricted to variance function powers between 1 and 2. A useful alternative to `quasi` when a full likelihood is desirable. Tweedie is for use with fixed $p$. `tw` is for use when $p$ is to be estimated during fitting. For fixed $p$ between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power $p$.

`tw` is only useable with `gam` and `bam` but not `gamm`. Tweedie works with all three.

Usage

```r
Tweedie(p=1, link = power(0))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```
Arguments

- **p**: the variance of an observation is proportional to its mean to the power p. p must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.
- **link**: The link function: one of "log", "identity", "inverse", "sqrt", or a **power** link (Tweedie only).
- **theta**: Related to the Tweedie power parameter by \( p = \frac{(a + b \exp(\theta))}{1 + \exp(\theta)} \).
  - If this is supplied as a positive value then it is taken as the fixed value for p. If it is a negative values then its absolute value is taken as the initial value for p.
  - a: lower limit on p for optimization.
  - b: upper limit on p for optimization.

Details

A Tweedie random variable with 1<p<2 is a sum of N gamma random variables where N has a Poisson distribution. The p=1 case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For 1<p<2 the distribution is supported on the positive reals with a point mass at zero. p=2 is a gamma distribution. As p gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at p=1, and is therefore highly multimodal. See 1dTweedie for more on this behaviour.

Tweedie is based partly on the poisson family, and partly on tweedie from the statmod package. It includes extra components to work with all mgcv GAM fitting methods as well as an aic function.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. \( p \) and the scale parameter. Without restricting \( p \) to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over quasi. If you need this case then the tweedie package is the place to start.

Value

For Tweedie, an object inheriting from class family, with additional elements

- **dvar**: the function giving the first derivative of the variance function w.r.t. mu.
- **d2var**: the function giving the second derivative of the variance function w.r.t. mu.
- **ls**: A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter.

For tw, an object of class extended.family.

Author(s)

Simon N. Wood <simon.wood@r-project.org>.

References

**twlss**

**Tweedie location scale family**

**Description**

Tweedie family in which the mean, power and scale parameters can all depend on smooth linear predictors. Restricted to estimation via the extended Fellner Schall method of Wood and Fasiolo (2017). Only usable with `gam`. Tweedie distributions are exponential family with variance given by $\phi \mu^p$ where $\phi$ is a scale parameter, $p$ a parameter (here between 1 and 2) and $\mu$ is the mean.

**Usage**

```r
twlss(link=list("log","identity","identity"),a=1.01,b=1.99)
```
Arguments

link  The link function list: currently no choice.

a     lower limit on the power parameter relating variance to mean.

b     upper limit on power parameter.

Details

A Tweedie random variable with 1<\(p<2\) is a sum of \(N\) gamma random variables where \(N\) has a Poisson distribution. The \(p=1\) case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For \(1<p<2\) the distribution is supported on the positive reals with a point mass at zero. \(p=2\) is a gamma distribution. As \(p\) gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at \(p=1\), and is therefore highly multimodal. See ldTweedie for more on this behaviour.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t. \(p\) and the scale parameter. Without restricting \(p\) to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over quasi. If you need this case then the tweedie package is the place to start.

Value

An object inheriting from class general.family.

---

### uniquecombs

**find the unique rows in a matrix**

#### Description

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit need not be the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

#### Usage

```r
uniquecombs(x, ordered=FALSE)
```

#### Arguments

- `x` is an `R` matrix (numeric), or data frame.
- `ordered` set to `TRUE` to have the rows of the returned object in the same order regardless of input ordering.

#### Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model.

When `x` has only one column then the routine uses `unique` and `match` to get the index. When there are multiple columns then it uses `paste0` to produce labels for each row, which should be unique if the row is unique. Then `unique` and `match` can be used as in the single column case. Obviously the pasting is inefficient, but still quicker for large `n` than the C based code that used to be called by this routine, which had O(nlog(n)) cost. In principle a hash table based solution in C would be only O(n) and much quicker in the multicolumn case.

`unique` and `duplicated`, can be used in place of this, if the full index is not needed. Relative performance is variable.

If `x` is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

#### Value

A matrix or data frame consisting of the unique rows of `x` (in arbitrary order).

The matrix or data frame has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row `i` of the original matrix.
WARNINGS

If a dataframe contains variables of a type other than numeric, logical, factor or character, which either have no as.character method, or whose as.character method is a many to one mapping, then the routine is likely to fail.

If the character representation of a dataframe variable (other than of class factor of character) contains * then in principle the method could fail (but with a warning).

stringsAsFactors=FALSE)
uniquecombs(df)

vcov.gam

Extract parameter (estimator) covariance matrix from GAM fit

Description

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted gam object.

Usage

## S3 method for class 'gam'
vcov(object, sandwich=FALSE, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)

vcov.gam
Arguments

object: fitted model object of class gam as produced by gam().
sandwich: compute sandwich estimate of covariance matrix. Currently expensive for discrete bam fits.
freq: TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters. The latter option includes the expected squared bias according to the Bayesian smoothing prior.
dispersion: a value for the dispersion parameter: not normally used.
unconditional: if TRUE (and freq==FALSE) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.
...: other arguments, currently ignored.

Details

Basically, just extracts object$Ve, object$Vp or object$Vc (if available) from a gamObject, unless sandwich==TRUE in which case the sandwich estimate is computed (with or without the squared bias component).

Value

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument freq.

Author(s)

Henric Nilsson. Maintained by Simon N. Wood <simon.wood@r-project.org>

gam

Examples

require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
vis.gam

Visualization of GAM objects

Description

Produces perspective or contour plot views of gam model predictions, fixing all but the values in view to the values supplied in cond.

Usage

vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA,
        color="heat", contour.col=NULL, se=-1, type="link",
        plot.type="persp", zlim=NULL, nCol=50, lp=1,...)

Arguments

x

a gam object, produced by gam()

view

an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won’t work as view variables, and vis.gam cannot detect that this has happened when setting defaults.

cond

a named list of the values to use for the other predictor terms (not in view). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occurring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median.

n.grid

The number of grid nodes in each direction used for calculating the plotted surface.

too.far

plot grid nodes that are too far from the points defined by the variables given in view can be excluded from the plot. too.far determines what is too far. The grid is scaled into the unit square along with the view variables and then grid nodes more than too.far from the predictor variables are excluded.

col

The colours for the facets of the plot. If this is NA then if se>0 the facets are transparent, otherwise the colour scheme specified in color is used. If col is not NA then it is used as the facet colour.

color

the colour scheme to use for plots when se<=0. One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when se>0.

contour.col

sets the colour of contours when using plot.type="contour". Default scheme used if NULL.

se

if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus se standard errors, one at the predicted values and one at the predicted values plus se standard errors.

type

"link" to plot on linear predictor scale and "response" to plot on the response scale.

plot.type

one of "contour" or "persp".
zlim a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.
nCol The number of colors to use in color schemes.
lp selects the linear predictor for models with more than one.
... other options to pass on to persp, image or contour. In particular ticktype="detailed" will add proper axes labelling to the plots.

Details

The x and y limits are determined by the ranges of the terms named in view. If se<=0 then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- se standard errors. Parts of the x-y plane too far from data can be excluded by setting too.far.

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the default values used by vis.gam.

Value

Simply produces a plot.

WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a view variable. When setting default view variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

### XWXd

**Description**

Routines for computing with discretized model matrices as described in Wood et al. (2017) and Li and Wood (2019).

**Usage**

```r
XWXd(X,w,k,ks,ts,dt,v,qc,nthreads=1,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,
     lt=NULL,rt=NULL)
XWyd(X,w,y,k,ks,ts,dt,v,qc,drop=NULL,ar.stop=-1,ar.row=-1,ar.w=-1,lt=NULL)
Xbd(X,beta,k,ks,ts,dt,v,qc,drop=NULL,lt=NULL)
diagXVXd(X,V,k,ks,ts,dt,v,qc,drop=NULL,nthreads=1,lt=NULL,rt=NULL)
```

**Arguments**

- **X**: A list of the matrices containing the unique rows of model matrices for terms of a full model matrix, or the model matrices of the terms margins. If term subsetting arguments `lt` and `rt` are non-NULL then this requires an "lpip" attribute: see details. The elements of `X` may be sparse matrices of class "dgCMatrix", in which case the list requires attributes "r" and "off" defining reverse indices (see details).

- **w**: An n-vector of weights
y n-vector of data.

beta coefficient vector.

k A matrix whose columns are index n-vectors each selecting the rows of an X[[i]] required to create the full matrix.

ks The ith term has index vectors ks[i,1]:((ks[i,1]-1)). The corresponding full model matrices are summed over.

ts The element of X at which each model term starts.

dt How many elements of X contribute to each term.

v v[i] is Householder vector for ith term, if qc[i]>0.

qc if qc[i]>0 then term has a constraint.

nthreads number of threads to use

drop list of columns of model matrix/parameters to drop

ar.stop Negative to ignore. Otherwise sum rows (ar.stop[i]+1):ar.stop[i] of the rows selected by ar.row and weighted by ar.w to get ith row of model matrix to use.

ar.row extract these rows...

ar.w weight by these weights, and sum up according to ar.stop. Used to implement AR models.

lt use only columns of X corresponding to these model matrix terms (for left hand X in XWXd). If NULL set to r.

rt as lt for right hand X. If NULL set to lt. If lt and rt are NULL use all columns.

V Coefficient covariance matrix.

Details

These functions are really intended to be internal, but are exported so that they can be used in the initialization code of families without problem. They are primarily used by bam to implement the methods given in the references. XWXd produces \( X^T W X \), \( XWy \) produces \( X^T W y \), Xbd produces \( X\beta \) and \( \text{diag}(XVXd) \) produces the diagonal of \( XVX^T \).

The "lpip" attribute of X is a list of the coefficient indices for each term. Required if subsetting via lt and rt.

X can be a list of sparse matrices of class "dgCMatrix", in which case reverse indices are needed, mapping stored matrix rows to rows in the full matrix (that is the reverse of k which maps full matrix rows to the stored unique matrix rows). r is the same dimension as k while off is a list with as many elements as k has columns. r and off are supplied as attributes to X. For simplicity let r and codeoff denote a single column and element corresponding to each other: then coder[off[j]:((off[j]+1)-1)] contains the rows of the full matrix corresponding to row j of the stored matrix. The reverse indices are essential for efficient computation with sparse matrices. See the example code for how to create them efficiently from the forward index matrix, k.

\textbf{Description}

Family for use with \texttt{gam} or \texttt{bam}, implementing regression for zero inflated Poisson data when the complimentary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

\textbf{Usage}

\texttt{ziP(theta = NULL, link = “identity”,b=0)}

\textbf{Arguments}

\texttt{theta} the 2 parameters controlling the slope and intercept of the linear transform of the mean controlling the zero inflation rate. If supplied then treated as fixed parameters (θ₁ and θ₂), otherwise estimated.

\texttt{link} The link function: only the “identity” is currently supported.

\texttt{b} a non-negative constant, specifying the minimum dependence of the zero inflation rate on the linear predictor.

\textbf{Details}

The probability of a zero count is given by 1 − p, whereas the probability of count \(y > 0\) is given by the truncated Poisson probability function \(p\mu^y/((\exp(\mu) - 1)y!)\). The linear predictor gives \(\log \mu\), while \(\eta = \log(-\log(1 - p))\) and \(\eta = \theta_1 + \{b + \exp(\theta_2)\} \log \mu\). The theta parameters are estimated alongside the smoothing parameters. Increasing the b parameter from zero can greatly reduce identifiability problems, particularly when there are very few non-zero data.

The fitted values for this model are the log of the Poisson parameter. Use the \texttt{predict} function with \texttt{type=”response”} to get the predicted expected response. Note that the theta parameters reported in model summaries are \(\theta_1\) and \(b + \exp(\theta_2)\).

These models should be subject to very careful checking, especially if fitting has not converged. It is quite easy to set up models with identifiability problems, particularly if the data are not really zero inflated, but simply have many zeroes because the mean is very low in some parts of the covariate space. See example for some obvious checks. Take convergence warnings seriously.
Value

An object of class extended.family.

WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes *given the model mean* may imply zero inflation.

plot(predict(b, type="response"), residuals(b))
plot(predict(b, type="response"), b$y); abline(0,1, col=2)
plot(b$linear.predictors, b$y)
qq.gam(b, rep=20, level=1)

## 3. Refit fixing the theta parameters at their estimated values, to check we
## get essentially the same fit...
thb <- b$family$getTheta()
b0 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=ziP(theta=thb), data=dat)
b; b0

## Example fit forcing minimum linkage of prob present and
## linear predictor. Can fix some identifiability problems.
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=ziP(b=.3), data=dat)

---

### ziplss

**Zero inflated (hurdle) Poisson location-scale model family**

**Description**

The ziplss family implements a zero inflated (hurdle) Poisson model in which one linear predictor controls the probability of presence and the other controls the mean given presence. Useable only with `gam`, the linear predictors are specified via a list of formulae. Should be used with care: simply having a large number of zeroes is not an indication of zero inflation.

Requires integer count data.

**Usage**

```r
ziplss(link=list("identity","identity"))
zipll(y,g,eta,deriv=0)
```

**Arguments**

- `link`: two item list specifying the link - currently only identity links are possible, as parameterization is directly in terms of log of Poisson response and logit of probability of presence.
- `y`: response
- `g`: gamma vector
- `eta`: eta vector
- `deriv`: number of derivatives to compute
Details

ziplss is used with `gam` to fit 2 stage zero inflated Poisson models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the Poisson parameter on the right hand side. The second is one sided, specifying the linear predictor for the probability of presence on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the log of the Poisson parameter, and the second column is the complementary log log of probability of presence. Predictions using `predict.gam` will also produce 2 column matrices for type “link” and "response".

The null deviance computed for this model assumes that a single probability of presence and a single Poisson parameter are estimated.

For data with large areas of covariate space over which the response is zero it may be advisable to use low order penalties to avoid problems. For 1D smooths uses e.g. `s(x,m=1)` and for isotropic smooths use `Duchon.splines` in place of thin plate terms with order 1 penalties e.g `s(x,z,m=c(1,.5))` — such smooths penalize towards constants, thereby avoiding extreme estimates when the data are uninformative.

zipl1 is a function used by ziplss, exported only to allow external use of the ziplss family. It is not usually called directly.

Value

For ziplss An object inheriting from class `general.family`.

WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes *given the model mean* may imply zero inflation.

Chapter 25

The nlme package

ACF

Autocorrelation Function

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls and lme.

Usage

ACF(object, maxLag, ...)

Arguments

object any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted.

maxLag maximum lag for which the autocorrelation should be calculated.

... some methods for this generic require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <Bates@stat.wisc.edu>

References

See Also

ACF.gls, ACF.lme, plot.ACF
Examples

## see the method function documentation

### ACF.gls

#### Autocorrelation Function for gls Residuals

**Description**

This method function calculates the empirical autocorrelation function for the residuals from a gls fit. If a grouping variable is specified in `form`, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```r
## S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

**Arguments**

- `object` an object inheriting from class "gls", representing a generalized least squares fitted model.
- `maxLag` an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.
- `resType` an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `form` an optional one sided formula of the form \(~ t\), or \(~ t | g\), specifying a time covariate t and, optionally, a grouping factor g. The time covariate must be integer valued. When a grouping factor is present in `form`, the autocorrelations are calculated using residual pairs within the same group. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.
- `na.action` a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes ACF.gls to print an error message and terminate if there are any incomplete observations.
- `...` some methods for this generic require additional arguments.

**Value**

A data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
ACF(fm1, form = ~ 1 | Mare)

# Pinheiro and Bates, p. 255-257
fm1Dial.gls <- gls(rate ~ (pressure+I(pressure^2)+I(pressure^3)+I(pressure^4))*QB, Dialyzer)

fm2Dial.gls <- update(fm1Dial.gls, weights = varPower(form = ~ pressure))

ACF(fm2Dial.gls, form = ~ 1 | Subject)

Description

This method function calculates the empirical autocorrelation function for the within-group residuals from an lme fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

Usage

## S3 method for class 'lme'  
ACF(object, maxLag, resType, ...)

Arguments

object an object inheriting from class "lme", representing a fitted linear mixed-effects model.
maxLag an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.
resType an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

... some methods for this generic require additional arguments – not used.
Alfalfa

Value

A data frame with columns lag and ACF representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

plot(ACF.fm1Over, alpha=0.01)

Alfalfa Split-Plot Experiment on Varieties of Alfalfa

Description

The Alfalfa data frame has 72 rows and 4 columns.

Format

This data frame contains the following columns:

Variety a factor with levels Cossack, Ladak, and Ranger
Date a factor with levels None S1 S20 07
Block a factor with levels 1 2 3 4 5 6
Yield a numeric vector
Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a 3x4 full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (Cossac, Ladak, and Ranger) were assigned randomly to the blocks and the dates of third cutting (None, S1—September 1, S20—September 20, and O7—October 7) were randomly assigned to the plots. All four dates were used on each block.

Source

Description

The extractor function is applied to each object in . . . , with the result being converted to a vector. A map attribute is included to indicate which pieces of the returned vector correspond to the original objects in dots.

Usage

allCoef(..., extract)

Arguments

... objects to which extract will be applied. Generally these will be model components, such as corStruct and varFunc objects.
extract an optional extractor function. Defaults to coef.

Value

a vector with all elements, generally coefficients, obtained by applying extract to the objects in . . . .

Author(s)

José' Pinheiro and Douglas Bates

See Also

lmeStruct, nlmeStruct

Examples

cs1 <- corAR1(0.1)
vf1 <- varPower(0.5)
allCoef(cs1, vf1)
Description

When only one fitted model object is present, a data frame with the numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms in not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic with the associated p-value is included in the returned data frame.

Usage

```
## S3 method for class 'gls'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

Arguments

- `object` an object inheriting from class "gls", representing a generalized least squares fit.
- `...` other optional fitted model objects inheriting from classes "gls","gnls","lm", "lme","lmList","nlme","nlsList", or "nls".
- `test` an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.
- `type` an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".
- `adjustSigma` an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by \(\sqrt{n_{\text{obs}}/(n_{\text{obs}} - n_{\text{par}})}\), converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
- `Terms` an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.
- `L` an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will
be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

verbose an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

Value a data frame inheriting from class "anova.lme".

Note Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

Compare Likelihoods of Fitted Objects

Description

When only one fitted model object is present, a data frame with the numerator degrees of freedom, denominator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms in not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic with the associated p-value is included in the returned data frame.

Usage

## S3 method for class 'lme'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
## S3 method for class 'anova.lme'
print(x, verbose, ...)

Arguments

object

an object inheriting from class "lme", representing a fitted linear mixed-effects model.

... other optional fitted model objects inheriting from classes "gls", "gnls", "lm", "lme", "lmList", "nlme", "nlsList", or "nls".
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in . . . . . Defaults to TRUE.</td>
</tr>
<tr>
<td>type</td>
<td>an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If &quot;sequential&quot;, the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if &quot;marginal&quot;, the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to &quot;sequential&quot;.</td>
</tr>
<tr>
<td>adjustSigma</td>
<td>an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{\hat{\sigma}^2/n_{\text{obs}}/(n_{\text{obs}}-n_{\text{par}})}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.</td>
</tr>
<tr>
<td>Terms</td>
<td>an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.</td>
</tr>
<tr>
<td>L</td>
<td>an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.</td>
</tr>
<tr>
<td>verbose</td>
<td>an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.</td>
</tr>
</tbody>
</table>

**Value**

a data frame inheriting from class "anova.lme".

**as.matrix.corStruct**  
*Matrix of a corStruct Object*

**Description**

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.
Usage

## S3 method for class 'corStruct'
as.matrix(x, ...)

Arguments

x an object inheriting from class "corStruct", representing a correlation structure.
...
further arguments passed from other methods.

Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

as.matrix.pdMat Matrix of a pdMat Object

Description

This method function extracts the positive-definite matrix represented by x.

Usage

## S3 method for class 'pdMat'
as.matrix(x, ...)

Arguments

x an object inheriting from class "pdMat", representing a positive-definite matrix.
...
further arguments passed from other methods.
as.matrix.reStruct

Description
This method function extracts the positive-definite matrices corresponding to the pdMat elements of object.

Usage
```r
## S3 method for class 'reStruct'
as.matrix(x, ...)
```

Arguments
- `x` an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `...` further arguments passed from other methods.

Value
a list with components given by the positive-definite matrices corresponding to the elements of object.

\textbf{asOneFormula} \hfill \textit{Combine Formulas of a Set of Objects}

\textbf{Description}

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

\textbf{Usage}

\begin{verbatim}
asOneFormula(..., omit)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item ... objects, or lists of objects, from which a formula can be extracted.
  \item omit an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(“.”, “pi”).
\end{itemize}

\textbf{Value}

a one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in omit.

asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))
\end{verbatim}
Assay data frame has 60 rows and 4 columns.

This data frame contains the following columns:

- **Block**: an ordered factor with levels 2 < 1 identifying the block where the wells are measured.
- **sample**: a factor with levels a to f identifying the sample corresponding to the well.
- **dilut**: a factor with levels 1 to 5 indicating the dilution applied to the well.
- **logDens**: a numeric vector of the log-optical density.

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

Source

---

`asTable` function:

Convert groupedData to a matrix

**Description**

Create a tabular representation of the response in a balanced groupedData object.

**Usage**

```R
asTable(object)
```

**Arguments**

- `object`: A balanced groupedData object
Details

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in `object`.

Value

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

groupedData, isBalanced, balancedGrouped

Examples

```r
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

Description

Predicted values are obtained at the specified values of `primary`. If `object` has a grouping structure (i.e. `getGroups(object)` is not NULL), predicted values are obtained for each group. If `level` has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides `primary` are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

```r
augPred(object, primary, minimum, maximum, length.out, ...)
```

## S3 method for class 'lme'

```r
augPred(object, primary = NULL,
        minimum = min(primary), maximum = max(primary),
        length.out = 51, level = Q, ...)
```
Arguments

- **object**: a fitted model object from which predictions can be extracted, using a `predict` method.
- **primary**: an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate `object` (using `getCovariate`), it will be used as `primary`.
- **minimum**: an optional lower limit for the primary covariate. Defaults to `min(primary)`.
- **maximum**: an optional upper limit for the primary covariate. Defaults to `max(primary)`.
- **length.out**: an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
- **level**: an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.
- ... some methods for the generic may require additional arguments.

Value

A data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: `original` for the observed values and `predicted` (single or no grouping factor) or `predict.groupVar` (multiple levels of grouping), with `groupVar` replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class "augPred".

Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

balancedGrouped

Create a groupedData object from a matrix

Description

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

Usage

balancedGrouped(form, data, labels=NULL, units=NULL)

Arguments

form
A formula of the form y ~ x | g giving the name of the response, the primary covariate, and the grouping factor.

data
A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate.

labels
an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.

units
an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.

Value

A balanced groupedData object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

units = list(x = "(yr)", y = "(mm)"))
Orth2[ 1:10, ]  ## check the first few entries

```r
# Pinheiro and Bates, p. 109
ergoStool.mat <- aTable(ergoStool)
balancedGrouped(effort~Type|Subject,
    data=ergoStool.mat)
```

### bdf

**Language scores**

**Description**

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

**Usage**

data(bdf)

**Format**

- `schoolNR` a factor denoting the school.
- `pupilNR` a factor denoting the pupil.
- `IQ.verb` a numeric vector of verbal IQ scores
- `IQ.perf` a numeric vector of IQ scores.
- `sex` Sex of the student.
- `Minority` a factor indicating if the student is a member of a minority group.
- `repeatgr` an ordered factor indicating if one or more grades have been repeated.
- `aritPRET` a numeric vector
- `classNR` a numeric vector
- `aritPOST` a numeric vector
- `langPRET` a numeric vector
- `langPOST` a numeric vector
- `ses` a numeric vector of socioeconomic status indicators.
- `denomina` a factor indicating if the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.
- `schoolSES` a numeric vector
- `satiprin` a numeric vector
- `natitest` a factor with levels 0 and 1
- `meetings` a numeric vector
- `currmeet` a numeric vector
- `mixedgra` a factor indicating if the class is a mixed-grade class.
- `permino` a numeric vector
- `aritdiff` a numeric vector
- `homework` a numeric vector
- `classsiz` a numeric vector
- `groupsiz` a numeric vector

BodyWeight

Rat weight over time for different diets

Description

The BodyWeight data frame has 176 rows and 4 columns.

Format

This data frame contains the following columns:

weight a numeric vector giving the body weight of the rat (grams).

Time a numeric vector giving the time at which the measurement is made (days).

Rat an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.

Diet a factor with levels 1 to 3 indicating the diet that the rat receives.

Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Source

Description

The Cefamandole data frame has 84 rows and 3 columns.

Format

This data frame contains the following columns:

- **Subject** a factor giving the subject from which the sample was drawn.
- **Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).
- **conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

Details

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

Source

Examples

plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "pdMat", "corStruct" and "varFunc" classes, "reStruct", and "modelStruct".

coefficients<- is an alias for coef<-.

Usage

coef(object, ...) <- value

coefficients(object, ...) <- value
Arguments

object any object representing a fitted model, or, by default, any object with a coef component.

... some methods for this generic function may require additional arguments.

value a value to be assigned to the coefficients associated with object.

Value

will depend on the method function; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`coef`

Description

This method function extracts the coefficients associated with the correlation structure represented by object.

Usage

## S3 method for class 'corStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'corStruct'
coef(object, ...) <- value

Arguments

object an object inheriting from class "corStruct", representing a correlation structure.

unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.

value a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef(object) and must be given in unconstrained form.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to object.
SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using Initialize) before new values can be assigned to its coefficients.

Author(s)

José Pinheiro and Douglas Bates

coef(cst1)

describe_coef.gnls

Extract gnls Coefficients

Description

The estimated coefficients for the nonlinear model represented by object are extracted.

Usage

```r
## S3 method for class 'gnls'
coef(object, ...)
```

Arguments

- **object**: an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the estimated coefficients for the nonlinear model represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gnls
**Examples**

```r
def1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean, weights = varPower())
coef(def1)
```

**Description**

The estimated coefficients at level \( i \) are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to \( i \). The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

**Usage**

```r
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN, omitGroupingFactor, subset, ...)
```

**Arguments**

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `augFrame`: an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `level`: an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
- `which`: an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
The coefficients of each `lm` object in the object list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

**Value**

a data frame inheriting from class "coef.lme" with the estimated coefficients at level `level` and, optionally, other covariates summarized over groups. The returned object also inherits from classes "ranef.lme" and "data.frame".

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`lme`, `ranef.lme`, `plot.ranef.lme`, `gsummary`

**Examples**

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

---

**Description**

Extract `lmList` Coefficients

The coefficients of each `lm` object in the object list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

**Usage**

```r
# S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
     omitGroupingFactor, ...)
```
Arguments

object an object inheriting from class "lmList", representing a list of \texttt{lm} objects with a common model.

augFrame an optional logical value. If \texttt{TRUE}, the returned data frame is augmented with variables defined in the data frame used to produce \texttt{object}; else, if \texttt{FALSE}, only the coefficients are returned. Defaults to \texttt{FALSE}.

data an optional data frame with the variables to be used for augmenting the returned data frame when \texttt{augFrame = TRUE}. Defaults to the data frame used to fit \texttt{object}.

which an optional positive integer or character vector specifying which columns of the data frame used to produce \texttt{object} should be used in the augmentation of the returned data frame. Defaults to all variables in the data.

FUN an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If \texttt{FUN} is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If \texttt{FUN} is a list of functions, the names in the list should designate classes of variables in the frame such as \texttt{ordered}, \texttt{factor}, or \texttt{numeric}. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are \texttt{mean} for numeric factors, and \texttt{Mode} for both \texttt{factor} and \texttt{ordered}. The \texttt{Mode} function, defined internally in \texttt{gsummary}, returns the modal or most popular value of the variable. It is different from the \texttt{mode} function that returns the S-language \texttt{mode} function.

omitGroupingFactor an optional logical value. When \texttt{TRUE} the grouping factor itself will be omitted from the group-wise summary of \texttt{data} but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to \texttt{FALSE}.

... some methods for this generic require additional arguments. None are used in this method.

Value

a data frame inheriting from class "coef.lmList" with the estimated coefficients for each "lm" component of \texttt{object} and, optionally, other covariates summarized over the groups corresponding to the "lm" components. The returned object also inherits from classes "ranef.lmList" and "\texttt{data.frame}".

**coef.modelStruct**

*Extract modelStruct Object Coefficients*

**Description**

This method function extracts the coefficients associated with each component of the `modelStruct` list.

**Usage**

```r
## S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

**Arguments**

- **object**: an object inheriting from class "modelStruct", representing a list of model components, such as "corStruct" and "varFunc" objects.
- **unconstrained**: a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
- **value**: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with all coefficients corresponding to the components of `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`Initialize`
Examples

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                  corStruct = corAR1(0.3))
coef(lms1)
```

Description

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

Usage

```r
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class "pdMat", representing a positive-definite matrix.
- `unconstrained`: a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to `TRUE`.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

coeff.reStruct

reStruct Object Coefficients

Description

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

Usage

## S3 method for class 'reStruct'
coef(object, unconstrained, ...)

## S3 replacement method for class 'reStruct'
coef(object, ...) <- value

Arguments

object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.

unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.

value a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef(object) and must be given in unconstrained form.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

coef.pdMat, reStruct, pdMat
Examples

```r
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
                   B = pdDiag(2 * diag(4), form = ~Educ)))
coef(rs1)
```

Description

This method function extracts the coefficients associated with the variance function structure represented by `object`.

Usage

```r
## S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent'
coef(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class `"varFunc"` representing a variance function structure.
- `unconstrained`: a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", generally constrained form. Defaults to `TRUE`.
- `allCoef`: a logical value. If `FALSE` only the coefficients which may vary during the optimization are returned. If `TRUE` all coefficients are returned. Defaults to `FALSE`.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be have the same length of `coef(object)` and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the coefficients corresponding to `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

coef(vf1) <- 2
```

collapse  

**Collapse According to Groups**

Description

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a `groupedData` method is available.

Usage

```
collapse(object, ...)
```

Arguments

- `object`: an object to be collapsed, usually a data frame.
- `...`: some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `collapse.groupedData`

Examples

```r
## see the method function documentation
```
Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

Usage

```r
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel, 
   outer, inner, preserve, FUN, subset, ...)
```

Arguments

- **object**: an object inheriting from class groupedData, generally with multiple grouping factors.
- **collapseLevel**: an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
- **displayLevel**: an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is collapseLevel.
- **outer**: an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor. If equal to TRUE, the displayLevel element `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.
- **inner**: an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor. If equal to TRUE, `attr(object, "outer")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.
- **preserve**: an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.
- **FUN**: an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables.
in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

subset

an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used.

...

some methods for this generic require additional arguments. None are used in this method.

Value

a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

**compareFits**  
*Compare Fitted Objects*

**Description**

The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

**Usage**

```
compareFits(object1, object2, which)
```

**Arguments**

- `object1, object2`
  - data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. lme and lmList objects).

- `which`
  - an optional integer or character vector indicating which columns in object1 and object2 are to be used in the returned object. Defaults to all columns.
Value

A three-dimensional array, with the third dimension given by the number of unique column names in either object1 or object2. To each column name there corresponds a matrix with as many rows as the rows in object1 and two columns, corresponding to object1 and object2. The returned object inherits from class compareFits.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

plot.compareFits, pairs.compareFits, comparePred, coef, random.effects

Examples

fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
(cF12 <- compareFits(coef(fm1), coef(fm2)))

description

Predicted values are obtained at the specified values of primary for each object. If either object1 or object2 have a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides primary are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

comparePred(object1, object2, primary, minimum, maximum,
            length.out, level, ...)

Arguments

object1,object2

Fitted model objects, from which predictions can be extracted using the predict method.

primary

An optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using getCovariate), it will be used as primary.

minimum

An optional lower limit for the primary covariate. Defaults to min(primary), after primary is evaluated in the data used in fitting object1.

maximum

An optional upper limit for the primary covariate. Defaults to max(primary), after primary is evaluated in the data used in fitting object1.
length.out an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.

level an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.

... some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects’ names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes comparePred and augPred.

Note

This function is generic: method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

```

---

corAR1 AR(1) Correlation Structure

Description

This function is a constructor for the corAR1 class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corAR1(value, form, fixed)
Correlation structure for a univariate series

Arguments

- **value**: the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).
- **form**: a one sided formula of the form \(\sim t\), or \(\sim t \mid g\), specifying a time covariate \(t\) and, optionally, a grouping factor \(g\). A covariate for this correlation structure must be integer valued. When a grouping factor is present in \(form\), the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(\sim 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

Value

An object of class `corAR1`, representing an autocorrelation structure of order 1.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**corARMA**

**ARMA(p,q) Correlation Structure**

**Description**

This function is a constructor for the corARMA class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

corARMA(value, form, p, q, fixed)

**Arguments**

- **value**
  a vector with the values of the autoregressive and moving average parameters, which must have length p + q and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.

- **form**
  a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **p, q**
  non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.

- **fixed**
  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.
corARMA

Value

an object of class corARMA, representing an autocorrelation-moving average correlation structure.

```
corCAR1

Continuous AR(1) Correlation Structure

Description

This function is a constructor for the corCAR1 class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate Initialize method.

Usage

corCAR1(value, form, fixed)

Arguments

value the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.
form a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. Covariates for this correlation structure need not be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corCAR1, representing an autocorrelation structure of order 1, with a continuous time covariate.

### `corClasses`  
**Correlation Structure Classes**

**Description**

Standard classes of correlation structures (`corStruct`) available in the `nlme` package.

**Value**

Available standard classes:

- `corAR1`: autoregressive process of order 1.
- `corARMA`: autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components.
- `corCAR1`: continuous autoregressive process (AR(1) process for a continuous time covariate).
- `corCompSymm`: compound symmetry structure corresponding to a constant correlation.
- `corExp`: exponential spatial correlation.
- `corGaus`: Gaussian spatial correlation.
- `corLin`: linear spatial correlation.
- `corRatio`: Rational quadratics spatial correlation.
- `corSpher`: spherical spatial correlation.
- `corSymm`: general correlation matrix, with no additional structure.

**Note**

Users may define their own `corStruct` classes by specifying a constructor function and, at a minimum, methods for the functions `corMatrix` and `coef`. For examples of these functions, see the methods for classes `corSymm` and `corAR1`.

**Author(s)**

José Pinheiro and Douglas Bates `<bates@stat.wisc.edu>`

**References**

corCompSymm

**Compound Symmetry Correlation Structure**

**Description**

This function is a constructor for the corCompSymm class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

corCompSymm(value, form, fixed)

**Arguments**

- **value**: the correlation between any two correlated observations. Defaults to 0.
- **form**: a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

**Value**

an object of class corCompSymm, representing a compound symmetry correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

corClasses, Initialize.corStruct, summary.corStruct
Examples

```r
## covariate is observation order and grouping factor is Subject
cs1 <- corCompSymm(0.5, form = ~ 1 | Subject)

# Pinheiro and Bates, pp. 222-225
fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())

# p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)

## Print/Summary methods for the empty case:
(cCS <- corCompSymm()) # Uninitialized correlation struct..
summary(cCS)
```

---

**corExp**  
**Exponential Correlation Structure**

**Description**

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-r/d)$ when no nugget effect is present and $(1-n)\exp(-r/d)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```r
corExp(value, form, nugget, metric, fixed)
```

**Arguments**

- `value`: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, value can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- `form`: a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
**corExp**

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.
- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

**Value**

An object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

---

**corFactor**

*Factor of a Correlation Matrix*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

**Usage**

`corFactor(object, ...)`

**Arguments**

- `object`  
an object from which a correlation matrix can be extracted.
- `...`  
some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`corFactor.corStruct, recalc.corStruct`

**Examples**

### see the method function documentation
corFactor.corStruct

Factor of a corStruct Object Matrix

Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse
square-root factors, of the correlation matrix, or list of correlation matrices, represented by object.
Letting Σ denote a correlation matrix, a square-root factor of Σ is any square matrix L such that
Σ = L'L. This method extracts L⁻¹.

Usage

## S3 method for class 'corStruct'
corFactor(object, ...)

Arguments

object an object inheriting from class "corStruct" representing a correlation structure, which must have been initialized (using Initialize).

... some methods for this generic require additional arguments. None are used in this method.

Value

If the correlation structure does not include a grouping factor, the returned value will be a vector
with a transpose inverse square-root factor of the correlation matrix associated with object stacked
column-wise. If the correlation structure includes a grouping factor, the returned value will be a
vector with transpose inverse square-root factors of the correlation matrices for each group, stacked
by group and stacked column-wise within each group.

Note

This method function is used intensively in optimization algorithms and its value is returned as
a vector for efficiency reasons. The corMatrix method function can be used to obtain transpose
inverse square-root factors in matrix form.

Examples

cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
**corGaus**  

**Gaussian Correlation Structure**

**Description**

This function is a constructor for the corGaus class, representing a Gaussian spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp\left(-\left(\frac{r}{d}\right)^2\right)$ when no nugget effect is present and $(1-n)\exp\left(-\left(\frac{r}{d}\right)^2\right)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate ‘Initialize method.

**Usage**

```r
corGaus(value, form, nugget, metric, fixed)
```

**Arguments**

- **value**
  - an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**
  - a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp | g`, specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**
  - an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

- **metric**
  - an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**
  - an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

an object of class `corGaus`, also inheriting from class `corSpatial`, representing a Gaussian spatial correlation structure.

corLin

Linear Correlation Structure

Description
This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting \(d\) denote the range and \(n\) denote the nugget effect, the correlation between two observations a distance \(r < d\) apart is \(1 - (r/d)\) when no nugget effect is present and \((1 - n)(1 - (r/d))\) when a nugget effect is assumed. If \(r \geq d\) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage
corLin(value, form, nugget, metric, fixed)
**corLin**

**Arguments**

- **value**: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form \(~ S1+\ldots+S_p\) or \(~ S1+\ldots+S_p \mid g\), specifying spatial covariates \(S_1\) through \(S_p\) and, optionally, a grouping factor \(g\). When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

- an object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

**corMatrix**  
*Extract Correlation Matrix*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

**Usage**

```r
corMatrix(object, ...)
```

**Arguments**

- `object`  
an object for which a correlation matrix can be extracted.
- `...`  
some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `corMatrix.corStruct`, `corMatrix.pdMat`

**Examples**

```r
## see the method function documentation
```
corMatrix.corStruct

Matrix of a corStruct Object

Description
This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to covariate and object. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L' L$. When $corr = \text{FALSE}$, this method extracts $L^{-t}$.

Usage

```r
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

Arguments

- **object**: an object inheriting from class "corStruct" representing a correlation structure.
- **covariate**: an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.
- **corr**: a logical value. If TRUE the function returns the correlation matrix, or list of correlation matrices, represented by object. If FALSE the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

corMatrix.pdMat

Extract Correlation Matrix from a pdMat Object

Description

The correlation matrix corresponding to the positive-definite matrix represented by object is obtained.

Usage

## S3 method for class 'pdMat'
corMatrix(object, ...)

Arguments

object an object inheriting from class "pdMat", representing a positive definite matrix.

... some methods for this generic require additional arguments. None are used in this method.

Value

the correlation matrix corresponding to the positive-definite matrix represented by object.

**corNatural** General correlation in natural parameterization

**Description**

This function is a constructor for the corNatural class, representing a general correlation structure in the “natural” parameterization, which is described under pdNatural. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```r
corNatural(value, form, fixed)
```

**Arguments**

- `value` an optional vector with the parameter values. Default is `numeric(0)`, which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

- `form` a one sided formula of the form `~ t`, or `~ t | g`, specifying a time covariate `t` and, optionally, a grouping factor `g`. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- `fixed` an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

an object of class corNatural representing a general correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

Initialize.corNatural, pdNatural, summary.corNatural

**Examples**

```r
## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
```
**Description**

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $1/(1 + (r/d)^2)$ when no nugget effect is present and $(1 - n)/(1 + (r/d)^2)$ when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

**Usage**

```r
corRatio(value, form, nugget, metric, fixed)
```

**Arguments**

- `value`: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- `form`: a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp | g`, specifying spatial covariates $S_1$ through $S_p$ and, optionally, a grouping factor $g$. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- `nugget`: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

- `metric`: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- `fixed`: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
                  random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())

# p 246
fm3BW.lme <- update(fm2BW.lme,
                     correlation = corExp(form = ~ Time))

# p. 249
fm5BW.lme <- update(fm3BW.lme, correlation =
                     corRatio(form = ~ Time))

# example gls(..., corRatio ...)
# Pinheiro and Bates, pp. 261, 263
fm1Wheat2 <- gls(yield ~ variety - 1, Wheat2)

# p. 263
fm3Wheat2 <- update(fm1Wheat2, corr =
                     corRatio(c(12.5, 0.2),
                              form = ~ latitude + longitude,
                              nugget = TRUE))
```

**corSpatial**

**Spatial Correlation Structure**

**Description**

This function is a constructor for the corSpatial class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: corExp, corGaus, corLin, corRatio, and corSpher. The returned object will inherit from one of these "real" classes, determined by the type argument, and from the "virtual" corSpatial class. Objects created using this constructor must later be initialized using the appropriate Initialize method.
corSpatial

Usage

corSpatial(value, form, nugget, type, metric, fixed)

Arguments

value
an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form
a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget
an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

type
an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions corSpher, corExp, corGaus, corLin, and corRatio for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".

metric
an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class determined by the type argument and also inheriting from class corSpatial, representing a spatial correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

sp1 <- corSpatial(form = ~ x + y + z, type = "g", metric = "man")
\end{verbatim}

---

**corSpher**

\textit{Spherical Correlation Structure}

**Description**

This function is a constructor for the \texttt{corSpher} class, representing a spherical spatial correlation structure. Letting \(d\) denote the range and \(n\) denote the nugget effect, the correlation between two observations a distance \(r < d\) apart is \(1 - 1.5(r/d) + 0.5(r/d)^2\) when no nugget effect is present and \((1 - n)(1 - 1.5(r/d) + 0.5(r/d)^2)\) when a nugget effect is assumed. If \(r \geq d\) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate \texttt{Initialize} method.

**Usage**

\begin{verbatim}
corSpher(value, form, nugget, metric, fixed)
\end{verbatim}

**Arguments**

- **value**: an optional vector with the parameter values in constrained form. If \texttt{nugget} is \texttt{FALSE}, value can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If \texttt{nugget} is \texttt{TRUE}, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to \texttt{numeric(0)}, which results in a range of 90\% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form \(~ S1+...+Sp\), or \(~ S1+...+Sp \mid g\), specifying spatial covariates \(S1\) through \(Sp\) and, optionally, a grouping factor \(g\). When a grouping factor is present in \texttt{form}, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to \texttt{FALSE}.
metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSpher, also inheriting from class corSpatial, representing a spherical spatial correlation structure.

corSymm

General Correlation Structure

Description

This function is a constructor for the corSymm class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corSymm(value, form, fixed)

Arguments

value
an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form
a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSymm representing a general correlation structure.

### Covariate Assign Covariate Values

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all “varFunc” classes.</td>
</tr>
</tbody>
</table>

### Usage

```r
covariate(object) <- value
```

### Arguments

- **object**: any object with a covariate component.
- **value**: a value to be assigned to the covariate associated with object.

### Value

- will depend on the method function; see the appropriate documentation.

covariate(vf1) <- Orthodont["age"]
Dialyzer

Description

The Dialyzer data frame has 140 rows and 5 columns.

Format

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject.
- **QB**: a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- **Pressure**: a numeric vector giving the transmembrane pressure (dmHg).
- **Rate**: the hemodialyzer ultrafiltration rate (mL/hr).
- **Index**: index of observation within subject—1 through 7.

Details

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dL/min or 300~dL/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

Dim

**Extract Dimensions from an Object**

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: "corSpatial", "corStruct", "pdCompSymm", "pdDiag", "pdIdent", "pdMat", and "pdSymm".

Usage

```
Dim(object, ...)
```
Arguments

object any object for which dimensions can be extracted.
... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Note

If dim allowed more than one argument, there would be no need for this generic function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Dim.pdMat, Dim.corStruct

Examples

## see the method function documentation

---

**Dim.corSpatial**

*Dimensions of a corSpatial Object*

Description

if groups is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

Usage

## S3 method for class 'corSpatial'
Dim(object, groups, ...)

Arguments

object an object inheriting from class "corSpatial", representing a spatial correlation structure.

groups an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.

... further arguments to be passed to or from methods.
Value

a list with components:

N  length of groups
M  number of groups
spClass  an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin
sumLenSq  sum of the squares of the number of observations per group
len  an integer vector with the number of observations per group
start  an integer vector with the starting position for the distance vectors in each group, beginning from zero

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Dim, Dim.corStruct

Examples

Dim(corGaus(), getGroups(Orthodont))
cs1ARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
cs1ARMA <- Initialize(cs1ARMA, data = Orthodont)
Dim(cs1ARMA)

---

Dim.corStruct  Dimensions of a corStruct Object

Description

if groups is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

Usage

## S3 method for class 'corStruct'
Dim(object, groups, ...)

Arguments

object  an object inheriting from class "corStruct", representing a correlation structure.
groups  an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
...  some methods for this generic require additional arguments. None are used in this method.
Dimensions of a pdMat Object

This method function returns the dimensions of the matrix represented by object.

## Usage

```r
## S3 method for class 'pdMat'
Dim(object, ...)
```

### Arguments

- `object` : an object inheriting from class "pdMat", representing a positive-definite matrix.
- `...` : some methods for this generic require additional arguments. None are used in this method.

### Value

an integer vector with the number of rows and columns of the matrix represented by object.

Dim

Examples

Dim(pdSymm(diag(3)))

<table>
<thead>
<tr>
<th>Earthquake</th>
<th>Earthquake Intensity</th>
</tr>
</thead>
</table>

Description

The Earthquake data frame has 182 rows and 5 columns.

Format

This data frame contains the following columns:

- **Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.
- **Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.
- **distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).
- **soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.
- **accel** maximum horizontal acceleration observed (g).

Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

Source

ergoStool  Ergometrics experiment with stool types

Description
The ergoStool data frame has 36 rows and 3 columns.

Format
This data frame contains the following columns:

- **effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.
- **Type** a factor with levels T1, T2, T3, and T4 giving the stool type.
- **Subject** an ordered factor giving a unique identifier for the subject in the experiment.

Details
Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

Source

Examples

```r
fm1 <-
  lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fm1 )
```

Fatigue  Cracks caused by metal fatigue

Description
The Fatigue data frame has 262 rows and 3 columns.

Format
This data frame contains the following columns:

- **Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.
- **cycles** number of test cycles at which the measurement is made (millions of cycles).
- **relLength** relative crack length (dimensionless).
Details

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

**fdHess**

*Finite difference Hessian*

---

**Description**

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

**Usage**

```r
fdHess(pars, fun, ..., 
       .relStep = .Machine$double.eps^(1/3), minAbsPar = 0)
```

**Arguments**

- **pars**
  - the numeric values of the parameters at which to evaluate the function `fun` and its derivatives.
- **fun**
  - a function depending on the parameters `pars` that returns a numeric scalar.
- **...**
  - Optional additional arguments to `fun`
- **.relStep**
  - The relative step size to use in the finite differences. It defaults to the cube root of `Machine$double.eps`
- **minAbsPar**
  - The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero.

**Details**

This function uses a second-order response surface design known as a “Koschal design” to determine the parameter values at which the function is evaluated.

**Value**

A list with components

- **mean**
  - the value of function `fun` evaluated at the parameter values `pars`
- **gradient**
  - an approximate gradient (of length `length(pars)`).
- **Hessian**
  - a matrix whose upper triangle contains an approximate Hessian.
Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

(fdH <- fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2]))))
stopifnot(length(fdH$ mean) == 1,
length(fdH$ gradient) == 2,
identical(dim(fdH$ Hessian), c(2L, 2L)))

Description

The fitted values for the linear model represented by object are extracted.

Usage

## S3 method for class 'glsStruct'
fitted(object, glsFit, ...)

Arguments

object an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.

object an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit")

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the fitted values for the linear model represented by object.

Note

This method function is generally only used inside gls and fitted.gls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, residuals.glsStruct
fitted.gnlsStruct  Calculate gnlsStruct Fitted Values

Description
The fitted values for the nonlinear model represented by object are extracted.

Usage
## S3 method for class 'gnlsStruct'
fitted(object, ...)

Arguments
- **object**: an object inheriting from class "gnlsStruct", representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value
a vector with the fitted values for the nonlinear model represented by object.

Note
This method function is generally only used inside gnls and fitted.gnls.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
gnls, residuals.gnlsStruct

fitted.lme  Extract lme Fitted Values

Description
The fitted values at level \( i \) are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to \( i \). The resulting values estimate the best linear unbiased predictions (BLUPs) at level \( i \).

Usage
## S3 method for class 'lme'
fitted(object, level, asList, ...)

...
Arguments

object  an object inheriting from class "lme", representing a fitted linear mixed-effects model.

level  an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

asList  an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE.

...  some methods for this generic require additional arguments. None are used in this method.

Value

If a single level of grouping is specified in level, the returned value is either a list with the fitted values split by groups (asList = TRUE) or a vector with the fitted values (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the napredict method is applied.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
fitted(fm1, level = 0:1)

fitted.lmeStruct  Calculate lmeStruct Fitted Values

Description

The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$. 

fitted.lmList

Usage
### S3 method for class 'lmeStruct'
fitted(object, level, conLin, lmeFit, ...)

Arguments

- **object**: an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object, "conLin").
- **lmeFit**: an optional list with components beta and b containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to attr(object, "lmeFit").
- **...**: some methods for this generic accept other optional arguments.

Value

- if a single level of grouping is specified in level, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside lme and fitted.lme.

fitted.lmList

Extract lmList Fitted Values

Description

The fitted values are extracted from each lm component of object and arranged into a list with as many components as object, or combined into a single vector.

Usage

### S3 method for class 'lmList'
fitted(object, subset, asList, ...)
Arguments

object  
an object inheriting from class "lmList", representing a list of \textit{lm} objects with a common model.

subset  
an optional character or integer vector naming the \textit{lm} components of \texttt{object} from which the fitted values are to be extracted. Default is \texttt{NULL}, in which case all components are used.

asList  
an optional logical value. If \texttt{TRUE}, the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to \texttt{FALSE}.

...  
some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by the fitted values of each \textit{lm} component of \texttt{object}, or a vector with the fitted values for all \textit{lm} components of \texttt{object}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{lmList, residuals.lmList}

Examples

\begin{verbatim}
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fitted(fm1)
\end{verbatim}
fixed.effects

Arguments

object an object inheriting from class "nlmeStruct", representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects, plus attributes specifying the underlying nonlinear model and the response variable.

level an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

conLin an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nlme model. Defaults to attr(object, "conLin").

... additional arguments that could be given to this method. None are used.

Value

if a single level of grouping is specified in level, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside nlme and fitted.nlme.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

fixef.lmList

Examples

## see the method function documentation

# fixef.lmList

Extract lmList Fixed Effects

Description

The average of the coefficients corresponding to the lm components of object is calculated.

Usage

## S3 method for class 'lmList'
fixef(object, ...)

Arguments

object an object inheriting from class "lmList", representing a list of lm objects with a common model.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the average of the individual lm coefficients in object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lmList, random.effects.lmList
Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fixed.effects(fm1)
```

---

**Description**

The `formula` attributes of the `pdMat` elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the `pdMat` elements do not have a `formula` attribute, a `NULL` value is returned.

**Usage**

```r
## S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

**Arguments**

- `x` an object inheriting from class "pdBlocked", representing a positive definite block diagonal matrix.
- `asList` an optional logical value. If `TRUE`, a list with the formulas for the individual block diagonal elements of `x` is returned; else, if `FALSE`, a one-sided formula combining all individual formulas is returned. Defaults to `FALSE`.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list of one-sided formulas, or a single one-sided formula, or `NULL`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`pdBlocked`, `pdMat`

**Examples**

```r
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```
Description

This method function extracts the formula associated with a `pdMat` object, in which the column and row names are specified.

Usage

```r
## S3 method for class 'pdMat'
formula(x, asList, ...)
```

Arguments

- `x` an object inheriting from class `"pdMat"`, representing a positive definite matrix.
- `asList` logical. Should the asList argument be applied to each of the components? Never used.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

- if `x` has a `formula` attribute, its value is returned, else `NULL` is returned.

Note

Because factors may be present in `formula(x)`, the `pdMat` object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`pdMat`

Examples

```r
pd1 <- pdSymm(~Sex*age)
formula(pd1)
```
**Description**

This method function extracts a formula from each of the components of x, returning a list of formulas.

**Usage**

```r
## S3 method for class 'reStruct'
formula(x, asList, ...)
```

**Arguments**

- `x` an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `asList` logical. Should the asList argument be applied to each of the components?
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with the formulas of each component of x.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `formula`

**Examples**

```r
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

---

**gapply**

**Apply a Function by Groups**

**Description**

Applies the function to the distinct sets of rows of the data frame defined by groups.

**Usage**

```r
gapply(object, which, FUN, form, level, groups, ...)
```
Arguments

object an object to which the function will be applied - usually a groupedData object or a data.frame. Must inherit from class "data.frame".

which an optional character or positive integer vector specifying which columns of object should be used with FUN. Defaults to all columns in object.

FUN function to apply to the distinct sets of rows of the data frame object defined by the values of groups.

form an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

level an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

groups an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

... optional additional arguments to the summary function FUN. Often it is helpful to specify na.rm = TRUE.

Value

Returns a data frame with as many rows as there are levels in the groups argument.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

table( gapply(Quinidine, "conc", function(x) sum(!is.na(x))) )
changeRecords <- gapply( Quinidine, FUN = function(frm)
  any(is.na(frm["conc"])) & is.na(frm["dose"]) )
```
Gasoline Refinery yield of gasoline

Description

The Gasoline data frame has 32 rows and 6 columns.

Format

This data frame contains the following columns:

- **yield**: a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation.
- **endpoint**: a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized.
- **Sample**: an ordered factor giving the inferred crude oil sample number.
- **API**: a numeric vector giving the crude oil gravity (degrees API).
- **vapor**: a numeric vector giving the vapor pressure of the crude oil (lbf/in^2).
- **ASTM**: a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

getcovariate Extract Covariate from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, corSpatial, data.frame, and varFunc.
Usage

getCovariate(object, form, data)

Arguments

object any object with a covariate component
form an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to formula(object).
data a data frame in which to evaluate the variables defined in form.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

Examples

## see the method function documentation

getCovariate.corStruct

Extract corStruct Object Covariate

Description

This method function extracts the covariate(s) associated with object.

Usage

## S3 method for class 'corStruct'
getcovariate(object, form, data)

Arguments

object an object inheriting from class corStruct representing a correlation structure.
form this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified.
data an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the covariate needs to be evaluated.
Value

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with object. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

glsls Extract gls Object Data

Description

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

Usage

## S3 method for class 'gls'
getData(object)

Arguments

object an object inheriting from class gls, representing a generalized least squares fitted linear model.

Value

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

gls, getData

Examples

fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
correlation = corAR1(form = ~ 1 | Mare))
getData(fm1)
**getData.lme**  

*Extract lme Object Data*

---

**Description**

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

**Usage**

```r  
## S3 method for class 'lme'  
getData(object)  
```

**Arguments**

- `object`: an object inheriting from class `lme`, representing a linear mixed-effects fitted model.

**Value**

If a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if `na.action = na.omit`, and does not omit at all if `na.action = na.exclude`. That is generally what is wanted for plotting, the main use of this function.

`lme`, `getData`

**Examples**

```r  
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,  
          random = ~ sin(2*pi*Time))  
getData(fm1)  
```
getGroups

Extract Grouping Factors from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, data.frame, gls, lme, lmList, and varFunc.

Usage

getGroups(object, form, level, data, sep)
getGroups.corStruct

Arguments

object    any object
form      an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object).
level     a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting.
data      a data frame in which to interpret the variables named in form. Optional for most methods.
sep       character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’.

Value

will depend on the method function used; see the appropriate documentation.

getGroups.corStruct Extract corStruct Groups

Description

This method function extracts the grouping factor associated with object, if any is present.

Usage

## S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
getGroups.data.frame

Extract Groups from a Data Frame

Arguments

- **object**: an object inheriting from class `corStruct` representing a correlation structure.
- **form**: this argument is included to make the method function compatible with the generic. It will be assigned the value of `formula(object)` and should not be modified.
- **level**: this argument is included to make the method function compatible with the generic and is not used.
- **data**: an optional data frame in which to evaluate the variables defined in `form`, in case `object` is not initialized and the grouping factor needs to be evaluated.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'.`

Value

if a grouping factor is present in the correlation structure represented by `object`, the function returns the corresponding factor vector; else the function returns `NULL`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `getGroups`

Examples

```r
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

Usage

```r
## S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
```
getGroups.gls

Arguments

- **object**: an object inheriting from class `data.frame`.
- **form**: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`.
- **level**: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.
- **data**: unused
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`.

Value

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

groupsFormula

Examples

groups(Pixel)
groups(Pixel, level = 2)

groups.gls Extract gls Object Groups

Description

If present, the grouping factor associated to the correlation structure for the linear model represented by `object` is extracted.

Usage

## S3 method for class 'gls'
groups(object, form, level, data, sep)
getGroups.lme

Arguments

object  an object inheriting from class gls, representing a generalized least squares fitted linear model.
form  an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object). Not used.
level  a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
data  a data frame in which to interpret the variables named in form. Optional for most methods. Not used.
sep  character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used.

Value

if the linear model represented by object incorporates a correlation structure and the corresponding corStruct object has a grouping factor, a vector with the group values is returned; else, NULL is returned.

gls, corClasses

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
   correlation = corAR1(form = ~ 1 | Mare))
getGroups(fm1)
```

```
getGroups.lme  Extract lme Object Groups
```

Description

The grouping factors corresponding to the linear mixed-effects model represented by object are extracted. If more than one level is indicated in level, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

Usage

```r
## S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```
**Arguments**

- **object**: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- **form**: this argument is included to make the method function compatible with the generic and is ignored in this method.
- **level**: an optional integer vector giving the level(s) of grouping to be extracted from `object`. Defaults to the highest or innermost level of grouping.
- **data**: unused
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’.

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

- [lme](#)

**Examples**

```r
fm1 <- lme(pixel ~ day + day^2, Pixel,
            random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
```

**Description**

The grouping factor determining the partitioning of the observations used to produce the `lm` components of `object` is extracted.

**Usage**

```r
## S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```
getGroups.varFunc

Arguments

- **object**: an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.
- **form**: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used.
- **level**: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
- **data**: a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. Not used.

Value

a vector with the grouping factor corresponding to the `lm` components of `object`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `lmList`

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
getGroups(fm1)
```

Description

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

Usage

```r
## S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```
getGroupsFormula

Arguments

object  an object inheriting from class varFunc, representing a variance function structure.
form    an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object). Not used.
level   a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
data    a data frame in which to interpret the variables named in form. Optional for most methods. Not used.
sep     character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’. Not used.

Value

if object has a groups attribute, its value is returned; else NULL is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)

getGroupsFormula Extract Grouping Formula

Description

The conditioning expression associated with formula(object) (i.e. the expression after the | operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of asList. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

Usage

getGroupsFormula(object, asList, sep)

Arguments

object  any object from which a formula can be extracted.
asList  an optional logical value. If TRUE the returned value with be a list of formulas; else, if FALSE the returned value will be a one-sided formula. Defaults to FALSE.
sep     character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’. 
getResponse

Value

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with formula(object). If no conditioning expression is present in formula(object) a NULL value is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

type: 1.5

Examples

groupsResponse(Orthodont)
getResponseFormula  

Extract Formula Specifying Response Variable

Description

The left hand side of \texttt{formula\{object\}} is returned as a one-sided formula.

Usage

generateResponseFormula\(\text{\texttt{\{object\}}}\)

Arguments

\texttt{\{object\}} \hspace{1cm} any object from which a formula can be extracted.

Value

a one-sided formula with the response variable associated with \texttt{formula\{object\}}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

generateResponse

test

Examples

generateResponseFormula(y \sim x | \texttt{\{g\}})

getVarCov  

Extract variance-covariance matrix

Description

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

Usage

generateVarCov\(\text{\texttt{\{obj, \ldots\}}}\)

## S3 method for class 'lme'
generateVarCov\(\text{\texttt{\{obj, individuals, 
  type = c('random.effects', 'conditional', 'marginal'), \ldots\}}}\)

## S3 method for class 'gls'
generateVarCov\(\text{\texttt{\{obj, individual = 1, \ldots\}}}\)

Arguments

- **obj**: A fitted model. Methods are available for models fit by `lme` and by `gls`.
- **individuals**: For models fit by `lme` a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.
- **individual**: For models fit by `gls` the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument `individual` specifies the group of responses.
- **type**: For models fit by `lme` the `type` argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional variance-covariance of the responses or "marginal" for the marginal variance-covariance of the responses.

... Optional arguments for some methods, as described above

Value

A variance-covariance matrix or a list of variance-covariance matrices.

getVarCov(fm1, individual = "F01", type = "marginal")
getVarCov(fm1, type = "conditional")
fm2 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
    correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
```

---

**gls**  
*Fit Linear Model Using Generalized Least Squares*

Description

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage

```r
gls(model, data, correlation, weights, subset, method, na.action, control, verbose)
```

## S3 method for class 'gls'

```r
update(object, model., ..., evaluate = TRUE)
```
Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted linear model.

model a two-sided linear formula object describing the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right.

model. Changes to the model – see update.formula for details.

data an optional data frame containing the variables named in model, correlation, weights, and subset. By default the variables are taken from the environment from which gls is called.

correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gls to print an error message and terminate if there are any incomplete observations.

control a list of control values for the estimation algorithm to replace the default values returned by the function glsControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Details

offset terms in model are an error since 3.1-157 (2022-03): previously they were silently ignored.

Value

an object of class "gls" representing the linear model fit. Generic functions such as print, plot, and summary have methods to show the results of the fit. See glsObject for the components of the fit. The functions resid, coef and fitted, can be used to extract some of its components.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

# AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,   
correlation = corAR1(form = ~ 1 | Mare))
# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())

glsControl

Control Values for gls Fit

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gls function.

Usage

glsControl(maxIter, msMaxIter, tolerance, msTol, msVerbose,   
singular.ok, returnObject = FALSE, apVar, .relStep,   
opt = c("nlminb", "optim"), optimMethod,   
minAbsParApVar, natural, sigma = NULL)
### glsControl

**Arguments**

- **maxIter**
  - maximum number of iterations for the gls optimization algorithm. Default is 50.

- **msMaxIter**
  - maximum number of iterations for the optimization step inside the gls optimization. Default is 50.

- **tolerance**
  - tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.

- **msTol**
  - tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.

- **msVerbose**
  - a logical value passed as the trace control value to the chosen optimizer (see documentation on that function). Default is FALSE.

- **singular.ok**
  - a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE.

- **returnObject**
  - a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.

- **apVar**
  - a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

- **.relStep**

- **opt**
  - the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default).

- **optimMethod**
  - character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".

- **minAbsParApVar**
  - numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

- **natural**
  - logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.

- **sigma**
  - optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

**Value**

A list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

**See Also**

gls

**Examples**

```r
# decrease the maximum number of iterations and request tracing
glsControl(msMaxIter = 20, msVerbose = TRUE)
```
glsObject  

**Fitted gls Object**

**Description**

An object returned by the `gls` function, inheriting from class "gls" and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "gls" object.

- **apVar**
  - an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the list of control values used in the call to `gls`, this component is equal to `NULL`.

- **call**
  - a list containing an image of the `gls` call that produced the object.

- **coefficients**
  - a vector with the estimated linear model coefficients.

- **contrasts**
  - a list of the contrast matrices used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.

- **dims**
  - a list with basic dimensions used in the model fit, including the components `N` - the number of observations in the data and `p` - the number of coefficients in the linear model.

- **fitted**
  - a vector with the fitted values.

- **modelStruct**
  - an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.

- **groups**
  - a vector with the correlation structure grouping factor, if any is present.

- **logLik**
  - the log-likelihood at convergence.

- **method**
  - the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

- **numIter**
  - the number of iterations used in the iterative algorithm.

- **residuals**
  - a vector with the residuals.

- **sigma**
  - the estimated residual standard error.

- **varBeta**
  - an approximate covariance matrix of the coefficients estimates.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`gls`, `glsStruct`
**glsStruct**

Generalized Least Squares Structure

**Description**

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A glsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the glsStruct list.

**Usage**

`glsStruct(corStruct, varStruct)`

**Arguments**

- `corStruct` an optional corStruct object, representing a correlation structure. Default is NULL.
- `varStruct` an optional varFunc object, representing a variance function structure. Default is NULL.

**Value**

A list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

corClasses, gls, residuals.glsStruct, varFunc

**Glucose**

Glucose levels over time

**Description**

The Glucose data frame has 378 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Subject** an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4
- **Time** a numeric vector
- **conc** a numeric vector of glucose levels
- **Meal** an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm
Source

---

**Glucose2**

*Glucose Levels Following Alcohol Ingestion*

Description
The Glucose2 data frame has 196 rows and 4 columns.

Format
This data frame contains the following columns:

- **Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.
- **Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.
- **Time** a numeric vector giving the time since alcohol ingestion (in min/10).
- **glucose** a numeric vector giving the blood glucose level (in mg/dl).

Details
Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

Source

---

**glns**

*Fit Nonlinear Model Using Generalized Least Squares*

Description
This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage
glns(model, data, params, start, correlation, weights, subset, na.action, naPattern, control, verbose)
Arguments

model a two-sided formula object describing the model, with the response on the left of a \(~\) operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame.

data an optional data frame containing the variables named in model, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which gnlS is called.

params an optional two-sided linear formula of the form \(p_1+...+p_n \sim x_1+...+x_m\), or list of two-sided formulas of the form \(p_1 \sim x_1+...+x_m\), with possibly different models for each parameter. The \(p_1,...,p_n\) represent parameters included on the right hand side of model and \(x_1+...+x_m\) define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of start.

start an optional named list, or numeric vector, with the initial values for the parameters in model. It can be omitted when a selfStarting function is used in model, in which case the starting estimates will be obtained from a single call to the nls function.

correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nls to print an error message and terminate if there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be regarded as missing.

control a list of control values for the estimation algorithm to replace the default values returned by the function gnlSControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

Value

an object of class gnlS, also inheriting from class gls, representing the nonlinear model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See
gnlsObject for the components of the fit. The functions resid, coef, and fitted can be used to extract some of its components.

**gnlsControl**

Control Values for gnls Fit

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gnls function.
Usage

gnlsControl(maxIter = 50, nlsMaxIter = 7, msMaxIter = 50, minScale = 0.001, 
tolerance = 1e-6, nlsTol = 0.001, msTol = 1e-7, 
returnObject = FALSE, msVerbose = FALSE, 
apVar = TRUE, .relStep =, 
opt = c("nlminb", "optim"), optimMethod = "BFGS", 
minAbsParApVar = 0.05, sigma = NULL)

Arguments

maxIter maximum number of iterations for the gnls optimization algorithm. Default is 50.
nlsMaxIter maximum number of iterations for the nls optimization step inside the gnls optimization. Default is 7.
msMaxIter maximum number of iterations for the optimization step inside the gnls optimization. Default is 50.
minScale minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the nls step. Default 0.001.
tolerance tolerance for the convergence criterion in the gnls algorithm. Default is 1e-6.
nlsTol tolerance for the convergence criterion in nls step. Default is 1e-3.
msTol tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.
returnObject a logical value indicating whether the fitted object should be returned with a warning (instead of an error via stop()) when the maximum number of iterations is reached without convergence of the algorithm.
msVerbose a logical value passed as the trace argument to the optimizer chosen by opt; see documentation on that. Default is FALSE.
apVar a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.reluStep relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3) (about 6e-6).
opt the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default).
optimMethod character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
minAbsParApVar numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
sigma optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

---

**gnlsObject**  
_Fitted gnls Object_

Description

An object returned by the `gnls` function, inheriting from class "gnls" and also from class "gls", and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

Value

The following components must be included in a legitimate "gnls" object.

- **apVar**
  - an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the control values used in the call to `gnls`, this component is equal to `NULL`.

- **call**
  - a list containing an image of the `gnls` call that produced the object.

- **coefficients**
  - a vector with the estimated nonlinear model coefficients.

- **contrasts**
  - a list of the contrast matrices used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.

- **dims**
  - a list with basic dimensions used in the model fit, including the components _N_- the number of observations used in the fit and _p_- the number of coefficients in the nonlinear model.

- **fitted**
  - a vector with the fitted values.

- **modelStruct**
  - an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.

- **groups**
  - a vector with the correlation structure grouping factor, if any is present.

- **logLik**
  - the log-likelihood at convergence.

- **numIter**
  - the number of iterations used in the iterative algorithm.

- **plist**

- **pmap**

- **residuals**
  - a vector with the residuals.

- **sigma**
  - the estimated residual standard error.

- **varBeta**
  - an approximate covariance matrix of the coefficients estimates.
**gnlsStruct**

**Author(s)**
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**
`gnls`, `gnlsStruct`

---

**Description**
A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

**Usage**

```r
gnlsStruct(corStruct, varStruct)
```

**Arguments**

- `corStruct` an optional `corStruct` object, representing a correlation structure. Default is `NULL`.
- `varStruct` an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

**Value**

A list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

**Author(s)**
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**
`gnls`, `corClasses`, `residuals.gnlsStruct` `varFunc`

**Examples**

```r
gnls1 <- gnlsStruct(corAR1(), varPower())
```
groupedData

Construct a groupedData Object

Description

An object of the groupedData class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of outer, inner, labels, and units that are given. If order.groups is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: nfnGroupedData - numeric covariate, single level of nesting; nffGroupedData - factor covariate, single level of nesting; and nmGroupedData - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a groupedData object to construct default plots and models.

Usage

groupedData(formula, data, order.groups, FUN, outer, inner, labels, units)

## S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN, outer, inner, labels, units, ...)

Arguments

object an object inheriting from class groupedData.
formula a formula of the form resp ~ cov | group where resp is the response, cov is the primary covariate, and group is the grouping factor. The expression 1 can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the / symbol as in fact1/fact2. In an expression like this the fact2 factor is nested within the fact1 factor.
data a data frame in which the expressions in formula can be evaluated. The resulting groupedData object will consist of the same data values in the same order but with additional attributes.
order.groups an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function FUN applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE.
FUN an optional summary function that will be applied to the values of the response for each level of the grouping factor, when order.groups = TRUE, to determine the ordering. Defaults to the max function.
groupedData

outer an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument `outer = TRUE` causes the panels to be determined by the outer formula. The points within the panels are associated by level of the grouping factor. Defaults to `NULL`, meaning that no outer covariates are present.

inner an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to `NULL`, meaning that no inner covariates are present.

labels an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named `x` and that for the response is named `y`. Either label can be omitted.

units an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named `x` and that for the response is named `y`. Either units string can be omitted.

... some methods for this generic require additional arguments. None are used in this method.

Value

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

Author(s)

Douglas Bates and José Pinheiro

Examples

Orth.new <- # create a new copy of the groupedData object
groupedData( distance ~ age | Subject,
  data = as.data.frame( Orthodont ),
  FUN = mean,
  outer = ~ Sex,
  labels = list( x = "Age",
  y = "Distance from pituitary to pterygomaxillary fissure" ),
  units = list( x = "(yr)", y = "(mm)" ) )
plot( Orth.new ) # trellis plot by Subject
formula( Orth.new ) # extractor for the formula
gsummary( Orth.new ) # apply summary by Subject
fm1 <- lme( Orth.new ) # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)

---

gsummary

### Summarize by Groups

**Description**

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a groupedData object to examine the variables by group.

**Usage**

```r
gsummary(object, FUN, omitGroupingFactor, form, level,
  groups, invariantsOnly, ...)  
```

**Arguments**

- **object**: an object to be summarized - usually a groupedData object or a data.frame.
- **FUN**: an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in object that vary within the groups defined by groups. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

- **omitGroupingFactor**: an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to FALSE.
form  
an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

level  
an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

groups  
an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

invariantsOnly  
an optional logical value. When TRUE only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in object. By definition, the grouping factor itself must be an invariant. When combined with omitGroupingFactor = TRUE, this option can be used to discover is there are invariant covariates in the data frame. Defaults to FALSE.

...  
optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify na.rm = TRUE.

Value

A data.frame with one row for each level of the grouping factor. The number of columns is at most the number of columns in object.

## within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
```
**Gun**

*Methods for firing naval guns*

**Description**

The *Gun* data frame has 36 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **rounds**: a numeric vector
- **Method**: a factor with levels M1 M2
- **Team**: an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H
- **Physique**: an ordered factor with levels Slight < Average < Heavy

**Details**

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

**Source**

---

**IGF**

*Radioimmunoassay of IGF-I Protein*

**Description**

The *IGF* data frame has 237 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Lot**: an ordered factor giving the radioactive tracer lot.
- **age**: a numeric vector giving the age (in days) of the radioactive tracer.
- **conc**: a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

**Details**

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.
Initialize

Initialize Object

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, lmeStruct, reStruct, and varFunc.

Usage
Initialize(object, data, ...)

Arguments
- object: any object requiring initialization, e.g. "plug-in" structures such as corStruct and varFunc objects.
- data: a data frame to be used in the initialization procedure.
- ...: some methods for this generic function require additional arguments.

Value
an initialized object with the same class as object. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also
Initialize.corStruct, Initialize.lmeStruct, Initialize.glsStruct, Initialize.varFunc, isInitialized

Examples
### see the method function documentation
Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

Usage

```
## S3 method for class 'corStruct'
Initialize(object, data, ...)
```

Arguments

- `object`: an object inheriting from class "corStruct" representing a correlation structure.
- `data`: a data frame in which to evaluate the variables defined in formula(object).
- `...`: this argument is included to make this method compatible with the generic.

Value

an initialized object with the same class as object representing a correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

`Dim.corStruct`

Examples

```
cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```
**Initialize.glsStruct**

Initialize a glsStruct Object

**Description**

The individual linear model components of the glsStruct list are initialized.

**Usage**

```r
## S3 method for class 'glsStruct'
Initialize(object, data, control, ...)
```

**Arguments**

- `object`: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and varFunc objects.
- `data`: a data frame in which to evaluate the variables defined in formula(object).
- `control`: an optional list with control parameters for the initialization and optimization algorithms used in gls. Defaults to list(singular.ok = FALSE), implying that linear dependencies are not allowed in the model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

a glsStruct object similar to object, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

gls, Initialize.corStruct, Initialize.varFunc, Initialize

---

**Initialize.lmeStruct**

Initialize an lmeStruct Object

**Description**

The individual linear mixed-effects model components of the lmeStruct list are initialized.

**Usage**

```r
## S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)
```
Initialize.reStruct

Arguments

object
an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
data
a data frame in which to evaluate the variables defined in formula(object).
groups
a data frame with the grouping factors corresponding to the lme model associated with object as columns, sorted from innermost to outermost grouping level.
conLin
an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object, "conLin").
control
an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to list(niterEM=20, gradHess=TRUE), implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the reStruct component of object and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm.
...
some methods for this generic require additional arguments. None are used in this method.

Value
an lmeStruct object similar to object, but with initialized model components.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
lme, Initialize.reStruct, Initialize.corStruct, Initialize.varFunc, Initialize

Description
Initial estimates for the parameters in the pdMat objects forming object, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in control.

Usage
## S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)

Initialize.reStruct  Initialize reStruct Object
Initialize.varFunc

Arguments

object: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.

data: a data frame in which to evaluate the variables defined in formula(object).

conLin: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix \( X \) combined with a response vector \( y \), and "logLik", corresponding to the log-likelihood of the underlying model.

control: an optional list with a single component niterEM controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other Initialize methods. Defaults to list(niterEM = 20).

...: some methods for this generic require additional arguments. None are used in this method.

Value

an reStruct object similar to object, but with all pdMat components initialized.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

reStruct, pdMat, Initialize

Initialize.varFunc

Initialize varFunc Object

Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data; determining if the covariate(s) need to be updated when the values of the coefficients associated with object change; initializing the log-likelihood and the weights associated with object; and assigning initial values for the coefficients in object, if none were present. The covariate(s) will only be initialized if no update is needed when coef(object) changes.

Usage

## S3 method for class 'varFunc'
Initialize(object, data, ...)

Arguments

object: an object inheriting from class "varFunc", representing a variance function structure.

data: a data frame in which to evaluate the variables named in formula(object).

...: this argument is included to make this method compatible with the generic.
Value

an initialized object with the same class as object representing a variance function structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Initiate

Examples

vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )

| intervals | Confidence Intervals on Coefficients |

Description

Confidence intervals on the parameters associated with the model represented by object are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

Usage

intervals(object, level, ...)

Arguments

object a fitted model object from which parameter estimates can be extracted.
level an optional numeric value for the interval confidence level. Defaults to 0.95.
... some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

### see the method documentation
Confidence Intervals on gls Parameters

Description

Approximate confidence intervals for the parameters in the linear model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

Usage

## S3 method for class 'gls'
intervals(object, level, which, ...)

Arguments

- **object**: an object inheriting from class "gls", representing a generalized least squares fitted linear model.
- **level**: an optional numeric value for the interval confidence level. Defaults to 0.95.
- **which**: an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all".
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- **coef**: linear model coefficients, only present when which is not equal to "var-cov".
- **corStruct**: correlation parameters, only present when which is not equal to "coef" and a correlation structure is used in object.
- **varFunc**: variance function parameters, only present when which is not equal to "coef" and a variance function structure is used in object.
- **sigma**: residual standard error.

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

intervals.lme

See Also
gls, intervals, print.intervals.gls

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
intervals(fm1)
```

Description

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The `pdNatural` parametrization is used for general positive-definite matrices.

Usage

```r
## S3 method for class 'lme'
intervals(object, level = 0.95,
          which = c("all", "var-cov", "fixed"), ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `level`: an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
- `which`: an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all".
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- `fixed`: fixed effects, only present when `which` is not equal to "var-cov".
- `reStruct`: random effects variance-covariance parameters, only present when `which` is not equal to "fixed".
corStruct  within-group correlation parameters, only present when which is not equal to "fixed" and a correlation structure is used in object.

varFunc  within-group variance function parameters, only present when which is not equal to "fixed" and a variance function structure is used in object.

sigma  within-group standard deviation.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also
lme, intervals, print.intervals.lme, pdNatural

Examples
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
intervals(fm1)

intervals.lmList

Description
Confidence intervals on the linear model coefficients are obtained for each lm component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by lower, est., and upper corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

Usage
## S3 method for class 'lmList'
intervals(object, level = 0.95, pool = attr(object, "pool"), ...)

Arguments
object  an object inheriting from class "lmList", representing a list of lm objects with a common model.

level  an optional numeric value with the confidence level for the intervals. Defaults to 0.95.

pool  an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").

...  some methods for this generic require additional arguments. None are used in this method.
isBalanced

Check a Design for Balance

Description

Check the design of the experiment or study for balance.

Usage

isBalanced(object, countOnly, level)

Arguments

object

A groupedData object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.

countOnly

A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to FALSE.

level

an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If countOnly is FALSE the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.
isInitialized

Value

TRUE or FALSE according to whether the data are balanced or not

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

table, groupedData

Examples

isBalanced(Orthodont)  # should return TRUE
isBalanced(Orthodont, countOnly = TRUE)  # should return TRUE
isBalanced(Pixel)  # should return FALSE
isBalanced(Pixel, level = 1)  # should return FALSE

isInitialized

Check if Object is Initialized

Description

Checks if object has been initialized (generally through a call to Initialize), by searching for components and attributes which are modified during initialization.

Usage

isInitialized(object)

Arguments

object any object requiring initialization.

Value

a logical value indicating whether object has been initialized.

Author(s)

José Pinheiro and Douglas Bates

See Also

Initialize

Examples

pd1 <- pdDiag(~age)
isInitialized(pd1)
LDEsysMat

Generate system matrix for LDEs

Description

Generate the system matrix for the linear differential equations determined by a compartment model.

Usage

LDEsysMat(pars, incidence)

Arguments

pars a numeric vector of parameter values.
incidence an integer matrix with columns named From, To, and Par. Values in the Par column must be in the range 1 to length(pars). Values in the From column must be between 1 and the number of compartments. Values in the To column must be between 0 and the number of compartments.

Details

A compartment model describes material transfer between k in a system of k compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

Value

A k by k numeric matrix.

  dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
Description

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

This page describes the formula method; the methods `lme.lmList` and `lme.groupedData` are documented separately.

Usage

```r
lme(fixed, data, random, correlation, weights, subset, method, na.action, control, contrasts = NULL, keep.data = TRUE)

## S3 method for class 'formula'
lme(fixed, data, random, correlation, weights, subset, method, na.action, control, contrasts = NULL, keep.data = TRUE)

## S3 method for class 'lme'
update(object, fixed., ..., evaluate = TRUE)
```

Arguments

- `object`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `fixed`: a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a `~` operator and the terms, separated by `+` operators, on the right, an `"lmList"` object, or a `"groupedData"` object. There is limited support for formulae such as `resp ~ 1` and `resp ~ 0`, and less prior to version ‘3.1-112’.
- `fixed.`: Changes to the fixed-effects formula – see `update.formula` for details.
- `data`: an optional data frame containing the variables named in `fixed`, `random`, `correlation`, `weights`, and `subset`. By default the variables are taken from the environment from which `lme` is called.
- `random`: optionally, any of the following: (i) a one-sided formula of the form `~ x1 + ... + xn | g1/.../gm`, with `x1 + ... + xn` specifying the model for the random effects and `g1/.../gm` the grouping structure (n may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form `~ x1 + ... + xn | g`, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form `~ x1 + ... + xn`, or a `pdMat` object with a formula (i.e. a non-NULL value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class "groupedData"; (iv) a named list of formulas or `pdMat` objects as in (iii), with the grouping factors
as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to a formula consisting of the right hand side of `fixed`.

correlation an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations.

weights an optional `varFunc` object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to `varFixed`, corresponding to fixed variance weights. See the documentation on `varClasses` for a description of the available `varFunc` classes. Defaults to `NULL`, corresponding to homoscedastic within-group errors.

subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action a function that indicates what should happen when the data contain `NA`s. The default action (`na.fail`) causes `lme` to print an error message and terminate if there are any incomplete observations.

control a list of control values for the estimation algorithm to replace the default values returned by the function `lmeControl`. Defaults to an empty list.

contrasts an optional list. See the `contrasts.arg` of `model.matrix.default`.

keep.data logical: should the `data` argument (if supplied and a data frame) be saved as part of the model object?

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Details

`offset` terms in `fixed` are an error since 3.1-157 (2022-03): previously they were silently ignored.

Value

An object of class "`lme" representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

Examples

```r
fm1 <- lme(distance ~ age, data = Orthodont) # random is ~ age
fm2 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
summary(fm1)
summary(fm2)
```

Description

The response variable and primary covariate in `formula(fixed)` are used to construct the fixed effects model formula. This formula and the groupedData object are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.
Usage

## S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
    subset, method, na.action, control, contrasts, keep.data = TRUE)

Arguments

fixed a data frame inheriting from class "groupedData".
data this argument is included for consistency with the generic function. It is ignored
in this method function.
random optionally, any of the following: (i) a one-sided formula of the form \(~x_1+\ldots+x_n\ \mid \ g_1/\ldots/g_m\), with \(x_1+\ldots+x_n\) specifying the model for the random effects and \(g_1/\ldots/g_m\) the grouping structure (\(m\) may be equal to 1, in which case no \(\mid\) is required). The random effects formula will be repeated for all levels of grouping,
in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the
form \(~x_1+\ldots+x_n\ \mid \ g\), with possibly different random effects models for each
grouping level. The order of nesting will be assumed the same as the order of
the elements in the list; (iii) a one-sided formula of the form \(~x_1+\ldots+x_n\), or
a \(\text{pdMat}\) object with a formula (i.e. a non-\(\text{NULL}\) value for \(\text{formula(object)}\)),
or a list of such formulas or \(\text{pdMat}\) objects. In this case, the grouping structure
formula will be derived from the data used to fit the linear mixed-effects model,
which should inherit from class \(\text{groupedData}\); (iv) a named list of formulas
or \(\text{pdMat}\) objects as in (iii), with the grouping factors as names. The order of
nesting will be assumed the same as the order of the elements in the list; (v) an \(\text{reStruct}\) object. See the documentation on \(\text{pdClasses}\) for a
description of the available \(\text{pdMat}\) classes. Defaults to a formula consisting of
the right hand side of \(\text{fixed}\).
correlation an optional \(\text{corStruct}\) object describing the within-group correlation struc-
ture. See the documentation of \(\text{corClasses}\) for a description of the available
\(\text{corStruct}\) classes. Defaults to \(\text{NULL}\), corresponding to no within-group corre-
lations.
weights an optional \(\text{varFunc}\) object or one-sided formula describing the within-group
heteroscedasticity structure. If given as a formula, it is used as the argument
to \(\text{varFixed}\), corresponding to fixed variance weights. See the documentation
on \(\text{varClasses}\) for a description of the available \(\text{varFunc}\) classes. Defaults to
\(\text{NULL}\), corresponding to homoscedastic within-group errors.
subset an optional expression indicating the subset of the rows of \(\text{data}\) that should be
used in the fit. This can be a logical vector, or a numeric vector indicating which
observation numbers are to be included, or a character vector of the row names
to be included. All observations are included by default.
method a character string. If "REML" the model is fit by maximizing the restricted log-
likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
na.action a function that indicates what should happen when the data contain \(\text{NA}\)s. The
default action (\(\text{na.fail}\)) causes \(\text{lme}\) to print an error message and terminate if
there are any incomplete observations.
control a list of control values for the estimation algorithm to replace the default values
returned by the function \(\text{lmeControl}\). Defaults to an empty list.
contrasts an optional list. See the \(\text{contrasts.arg}\) of \(\text{model.matrix.default}\).
keep.data logical: should the \(\text{data}\) argument (if supplied and a data frame) be saved as
part of the model object?
Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

lme, groupedData, lmeObject

Examples

fm1 <- lme(Orthodont)
summary(fm1)
**Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

**Usage**

```r
## S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method, na.action, control, contrasts, keep.data)
```

**Arguments**

- `fixed`: an object inheriting from class "lmList.", representing a list of `lm` fits with a common model.
- `data`: this argument is included for consistency with the generic function. It is ignored in this method function.
- `random`: an optional one-sided linear formula with no conditioning expression, or a `pdMat` object with a `formula` attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of `formula(fixed)`.
- `correlation`: an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to NULL, corresponding to no within-group correlations.
- `weights`: an optional `varFunc` object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to `varFixed`, corresponding to fixed variance weights. See the documentation on `varClasses` for a description of the available `varFunc` classes. Defaults to NULL, corresponding to homoscedastic within-group errors.
- `subset`: an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `method`: a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `lme` to print an error message and terminate if there are any incomplete observations.
- `control`: a list of control values for the estimation algorithm to replace the default values returned by the function `lmeControl`. Defaults to an empty list.
contrasts
an optional list. See the contrasts.arg of model.matrix.default.

keep.data
logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

fml <- lmList(Orthodont)
fm2 <- lme(fml)
summary(fml)
summary(fm2)
Specifying Control Values for lme Fit

Description

The values supplied in the lmeControl() call replace the defaults, and a list with all settings (i.e., values for all possible arguments) is returned. The returned list is used as the control argument to the lme function.

Usage

lmeControl(maxIter = 50, msMaxIter = 50, tolerance = 1e-6, niterEM = 25, 
msMaxEval = 200, 
msTol = 1e-7, msVerbose = FALSE, 
returnObject = FALSE, gradHess = TRUE, apVar = TRUE, 
.relStep = .Machine$double.eps^*(1/3), minAbsParApVar = 0.05, 
opt = c("nlminb", "optim"), 
optimMethod = "BFGS", natural = TRUE, 
sigma = NULL, 
allow.n.lt.q = FALSE, 
...)

Arguments

maxIter maximum number of iterations for the lme optimization algorithm. Default is 50.
msMaxIter maximum number of iterations for the optimization step inside the lme optimization. Default is 50.
tolerance tolerance for the convergence criterion in the lme algorithm. Default is 1e-6.
niterEM number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
msMaxEval maximum number of evaluations of the objective function permitted for nlminb. Default is 200.
msTol tolerance for the convergence criterion on the first iteration when optim is used. Default is 1e-7.
msVerbose a logical value passed as the trace argument to nlminb or optim. Default is FALSE.
returnObject a logical value indicating whether the fitted object should be returned with a warning (instead of an error via stop()) when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
gradHess a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE.
apVar a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.relStep  relative step for numerical derivatives calculations. Default is .Machine$double.eps^{(1/3)}.

opt    the optimizer to be used, either "nlminb" (the default) or "optim".

optimMethod character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".

minAbsParApVar numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

natural a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

sigma optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

allow.n.lt.q logical indicating if it is ok to have less observations than random effects for each group. The default, FALSE signals an error; if NA, such a situation only gives a warning, as in nlme versions prior to 2019; if true, no message is given at all.

... further named control arguments to be passed, depending on opt, to nlminb (those from abs.tol down) or optim (those except trace and maxit; reltol is used only from the second iteration).

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

Examples

# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
str(lCtr <- lmeControl(msMaxIter = 20, msVerbose = TRUE))
## This should always work:
do.call(lmeControl, lCtr)

lmeObject  Fitted lme Object

Description

An object returned by the lme function, inheriting from class "lme" and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, sigma, summary, update, and vcov.
Value

The following components must be included in a legitimate "lme" object.

- **apVar**: an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the control values used in the call to `lme`, this component is `NULL`.
- **call**: a list containing an image of the `lme` call that produced the object.
- **coefficients**: a list with two components, `fixed` and `random`, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the `random` list, the columns refer to the random effects and the rows to the groups.
- **contrasts**: a list of the contrast matrices used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the `lme` model, this component will be an empty list.
- **dims**: a list with basic dimensions used in the `lme` fit, including the components `N` - the number of observations in the data, `Q` - the number of grouping levels, `qvec` - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), `ngrps` - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and `ncol` - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
- **fitted**: a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
- **fixDF**: a list with components `X` and `terms` specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
- **groups**: a data frame with the grouping factors as columns. The grouping level increases from left to right.
- **logLik**: the (restricted) log-likelihood at convergence.
- **method**: the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
- **modelStruct**: an object inheriting from class `lmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- **numIter**: the number of iterations used in the iterative algorithm.
- **residuals**: a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
- **terms**: the `terms`, including `formula`, see also `terms.object`.
- **sigma**: the estimated within-group error standard deviation.
- **varFix**: an approximate covariance matrix of the fixed effects estimates.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `lmeStruct` list.

### Usage

```r
lmeStruct(reStruct, corStruct, varStruct)
```

### Arguments

- **reStruct**: a `reStruct` representing a random effects structure.
- **corStruct**: an optional `corStruct` object, representing a correlation structure. Default is NULL.
- **varStruct**: an optional `varFunc` object, representing a variance function structure. Default is NULL.

### Value

A list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

- `corClasses`, `lme`, `residuals.lmeStruct`, `reStruct`, `varFunc`

### Examples

```r
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
```
lmList

List of lm Objects with a Common Model

Description

Data is partitioned according to the levels of the grouping factor \( g \) and individual \( \text{lm} \) fits are obtained for each data partition, using the model defined in \( \text{object} \).

Usage

\[
\text{lmList}(\text{object}, \text{data}, \text{level}, \text{subset}, \text{na.action} = \text{na.fail}, \\
\quad \text{pool} = \text{TRUE}, \text{warn.lm} = \text{TRUE})
\]

## S3 method for class 'formula'
\[
\text{lmList}(\text{object}, \text{data}, \text{level}, \text{subset}, \text{na.action} = \text{na.fail}, \\
\quad \text{pool} = \text{TRUE}, \text{warn.lm} = \text{TRUE})
\]

## S3 method for class 'lmList'
\[
\text{update}(\text{object}, \text{formula.}, \ldots, \text{evaluate} = \text{TRUE})
\]

## S3 method for class 'lmList'
\[
\text{print}(x, \text{pool}, \ldots)
\]

Arguments

- **object**
  - For \( \text{lmList} \), either a linear formula object of the form \( y \sim x_1+x_2+...+x_n \mid g \) or a \text{groupedData} object. In the formula object, \( y \) represents the response, \( x_1, ... , x_n \) the covariates, and \( g \) the grouping factor specifying the partitioning of the data according to which different \( \text{lm} \) fits should be performed. The grouping factor \( g \) may be omitted from the formula, in which case the grouping structure will be obtained from \( \text{data} \), which must inherit from class \text{groupedData}. The method function \text{lmList.groupedData} is documented separately. For the method \text{update.lmList}, \text{object} is an object inheriting from class \text{lmList}.

- **formula** (used in \text{update.lmList} only)
  - a two-sided linear formula with the common model for the individuals \( \text{lm} \) fits.

- **formula.**
  - Changes to the formula – see \text{update.formula} for details.

- **data**
  - a data frame in which to interpret the variables named in \( \text{object} \).

- **level**
  - an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.

- **subset**
  - an optional expression indicating which subset of the rows of \( \text{data} \) should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

- **na.action**
  - a function that indicates what should happen when the data contain \text{NAs}. The default action (\text{na.fail}) causes \text{lmList} to print an error message and terminate if there are any incomplete observations.

- **pool**
  - an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.
lmList.groupedData

Description

The response variable and primary covariate in formula(object) are used to construct the linear model formula. This formula and the groupedData object are passed as the object and data arguments to lmList.formula, together with any other additional arguments in the function call. See the documentation on lmList.formula for a description of that function.

Usage

## S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action = na.fail,
       pool = TRUE, warn.lm = TRUE)

Arguments

- **object**: a data frame inheriting from class "groupedData".
- **data**: this argument is included for consistency with the generic function. It is ignored in this method function.
- **level**: an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
subset an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations.

pool, warn.lm optional logicals, see lmList.

Value

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

See Also

groupedData, lm, lme.lmList, lmList, lmList.formula

summary(fm1)

logDet Extract the Logarithm of the Determinant

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, several pdMat classes, and reStruct.

Usage

logDet(object, ...)

Arguments

object any object from which a matrix, or list of matrices, can be extracted

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
logDet.corStruct

See Also

logLik, logDet.corStruct, logDet.pdMat, logDet.reStruct

Examples

## see the method function documentation

cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)

Description

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

Usage

## S3 method for class 'corStruct'
logDet(object, covariate, ...)

Arguments

object an object inheriting from class "corStruct", representing a correlation structure.
covariate an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to getCovariate(object).
... some methods for this generic require additional arguments. None are used in this method.

Value

the log-determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

logLik.corStruct, corMatrix.corStruct, logDet

Examples

cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
**logDet.pdMat**

*Extract Log-Determinant from a pdMat Object*

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Usage**

```r
## S3 method for class 'pdMat'
logDet(object, ...)
```

**Arguments**

- `object` an object inheriting from class `"pdMat"`, representing a positive definite matrix.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`pdMat`, `logDet`

**Examples**

```r
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

---

**logDet.reStruct**

*Extract reStruct Log-Determinants*

**Description**

Calculates, for each of the `pdMat` components of `object`, the logarithm of the determinant of a square-root factor.

**Usage**

```r
## S3 method for class 'reStruct'
logDet(object, ...)
```
Arguments

object: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.

Value

a vector with the log-determinants of square-root factors of the pdMat components of object.

Author(s)

José Pinheiro

See Also

reStruct, pdMat, logDet

Examples

rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
                   B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)

Description

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by object.

Usage

## S3 method for class 'corStruct'
logLik(object, data, ...)

Arguments

object: an object inheriting from class "corStruct", representing a correlation structure.

data: this argument is included to make this method function compatible with other logLik methods and will be ignored.

Value

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by object.
logLik.glsStruct

Description

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

Usage

## S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)

Arguments

- **object**: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.
- **Pars**: the parameter values at which the (restricted) log-likelihood is to be evaluated.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to attr(object, "conLin").
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the (restricted) log-likelihood for the linear model described by object, evaluated at Pars.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, glsStruct, logLik.lme
logLik.gnls

Log-Likelihood of a gnls Object

Description

Returns the log-likelihood value of the nonlinear model represented by object evaluated at the estimated coefficients.

Usage

## S3 method for class 'gnls'
logLik(object, REML, ...)

Arguments

object           an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
REML             an logical value for consistency with logLik,gls, but only FALSE is accepted.
...              some methods for this generic require additional arguments. None are used in this method.

Value

the log-likelihood of the linear model represented by object evaluated at the estimated coefficients.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gnls, logLik.lme

Examples

fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean, weights = varPower())
logLik(fm1)

logLik.gnlsStruct

Log-Likelihood of a gnlsStruct Object

Description

Pars is used to update the coefficients of the model components of object and the individual log-likelihood contributions of each component are added together.

Usage

## S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)

Arguments

object an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.

Pars the parameter values at which the log-likelihood is to be evaluated.

conLin an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to `attr(object, "conLin")`.

... some methods for this generic require additional arguments. None are used in this method.

Value

the log-likelihood for the linear model described by `object`, evaluated at `Pars`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gnls, gnlsStruct, logLik.gnls

logLik.lme

Log-Likelihood of an lme Object

Description

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by `object` evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

Usage

```r
## S3 method for class 'lme'
logLik(object, REML, ...)
```

Arguments

object an object inheriting from class "lme", representing a fitted linear mixed-effects model.

REML an optional logical value. If `TRUE` the restricted log-likelihood is returned, else, if `FALSE`, the log-likelihood is returned. Defaults to the method of estimation used, that is `TRUE` if and only if `object` was fitted with `method = "REML"` (the default for these fitting functions).

... some methods for this generic require additional arguments. None are used in this method.
The (restricted) log-likelihood of the model represented by `object` evaluated at the estimated coefficients.

logLik(fm1)
logLik(fm1, REML = TRUE)
```

---

**Description**

`Pars` is used to update the coefficients of the model components of `object` and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the `settings` attribute of `object`.

**Usage**

```r
## S3 method for class 'lmeStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

- `object` an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- `Pars` the parameter values at which the (restricted) log-likelihood is to be evaluated.
- `conLin` an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`.
- `...` some methods for this generic require additional arguments. None are used in this method.
Value

the (restricted) log-likelihood for the linear mixed-effects model described by object, evaluated at Pars.

fm1 <- lmList(distance ~ age | Subject, Orthodont)
logLik(fm1)  # returns NA when it should not
```

---

**logLik.reStruct**

*Calculate reStruct Log-Likelihood*

**Description**

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The settings attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

**Usage**

```r
## S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

**Arguments**

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef(object)`. 

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct, pdMat, logLik.lme`
**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by `object`, which is equal to the sum of the logarithms of the corresponding weights.

**Usage**

```r
## S3 method for class 'varFunc'
logLik(object, data, ...)
```

**Arguments**

- `object`: an object inheriting from class "varFunc", representing a variance function structure.
- `data`: this argument is included to make this method function compatible with other `logLik` methods and will be ignored.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

the sum of the logarithms of the weights corresponding to the variance function structure represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `logLik.lme`

**Examples**

```r
vf1 <- varPower(form = ~age)
vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.1
logLik(vf1)
```
Machines

**Description**

The Machines data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Worker** an ordered factor giving the unique identifier for the worker.
- **Machine** a factor with levels A, B, and C identifying the machine brand.
- **score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

MathAchieve

**Description**

The MathAchieve data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

- **School** an ordered factor identifying the school that the student attends
- **Minority** a factor with levels No Yes indicating if the student is a member of a minority racial group.
- **Sex** a factor with levels Male Female
- **SES** a numeric vector of socio-economic status.
- **MathAch** a numeric vector of mathematics achievement scores.
- **MEANSES** a numeric vector of the mean SES for the school.
Details

Each row in this data frame contains the data for one student.

Examples

summary(MathAchieve)

MathAchSchool  
School demographic data for MathAchieve

Description

The MathAchSchool data frame has 160 rows and 7 columns.

Format

This data frame contains the following columns:

- **School** a factor giving the school on which the measurement is made.
- **Size** a numeric vector giving the number of students in the school
- **Sector** a factor with levels Public Catholic
- **PRACAD** a numeric vector giving the percentage of students on the academic track
- **DISCLIM** a numeric vector measuring the discrimination climate
- **HIMINTY** a factor with levels 0 1
- **MEANSES** a numeric vector giving the mean SES score.

Details

These variables give the school-level demographic data to accompany the MathAchieve data.

Matrix

Assign Matrix Values

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include pdMat, pdBlocked, and reStruct.

Usage

```r
matrix(object) <- value
```

Arguments

<table>
<thead>
<tr>
<th>object</th>
<th>any object to which as.matrix can be applied.</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>a matrix, or list of matrices, with the same dimensions as as.matrix(object) with the new values to be assigned to the matrix associated with object.</td>
</tr>
</tbody>
</table>
Matrix.pdMat

Assign Matrix to a pdMat or pdBlocked Object

Description

The positive-definite matrix represented by object is replaced by value. If the original matrix had row and/or column names, the corresponding names for value can either be NULL, or a permutation of the original names.

Usage

## S3 replacement method for class 'pdMat'
matrix(object) <- value
## S3 replacement method for class 'pdBlocked'
matrix(object) <- value

Arguments

object an object inheriting from class "pdMat", representing a positive definite matrix.
value a matrix with the new values to be assigned to the positive-definite matrix represented by object. Must have the same dimensions as as.matrix(object).

Value

a pdMat or pdBlocked object similar to object, but with its coefficients modified to produce the matrix in value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

pdMat, "matrix<-

Examples

class(pd1 <- pdSymm(diag(3))) # "pdSymm" "pdMat"
matrix(pd1) <- diag(1:3)
pd1
Matrix.reStruct  Assign reStruct Matrices

Description
The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

Usage
## S3 replacement method for class 'reStruct'
matrix(object) <- value

Arguments
- object: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- value: a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object.

Value
an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
reStruct, pdMat,"matrix<-"

Examples
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)

Meat  Tenderness of meat

Description
The Meat data frame has 30 rows and 4 columns.
Milk

Format

This data frame contains the following columns:

- **Storage**: an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)
- **score**: a numeric vector giving the tenderness score of beef roast.
- **Block**: an ordered factor identifying the muscle from which the roast was extracted with levels II < V < I < III < IV
- **Pair**: an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < ... < IV-1

Details

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

Milk

Protein content of cows’ milk

Description

The Milk data frame has 1337 rows and 4 columns.

Format

This data frame contains the following columns:

- **protein**: a numeric vector giving the protein content of the milk.
- **Time**: a numeric vector giving the time since calving (weeks).
- **Cow**: an ordered factor giving a unique identifier for each cow.
- **Diet**: a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

Details

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows’ milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

Source

Description

The model matrices for each element of formula(object), calculated using data, are bound together column-wise. When multiple grouping levels are present (i.e. when length(object) > 1), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

Usage

```r
## S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)
```

Arguments

- `object` an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of `pdMat` objects.
- `data` a data frame in which to evaluate the variables defined in formula(object).
- `contrast` an optional named list specifying the contrasts to be used for representing the factor variables in data. The components names should match the names of the variables in data for which the contrasts are to be specified. The components of this list will be used as the contrasts attribute of the corresponding factor. If missing, the default contrast specification is used.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

a matrix obtained by binding together, column-wise, the model matrices for each element of formula(object).

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `model.matrix`
- `contrasts`, `reStruct`, `formula.reStruct`

Examples

```r
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
```
**Description**

The `Muscle` data frame has 60 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Strip** an ordered factor indicating the strip of muscle being measured.
- **conc** a numeric vector giving the concentration of CaCl$_2$
- **length** a numeric vector giving the shortening of the heart muscle strip.

**Details**

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl$_2$ solution. The muscle strips are taken from the left auricle of a rat’s heart.

**Source**

---

**Names**

*Names Associated with an Object*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

**Usage**

```r
Names(object, ...)  
Names(object, ...) <- value
```

**Arguments**

- **object** any object for which names can be extracted and/or assigned.
- **...** some methods for this generic function require additional arguments.
- **value** names to be assigned to object.

**Value**

will depend on the method function used; see the appropriate documentation.
SIDE EFFECTS

On the left side of an assignment, sets the names associated with object to value, which must have an appropriate length.

Note

If names were generic, there would be no need for this generic function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Names.formula, Names.pdMat

Examples

## see the method function documentation

---

### Description

This method function returns the names of the terms corresponding to the right hand side of object (treated as a linear formula), obtained as the column names of the corresponding model.matrix.

### Usage

```r
## S3 method for class 'formula'
Names(object, data, exclude, ...)
```

### Arguments

- **object**: an object inheriting from class `"formula"`.
- **data**: an optional data frame containing the variables specified in object. By default the variables are taken from the environment from which Names.formula is called.
- **exclude**: an optional character vector with names to be excluded from the returned value. Default is `c("pi","."),`
- **...**: some methods for this generic require additional arguments. None are used in this method.

### Value

A character vector with the column names of the model.matrix corresponding to the right hand side of object which are not listed in excluded.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
Names.pdBlocked

See Also

model.matrix, terms, Names

Examples

Names(distance ~ Sex * age, data = Orthodont)

d1 <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(d1)
Names.pdMat

Names of a pdMat Object

Description

This method function returns the first element of the Dimnames attribute of object, which contains the column names of the matrix represented by object.

Usage

```r
## S3 method for class 'pdMat'
Names(object, ...)
## S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

Arguments

- `object` an object inheriting from class "pdMat", representing a positive-definite matrix.
- `value` a character vector with the replacement values for the column and row names of the matrix represented by object. It must have length equal to the dimension of the matrix represented by object and, if names have been previously assigned to object, it must correspond to a permutation of the original names.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

if `object` has a Dimnames attribute then the first element of this attribute is returned; otherwise NULL.

SIDE EFFECTS

On the left side of an assignment, sets the Dimnames attribute of object to `list(value, value)`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Names, Names.pdBlocked

Examples

```r
pd1 <- pdSymm(~age, data = Orthodont)
Names(pd1)
```
Names.reStruct

Names of an reStruct Object

Description

This method function extracts the column names of each of the positive-definite matrices represented the pdMat elements of object.

Usage

## S3 method for class 'reStruct'
Names(object, ...)
## S3 replacement method for class 'reStruct'
Names(object, ...) <- value

Arguments

- **object**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **value**: a list of character vectors with the replacement values for the names of the individual pdMat objects that form object. It must have the same length as object.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a list containing the column names of each of the positive-definite matrices represented by the pdMat elements of object.

SIDE EFFECTS

On the left side of an assignment, sets the Names of the pdMat elements of object to the corresponding element of value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

reStruct, pdMat, Names.pdMat

Examples

rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)

needUpdate  

Description  
This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a needUpdate attribute of object. If this is NULL or FALSE it returns FALSE; else it returns TRUE. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage  
needUpdate(object)

Arguments  
object  any object

Value  
a logical value indicating whether object needs to be updated.

Author(s)  
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also  
needUpdate.modelStruct

Examples  
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)

needUpdate.modelStruct  

Description  
This method function checks if any of the elements of object needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage  
## S3 method for class 'modelStruct'
needUpdate(object)
Arguments

object an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.

Value

a logical value indicating whether any element of object needs to be updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

needUpdate

Examples

lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),

Nitrendipene Assay of nitrendipene

Description

The Nitrendipene data frame has 89 rows and 4 columns.

Format

This data frame contains the following columns:

activity a numeric vector
NIF a numeric vector
Tissue an ordered factor with levels 2 < 1 < 3 < 4
log.NIF a numeric vector

Source

nlme Nonlinear Mixed-Effects Models

Description

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

Usage

```r
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
```

## S3 method for class 'formula'

```r
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
```

Arguments

- `model` a nonlinear model formula, with the response on the left of a ~ operator and an expression involving parameters and covariates on the right, or an `nlsList` object. If data is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function `nlme.nlsList` is documented separately.
- `data` an optional data frame containing the variables named in `model`, `fixed`, `random`, `correlation`, `weights`, `subset`, and `naPattern`. By default the variables are taken from the environment from which `nlme` is called.
- `fixed` a two-sided linear formula of the form \( f_1 + \ldots + f_n \sim x_1 + \ldots + x_m \), or a list of two-sided formulas of the form \( f_1 \sim x_1 + \ldots + x_m \), with possibly different models for different parameters. The \( f_1, \ldots, f_n \) are the names of parameters included on the right hand side of `model` and the \( x_1 + \ldots + x_m \) expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).
- `random` optionally, any of the following: (i) a two-sided formula of the form \( r_1 + \ldots + r_n \sim x_1 + \ldots + x_m | g_1/\ldots/g_Q \), with \( r_1, \ldots, r_n \) naming parameters included on the right hand side of `model`, \( x_1 + \ldots + x_m \) specifying the random-effects model for these parameters and \( g_1/\ldots/g_Q \) the grouping structure (\( Q \) may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form \( r_1 + \ldots + r_n \sim x_1 + \ldots + x_m \), a list of two-sided formulas of the form \( r_1 \sim x_1 + \ldots + x_m \), with possibly different random-effects models for different parameters, a `pdMat` object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for `formula(random)`), or a list of `pdMat` objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in groups, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class `groupedData`; (iii) a named list of formulas, lists of formulas, or `pdMat` objects.
objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (iv) an reStruct object. See the documentation on pdClasses for a description of the available pdMat classes. Defaults to fixed, resulting in all fixed effects having also random effects.

**groups**

an optional one-sided formula of the form \(~g_1\) (single level of nesting) or \(~g_1/\ldots/g_Q\) (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. \(g_1, \ldots, g_Q\) must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. \(g_1\) is the first level, \(g_2\) the second, etc.).

**start**

an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component fixed, given by the vector. The fixed component is required, unless the model function inherits from class selfStart, in which case initial values will be derived from a call to nlsList. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.

**correlation**

an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

**weights**

an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

**subset**

an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

**method**

a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

**na.action**

a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nls to print an error message and terminate if there are any incomplete observations.

**naPattern**

an expression or formula object, specifying which returned values are to be regarded as missing.

**control**

a list of control values for the estimation algorithm to replace the default values returned by the function nlsControl. Defaults to an empty list.

**verbose**

an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

**Value**

an object of class nlme representing the nonlinear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.
Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

nlme.nlsList

NLME fit from nlsList Object

Description

If the random effects names defined in random are a subset of the lmList object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in random). formula(fixed) and the data argument in the calling sequence used to obtain fixed are passed as the fixed and data arguments to nlme.formula, together with any other additional arguments in the function call. See the documentation on nlme.formula for a description of that function.

Usage

## S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
Arguments

model  an object inheriting from class "nlsList", representing a list of nls fits with a common model.
data  this argument is included for consistency with the generic function. It is ignored in this method function.
fixed  this argument is included for consistency with the generic function. It is ignored in this method function.
random  an optional one-sided linear formula with no conditioning expression, or a pdMat object with a formula attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of formula(fixed).
groups  an optional one-sided formula of the form ~g1 (single level of nesting) or ~g1/.../gQ (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. g1,...,gQ must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. g1 is the first level, g2 the second, etc.).
start  an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component fixed, given by the vector. The fixed component is required, unless the model function inherits from class selfStart, in which case initial values will be derived from a call to nlsList. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
correlation  an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.
weights  an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.
subset  an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
method  a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".
na.action  a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nls to print an error message and terminate if there are any incomplete observations.
naPattern  an expression or formula object, specifying which returned values are to be regarded as missing.
control  a list of control values for the estimation algorithm to replace the default values returned by the function nlsControl. Defaults to an empty list.
verbose  an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.
Value

an object of class \texttt{nlme} representing the linear mixed-effects model fit. Generic functions such as \texttt{print}, \texttt{plot} and \texttt{summary} have methods to show the results of the fit. See \texttt{nlmeObject} for the components of the fit. The functions \texttt{resid}, \texttt{coef}, \texttt{fitted}, \texttt{fixed.effects}, and \texttt{random.effects} can be used to extract some of its components.

Control Values for nlme Fit

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the \texttt{nlme} function.

Usage

\texttt{nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,}
\texttt{ tolerance, niterEM, pnlsTo1, msTo1,}
\texttt{returnObject, msVerbose, msWarnNoConv,}
\texttt{ gradHess, apVar, .relStep, minAbsParApVar = 0.05,}
\texttt{ opt = c("nlminb", "nlm"), natural = TRUE, sigma = NULL, ...)}

Arguments

\begin{itemize}
\item \texttt{maxIter} maximum number of iterations for the \texttt{nlme} optimization algorithm. Default is 50.
\item \texttt{pnlsMaxIter} maximum number of iterations for the PNLS optimization step inside the \texttt{nlme} optimization. Default is 7.
\item \texttt{msMaxIter} maximum number of iterations for \texttt{nlminb} (iter.max) or the \texttt{nlm} (iterlim, from the 10-th step) optimization step inside the \texttt{nlme} optimization. Default is 50 (which may be too small for e.g. for overparametrized cases).
\item \texttt{minScale} minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.
\item \texttt{tolerance} tolerance for the convergence criterion in the \texttt{nlme} algorithm. Default is 1e-6.
\item \texttt{niterEM} number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
\item \texttt{pnlsTo1} tolerance for the convergence criterion in PNLS step. Default is 1e-3.
\item \texttt{msTo1} tolerance for the convergence criterion in \texttt{nlm}, passed as the gradtol argument to the function (see documentation on \texttt{nlm}). Default is 1e-7.
\item \texttt{returnObject} a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is \texttt{FALSE}.
\item \texttt{msVerbose} a logical value passed as the trace to \texttt{nlminb}(...) or as argument print.level to \texttt{nlm}(). Default is \texttt{FALSE}.
\item \texttt{msWarnNoConv} logical indicating if a \texttt{warning} should be signalled whenever the minimization (by \texttt{opt}) in the LME step does not converge; defaults to \texttt{TRUE}.
\item \texttt{gradHess} a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the \texttt{nlm} optimization. This option is only available when the correlation structure (\texttt{corStruct}) and the variance function structure (\texttt{varFunc}) have no "varying" parameters and the \texttt{pdMat} classes used in the random effects structure are \texttt{pdSymm} (general positive-definite), \texttt{pdDiag} (diagonal), \texttt{pdIdent} (multiple of the identity), or \texttt{pdCompSymm} (compound symmetry). Default is \texttt{TRUE}.
\end{itemize}
apVar a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

minAbsParApVar numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

opt the optimizer to be used, either "nlminb" (the default) or "nlm".

natural a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

sigma optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

Value a list with components for each of the possible arguments.

Author(s) José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

See Also nlme, nlm, optim, nlmeStruct

Examples

# decrease the maximum number of iterations and request tracing
nlmeControl(msMaxIter = 20, msVerbose = TRUE)

dlmeObject Fitted nlme Object

Description An object returned by the nlme function, inheriting from class "nlme", also inheriting from class "lme", and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, summary, and update.
Value

The following components must be included in a legitimate "nlme" object.

- **apVar**
  An approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the control values used in the call to `nlme`, this component is `NULL`.

- **call**
  A list containing an image of the `nlme` call that produced the object.

- **coefficients**
  A list with two components, `fixed` and `random`, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the `random` list, the columns refer to the random effects and the rows to the groups.

- **contrasts**
  A list of the contrast matrices used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the `nlme` model, this component will be an empty list.

- **dims**
  A list with basic dimensions used in the `nlme` fit, including the components `N` - the number of observations in the data, `Q` - the number of grouping levels, `qvec` - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), `ngrps` - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and `ncol` - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

- **fitted**
  A data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.

- **fixDF**
  A list with components `X` and `terms` specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.

- **groups**
  A data frame with the grouping factors as columns. The grouping level increases from left to right.

- **logLik**
  The (restricted) log-likelihood at convergence.

- **map**
  A list with components `fmap`, `rmap`, `rmapRel`, and `bmap`, specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.

- **method**
  The estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

- **modelStruct**
  An object inheriting from class `nlmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.

- **numIter**
  The number of iterations used in the iterative algorithm.

- **residuals**
  A data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.

- **sigma**
  The estimated within-group error standard deviation.

- **varFix**
  An approximate covariance matrix of the fixed effects estimates.
nlmeStruct

Nonlinear Mixed-Effects Structure

Description

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An nlmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the nlmeStruct list.

Usage

nlmeStruct(reStruct, corStruct, varStruct)

Arguments

reStruct a reStruct representing a random effects structure.
corStruct an optional corStruct object, representing a correlation structure. Default is NULL.
varStruct an optional varFunc object, representing a variance function structure. Default is NULL.

Value

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corClasses, nlme, residuals.nlmeStruct, reStruct, varFunc

Examples

nlms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
**nlsList**  
*List of nls Objects with a Common Model*

**Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual `nls` fits are obtained for each data partition, using the model defined in `model`.

**Usage**

```r
nlsList(model, data, start, control, level, subset,  
na.action = na.fail, pool = TRUE, warn.nls = NA)
```

```r
## S3 method for class 'formula'
nlsList(model, data, start, control, level, subset,  
na.action = na.fail, pool = TRUE, warn.nls = NA)
```

```r
## S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

- `object` an object inheriting from class `nlsList`, representing a list of fitted `nls` objects.
- `model` either a nonlinear model formula, with the response on the left of a `~` operator and an expression involving parameters, covariates, and a grouping factor separated by the `|` operator on the right, or a `selfStart` function. The method function `nlsList.selfStart` is documented separately.
- `model.` changes to the model – see `update.formula` for details.
- `data` a data frame in which to interpret the variables named in `model`.
- `start` an optional named list with initial values for the parameters to be estimated in `model`. It is passed as the `start` argument to each `nls` call and is required when the nonlinear function in `model` does not inherit from class `selfStart`.
- `control` a list of control values passed as the `control` argument to `nls`. Defaults to an empty list.
- `level` an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
- `subset` an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `na.action` a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `nlsList` to print an error message and terminate if there are any incomplete observations.
- `pool` an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for `pool` in calculations of standard deviations or standard errors for summaries.
- `warn.nls` logical indicating if `nls()` errors (all of which are caught by `tryCatch`) should be signalled as a “summarizing” warning.
... some methods for this generic require additional arguments. None are used in this method.

**evaluate**

If TRUE evaluate the new call else return the call.

**Details**

As `nls(.)` is called on each sub group, and convergence of these may be problematic, these calls happen with error catching.

Since `nlme` version 3.1-127 (2016-04), all the errors are caught (via `tryCatch`) and if present, a “summarizing” warning is stored as attribute of the resulting “nlsList” object and signalled unless suppressed by `warn.nls = FALSE` or currently also when `warn.nls = NA` (default) and `getOption("show.error.messages")` is false.

`nlsList()` originally had used `try(*)` (with its default silent=FALSE) and hence all errors were printed to the console unless the global option `show.error.messages` was set to true. This still works, but has been deprecated.

**Value**

A list of `nls` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

**Examples**

```r
fm1 <- nlsList(uptake ~ SSasympOff(conc, Asym, lrc, c0),
               data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
cfm1 <- confint(fm1) # via profiling each % FIXME: only *one* message instead of one *each*
mat.class <- class(matrix(1)) # ("matrix", "array") for R >= 4.0.0; ("matrix" in older R)
[i.ok <- which(vapply(cfm1,
                  function(r) identical(class(r), mat.class), NA))
stopifnot(length(i.ok) > 0, !anyNA(match(c(2:4, 6:9, 12), i.ok)))
## where as (some of) the others gave errors during profile re-fitting :
str(cfm1[- i.ok])
```

---

**nlsList.selfStart**

*nlsList Fit from a selfStart Function*

**Description**

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a selfStarting model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.
Usage

### S3 method for class 'selfStart'

```r
nlsList(model, data, start, control, level, subset,
        na.action = na.fail, pool = TRUE, warn.nls = NA)
```

Arguments

- `model`: a "selfStart" model function, which calculates initial estimates for the model parameters from `data`.
- `data`: a data frame in which to interpret the variables in `model`. Because no grouping factor can be specified in `model`, `data` must inherit from class "groupedData".
- `start`: an optional named list with initial values for the parameters to be estimated in `model`. It is passed as the `start` argument to each `nls` call and is required when the nonlinear function in `model` does not inherit from class `selfStart`.
- `control`: a list of control values passed as the `control` argument to `nls`. Defaults to an empty list.
- `level`: an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
- `subset`: an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (`na.fail`) causes `nlsList` to print an error message and terminate if there are any incomplete observations.
- `pool`, `warn.nls`: optional `logicals`, see `nlsList`.

Value

A list of `nls` objects with as many components as the number of groups defined by the grouping factor. A NULL value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

See Also

- `selfStart`, `groupedData`, `nls`, `nlsList`, `nlme`, `nlList`, `nlList.formula`

Examples

```r
fm1 <- nlsList(SSasympOff, CO2)
summary(fm1)
```
**Oats**  
*Split-plot Experiment on Varieties of Oats*

**Description**

The *Oats* data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Block** an ordered factor with levels VI < V < III < IV < II < I
- **Variety** a factor with levels Golden Rain Marvellous Victory
- **nitro** a numeric vector
- **yield** a numeric vector

**Details**

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a $3 \times 4$ full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

**Source**

**Orthodont**  
*Growth curve data on an orthodontic measurement*

**Description**

The *Orthodont* data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

**Format**

This data frame contains the following columns:

- **distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.
- **age** a numeric vector of ages of the subject (yr).
- **Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.
- **Sex** a factor with levels Male and Female
Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

Examples

formula(Orthodont)
plot(Orthodont)

Ovary

Counts of Ovarian Follicles

Description

The Ovary data frame has 308 rows and 3 columns.

Format

This data frame contains the following columns:

Mare an ordered factor indicating the mare on which the measurement is made.

Time time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

follicles the number of ovarian follicles greater than 10 mm in diameter.

Details

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

Source

**Oxboys**  
*Heights of Boys in Oxford*

**Description**

The Oxboys data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Subject** an ordered factor giving a unique identifier for each boy in the experiment
- **age** a numeric vector giving the standardized age (dimensionless)
- **height** a numeric vector giving the height of the boy (cm)
- **Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

**Details**

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

**Source**

**Oxide**  
*Variability in Semiconductor Manufacturing*

**Description**

The Oxide data frame has 72 rows and 5 columns.

**Format**

This data frame contains the following columns:

- **Source** a factor with levels 1 and 2
- **Lot** a factor giving a unique identifier for each lot.
- **Wafer** a factor giving a unique identifier for each wafer within a lot.
- **Site** a factor with levels 1, 2, and 3
- **Thickness** a numeric vector giving the thickness of the oxide layer.
Details

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

**pairs.compareFits**

*Pairs Plot of compareFits Object*

**Description**

Scatter plots of the values being compared are generated for each pair of coefficients in x. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the trellis function `xyplot` is used; otherwise the trellis function `splom` is used.

**Usage**

```r
## S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

**Arguments**

- `x` an object of class `compareFits`.
- `subset` an optional logical or integer vector specifying which rows of x should be used in the plots. If missing, all rows are used.
- `key` an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the `trellis` function generating the plots (splom or xyplot). Defaults to TRUE.
- `...` optional arguments passed down to the `trellis` function generating the plots.

**Value**

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

Examples

eexample(compareFits) # cF12 <- compareFits(coef(lmList(Orthodont)), .. lme(*))
pairs(cF12)

pairs.lme

Pairs Plot of an lme Object

Description

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable
flexibility in the type of plot specification. A conditioning expression (on the right side of a | oper-
ator) always implies that different panels are used for each level of the conditioning factor,
according to a Trellis display. The expression on the right hand side of the formula, before a |
operator, must evaluate to a data frame with at least two columns. If the data frame has two columns,
a scatter plot of the two variables is displayed (the Trellis function xyplot is used). Otherwise, if
more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns
in the data frame is displayed (the Trellis function splom is used).

Usage

## S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)

Arguments

x
an object inheriting from class "lme", representing a fitted linear mixed-effects
model.

form
an optional one-sided formula specifying the desired type of plot. Any variable
present in the original data frame used to obtain x can be referenced. In addition,
x itself can be referenced in the formula using the symbol ".". Conditional
expressions on the right of a | operator can be used to define separate panels in
a Trellis display. The expression on the right hand side of form, and to the left of
the | operator, must evaluate to a data frame with at least two columns. Default
is ~ coef(.) , corresponding to a pairs plot of the coefficients evaluated at the
innermost level of nesting.

label
an optional character vector of labels for the variables in the pairs plot.

id
an optional numeric value, or one-sided formula. If given as a value, it is used
as a significance level for an outlier test based on the Mahalanobis distances of
the estimated random effects. Groups with random effects distances greater than
the 1 − value percentile of the appropriate chi-square distribution are identified
in the plot using idLabels. If given as a one-sided formula, its right hand side
must evaluate to a logical, integer, or character vector which is used to identify
points in the plot. If missing, no points are identified.
pairs.lmList

idLabels

grid

Value

lme, pairs.compareFits, pairs.lmList, xyplot, splom

Examples

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)

# scatter plot of coefficients by gender, identifying unusual subjects
pairs(fm1, ~coef(., augFrame = TRUE) | Sex, id = 0.1, adj = -0.5)

# scatter plot of estimated random effects:
pairs(fm1, ~ranef(.))
Arguments

x  an object inheriting from class "lmList", representing a list of lm objects with a common model.

form  an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form, and to the left of the | operator, must evaluate to a data frame with at least two columns. Default is ~ coef(.), corresponding to a pairs plot of the coefficients of x.

label  an optional character vector of labels for the variables in the pairs plot.

id  an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - \text{value}$ percentile of the appropriate chi-square distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.

idLabels  an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.

grid  an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

...  optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot.

Effect of Phenylbiguanide on Blood Pressure

Description

The PBG data frame has 60 rows and 5 columns.

Format

This data frame contains the following columns:

- `deltaBP`: a numeric vector
- `dose`: a numeric vector
- `Run`: an ordered factor with levels `T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1`
- `Treatment`: a factor with levels `MDL 72222 Placebo`
- `Rabbit`: an ordered factor with levels `5 < 3 < 2 < 4 < 1`

Details

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

Source

Description

This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.
Usage

pdBlocked(value, form, nam, data, pdClass)

Arguments

value
an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object.

form
an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.

nam
an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.

data
an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.

pdClass
an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

pd1
**pdClasses**

**Positive-Definite Matrix Classes**

**Description**

Standard classes of positive-definite matrices (pdMat) structures available in the nlme package.

**Value**

Available standard classes:

- **pdSymm**: general positive-definite matrix, with no additional structure
- **pdLogChol**: general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization
- **pdDiag**: diagonal
- **pdIdent**: multiple of an identity
- **pdCompSymm**: compound symmetry structure (constant diagonal and constant off-diagonal elements)
- **pdBlocked**: block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class
- **pdNatural**: general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization.

**Note**

Users may define their own pdMat classes by specifying a construct function and, at a minimum, methods for the functions pdConstruct, pdMatrix and coef. For examples of these functions, see the methods for classes pdSymm and pdDiag.

pdBlocked, pdCompSymm, pdDiag, pdFactor, pdIdent, pdMat, pdMatrix, pdNatural, pdSymm, pdLogChol
Description

This function is a constructor for the pdCompSymm class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdCompSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

Usage

pdCompSymm(value, form, nam, data)

Arguments

value
  an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length 2. Defaults to numeric(0), corresponding to an uninitialized object.

form
  an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam
  an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data
  an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

A pdCompSymm object representing a positive-definite matrix with compound symmetry structure, also inheriting from class pdMat.

pdConstruct Construct pdMat Objects

Description
This function is an alternative constructor for the pdMat class associated with object and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

Usage
pdConstruct(object, value, form, nam, data, ...)

Arguments
object an object inheriting from class pdMat, representing a positive definite matrix.
value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.
nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
...
optional arguments for some methods.

Value
a pdMat object representing a positive-definite matrix, inheriting from the same classes as object.

`pdCompSymm`, `pdDiag`, `pdIdent`, `pdNatural`, `pdSymm`

Examples

```r
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

Description

This function gives an alternative constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

Usage

```r
## S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass, ...)
```

Arguments

- **object**: an object inheriting from class "pdBlocked", representing a positive definite block-diagonal matrix.
- **value**: an optional list with elements to be used as the `value` argument to other `pdMat` constructors. These include: `pdMat` objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to `numeric(0)`, corresponding to an uninitialized object.
- **form**: an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by `object`. Because factors may be present in `form`, the formulas needs to be evaluated on a data.frame to resolve the names they defines. This argument is ignored when `value` is a list of one-sided formulas. Defaults to `NULL`.
- **nam**: an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by `object`. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when `value` is a list of vector of character strings. Defaults to `NULL`. 
data

an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

pdClass

an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

pd1 <- pdBlocked(list(c("A","B"), c("a1", "a2", "a3"))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))

Description

This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension n, it is represented by n unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

Usage

pdDiag(value, form, nam, data)
Arguments

value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdDiag object representing a diagonal positive-definite matrix, also inheriting from class pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

Examples

pd1 <- pdDiag(diag(1:3), nam = c("A","B","C"))
pd1

Description

A square-root factor of the positive-definite matrix represented by object is obtained. Letting Σ denote a positive-definite matrix, a square-root factor of Σ is any square matrix L such that Σ = L'L. This function extracts L.
Usage

pdFactor(object)

Arguments

object: an object inheriting from class `pdMat`, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`).

Value

a vector with a square-root factor of the positive-definite matrix associated with `object` stacked column-wise.

Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

*Extract Square-Root Factor from Components of an reStruct Object*

Description

This method function extracts square-root factors of the positive-definite matrices corresponding to the `pdMat` elements of `object`.

Usage

```r
## S3 method for class 'reStruct'
pdFactor(object)
```

Arguments

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of `pdMat` objects.
pdIdent

Value

a vector with square-root factors of the positive-definite matrices corresponding to the elements of object stacked column-wise.

Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The pdMatrix function can be used to obtain square-root factors in matrix form.

Description

This function is a constructor for the pdIdent class, representing a multiple of the identity positive-definite matrix. The matrix associated with object is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdIdent object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

Usage

pdIdent(value, form, nam, data)
**Arguments**

- **value**: an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric value. Defaults to `numeric(0)`, corresponding to an uninitialized object.

- **form**: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.

- **nam**: an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`.

- **data**: an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

- a pdIdent object representing a multiple of the identity positive-definite matrix, also inheriting from class pdMat.

**pdLogChol**

*General Positive-Definite Matrix*
pdLogChol

Description

This function is a constructor for the pdLogChol class, representing a general positive-definite matrix. If the matrix associated with object is of dimension \( n \), it is represented by \( n(n + 1)/2 \) unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996).

- When value is numeric(\( \emptyset \)), an uninitialized pdMat object, a one-sided formula, or a character vector, object is returned as an uninitialized pdLogChol object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions.
- If value is an initialized pdMat object, object will be constructed from as.matrix(value).
- Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

Usage

pdLogChol(value, form, nam, data)

Arguments

value

an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(\( \emptyset \)), corresponding to an uninitialized object.

form

an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam

an optional character vector specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a character vector. Defaults to NULL.

data

an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Details

Internally, the pdLogChol representation of a symmetric positive definite matrix is a vector starting with the logarithms of the diagonal of the Choleski factorization of that matrix followed by its upper triangular portion.

Value

a pdLogChol object representing a general positive-definite matrix, also inheriting from class pdMat.

pdMat  Positive-Definite Matrix

Description

This function gives an alternative way of constructing an object inheriting from the pdMat class
named in pdClass, or from data.class(object) if object inherits from pdMat, and is mostly
used internally in other functions. See the documentation on the principal constructor function,
generally with the same name as the pdMat class of object.

Usage

pdMat(value, form, nam, data, pdClass)

Arguments

value an optional initialization value, which can be any of the following: a pdMat ob-
ject, a positive-definite matrix, a one-sided linear formula (with variables sepa-
rated by +), a vector of character strings, or a numeric vector. Defaults to
numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the
matrix represented by object. Because factors may be present in form, the
formula needs to be evaluated on a data.frame to resolve the names it defines.
This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam an optional vector of character strings specifying the row/column names for the
matrix represented by object. It must have length equal to the dimension of the
underlying positive-definite matrix and unreplicated elements. This argument is
ignored when value is a vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and
form. It is used to obtain the levels for factors, which affect the dimensions
and the row/column names of the underlying matrix. If NULL, no attempt is
made to obtain information on factors appearing in the formulas. Defaults to the
parent frame from which the function was called.
pdMatrix

pdClass

an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to "pdSymm".

Value

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

pdMatrix

Extract Matrix or Square-Root Factor from a pdMat Object

Description

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting $\Sigma$ denote a positive-definite matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. This function extracts $\Sigma$ or $L$.

Usage

pdMatrix(object, factor)

Arguments

object an object inheriting from class pdMat, representing a positive definite matrix.

factor an optional logical value. If TRUE, a square-root factor of the positive-definite matrix represented by object is returned; else, if FALSE, the positive-definite matrix is returned. Defaults to FALSE.

Value

if factor is FALSE the positive-definite matrix represented by object is returned; else a square-root of the positive-definite matrix is returned.
pdMatrix.reStruct

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also
as.matrix.pdMat, pdClasses, pdFactor, pdMat, pdMatrix.reStruct, corMatrix

Examples
pd1 <- pdSymm(diag(1:4))
pdMatrix(pd1)

Description
This method function extracts the positive-definite matrices corresponding to the pdMat elements of object, or square-root factors of the positive-definite matrices.

Usage
## S3 method for class 'reStruct'
pdMatrix(object, factor)

Arguments
object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
factor an optional logical value. If TRUE, square-root factors of the positive-definite matrices represented by the elements of object are returned; else, if FALSE, the positive-definite matrices are returned. Defaults to FALSE.

Value
a list with components given by the positive-definite matrices corresponding to the elements of object, or square-root factors of the positive-definite matrices.

pdNatural

General Positive-Definite Matrix in Natural Parametrization

Description

This function is a constructor for the pdNatural class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with object is of dimension n, it is represented by n(n + 1)/2 parameters. Letting σ_{ij} denote the ij-th element of the underlying positive definite matrix and ρ_{ij} = σ_{i}/\sqrt{σ_{ii}σ_{jj}}, i ≠ j denote the associated "correlations", the "natural" parameters are given by √σ_{ii}, i = 1, ..., n and log((1 + ρ_{ij})/(1 − ρ_{ij})), i ≠ j. Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

Usage

pdNatural(value, form, nam, data)

Arguments

value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Examples

rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
pdMatrix(rs1)
Value

A `pdNatural` object representing a general positive-definite matrix in natural parametrization, also inheriting from class `pdMat`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

`as.matrix.pdMat`, `coef.pdMat`, `pdClasses`, `matrix<-.pdMat`

Examples

```r
pdNatural(diag(1:3))
```

Description

This function is a constructor for the `pdSymm` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension `n`, it is represented by \( n(n + 1)/2 \) unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

Usage

```r
pdSymm(value, form, nam, data)
```

Arguments

- `value`: an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector. Defaults to `numeric(0)`, corresponding to an uninitialized object.
- `form`: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`. 
nam  an optional vector of character strings specifying the row/column names for the
      matrix represented by object. It must have length equal to the dimension of
      the underlying positive-definite matrix and unreplicated elements. This argument is
      ignored when value is a vector of character strings. Defaults to NULL.

data  an optional data frame in which to evaluate the variables named in value and
      form. It is used to obtain the levels for factors, which affect the dimensions
      and the row/column names of the underlying matrix. If NULL, no attempt is
      made to obtain information on factors appearing in the formulas. Defaults to
      the parent frame from which the function was called.

Value

  a pdSymm object representing a general positive-definite matrix, also inheriting from class pdMat.

Author(s)

  José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Phenobarb  Phenobarbitol Kinetics

Description

  The Phenobarb data frame has 744 rows and 7 columns.

Format

  This data frame contains the following columns:

    Subject  an ordered factor identifying the infant.
    Wt       a numeric vector giving the birth weight of the infant (kg).
    Apgar    an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of
              health of the newborn infant.
    ApgarInd a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.
    time     a numeric vector giving the time when the sample is drawn or drug administered (hr).
    dose     a numeric vector giving the dose of drug administered (ug/kg).
    conc      a numeric vector giving the phenobarbital concentration in the serum (ug/L).
Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn (1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

Source

Grasela and Donn (1985), Neonatal population pharmacokinetics of phenobarbital derived from routine clinical data, *Developmental Pharmacology and Therapeutics*, 8, 374-383.

---

**phenoModel**

*Model function for the Phenobarb data*

Description

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

Usage

```r
phenoModel(Subject, time, dose, lCl, lV)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subject</td>
<td>an integer vector of subject identifiers. These should be sorted in increasing order.</td>
</tr>
<tr>
<td>time</td>
<td>numeric. A vector of the times at which the sample was drawn or the drug administered (hr).</td>
</tr>
<tr>
<td>dose</td>
<td>numeric. A vector of doses of drug administered (ug/kg).</td>
</tr>
<tr>
<td>lCl</td>
<td>numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.</td>
</tr>
<tr>
<td>lV</td>
<td>numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.</td>
</tr>
</tbody>
</table>

Details

See the details section of *Phenobarb* for a description of the model function that phenoModel evaluates.
**Value**

a numeric vector of predicted phenobarbital concentrations.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Pixel**

*X-ray pixel intensities over time*

**Description**

The **Pixel** data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time.

**Format**

This data frame contains the following columns:

- **Dog** a factor with levels 1 to 10 designating the dog on which the scan was made
- **Side** a factor with levels L and R designating the side of the dog being scanned
- **day** a numeric vector giving the day post injection of the contrast on which the scan was made
- **pixel** a numeric vector of pixel intensities

**Source**

**Examples**

```r
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel, 
            random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```
plot.ACF

Plot an ACF Object

Description

An xyplot of the autocorrelations versus the lags, with type = "h", is produced. If alpha > 0, curves representing the critical limits for a two-sided test of level alpha for the autocorrelations are added to the plot.

Usage

```r
## S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

Arguments

- `x`: an object inheriting from class ACF, consisting of a data frame with two columns named lag and ACF, representing the autocorrelation values and the corresponding lags.
- `alpha`: an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level alpha are added to the plot. Default is 0, in which case no lines are plotted.
- `xlab`, `ylab`: optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".
- `grid`: an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- `...`: optional arguments passed to the `xyplot` function.

Value

An `xyplot` Trellis plot.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`ACF`, `xyplot`

Examples

```r
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```
Description

A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

Usage

```r
## S3 method for class 'augPred'
plot(x, key, grid, ...)
```

Arguments

- `x` an object of class "augPred".
- `key` an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the `trellis` function generating the plots (`xyplot`). Defaults to TRUE.
- `grid` an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- `...` optional arguments passed down to the `trellis` function generating the plots.

Value

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`augPred`, `xyplot`

Examples

```r
fm1 <- lme(Orthodont)
plot(augPred(fm1, level = 0:1, length.out = 2))
```
Description

A Trellis dotplot of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

Usage

```r
## S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)
```

Arguments

- `x`: an object of class "compareFits".
- `subset`: an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used.
- `key`: an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (dotplot). Defaults to TRUE.
- `mark`: an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.
- `...`: optional arguments passed down to the `trellis` function generating the plots.

Value

A Trellis dotplot of the values being compared, with rows determined by the groups and panels by the coefficients.

plot(cF12)
```
plot.gls

Plot a gls Object

Description

Diagnostic plots for the linear model fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

## S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)

Arguments

x  
an object inheriting from class "gls", representing a generalized least squares fitted linear model.

form  
an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "p") ~ fitted(.,), corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.

abline  
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id  
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels  
an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.

idResType  
an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized...
residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

... optional arguments passed to the Trellis plot function.

Value
a diagnostic Trellis plot.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

gls, xyplot, bwplot, histogram

Examples
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
    correlation = corAR1(form = ~ 1 | Mare))
# standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") - fitted(.) | Mare, abline = 0)
# box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.))
# observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))

Description
A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the lm components of the lmList object used to produce x. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+".

This is based on function dotplot() from package lattice.

Usage
## S3 method for class 'intervals.lmList'
plot(x, xlab = "", ylab = attr(x, "groupsName"),
    strip = function(...) strip.default(..., style = 1),
    ...)
Arguments

**x**

an object inheriting from class "intervals.lmList", representing confidence intervals and estimates for the coefficients in the lm components of the lmList object used to produce x.

**xlab, ylab**

axis labels, each with a sensible default.

**strip**

a function or FALSE, see dotplot() from package lattice.

**...**

optional arguments passed to the dotplot function (see above).

Value

a Trellis plot with the confidence intervals on the coefficients of the individual lm components of the lmList that generated x.

**plot.lme**

*Plot an lme or nls object*

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

**Usage**

```r
## S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```
Arguments

- **x**: an object inheriting from class "lme", representing a fitted linear mixed-effects model, or from nls, representing an fitted nonlinear least squares model.
- **form**: an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(. , type = "p") ~ fitted(.), corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.
- **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
- **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
- **idLabels**: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
- **idResType**: an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals premultiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- **grid**: an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

Value

a diagnostic Trellis plot.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

plot.lmList

Plot an lmList Object

Description

Diagnostic plots for the linear model fits corresponding to the \texttt{x} components are obtained. The \texttt{form} argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a \texttt{|} operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If \texttt{form} is a one-sided formula, histograms of the variable on the right hand side of the formula, before a \texttt{|} operator, are displayed (the Trellis function \texttt{histogram} is used). If \texttt{form} is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function \texttt{xyplot} is used). Finally, if \texttt{form} is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function \texttt{bwplot} is used).

Usage

```r
## S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

Arguments

- \texttt{x} an object inheriting from class \texttt{"lmList"}, representing a list of \texttt{lm} objects with a common model.
- \texttt{form} an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain \texttt{x} can be referenced. In addition, \texttt{x} itself can be referenced in the formula using the symbol \texttt{"."}. Conditional expressions on the right of a \texttt{|} operator can be used to define separate panels in a Trellis display. Default is \texttt{resid(., type = "pool") ~ fitted(.)}, corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.
- \texttt{abline} an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
- \texttt{id} an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the \texttt{1 - value}/2 quantile of the standard normal distribution are identified in the plot using \texttt{idLabels}. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
idLabels

| Description
|---|
| An optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is getGroups(x).

grid

| Description
|---|
| An optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

optional arguments passed to the Trellis plot function.

Value

A diagnostic Trellis plot.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

| lmList, predict.lm, xyplot, bwplot, histogram |

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```
Arguments

- **x**: an object inheriting from class *nffGroupedData*, representing a *groupedData* object with a factor primary covariate and a single grouping level.
- **outer**: an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to *TRUE*, `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.
- **inner**: an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to *TRUE*, `attr(object, "inner")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.
- **innerGroups**: an optional one-sided formula specifying a factor to be used for grouping the levels of the `inner` covariate. Different colors, or symbols, are used for each level of the `innerGroups` factor. Default is `NULL`, meaning that no `innerGroups` covariate is present.
- **xlab**: an optional character string with the label for the horizontal axis. Default is the *y* elements of `attr(object, "labels")` and `attr(object, "units")` pasted together.
- **ylab**: an optional character string with the label for the vertical axis. Default is the grouping factor name.
- **strip**: an optional function passed as the `strip` argument to the `dotplot` function. Default is `strip.default(...., style = 1)` (see `trellis.args`).
- **panel**: an optional function used to generate the individual panels in the Trellis display, passed as the `panel` argument to the `dotplot` function.
- **key**: an optional logical function or function. If *TRUE* and either `inner` or `innerGroups` are non-*NULL*, a legend for the different `inner` (`innerGroups`) levels is included at the top of the plot. If given as a function, it is passed as the key argument to the `dotplot` function. Default is *TRUE* is either `inner` or `innerGroups` are non-*NULL* and *FALSE* otherwise.
- **grid**: this argument is included for consistency with the `plot.nfnGroupedData` method calling sequence. It is ignored in this method function.
- **...**: optional arguments passed to the `dotplot` function.

Value

A Trellis dot-plot of the response by group.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

plot.nfnGroupedData

See Also
groupedData, dotplot

Examples

plot(Machines)
plot(Machines, inner = TRUE)

Description

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function xyplot is used.

Usage

## S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
key, grid, ...)

Arguments

x
an object inheriting from class nfnGroupedData, representing a groupedData object with a numeric primary covariate and a single grouping level.

outer
an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.

inner
an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object, "inner") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.

innerGroups
an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or line types, are used for each level of the innerGroups factor. Default is NULL, meaning that no innerGroups covariate is present.

xlab, ylab
optional character strings with the labels for the plot. Default is the corresponding elements of attr(object, "labels") and attr(object, "units") pasted together.
strip  an optional function passed as the strip argument to the xyplot function. Default is strip.default(., style = 1) (see trellis.args).

aspect an optional character string indicating the aspect ratio for the plot passed as the aspect argument to the xyplot function. Default is "xy" (see trellis.args).

panel  an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the xyplot function.

key  an optional logical function or function. If TRUE and innerGroups is non-NULL, a legend for the different innerGroups levels is included at the top of the plot. If given as a function, it is passed as the key argument to the xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE otherwise.

grid  an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

...  optional arguments passed to the xyplot function.

Value

a Trellis plot of the response versus the primary covariate.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

# different panels per Subject
plot(Orthodont)
# different panels per gender
plot(Orthodont, outer = TRUE)

plot.nmGroupedData  Plot an nmGroupedData Object

Description

The groupedData object is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor, which is plotted using the appropriate plot method for groupedData objects with single level of grouping.
## Usage

```r
## S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
     preserve, FUN, subset, key, grid, ...)
```

### Arguments

- **x**: an object inheriting from class `nmGroupedData`, representing a groupedData object with multiple grouping factors.
- **collapseLevel**: an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
- **displayLevel**: an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when `outer` is missing. Default is `collapseLevel`.
- **outer**: an optional logical value or one-sided formula, indicating covariates that are outer to the `displayLevel` grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, the `displayLevel` element `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.
- **inner**: an optional logical value or one-sided formula, indicating a covariate that is inner to the `displayLevel` grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, `attr(object, "outer")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.
- **preserve**: an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the `collapseLevel` grouping factor. The collapsing factor is obtained by pasting together the levels of the `collapseLevel` grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.
- **FUN**: an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by `collapseLevel`. Invariant variables are always summarized by group using the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the data such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
- **subset**: an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is NULL, meaning that all levels are used.
An optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE.

grid

an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

... optional arguments passed to the Trellis plot function.

Value

a Trellis display of the data collapsed over the values of the collapseLevel grouping factor and grouped according to the displayLevel grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

# no collapsing, panels by Dog
plot(Pixel, display = "Dog", inner = ~Side)
# collapsing by Dog, preserving day
plot(Pixel, collapse = "Dog", preserve = ~day)
Arguments

- **x**: an object inheriting from class "ranef.lme", representing the estimated coefficients or estimated random effects for the lme object from which it was produced.

- **form**: an optional formula specifying the desired type of plot.
  - If given as a one-sided formula, a `dotplot()` of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned.
  - If given as a two-sided formula (or by default, NULL), an `xyplot()` Trellis display of the random effect (coefficient) versus the named covariates is returned. In NULL case the row names of the random effects (coefficients) are used (as covariates).

See also ‘Details’.

- **omitFixed**: an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is `TRUE`.

- **level**: an optional integer value giving the level of grouping to be used for `x`. Only used when `x` is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.

- **grid**: an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is `TRUE`.

- **control**: an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is `TRUE`); `span.loess`, used as the span argument in the call to `panel.loess` (default is `2/3`); `degree.loess`, used as the degree argument in the call to `panel.loess` (default is `1`); `cex.axis`, the character expansion factor for the x-axis (default is `0.8`); `srt.axis`, the rotation factor for the x-axis (default is `0`); and `mgp.axis`, the margin parameters for the x-axis (default is `c(2, 0.5, 0)`).

- **xlab, ylab**: axis labels, each with a sensible default.

- **strip**: a function or `FALSE`, see `dotplot()` from package lattice.

- **...**: optional arguments passed to the Trellis `dotplot` function.

Details

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot (via `dotplot()` from pkg lattice) of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). Single factors (`~g`) or crossed factors (`~g1*g2`) are allowed. For a single factor, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula.

If `form` is a two-sided formula, the left hand side must be a single random effect (coefficient) and the right hand side is formed by covariates in `x` separated by `+`. An `xyplot()` Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (Factor or ordered) variables.
plot.ranef.lmList

Plot a ranef.lmList Object

Description

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

Usage

```r
## S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

Arguments

- `x` an object inheriting from class “`ranef.lmList`”, representing the estimated coefficients or estimated random effects for the `lmList` object from which it was produced.
- `form` an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned. Single factors (~g) or crossed factors (~g1*g2) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in `x` separated by +. A Trellis
display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used.

grid

an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is FALSE.

control

an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is 0.8); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

... optional arguments passed to the Trellis dotplot function.

Value

data frame of the estimated random-effects (coefficients) versus covariates, or groups.

fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex)

plot.Variogram

Plot a Variogram Object

Description

an xyplot of the semi-variogram versus the distances is produced. If smooth = TRUE, a loess smoother is added to the plot. If showModel = TRUE and x includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

Usage

# S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab, ylab, type, ylim, grid, ...)
Arguments

x

an object inheriting from class "Variogram", consisting of a data frame with two columns named variog and dist, representing the semi-variogram values and the corresponding distances.

smooth

an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to TRUE, when showModel is FALSE.

showModel

an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of x, if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present.

sigma

an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn.

span

an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.

xlab,ylab

optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".

type

an optional character indicating the type of plot. Defaults to "p".

ylim

an optional numeric vector with the limits for the y-axis. Defaults to c(0, max(x$variog)).

grid

an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

... optional arguments passed to the Trellis xyplot function.

Value

an xyplot Trellis plot.

pooledSD

Extract Pooled Standard Deviation

Description

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of object, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.
predict.gls

**Usage**

pooledSD(object)

**Arguments**

object  
an object inheriting from class lmList.

**Value**

the pooled standard deviation for the non-null elements of object, with an attribute df with the number of degrees-of-freedom used in the estimation.

**predict.gls**  
*Predictions from a gls Object*

**Description**

The predictions for the linear model represented by object are obtained at the covariate values defined in newdata.

**Usage**

## S3 method for class 'gls'
predict(object, newdata, na.action, ...)

**Arguments**

object  
an object inheriting from class "gls", representing a generalized least squares fitted linear model.

newdata  
an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.

na.action  
a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.

...  
some methods for this generic require additional arguments. None are used in this method.
predict.gnls

Value

a vector with the predicted values.

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
newOvary <- data.frame(Time = c(-0.75, -0.5, 0, 0.5, 0.75))
predict(fm1, newOvary)
```

predict.gnls  Predictions from a gnls Object

Description

The predictions for the nonlinear model represented by object are obtained at the covariate values defined in newdata.

Usage

```r
## S3 method for class 'gnls'
predict(object, newdata, na.action, naPattern, ...)
```

Arguments

- **object**: an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
- **newdata**: an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned.
- **na.action**: a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- **naPattern**: an expression or formula object, specifying which returned values are to be regarded as missing.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the predicted values.
predict.lme

Predictions from an lme Object

Description

The predictions at level \( i \) are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to \( i \). The resulting values estimate the best linear unbiased predictions (BLUPs) at level \( i \). If group values not included in the original grouping factors are present in \( \text{newdata} \), the corresponding predictions will be set to \( \text{NA} \) for levels greater or equal to the level at which the unknown groups occur.

Usage

## S3 method for class 'lme'
predict(object, newdata, level = Q, asList = FALSE, 
na.action = na.fail, ...)

Arguments

object 
an object inheriting from class \"lme\", representing a fitted linear mixed-effects model.

newdata 
an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.

level 
an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.

asList 
an optional logical value. If TRUE and a single value is given in \( \text{level} \), the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of \( \text{level} \).

na.action 
a function that indicates what should happen when \( \text{newdata} \) contains NAs. The default action (\( \text{na.fail} \)) causes the function to print an error message and terminate if there are any incomplete observations.

... 
some methods for this generic require additional arguments. None are used in this method.
predict.lmList

Value

if a single level of grouping is specified in level, the returned value is either a list with the predictions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

lme, fitted.lme

Examples

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male","Male","Female","Female","Male","Male"),
                      age = c(15, 20, 10, 12, 2, 4),
                      Subject = c("M01","M01","F30","F30","M04","M04"))
## The 'Orthodont' data has *no* 'F30', so predict NA at level 1:
predict(fm1, newOrth, level = 0:1)

Description

If the grouping factor corresponding to object is included in newdata, the data frame is partitioned according to the grouping factor levels; else, newdata is repeated for all lm components. The predictions and, optionally, the standard errors for the predictions, are obtained for each lm component of object, using the corresponding element of the partitioned newdata, and arranged into a list with as many components as object, or combined into a single vector or data frame (if se.fit=TRUE).

Usage

## S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...)

Arguments

object an object inheriting from class "lmList", representing a list of lm objects with a common model.
newdata an optional data frame to be used for obtaining the predictions. All variables used in the object model formula must be present in the data frame. If missing, the same data frame used to produce object is used.
subset an optional character or integer vector naming the lm components of object from which the predictions are to be extracted. Default is NULL, in which case all components are used.
asList an optional logical value. If TRUE, the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to FALSE.
**predict.nlme**

Predictions from an nlme Object

**Description**

The predictions at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```r
## S3 method for class 'nlme'
predict(object, newdata, level = Q, asList = FALSE,
        na.action = na.fail, naPattern = NULL, ...)
```

**Arguments**

- `object`: an object inheriting from class "nlme", representing a fitted nonlinear mixed-effects model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.

**Value**

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each lm component of object, a vector with the predictions from all lm components of object, or a data frame with columns given by the predictions and their corresponding standard errors.

**Author(s)**

print.summary.pdMat

Description

The standard deviations and correlations associated with the positive-definite matrix represented by object (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated object, if any are present.

Usage

## S3 method for class 'summary.pdMat'

print(x, sigma, rdig, Level, resid, ...)

Arguments

- **x**: an object inheriting from class "summary.pdMat", generally resulting from applying summary to an object inheriting from class "pdMat".
- **sigma**: an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by object (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
- **rdig**: an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.
- **Level**: an optional character string with a description of the grouping level associated with object (generally corresponding to levels of grouping in a mixed-effects model). Defaults to NULL.
- **resid**: an optional logical value. If TRUE an extra row with the "residual" standard deviation given in sigma will be included in the output. Defaults to FALSE.
- **...**: optional arguments passed to print.default; see the documentation on that method function.

qqnorm.gls  
*Normal Plot of Residuals from a gls Object*

**Description**

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a \( | \) operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```r
## S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)  
```
Arguments

y: an object inheriting from class "gls", representing a generalized least squares fitted model.

form: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form and to the left of a | operator must evaluate to a residuals vector. Default is ~ resid(., type = "p"), corresponding to a normal plot of the standardized residuals.

abline: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the 1 - value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

grid: an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

...: optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot for assessing normality of residuals.

qqnorm(fml, abline = c(0,1))
**qqnorm.lme**

Normal Plot of Residuals or Random Effects from an lme Object

Description

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

Usage

```r
## S3 method for class 'lme'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

Arguments

- **y**: an object inheriting from class "lme", representing a fitted linear mixed-effects model or from class "lmList", representing a list of lm objects, or from class "lm", representing a fitted linear model, or from class "nls", representing a nonlinear least squares fitted model.

- **form**: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form` and to the left of a | operator must evaluate to a residuals vector, or a random effects matrix. Default is ~ resid(., type = "p"), corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting.

- **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

- **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the 1 - `value`/2 quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

- **idLabels**: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

- **grid**: an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

- **...**: optional arguments passed to the Trellis plot function.
Value

a diagnostic Trellis plot for assessing normality of residuals or random effects.

lme, plot.lme

Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
## normal plot of standardized residuals by gender
qqnorm(fm1, resid(., type = "p") | Sex, abline = c(0, 1))
## normal plots of random effects
qqnorm(fm1, ranef(.))
```
Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation or ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

Source

quinModel

Model function for the Quinidine data

Description

A model function for a model used with the Quinidine data. This function calls compiled C code.

Usage

quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subject</td>
<td>a factor identifying the patient on whom the data were collected.</td>
</tr>
<tr>
<td>time</td>
<td>a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.</td>
</tr>
<tr>
<td>conc</td>
<td>a numeric vector giving the serum quinidine concentration (mg/L).</td>
</tr>
<tr>
<td>dose</td>
<td>a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.</td>
</tr>
<tr>
<td>interval</td>
<td>a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.</td>
</tr>
<tr>
<td>lV</td>
<td>numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.</td>
</tr>
<tr>
<td>lKa</td>
<td>numeric. A vector of values of the natural log of the absorption rate constant according to Subject and time.</td>
</tr>
<tr>
<td>lCl</td>
<td>numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.</td>
</tr>
</tbody>
</table>
**Details**

See the details section of *Quinidine* for a description of the model function that *quinModel* evaluates.

**Value**

a numeric vector of predicted quinidine concentrations.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

---

**Description**

The *Rail* data frame has 18 rows and 2 columns.

**Format**

This data frame contains the following columns:

- **Rail**: an ordered factor identifying the rail on which the measurement was made.
- **travel**: a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds). The value given is the original travel time minus 36,100 nanoseconds.

**Details**

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

random.effects  

Extract Random Effects

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include \texttt{lmList} and \texttt{lme}.

Usage

\begin{verbatim}
random.effects(object, ...)  
ranef(object, ...)
\end{verbatim}

Arguments

- **object**: any fitted model object from which random effects estimates can be extracted.
- **...**: some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

References

See Also

\texttt{ranef.lmList}, \texttt{ranef.lme}

Examples

\begin{verbatim}
## see the method function documentation
\end{verbatim}

ranef.lme  

Extract lme Random Effects

Description

The estimated random effects at level $i$ are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

Usage

\begin{verbatim}
## S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,  
standard, omitGroupingFactor, subset, ...)
\end{verbatim}
ranef.lme

**Arguments**

- **object**: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- **augFrame**: an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- **level**: an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.
- **data**: an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
- **which**: an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
- **FUN**: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
- **standard**: an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to FALSE.
- **omitGroupingFactor**: an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.
- **subset**: an optional expression indicating for which rows the random effects should be extracted.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

A data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in level and, optionally, other covariates summarized over groups. The returned object inherits from classes random.effects.lme and data.frame.

random.effects(fm1, augFrame = TRUE)
```

---

**ranef.lmList**

**Extract lmList Random Effects**

**Description**

The difference between the individual lm components coefficients and their average is calculated.

**Usage**

```r
## S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard,
      omitGroupingFactor, ...)
```

**Arguments**

- `object`: an object inheriting from class "lmList", representing a list of lm objects with a common model.
- `augFrame`: an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
- `which`: an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
standard: an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.

omitGroupingFactor: an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

...some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the differences between the individual lm coefficients in object and their average.

RatPupWeight

The weight of rat pups

Description

The RatPupWeight data frame has 322 rows and 5 columns.

Format

This data frame contains the following columns:

- **weight**: a numeric vector
- **sex**: a factor with levels Male Female
- **Litter**: an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12
- **Lsize**: a numeric vector
- **Treatment**: an ordered factor with levels Control < Low < High
Recalc {Recalculate Condensed Linear Model Object}

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, modelStruct, reStruct, and varFunc.

Usage

recalc(object, conLin, ...)

Arguments

- object: any object which induces a recalculation of the condensed linear model object conLin.
- conLin: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- ...: some methods for this generic can take additional arguments.

Value

the recalculated condensed linear model object.

Note

This function is only used inside model fitting functions, such as lme and gls, that require recalculation of a condensed linear model object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

recalc.corStruct, recalc.modelStruct, recalc.reStruct, recalc.varFunc

Examples

## see the method function documentation
Recalculate for `corStruct` Object

Description

This method function pre-multiplies the "Xy" component of `conLin` by the transpose square-root factor(s) of the correlation matrix (matrices) associated with `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`.

Usage

```r
## S3 method for class 'corStruct'
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "`corStruct`", representing a correlation structure.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow correlated error terms.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

corfactor, logLik.corStruct
Recalculate for a modelStruct Object

Description

This method function recalculates the condensed linear model object using each element of object sequentially from last to first.

Usage

```r
## S3 method for class 'modelStruct'
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to `attr(object, "conLin")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is generally only used inside model fitting functions, such as `lme` and `gls`, that allow model components, such as correlated error terms and variance functions.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`recalc.corStruct`, `recalc.reStruct`, `recalc.varFunc`
Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by object and conLin (assuming spherical within-group covariance structure), evaluated at coef(object) is calculated and added to the logLik component of conLin. The settings attribute of object determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

Usage

```r
## S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the condensed linear model with its logLik component updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `logLik`, `lme`, `recalc`, `reStruct`
Usage

```r
## S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "varFunc", representing a variance function structure.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow heteroscedastic error terms.

### Relaxin

**Assay for Relaxin**

**Description**

The Relaxin data frame has 198 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Run**: an ordered factor with levels 5 < 8 < 9 < 3 < 4 < 2 < 7 < 1 < 6
- **conc**: a numeric vector
- **cAMP**: a numeric vector

**Source**

Remifentanil

Pharmacokinetics of Remifentanil

Description

Intravenous infusion of remifentanil (a strong analgesic) in different rates over varying time periods was applied to a total of 65 patients. Concentration measurements of remifentanil were taken along with several covariates resulting in the Remifentanil data frame with 2107 rows and 12 columns.

Usage

data("Remifentanil", package = "nlme")

Format

This data frame (of class "groupedData", specifically "nfnGroupedData") contains the following columns:

ID: numerical (patient) IDs.

Subject: an ordered factor with 65 levels (of the IDs): 30 < 21 < 25 < 23 < 29 < …… < 36 < 6 < 5 < 10 < 9.

Time: time from beginning of infusion in minutes (numeric).

conc: remifentanil concentration in [ng / ml] (numeric).

Rate: infusion rate in [µg / min].

Amt: amount of remifentanil given in the current time interval in [µg].

Age: age of the patient in years.

Sex: gender of the patient, a factor with levels Female and Male.

Ht: height of the patient in cm.

Wt: weight of the patient in kg.

BSA: body surface area (DuBois and DuBois 1916): \( BSA := Wt^{0.425} \cdot Ht^{0.725} \cdot 0.007184. \)

LBM: lean body mass (James 1976), with slightly different formula for men \( LBM_m := 1.1Wt - 128(Wt/Ht)^2, \) and women \( LBM_f := 1.07Wt - 148(Wt/Ht)^2. \)

Author(s)

of this help page: Niels Hagenbuch and Martin Maechler, SfS ETH Zurich.

References

Examples

plot(Remifentanil, type = "l", lwd = 2) # shows the 65 patients' remi profiles

## The same on log-log scale (*more* sensible for modeling?):
plot(Remifentanil, type = "l", lwd = 2, scales = list(log=TRUE))

str(Remifentanil)
summary(Remifentanil)

plot(xtabs(~Subject, Remifentanil))
summary(unclass(table(Remifentanil$Subject)))
## between 20 and 54 measurements per patient (median: 24; mean: 32.42)

## Only first measurement of each patient:

LBMfn <- function(Wt, Ht, Sex) ifelse(Sex == "Female",
  1.07 * Wt - 148*(Wt/Ht)^2,
  1.1 * Wt - 128*(Wt/Ht)^2)

with(Remi.1,
  stopifnot(all.equal(BSA, Wt^{0.425} * Ht^{0.725} * 0.007184, tol = 1.5e-5),
  all.equal(LBM, LBMfn(Wt, Ht, Sex),
            tol = 7e-7))

## Rate: typically 3 µg / kg body weight, but:
sunflowerplot(Rate ~ Wt, Remifentanil)
abline(0,3, lty=2, col=adjustcolor("black", 0.5))

residuals.gls

Extract gls Residuals

Description

The residuals for the linear model represented by object are extracted.

Usage

## S3 method for class 'gls'
residuals(object, type, ...)

Arguments

object: an object inheriting from class "gls", representing a generalized least squares fitted linear model, or from class gnls, representing a generalized nonlinear least squares fitted linear model.

type: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response".

... some methods for this generic function require additional arguments. None are used in this method.

Value

a vector with the residuals for the linear model represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, correlation = corAR1(form = ~ 1 | Mare))
residuals(fm1)
```

Arguments

object

an object inheriting from class "glsStruct", representing a list of model components, such as corStruct and "varFunc" objects.

glsFit

an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit").

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the residuals for the linear model represented by object.

Note

This method function is primarily used inside gls and residuals.gls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**residuals.gnlsStruct**

Calculate gnlsStruct Residuals

Description

The residuals for the nonlinear model represented by object are extracted.

Usage

```r
## S3 method for class 'gnlsStruct'
residuals(object, ...)
```

Arguments

object

an object inheriting from class "gnlsStruct", representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the residuals for the nonlinear model represented by object.
residuals.lme

Note

This method function is primarily used inside gnls and residuals.gnls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gnls, residuals.gnls, fitted.gnlsStruct

---

residuals.lme  
Extract lme Residuals

Description

The residuals at level i are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if type="pearson"). The fitted values at level i are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to i.

Usage

## S3 method for class 'lme'
residuals(object, level = Q,
    type = c("response", "pearson", "normalized"), asList = FALSE, ...)

Arguments

object  
an object inheriting from class "lme", representing a fitted linear mixed-effects model.

level  
an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.

type  
an optional character string specifying the type of residuals to be used. If "response", as by default, the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided.

asList  
an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE.

...  
some methods for this generic require additional arguments. None are used in this method.
Value

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`lme`, `fitted.lme`

Examples

```r
fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
head(residuals(fm1, level = 0:1))
summary(residuals(fm1) /
    residuals(fm1, type = "p")) # constant scaling factor 1.432
```

---

residuals.lmeStruct  Calculate lmeStruct Residuals

Description

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$.

Usage

```r
## S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

Arguments

- `object` an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- `level` an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- `conLin` an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix ($X$) combined with a response vector ($y$), and "logLik", corresponding to the log-likelihood of the underlying `lme` model. Defaults to `attr(object, "conLin")`.
- `lmeFit` an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to `attr(object, "lmeFit")`.
- `...` some methods for this generic accept optional arguments.
residuals.lmList

Value

if a single level of grouping is specified in level, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the residuals at different levels.

Note

This method function is primarily used within the lme function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lme, residuals.lme, fitted.lmeStruct

residuals.lmList

Extract lmList Residuals

Description

The residuals are extracted from each lm component of object and arranged into a list with as many components as object, or combined into a single vector.

Usage

## S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)

Arguments

object an object inheriting from class "lmList", representing a list of lm objects with a common model.
subset an optional character or integer vector naming the lm components of object from which the residuals are to be extracted. Default is NULL, in which case all components are used.
type an optional character string specifying the type of residuals to be extracted. Options include "response" for the "raw" residuals (observed - fitted), "pearson" for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each lm fit, and "pooled.pearson" for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response".
asList an optional logical value. If TRUE, the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to FALSE.
...
some methods for this generic require additional arguments. None are used in this method.
residuals.nlmeStruct

Value

A list with components given by the residuals of each \texttt{lm} component of \texttt{object}, or a vector with the residuals for all \texttt{lm} components of \texttt{object}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{lmList}, \texttt{fitted.lmList}

Examples

\begin{verbatim}
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
\end{verbatim}

Description

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters.

Usage

\begin{verbatim}
## S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
\end{verbatim}

Arguments

- \texttt{object} an object inheriting from class "\texttt{nlmeStruct}", representing a list of mixed-effects model components, such as \texttt{reStruct}, \texttt{corStruct}, and \texttt{varFunc} objects.
- \texttt{level} an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from \texttt{object}. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- \texttt{conLin} an optional condensed linear model object, consisting of a list with components "\texttt{Xy}" corresponding to a regression matrix ($X$) combined with a response vector ($y$), and "\texttt{logLik}" corresponding to the log-likelihood of the underlying nlme model. Defaults to \texttt{attr(object, "conLin")}.
- ... optional arguments to the residuals generic. Not used.

Value

If a single level of grouping is specified in \texttt{level}, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in \texttt{level}, the returned object is a matrix with columns given by the residuals at different levels.
Note

This method function is primarily used within the \textit{nlme} function.

\textit{reStruct} \hspace{1cm} Random Effects Structure

Description

This function is a constructor for the \textit{reStruct} class, representing a random effects structure and consisting of a list of pd\textit{Mat} objects, plus a \textit{settings} attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

Usage

\begin{verbatim}
reStruct(object, pdClass, REML, data)
## S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{object} any of the following: (i) a one-sided formula of the form $\sim x_1+\ldots+x_n \vert g_1/\ldots/g_m$, with $x_1+\ldots+x_n$ specifying the model for the random effects and $g_1/\ldots/g_m$ the grouping structure ($m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1+\ldots+x_n \vert g$, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1+\ldots+x_n$, or a pd\textit{Mat} object with a formula (i.e. a non-\texttt{NULL} value for \texttt{formula(object)}), or a list of such formulas or pd\textit{Mat} objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class \texttt{groupedData}; (iv) a named list of formulas or pd\textit{Mat} objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an \textit{reStruct} object.
  \item \texttt{pdClass} an optional character string with the name of the pd\textit{Mat} class to be used for the formulas in \texttt{object}. Defaults to "pdLogChol" which corresponds to a general positive-definite matrix (Log-Cholesky parametrization).
\end{itemize}
simulate.lme

**Description**

The model object is fit to the data. Using the fitted values of the parameters, `nsim` new data vectors from this model are simulated. Both `object` and `m2` are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

**Usage**

```r
## S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2,
method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)
```

**Value**

an object inheriting from class `reStruct`, representing a random effects structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
**simulate.lme**

Arguments

- **object**: an object inheriting from class "lme", representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to lme. This argument defines the null model.

- **m2**: an "lme" object or a list, like object containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model object and m2 need to be specified.

- **seed**: an optional integer that is passed to set.seed. Defaults to a random integer.

- **method**: an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to c("REML", "ML"), in which case both methods are used.

- **nsim**: an optional positive integer specifying the number of simulations to perform. Defaults to 1. **This has changed. Previously the default was 1000.**

- **niterEM**: an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the object and m2 to each simulated set of data. Defaults to c(40, 200).

- **useGen**: an optional logical value. If TRUE, the nlminb optimizer is used with numerical derivatives of the log-likelihood. If FALSE, the nlm algorithm is used with an analytic gradient. The default depends on the "pdMat" classes used in object and m2: if both are standard classes (see pdClasses) then defaults to FALSE, otherwise defaults to TRUE.

- **...**: optional additional arguments. None are used.

Value

an object of class simulate.lme with components null and alt. Each of these has components ML and/or REML which are matrices. An attribute called seed contains the seed that was used for the random number generator.

simulate.lme(list(fixed = distance ~ age, data = Orthodont, random = ~ 1 | Subject), nsim = 200, m2 = list(random = ~ age | Subject))
```
**solve.pdMat**  
*Calculate Inverse of a Positive-Definite Matrix*

**Description**

The positive-definite matrix represented by `a` is inverted and assigned to `a`.

**Usage**

```r
## S3 method for class 'pdMat'
solve(a, b, ...)
```

**Arguments**

- `a`: an object inheriting from class "pdMat", representing a positive definite matrix.
- `b`: this argument is only included for consistency with the generic function and is not used in this method function.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

A `pdMat` object similar to `a`, but with coefficients corresponding to the inverse of the positive-definite matrix represented by `a`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `pdMat`

**Examples**

```r
pd1 <- pdCompSymm(3 * diag(3) + 1)
solve(pd1)
```

---

**solve.reStruct**  
*Apply Solve to an reStruct Object*

**Description**

Solve is applied to each `pdMat` component of `a`, which results in inverting the positive-definite matrices they represent.

**Usage**

```r
## S3 method for class 'reStruct'
solve(a, b, ...)
```
Arguments

a  an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
b  this argument is only included for consistency with the generic function and is not used in this method function.

... some methods for this generic require additional arguments. None are used in this method.

Value

an reStruct object similar to a, but with the pdMat components representing the inverses of the matrices represented by the components of a.

Soybean

Growth of soybean plants

Description

The Soybean data frame has 412 rows and 5 columns.

Format

This data frame contains the following columns:

Plot  a factor giving a unique identifier for each plot.
Variety  a factor indicating the variety; Forrest (F) or Plant Introduction #416937 (P).
Year  a factor indicating the year the plot was planted.
Time  a numeric vector giving the time the sample was taken (days after planting).
weight  a numeric vector giving the average leaf weight per plant (g).

Details

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction #416937 (P), an experimental strain, and Forrest (F), a commercial variety.”
Source

Examples

```r
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

**splitFormula**

### Split a Formula

**Description**

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

**Usage**

```r
splitFormula(form, sep)
```

**Arguments**

- `form`: a formula object.
- `sep`: an optional character string specifying the separator to be used for splitting the formula. Defaults to `/`.

**Value**

A list of formulas, corresponding to the split of `form` according to `sep`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`formula`

**Examples**

```r
splitFormula(~ g1/g2/g3)
```
Spruce

Growth of Spruce Trees

Description
The Spruce data frame has 1027 rows and 4 columns.

Format
This data frame contains the following columns:
- **Tree** a factor giving a unique identifier for each tree.
- **days** a numeric vector giving the number of days since the beginning of the experiment.
- **logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.
- **plot** a factor identifying the plot in which the tree was grown.

Details
Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

**summary.corStruct**

**Summarize a corStruct Object**

Description
This method function prepares object to be printed using the `print.summary` method, by changing its class and adding a `structName` attribute to it.

Usage
```r
## S3 method for class 'corStruct'
summary(object, structName, ...)
```

Arguments
- **object** an object inheriting from class "corStruct", representing a correlation structure.
- **structName** an optional character string defining the type of correlation structure associated with object, to be used in the `print.summary` method. Defaults to `class(object)[1]`.
- **...** some methods for this generic require additional arguments. None are used in this method.
Value

an object identical to object, but with its class changed to summary.corStruct and an additional attribute structName. The returned value inherits from the same classes as object.

Author(s)

José Pinheiro and Douglas Bates

See Also

corClasses, corNatural, Initialize.corStruct, summary

Examples

cs1 <- corAR1(0.2)
summary(cs1)
residuals if more than five observations are used in the gls fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.

AIC the Akaike Information Criterion corresponding to object.

BIC the Bayesian Information Criterion corresponding to object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
AIC, BIC, gls, summary

Examples
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
correlation = corAR1(form = ~ 1 | Mare))
summary(fm1)
coef(summary(fm1)) # "the matrix"

summary.lme Summarize an lme Object

Description
Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object has a print and a coef method, the latter returning the coefficient's tTtable.

Usage
## S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
## S3 method for class 'summary.lme'
print(x, verbose = FALSE, ...)

Arguments
object an object inheriting from class "lme", representing a fitted linear mixed-effects model.
adjustSigma an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$, converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
verbose an optional logical value used to control the amount of output in the print.summary.lme method. Defaults to FALSE.
... additional optional arguments passed to methods, mainly for the print method.
x a "summary.lme" object.
Value

an object inheriting from class `summary.lme` with all components included in `object` (see `lmeObject` for a full description of the components) plus the following components:

- `corFixed`: approximate correlation matrix for the fixed effects estimates.
- `tTable`: a matrix with columns named `Value`, `Std. Error`, `DF`, `t-value`, and `p-value` representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects.
- `residuals`: if more than five observations are used in the `lme` fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.
- `AIC`: the Akaike Information Criterion corresponding to `object`.
- `BIC`: the Bayesian Information Criterion corresponding to `object`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`AIC`, `BIC`, `lme`.

Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
(s1 <- summary(fm1))
coef(s1) # the (coef | Std.E | t | P-v ) matrix
```

**summary.lmList** Summarize an lmList Object

Description

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

Usage

```r
## S3 method for class 'lmList'
summary(object, pool, ...)
```

Arguments

- `object`: an object inheriting from class "lmList", representing a list of lm fitted objects.
- `pool`: an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.
Value

A list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of `value` are:

- **call**: A list containing an image of the `lmList` call that produced `object`.
- **coefficients**: A three-dimensional array with summary information on the `lm` coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
- **correlation**: A three-dimensional array with the correlations between the individual `lm` coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by `lm` component.
- **cov.unscaled**: A three-dimensional array with the unscaled variances/covariances for the individual `lm` coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by `lm` component.
- **df**: An array with the number of degrees of freedom for the model and for residuals, for each `lm` component.
- **df.residual**: The total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all `lm` components.
- **fstatistics**: An array with the F test statistics and corresponding degrees of freedom, for each `lm` component.
- **pool**: The value of the `pool` argument to the function.
- **r.squared**: A vector with the multiple R-squared statistics for each `lm` component.
- **residuals**: A list with components given by the residuals from individual `lm` fits.
- **RSE**: The pooled estimate of the residual standard error.
- **sigma**: A vector with the residual standard error estimates for the individual `lm` fits.
- **terms**: The terms object used in fitting the individual `lm` components.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`lmList`, `summary`

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```
Summary

This method function applies `summary` to each element of `object`.

**Usage**

```r
## S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

- `object` an object inheriting from class "modelStruct", representing a list of model components, such as `reStruct`, `corStruct` and `varFunc` objects.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with elements given by the summarized components of `object`. The returned value is of class `summary.modelStruct`, also inheriting from the same classes as `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `summary`

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                   corStruct = corAR1(0.3))
summary(lms1)
```

---

**Summary.nlsList**

**Summarize an nlsList Object**

**Description**

The `summary` function is applied to each `nls` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.nlsList` method.

**Usage**

```r
## S3 method for class 'nlsList'
summary(object, ...)
```
Arguments

object an object inheriting from class "\texttt{nlsList}" representing a list of \texttt{nls} fitted objects.

... optional arguments to the \texttt{summary.lmList} method. One such optional argument is \texttt{pool}, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is \texttt{attr(object, "pool")}.

Value

a list with summary statistics obtained by applying \texttt{summary} to the elements of \texttt{object}, inheriting from class \texttt{summary.nlsList}. The components of \texttt{value} are:

- \texttt{call} a list containing an image of the \texttt{nlsList} call that produced \texttt{object}.
- \texttt{parameters} a three dimensional array with summary information on the \texttt{nls} coefficients. The first dimension corresponds to the names of the \texttt{nls} components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
- \texttt{correlation} a three dimensional array with the correlations between the individual \texttt{nls} coefficient estimates. The first dimension corresponds to the names of the \texttt{object} components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by \texttt{nls} component.
- \texttt{cov.unscaled} a three dimensional array with the unscaled variances/covariances for the individual \texttt{lm} coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the \texttt{object} components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by \texttt{nls} component.
- \texttt{df} an array with the number of degrees of freedom for the model and for residuals, for each \texttt{nls} component.
- \texttt{df.residual} the total number of degrees of freedom for residuals, corresponding to the sum of residuals \texttt{df} of all \texttt{nls} components.
- \texttt{pool} the value of the \texttt{pool} argument to the function.
- \texttt{RSE} the pooled estimate of the residual standard error.
- \texttt{sigma} a vector with the residual standard error estimates for the individual \texttt{lm} fits.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

\texttt{nlsList}, \texttt{summary}

Examples

```r
fm1 <- nlsList(SSasymp, Loblolly)
summary(fm1)
```
**summary.pdMat**

---

**Summarize a pdMat Object**

**Description**

Attributes `structName` and `noCorrelation`, with the values of the corresponding arguments to the method function, are appended to `object` and its class is changed to `summary.pdMat`.

**Usage**

```r
## S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

**Arguments**

- `object` an object inheriting from class "pdMat", representing a positive definite matrix.
- `structName` an optional character string with a description of the pdMat class. Default depends on the method function: "Blocked" for `pdBlocked`, "Compound Symmetry" for `pdCompSymm", "Diagonal" for `pdDiag", "Multiple of an Identity" for `pdIdent", "General Positive-Definite, Natural Parametrization" for `pdNatural", "General Positive-Definite" for `pdSymm", and `data.class(object)` for `pdMat`.
- `noCorrelation` an optional logical value indicating whether correlations are to be printed in `print.summary.pdMat`. Default depends on the method function: FALSE for `pdDiag` and `pdIdent`, and TRUE for all other classes.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object`, with additional attributes `structName` and `noCorrelation`, inheriting from class `summary.pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`print.summary.pdMat, pdMat`

**Examples**

summary(pdSymm(diag(4)))
```
Summary.varFunc

Summarize "varFunc" Object

**Description**

A `structName` attribute, with the value of corresponding argument, is appended to `object` and its class is changed to `summary.varFunc`.

**Usage**

```r
## S3 method for class 'varFunc'
summary(object, structName, ...)
```

**Arguments**

- `object`:
  - an object inheriting from class "varFunc", representing a variance function structure.

- `structName`:
  - an optional character string with a description of the `varFunc` class. Default depends on the method function:
    - for `varComb`: "Combination of variance functions",
    - for `varConstPower`: "Constant plus power of variance covariate",
    - for `varConstProp`: "Constant plus proportion of variance covariate",
    - for `varExp`: "Exponential of variance covariate",
    - for `varIdent`: "Different standard deviations per stratum",
    - for `varPower`: "Power of variance covariate",
    - for `varFunc`: `data.class(object)`.

- `...`:
  - some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object`, with an additional attribute `structName`, inheriting from class `summary.varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

- **conc** a numeric vector
- **Time** a numeric vector
- **Subject** an ordered factor with levels 4 < 5 < 2 < 1 < 3
- **Formulation** a factor with levels Berkmycin tetramycin

Source
update.modelStruct | Update a modelStruct Object

**Description**

This method function updates each element of `object`, allowing the access to data.

**Usage**

```r
## S3 method for class 'modelStruct'
update(object, data, ...)
```

**Arguments**

- `object`: an object inheriting from class "modelStruct", representing a list of model components, such as `corStruct` and `varFunc` objects.
- `data`: a data frame in which to evaluate the variables needed for updating the elements of `object`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object` (same class, length, and names), but with updated elements.

**Note**

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`

update.varFunc | Update varFunc Object

**Description**

If the `formula(object)` includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.
Usage

## S3 method for class 'varFunc'
update(object, data, ...)

Arguments

object an object inheriting from class "varFunc", representing a variance function structure.
data a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s).
...
... some methods for this generic require additional arguments. None are used in this method.

Value

if formula(object) includes a "." term, an varFunc object similar to object, but with the variance covariate reevaluated at the current fitted object value; else object is returned unchanged.

needUpdate, covariate<-.varFunc

---

**varClasses**

Variance Function Classes

Description

Standard classes of variance function structures (varFunc) available in the nlme package. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

Value

Available standard classes:

- **varExp**: exponential of a variance covariate.
- **varPower**: power of a variance covariate.
- **varConstPower**: constant plus power of a variance covariate.
- **varConstProp**: constant plus proportion of a variance covariate.
- **varIdent**: constant variance(s), generally used to allow different variances according to the levels of a classification factor.
- **varFixed**: fixed weights, determined by a variance covariate.
- **varComb**: combination of variance functions.
Note

Users may define their own varFunc classes by specifying a constructor function and, at a minimum, methods for the functions coef, coef<-, and initialize. For examples of these functions, see the methods for class varPower.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

varComb

Combination of Variance Functions

Description
This function is a constructor for the varComb class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the varFunc objects listed in ....

Usage
varComb(...)

Arguments
...

objects inheriting from class varFunc representing variance function structures.

Value
a varComb object representing a combination of variance functions, also inheriting from class varFunc.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also
varClasses, varWeights.varComb, coef.varComb
Examples

vf1 <- varComb(varIdent(form = ~1|Sex), varPower())

---

**varConstPower**

**Constant Plus Power Variance Function**

**Description**

This function is a constructor for the `varConstPower` class, representing a constant plus power variance function structure. Letting \( v \) denote the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the constant plus power variance function is defined as \( \sigma^2(v) = (\theta_1 + |v|^\theta_2)^2 \), where \( \theta_1, \theta_2 \) are the variance function coefficients. When a grouping factor is present, different \( \theta_1, \theta_2 \) are used for each factor level.

**Usage**

```r
varConstPower(const, power, form, fixed)
```

**Arguments**

- `const, power` optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in `form`. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for `const`. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- `form` an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate \( v \) and, optionally, a grouping factor `g` for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (\( \text{fitted(.)} \)) and residuals (\( \text{resid(.)} \)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, as in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- `fixed` an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.
Value

A varConstPower object representing a constant plus power variance function structure, also inher-
iting from class varFunc.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

varClasses, varWeights.varFunc, coef.varConstPower

Examples

vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)

Description

This function is a constructor for the varConstProp class, representing a variance function structure
(corresponding to a two-component error model (additive and proportional error). Letting \( v \)
be the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the two-component
variance function is defined as \( \sigma^2(v) = a^2 + b^2 \cdot v^2 \), where \( a \) is the additive component and \( b \) is the
relative error component. In order to avoid overparameterisation of the model, it is recommended
to use the possibility to fix sigma, preferably to a value of 1 (see examples).

Usage

varConstProp(const, prop, form, fixed)

Arguments

const, prop optional numeric vectors, or lists of numeric values, with, respectively, the coeffi-
cients for the constant and the proportional error terms. Both arguments must
have length one, unless a grouping factor is specified in form. If either argument
has length greater than one, it must have names which identify its elements to
the levels of the grouping factor defined in form. If a grouping factor is present
in form and the argument has length one, its value will be assigned to all group-
ing levels. Only positive values are allowed for const. Default is 0.1 for both
const and prop.

form an optional one-sided formula of the form \( \sim v \), or \( \sim v \mid g \), specifying a variance
covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance
covariate must evaluate to a numeric vector and may involve expressions using
\("\)\) representing a fitted model object from which fitted values (fitted(.))
and residuals (resid(.)) can be extracted (this allows the variance covariate
to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, as in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

**fixed**

an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

**Value**

a `varConstProp` object representing a constant plus proportion variance function structure, also inheriting from class `varFunc`.

**Note**

The error model underlying this variance function structure can be understood to result from two uncorrelated sequences of standardized random variables (Lavielle(2015), p. 55) and has been proposed for use in analytical chemistry (Werner et al. (1978), Wilson et al. (2004)) and chemical degradation kinetics (Ranke and Meinecke (2019)). Note that the two-component error model proposed by Rocke and Lorenzato (1995) assumed a log-normal distribution of residuals at high absolute values, which is not compatible with the `varFunc` structures in package `nlme`.

**Author(s)**

José Pinheiro and Douglas Bates (for `varConstPower`) and Johannes Ranke (adaptation to `varConstProp()`).

  weights = varConstProp())

AIC(f_const, f_varPower, f_varConstPower, f_varConstPower_sf,
    f_varConstProp, f_varConstProp_sf)

# The error model parameters 3 and 0.07 are approximately recovered
intervals(f_varConstProp_sf)
```
VarCorr

Extract variance and correlation components

Description

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class "lme", or a nonlinear mixed-effects model, of class "nlme". The within-group error variance and standard deviation are also calculated.

Usage

VarCorr(x, sigma = 1, ...)  
## S3 method for class 'lme'  
VarCorr(x, sigma = x$sigma, rdig = 3, ...)  
## S3 method for class 'pdMat'  
VarCorr(x, sigma = 1, rdig = 3, ...)  
## S3 method for class 'pdBlocked'  
VarCorr(x, sigma = 1, rdig = 3, ...)

Arguments

x a fitted model object, usually an object inheriting from class "lme".

sigma an optional numeric value used as a multiplier for the standard deviations. The default is x$sigma or 1 depending on class(x).

rdig an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3.

... further optional arguments passed to other methods (none for the methods documented here).

Value

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named Variance and StdDev, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named Corr, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)
```

---

**Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting \( v \) denote the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the exponential variance function is defined as \( \sigma^2(v) = \exp(2\theta v) \), where \( \theta \) is the variance function coefficient. When a grouping factor is present, a different \( \theta \) is used for each factor level.

**Usage**

```r
varExp(value, form, fixed)
```

**Arguments**

- **value**: an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- **form**: an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, like in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- **fixed**: an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

**Value**

A `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`. 
**Description**
This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting \( v \) denote the variance covariate defined in value, the variance function \( \sigma^2(v) \) for this class is \( \sigma^2(v) = |v| \). The variance covariate \( v \) is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**
```r
varFixed(value)
```

**Arguments**
- `value` a one-sided formula of the form \( \sim v \) specifying a variance covariate \( v \). Grouping factors are ignored.

**Value**
a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

**Examples**
```r
vf1 <- varFixed(~age)
```
**Description**

If `object` is a one-sided formula, it is used as the argument to `varFixed` and the resulting object is returned. Else, if `object` inherits from class `varFunc`, it is returned unchanged.

**Usage**

```r
varFunc(object)
```

**Arguments**

- `object`: either an one-sided formula specifying a variance covariate, or an object inheriting from class `varFunc`, representing a variance function structure.

**Value**

an object from class `varFunc`, representing a variance function structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `summary.varFunc`, `varFixed`, `varWeights.varFunc`, `coef.varFunc`

**Examples**

```r
vf1 <- varFunc(~age)
```

---

**Description**

This function is a constructor for the `varIdent` class, representing a constant variance function structure. If no grouping factor is present in `form`, the variance function is constant and equal to one, and no coefficients required to represent it. When `form` includes a grouping factor with $M > 1$ levels, the variance function allows $M$ different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only $M - 1$ coefficients are needed to represent the variance function. By default, if the elements in `value` are unnamed, the first group level is taken as the reference level.

**Usage**

```r
varIdent(value, form, fixed)
```
Arguments

value
   an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in form, this argument is ignored, as the resulting variance function contains no coefficients. If value has length one, its value is repeated for all coefficients in the variance function. If value has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

form
   an optional one-sided formula of the form ~ v, or ~ v | g, specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in form, a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the * operator, like in ~ v | g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ 1.

fixed
   an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.

Value

   a varIdent object representing a constant variance function structure, also inheriting from class varFunc.

Examples

   vf1 <- varIdent(c(Female = 0.5), form = ~ 1 | Sex)
Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include default, gls and lme. See the appropriate method documentation for a description of the arguments.

Usage

Variogram(object, distance, ...)

Arguments

- **object**: a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
- **distance**: a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs (1,2), (1,3), ..., (n-1,n), with n representing the length of object, and must have length \( n(n-1)/2 \).
- **...**: some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Variogram.corExp  

Calculate Semi-variogram for a corExp Object

Description

This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

```r
## S3 method for class 'corExp'
Variogram(object, distance, sig2, length.out, ...)
```

Arguments

- `object`:
  - an object inheriting from class "corExp", representing an exponential spatial correlation structure.
- `distance`:
  - an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used.
- `sig2`:
  - an optional numeric value representing the process variance. Defaults to 1.
- `length.out`:
  - an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to 50.
- `...`:
  - some methods for this generic require additional arguments. None are used in this method.

Value

- a data frame with columns `vario` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

Variogram.corGaus

Calculate Semi-variogram for a corGaus Object

Description

This method function calculates the semi-variogram values corresponding to the Gaussian correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

## S3 method for class 'corGaus'
Variogram(object, distance, sig2, length.out, ...)

Arguments

object an object inheriting from class "corGaus", representing an Gaussian spatial correlation structure.
distance an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
sig2 an optional numeric value representing the process variance. Defaults to 1.
length.out an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
... some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Calculate Semi-variogram for a corLin Object

Description
This method function calculates the semi-variogram values corresponding to the Linear correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

Usage
```r
## S3 method for class 'corLin'
Variogram(object, distance, sig2, length.out, ...)
```

Arguments
- `object`: an object inheriting from class "corLin", representing an Linear spatial correlation structure.
- `distance`: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used.
- `sig2`: an optional numeric value representing the process variance. Defaults to 1.
- `length.out`: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to 50.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

**Variogram.corRatio**  

*Calculate Semi-variogram for a corRatio Object*

**Description**

This method function calculates the semi-variogram values corresponding to the Rational Quadratic correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

**Usage**

```r
## S3 method for class 'corRatio'
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

- `object`: an object inheriting from class "corRatio", representing an Rational Quadratic spatial correlation structure.
- `distance`: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- `sig2`: an optional numeric value representing the process variance. Defaults to 1.
- `length.out`: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Variogram.corSpatial  

Calculate Semi-variogram for a corSpatial Object

Description

This method function calculates the semi-variogram values corresponding to the model defined in FUN, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

## S3 method for class 'corSpatial'
Variogram(object, distance, sig2, length.out, FUN, ...)

Arguments

- object: an object inheriting from class "corSpatial", representing spatial correlation structure.
- distance: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- sig2: an optional numeric value representing the process variance. Defaults to 1.
- length.out: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- FUN: a function of two arguments, the distance and the range corresponding to object, specifying the semi-variogram model.
- ...: some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.corSpher

Calculate Semi-variogram for a corSpher Object

Description

This method function calculates the semi-variogram values corresponding to the Spherical correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

```r
## S3 method for class 'corSpher'
Variogram(object, distance, sig2, length.out, ...)
```

Arguments

- `object`: an object inheriting from class "corSpher", representing an Spherical spatial correlation structure.
- `distance`: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length `length.out` between the minimum and maximum values of `getCovariate(object)` is used.
- `sig2`: an optional numeric value representing the process variance. Defaults to 1.
- `length.out`: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when `distance = NULL`. Defaults to 50.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

Variogram.default  Calculate Semi-variogram

Description

This method function calculates the semi-variogram for an arbitrary vector object, according to the
distances in distance. For each pair of elements \( x, y \) in object, the corresponding semi-variogram
is \((x - y)^2/2\). The semi-variogram is useful for identifying and modeling spatial correlation struc-
tures in observations with constant expectation and constant variance.

Usage

## Default S3 method:
Variogram(object, distance, ...)  

Arguments

object  a numeric vector with the values to be used for calculating the semi-variogram,
usually a residual vector from a fitted model.

distance  a numeric vector with the pairwise distances corresponding to the elements of
object. The order of the elements in distance must correspond to the pairs
\((1,2), (1,3), \ldots, (n-1,n)\), with \(n\) representing the length of object, and
must have length \(n(n-1)/2\).

...  some methods for this generic require additional arguments. None are used in
this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values
and the corresponding distances. The returned value inherits from class Variogram.

Variogram, Variogram.gls, Variogram.lme, plot.Variogram

Examples

fm1 <- lm(follicles ~ sin(2 * pi * Time) + cos(2 * pi * Time), Ovary,
  subset = Mare == 1)
Variogram(resid(fm1), dist(1:29))[1:10,]
Variogram.gls

*Calculate Semi-variogram for Residuals from a gls Object*

**Description**

This method function calculates the semi-variogram for the residuals from a *gls* fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

**Usage**

```r
## S3 method for class 'gls'
Variogram(object, distance, form, resType, data, 
            na.action, maxDist, length.out, collapse, nint, breaks, 
            robust, metric, ...)
```

**Arguments**

- `object`: an object inheriting from class "*gls*", representing a generalized least squares fitted model.
- `distance`: an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments `form`, `data`, and `metric`, unless `object` includes a `corSpatial` element, in which case the associated covariate (obtained with the `getCovariate` method) is used.
- `form`: an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a | operator in `form`). Default is ~1, implying that the observation order within the groups is used to obtain the distances.
- `resType`: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `data`: an optional data frame in which to interpret the variables in `form`. By default, the same data used to fit `object` is used.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
- `maxDist`: an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.
length.out: an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse: an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint: an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust: an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks: an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

...: some methods for this generic require additional arguments. None are used in this method.

Value: a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

Author(s): José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

```r
fml <- gls(weight ~ Time * Diet, BodyWeight)
Vm1 <- Variogram(fml, form = ~ Time | Rat)
print(head(Vm1), digits = 3)
```

Description

This method function calculates the semi-variogram for the within-group residuals from an `lme` fit. The semi-variogram values are calculated for pairs of residuals within the same group. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

```r
## S3 method for class 'lme'
Variogram(object, distance, form, resType, data, na.action, maxDist, length.out, collapse, nint, breaks, robust, metric, ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `distance`: an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments `form`, `data`, and `metric`, unless `object` includes a `corSpatial` element, in which case the associated covariate (obtained with the `getCovariate` method) is used.
- `form`: an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a `|` operator in `form`). Default is ~1, implying that the observation order within the groups is used to obtain the distances.
- `resType`: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `data`: an optional data frame in which to interpret the variables in `form`. By default, the same data used to fit `object` is used.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
maxDist

an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

length.out

an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse

an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint

an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust

an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks

an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric

an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

... some methods for this generic require additional arguments. None are used in this method.

Value

da data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

**Examples**

```r
define your code here
```

---

**Description**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the power variance function is defined as $\sigma^2(v) = |v|^{2\theta}$, where $\theta$ is the variance function coefficient. When a grouping factor is present, a different $\theta$ is used for each factor level.

**Usage**

```r
varPower(value, form, fixed)
```

**Arguments**

- `value`: an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- `form`: an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using `\"\.`\`, representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `\*` operator, like in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- `fixed`: an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

**Value**

A `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

---

### Notes

- The function `varPower` is designed to work with the `lme` function from the `nlme` package in R for fitting linear mixed-effects models. The `varPower` function allows for the specification of a power variance structure, which is useful in situations where the variance is proportional to the square of the covariate.

- The expression `|v|^{2\theta}` represents a power variance function, where $\theta$ controls the rate at which the variance increases with the covariate $v$. A higher value of $\theta$ leads to a more rapidly increasing variance.

- When using a grouping factor, a separate power variance function is estimated for each level of the grouping factor. This allows for modeling different variances across different groups.

- The `form` argument allows for specifying the variance covariate and, optionally, a grouping factor. The covariate must evaluate to a numeric vector, and the grouping factor defines the levels of the grouping factor used to group the observations.

- The `fixed` argument allows for specifying which coefficients should be fixed during the optimization process. This is useful for controlling the flexibility of the variance function.

---

### Example Code

```r
# Load necessary packages
library(nlme)

# Define the model
fm1 <- lme(weight ~ Time * Diet, data=BodyWeight, ~ Time | Rat)

# Variogram using the varPower function
Variogram(fm1, form = ~ Time | Rat, nint = 10, robust = TRUE)
```

[.pdMat  

Subscript a pdMat Object

Description

This method function extracts sub-matrices from the positive-definite matrix represented by \( x \).

Usage

```r
## S3 method for class 'pdMat'
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat'
x[i, j] <- value
```

Arguments

- `x`: an object inheriting from class "pdMat" representing a positive-definite matrix.
- `i, j`: optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by object. When \( i \) (\( j \)) is omitted, all rows (columns) are extracted.
- `drop`: a logical value. If TRUE, single rows or columns are converted to vectors. If FALSE the returned value retains its matrix representation.
- `value`: a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by \( x \).

Value

If \( i \) and \( j \) are identical, the returned value will be pdMat object with the same class as \( x \). Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

The nnet package

class.ind

Generates Class Indicator Matrix from a Factor

Description

Generates a class indicator function from a given factor.

Usage

class.ind(cl)

Arguments

cl factor or vector of classes for cases.

Value

a matrix which is zero except for the column corresponding to the class.

References

Examples

# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[(1:n) + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}
multinom  

*Fit Multinomial Log-linear Models*

**Description**

Fits multinomial log-linear models via neural networks.

**Usage**

```r
multinom(formula, data, weights, subset, na.action,
        contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
        model = FALSE, ...)
```

**Arguments**

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor or a matrix with K columns, which will be interpreted as counts for each of K classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with K columns if the response is either a matrix with K columns or a factor with K \( \geq 2 \) classes, or a numeric vector for a response factor with 2 levels. See the documentation of `formula()` for other details.

- `data`: an optional data frame in which to interpret the variables occurring in `formula`.

- `weights`: optional case weights in fitting.

- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

- `na.action`: a function to filter missing data.

- `contrasts`: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

- `Hess`: logical for whether the Hessian (the observed/expected information matrix) should be returned.

- `summ`: integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance.

- `censored`: If Y is a matrix with K columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.

- `model`: logical. If true, the model frame is saved as component `model` of the returned object.

- `...`: additional arguments for `nnet`

**Details**

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to \([0,1]\) or the fit will be slow or may not converge at all.
**Value**

A `nnet` object with additional components:

- `deviance`: the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood.
- `edf`: the (effective) number of degrees of freedom used by the model
- `AIC`: the AIC for this fit.
- `Hessian`: (if `Hess` is true).
- `model`: (if `model` is true).

**References**

**See Also**

`nnet`

**Examples**

```r
oc <- options(contrasts = c("contr.treatment", "contr.poly"))
library(MASS)
example(birthwt)
(bwt.mu <- multinom(low ~ ., bwt))
options(oc)
```

---

**nnet**  
*Fit Neural Networks*

**Description**

Fit single-hidden-layer neural network, possibly with skip-layer connections.

**Usage**

```r
nnet(x, ...)
```

### S3 method for class 'formula'

```r
nnet(formula, data, weights, ..., 
    subset, na.action, contrasts = NULL)
```

### Default S3 method:

```r
nnet(x, y, weights, size, Wts, mask, 
    linout = FALSE, entropy = FALSE, softmax = FALSE, 
    censored = FALSE, skip = FALSE, rang = 0.7, decay = 0, 
    maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000, 
    abstol = 1.0e-4, reltol = 1.0e-8, ...)
```
Arguments

`formula`  A formula of the form `class ~ x1 + x2 + ...`
`x`  matrix or data frame of x values for examples.
`y`  matrix or data frame of target values for examples.
`weights`  (case) weights for each example – if missing defaults to 1.
`size`  number of units in the hidden layer. Can be zero if there are skip-layer units.
`data`  Data frame from which variables specified in formula are preferentially to be taken.
`subset`  An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
`na.action`  A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
`contrasts`  a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
`Wts`  initial parameter vector. If missing chosen at random.
`mask`  logical vector indicating which parameters should be optimized (default all).
`linout`  switch for linear output units. Default logistic output units.
`entropy`  switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.
`softmax`  switch for softmax (log-linear model) and maximum conditional likelihood fitting. linout, entropy, softmax and censored are mutually exclusive.
`censored`  A variant on softmax, in which non-zero targets mean possible classes. Thus for softmax a row of (0, 1, 1) means one example each of classes 2 and 3, but for censored it means one example whose class is only known to be 2 or 3.
`skip`  switch to add skip-layer connections from input to output.
`rang`  Initial random weights on [\(-rang, rang\)]. Value about 0.5 unless the inputs are large, in which case it should be chosen so that rang \* max(|x|) is about 1.
`decay`  parameter for weight decay. Default 0.
`maxit`  maximum number of iterations. Default 100.
`Hess`  If true, the Hessian of the measure of fit at the best set of weights found is returned as component Hessian.
`trace`  switch for tracing optimization. Default TRUE.
`MaxNWts`  The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing MaxNWts will probably allow fits that are very slow and time-consuming.
`abstol`  Stop if the fit criterion falls below abstol, indicating an essentially perfect fit.
`reltol`  Stop if the optimizer is unable to reduce the fit criterion by a factor of at least 1 - reltol.
`...`  arguments passed to or from other methods.
**Details**

If the response in formula is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to nnet.default.

Optimization is done via the BFGS method of optim.

**Value**

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

- `wts`: the best set of weights found
- `value`: value of fitting criterion plus weight decay term.
- `fitted.values`: the fitted values for the training data.
- `residuals`: the residuals for the training data.
- `convergence`: 1 if the maximum number of iterations was reached, otherwise 0.

table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
```
nnetHess  

Evaluates Hessian for a Neural Network

Description

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument Hess=TRUE to nnet or via vcov.multinom.

Usage

nnetHess(net, x, y, weights)

Arguments

net  
object of class nnet as returned by nnet.

x  
training data.

y  
classes for training data.

weights  
the (case) weights used in the nnet fit.

Value

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

predict.nnet

Predict New Examples by a Trained Neural Net

Description

Predict new examples by a trained neural net.

Usage

## S3 method for class 'nnet'
predict(object, newdata, type = c("raw", "class"), ...)

Arguments

object an object of class nnet as returned by nnet.
newdata matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case.
type Type of output
... arguments passed to or from other methods.

Details

This function is a method for the generic function predict() for class "nnet". It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.nnet(x) regardless of the class of the object.

Value

If type = "raw", the matrix of values returned by the trained network; if type = "class", the corresponding class (which is probably only useful if the net was generated by nnet.formula).

\texttt{\textbf{which.is.max}}

\textit{Find Maximum Position in Vector}

Description

Find the maximum position in a vector, breaking ties at random.

Usage

\texttt{\textbf{which.is.max}(x)}

Arguments

\texttt{x} \hspace{1cm} \text{a vector}

Details

Ties are broken at random.

Value

index of a maximal value.

car.test.frame Automobile Data from 'Consumer Reports' 1990

Description

The car.test.frame data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of Consumer Reports. This is part of a larger dataset, some columns of which are given in cu.summary.

Usage

car.test.frame

Format

This data frame contains the following columns:

Price a numeric vector giving the list price in US dollars of a standard model
Country of origin, a factor with levels 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'
Reliability a numeric vector coded 1 to 5.
Mileage fuel consumption miles per US gallon, as tested.
Type a factor with levels Compact Large Medium Small Sporty Van
Weight kerb weight in pounds.
Disp. the engine capacity (displacement) in litres.
HP the net horsepower of the vehicle.

Examples
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

car90 Automobile Data from 'Consumer Reports' 1990

Description

Usage
data(car90)

Format
The data frame contains the following columns

- **Country** a factor giving the country in which the car was manufactured
- **Disp** engine displacement in cubic inches
- **Disp2** engine displacement in liters
- **Eng.Rev** engine revolutions per mile, or engine speed at 60 mph
- **Front.Hd** distance between the car’s head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU
- **Frt.Leg.Room** maximum front leg room, in inches, as measured by CU
- **Frt.Shld** front shoulder room, in inches, as measured by CU
- **Gear.Ratio** the overall gear ratio, high gear, for manual transmission
- **Gear2** the overall gear ratio, high gear, for automatic transmission
- **HP** net horsepower
- **HP.revs** the red line—the maximum safe engine speed in rpm
- **Height** height of car, in inches, as supplied by manufacturer
- **Length** overall length, in inches, as supplied by manufacturer
- **Luggage** luggage space
- **Mileage** a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.
- **Model2** alternate name, if the car was sold under two labels
- **Price** list price with standard equipment, in dollars
- **Rear.Hd** distance between the car’s head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU
- **Rear.Seating** rear fore-and-aft seating room, in inches, as measured by CU
RearShld  rear shoulder room, in inches, as measured by CU

Reliability  an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better': contains NAs.

Rim  factor giving the rim size

Sratio.m  Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

Sratio.p  Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

Steering  steering type offered: manual, power, or both

Tank  fuel refill capacity in gallons

Tires  factor giving tire size

Trans1  manual transmission, a factor with levels '', 'man.4', 'man.5' and 'man.6'

Trans2  automatic transmission, a factor with levels '', 'auto.3', 'auto.4', and 'auto.CVT'. No car is missing both the manual and automatic transmission variables, but several had both as options.

Turning  the radius of the turning circle in feet

Type  a factor giving the general type of car. The levels are: 'Small', 'Sporty', 'Compact', 'Medium', 'Large', 'Van'

Weight  an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

Wheel.base  length of wheelbase, in inches, as supplied by manufacturer

Width  width of car, in inches, as supplied by manufacturer

Source

This is derived (with permission) from the data set car.all in S-PLUS, but with some further clean up of variable names and definitions.

     xlab = "Price (thousands)", ylab = "Weight (lbs)"
)
mlowess <- function(x, y, ...) {
  keep <- !(is.na(x) | is.na(y))
  lowess(x[keep], y[keep], ...)
}
with(car90, lines(mlowess(Price/1000, Weight, f = 0.5)))
### Description

The `cu.summary` data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

### Usage

cu.summary

### Format

This data frame contains the following columns:

- **Price**: a numeric vector giving the list price in US dollars of a standard model
- **Reliability**: an ordered factor with levels `’Much worse’ < ’worse’ < ’average’ < ’better’ < ’Much better’`
- **Mileage**: fuel consumption miles per US gallon, as tested.
- **Type**: a factor with levels `Compact, Large, Medium, Small, Sporty, Van`

```
kyphosis

Data on Children who have had Corrective Spinal Surgery

Description
The kyphosis data frame has 81 rows and 4 columns, representing data on children who have had corrective spinal surgery.

Usage
kyphosis

Format
This data frame contains the following columns:
- **Kyphosis** a factor with levels absent present indicating if a kyphosis (a type of deformation) was present after the operation.
- **Age** in months
- **Number** the number of vertebrae involved
- **Start** the number of the first (topmost) vertebra operated on.

Source

Examples
```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
              control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

labels.rpart

Create Split Labels For an Rpart Object

Description
This function provides labels for the branches of an rpart tree.

Usage
```
## S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```
Arguments

object fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

digits the number of digits to be used for numeric values. All of the rpart functions that call labels explicitly set this value, with options("digits") as the default.

minlength the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than , the abbreviate function is used, passed the minlength argument.

pretty an argument included for compatibility with the original Splus tree package: pretty = 0 implies minlength = 0L, pretty = NULL implies minlength = 1L, and pretty = TRUE implies minlength = 4L.

collapse logical. The returned set of labels is always of the same length as the number of nodes in the tree.

If collapse = TRUE (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node.

If FALSE, the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes.

... optional arguments to abbreviate.

Value

Vector of split labels (collapse = TRUE) or matrix of left and right splits (collapse = FALSE) for the supplied rpart object. This function is called by printing methods for rpart and is not intended to be called directly by the users.

See Also

abbreviate

meanvar.rpart  Mean-Variance Plot for an Rpart Object

Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

Usage

meanvar(tree, ...)

## S3 method for class 'rpart'
meanvar(tree, xlab = "ave(y)", ylab = "ave(deviance)", ...)
Arguments

tree fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

xlab x-axis label for the plot.

ylab y-axis label for the plot.

... additional graphical parameters may be supplied as arguments to this function.

Value

an invisible list containing the following vectors is returned.

x fitted value at terminal nodes (yval).

y deviance of node divided by number of observations at node.

label node number.

Side Effects

a plot is put on the current graphics device.

See Also

plot.rpart.

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')

na.rpart Handles Missing Values in an Rpart Object

Description

Handles missing values in an "rpart" object.

Usage

na.rpart(x)

Arguments

x a model frame.

Details

Default function that handles missing values when calling the function rpart. It omits cases where part of the response is missing or all the explanatory variables are missing.
path.rpart

Follow Paths to Selected Nodes of an Rpart Object

Description

Returns a names list where each element contains the splits on the path from the root to the selected nodes.

Usage

path.rpart(tree, nodes, pretty = 0, print.it = TRUE)

Arguments

tree
fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

nodes
an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.

pretty
an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A NULL, the default, signifies using elements of letters to represent the different factor levels.

print.it
Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if nodes argument is supplied.

Details

The function has a required argument as an rpart object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

Value

A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

Graphical Interaction

A dendrogram of the rpart object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

References

This function was modified from path.tree in S.

Examples

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, nodes = c(11, 22))
```

---

**plot.rpart**

*Plot an Rpart Object*

**Description**

Plots an rpart object on the current graphics device.

**Usage**

```r
## S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace,
     margin = 0, minbranch = 0.3, branch.col = 1, branch.lty = 1,
     branch.lwd = 1, ...
)
```

**Arguments**

- `x`: a fitted object of class "rpart", containing a classification, regression, or rate tree.
- `uniform`: if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
- `branch`: controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
- `compress`: if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes uniform = TRUE; surprisingly, the result is usually an improvement even when that is not the case.
- `nspace`: the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of branch.
- `margin`: an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
- `minbranch`: set the minimum length for a branch to minbranch times the average branch length. This parameter is ignored if uniform = TRUE. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
- `branch.col`: set the color of the branches.
- `branch.lty`: set the line type of the branches.
- `branch.lwd`: set the line width of the branches.
- `...`: arguments to be passed to or from other methods.
Details

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.

Value

The coordinates of the nodes are returned as a list, with components `x` and `y`.

Side Effects

An unlabeled plot is produced on the current graphics device: one being opened if needed. In order to build up a plot in the usual S style, e.g., a separate `text` command for adding labels, some extra information about the plot needs be retained. This is kept in an environment in the package.

See Also

`rpart`, `text.rpart`

Examples

```r
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```

---

**plotcp**

*Plot a Complexity Parameter Table for an Rpart Fit*

Description

Gives a visual representation of the cross-validation results in an `rpart` object.

Usage

```r
plotcp(x, minline = TRUE, lty = 3, col = 1, upper = c("size", "splits", "none"), ...)
```

Arguments

- `x` : an object of class "rpart"
- `minline` : whether a horizontal line is drawn 1SE above the minimum of the curve.
- `lty` : line type for this line
- `col` : colour for this line
- `upper` : what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing.
- `...` : additional plotting parameters
post.rpart

Details
The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of cp for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by rpart. The cptable in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of cp for pruning is often the leftmost value for which the mean lies below the horizontal line.

Value
None.

Side Effects
A plot is produced on the current graphical device.

See Also
rpart, printcp, rpart.object

post.rpart  PostScript Presentation Plot of an Rpart Object

Description
Generates a PostScript presentation plot of an rpart object.

Usage
post(tree, ...)
## S3 method for class 'rpart'
post(tree, title.,
    filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
    digits = getOption("digits") - 2, pretty = TRUE,
    use.n = TRUE, horizontal = TRUE, ...)

Arguments
tree  fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
title. a title which appears at the top of the plot. By default, the name of the rpart endpoint is printed out.
filename ASCII file to contain the output. By default, the name of the file is the name of the object given by rpart (with the suffix .ps added). If filename = "", the plot appears on the current graphical device.
digits number of significant digits to include in numerical data.
predict.rpart

Predictions from a Fitted rpart Object

Description

Returns a vector of predicted responses from a fitted rpart object.

Usage

## S3 method for class 'rpart'
predict(object, newdata, 
type = c("vector", "prob", "class", "matrix"), 
na.action = na.pass, ...)
predict.rpart

Arguments

object fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

newdata data frame containing the values at which predictions are required. The predictors referred to in the right side of formula(object) must be present by name in newdata. If missing, the fitted values are returned.

type character string denoting the type of predicted value returned. If the rpart object is a classification tree, then the default is to return prob predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of tree). Otherwise, a vector result is returned.

na.action a function to determine what should be done with missing values in newdata. The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are na.omit and na.fail.

... further arguments passed to or from other methods.

Details

This function is a method for the generic function predict for class "rpart". It can be invoked by calling predict for an object of the appropriate class, or directly by calling predict.rpart regardless of the class of the object.

Value

A new object is obtained by dropping newdata down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and frame$yval at the node is the prediction.

If type = "vector":
vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If type = "prob":
(for a classification tree) a matrix of class probabilities.

If type = "matrix":
a matrix of the full responses (frame$yval2 if this exists, otherwise frame$yval). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of at least the predicted class, the class counts at that node in the fitted tree, and the class probabilities (some versions of rpart may contain further columns).

If type = "class":
(for a classification tree) a factor of classifications based on the responses.

See Also

predict.rpart.object

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
predict(fit, type = "prob")  # class probabilities (default)
predict(fit, type = "vector")  # level numbers
predict(fit, type = "class")  # factor
predict(fit, type = "matrix")  # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data = iris, subset = sub)
fit
table(predict(fit, iris[-sub,], type = "class"), iris[-sub, "Species"])

print.rpart

Print an Rpart Object

Description
This function prints an rpart object. It is a method for the generic function print of class "rpart".

Usage

## S3 method for class 'rpart'
print(x, minlength = 0, spaces = 2, cp, digits = getOption("digits"),
      nsmall = min(20, digits), ...)

Arguments

x  fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

minlength  Controls the abbreviation of labels: see labels.rpart.

spaces  the number of spaces to indent nodes of increasing depth.

digits  the number of digits of numbers to print.

nsmall  the number of digits to the right of the decimal. See format.

cp  prune all nodes with a complexity less than cp from the printout. Ignored if unspecified.

...  arguments to be passed to or from other methods.

Details
This function is a method for the generic function print for class "rpart". It can be invoked by calling print for an object of the appropriate class, or directly by calling print.rpart regardless of the class of the object.

Side Effects
A semi-graphical layout of the contents of x$frame is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the "class" method, the class probabilities are also printed.
printcp

## End(Not run)

printcp

Displays CP table for Fitted Rpart Object

Description

Displays the cp table for fitted rpart object.

Usage

printcp(x, digits = getOption("digits") - 2)

Arguments

x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits the number of digits of numbers to print.

Details

Prints a table of optimal prunings based on a complexity parameter.

**prune.rpart**

Cost-complexity Pruning of an Rpart Object

Description

Determines a nested sequence of subtrees of the supplied `rpart` object by recursively snipping off the least important splits, based on the complexity parameter (`cp`).

Usage

```r
prune(tree, ...)
```

### S3 method for class 'rpart'

```r
prune(tree, cp, ...)
```

Arguments

- `tree` fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `cp` Complexity parameter to which the `rpart` object will be trimmed.
- `...` further arguments passed to or from other methods.

Value

A new `rpart` object that is trimmed to the value `cp`.

See Also

`rpart`
Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) # plot smaller rpart object
```

---

**Description**

Method for residuals for an `rpart` object.

**Usage**

```r
## S3 method for class 'rpart'
residuals(object, type = c("usual", "pearson", "deviance"), ...)
```

**Arguments**

- `object` fitted model object of class "rpart".
- `type` Indicates the type of residual desired.
  - For regression or anova trees all three residual definitions reduce to `y - fitted`. This is the residual returned for user method trees as well.
  - For classification trees the usual residuals are the misclassification losses \( L(\text{actual}, \text{predicted}) \) where \( L \) is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The pearson residual is \( (1 - \text{fitted})/\sqrt{\text{fitted}(1 - \text{fitted})} \) and the deviance residual is \( \sqrt{-2 \log \text{arithm of fitted}} \).
  - For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The pearson and deviance residuals are as defined in McCullagh and Nelder.
- `...` further arguments passed to or from other methods.

**Value**

Vector of residuals of type `type` from a fitted `rpart` object.

**References**

**Examples**

```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
data = solder.balance, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```
rpart

Recursive Partitioning and Regression Trees

Description

Fit a rpart model

Usage

rpart(formula, data, weights, subset, na.action = na.rpart, method,
       model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)

Arguments

formulaa formula, with a response but no interaction terms. If this is a data frame, it is
taken as the model frame (see model.frame).
dataan optional data frame in which to interpret the variables named in the formula.
weightsoptional case weights.
subsetoptional expression saying that only a subset of the rows of the data should be
used in the fit.
na.actionthe default action deletes all observations for which y is missing, but keeps those
in which one or more predictors are missing.
methodone of "anova", "poisson", "class" or "exp". If method is missing then the
routine tries to make an intelligent guess. If y is a survival object, then method =
"exp" is assumed, if y has 2 columns then method = "poisson" is assumed, if
y is a factor then method = "class" is assumed, otherwise method = "anova" is
assumed. It is wisest to specify the method directly, especially as more criteria
may added to the function in future.

Alternatively, method can be a list of functions named init, split and eval.
Examples are given in the file ‘tests/usersplits.R’ in the sources, and in the
vignettes ‘User Written Split Functions’.

modelif logical: keep a copy of the model frame in the result? If the input value for
model is a model frame (likely from an earlier call to the rpart function), then
this frame is used rather than constructing new data.

xkeep a copy of the x matrix in the result.
ykeep a copy of the dependent variable in the result. If missing and model is
supplied this defaults to FALSE.

parmsoptional parameters for the splitting function.

Anova splitting has no parameters.

Poisson splitting has a single parameter, the coefficient of variation of the prior
distribution on the rates. The default value is 1.

Exponential splitting has the same parameter as Poisson.

For classification splitting, the list can contain any of: the vector of prior prob-
babilities (component prior), the loss matrix (component loss) or the splitting
index (component split). The priors must be positive and sum to 1. The loss
matrix must have zeros on the diagonal and positive off-diagonal elements. The
splitting index can be gini or information. The default priors are proportional
to the data counts, the losses default to 1, and the split defaults to gini.
control

control is a list of options that control details of the rpart algorithm. See rpart.control.

cost

cost is a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.

... arguments to rpart.control may also be specified in the call to rpart. They are checked against the list of valid arguments.

Details

This differs from the tree function in S mainly in its handling of surrogate variables. In most details it follows Breiman et al. (1984) quite closely. R package tree provides a re-implementation of tree.

Value

An object of class rpart. See rpart.object.

References

See Also

rpart.control, rpart.object, summary.rpart, print.rpart

Examples

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
       parms = list(prior = c(.65,.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
       control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
Arguments

**minsplits**
the minimum number of observations that must exist in a node in order for a split to be attempted.

**minbucket**
the minimum number of observations in any terminal leaf node. If only one of minbucket or minsplits is specified, the code either sets minsplits to minbucket*3 or minbucket to minsplits/3, as appropriate.

**cp**
complexity parameter. Any split that does not decrease the overall lack of fit by a factor of cp is not attempted. For instance, with anova splitting, this means that the overall R-squared must increase by cp at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by cp will likely be pruned off by cross-validation, and that hence the program need not pursue it.

**maxcompete**
the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.

**maxsurrogate**
the number of surrogate splits retained in the output. If this is set to zero the compute time will be reduced, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.

**usesurrogate**
how to use surrogates in the splitting process. 0 means display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1 means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value 2, if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of tree, and 2 to the recommendations of Breiman et.al (1984).

**xval**
number of cross-validations.

**surrogatetstyle**
controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.

**maxdepth**
Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 rpart will give nonsense results on 32-bit machines.

... mop up other arguments.

Value

A list containing the options.

See Also

rpart
Description

This function does the initialization step for rpart, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

Usage

rpart.exp(y, offset, parms, wt)

Arguments

y the response, which will be of class Surv
offset optional offset
parms parameters controlling the fit. This is a list with components shrink and method. The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root.
wt case weights, if present

Value

a list with the necessary initialization components

Author(s)

Terry Therneau

See Also

rpart

rpart.object Recursive Partitioning and Regression Trees Object

Description

These are objects representing fitted rpart trees.
Value

```r
frame
```
data frame with one row for each node in the tree. The row.names of frame contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of frame include var, a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level "<leaf>"), n, the number of observations reaching the node, wt, the sum of case weights for observations reaching the node, dev, the deviance of the node, yval, the fitted value of the response at the node, and splits, a two column matrix of left and right split labels for each node. Also included in the frame are complexity, the complexity parameter at which this split will collapse, ncompete, the number of competitor splits recorded, and nsurrogate, the number of surrogate splits recorded. Extra response information which may be present is in yval2, which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node, the class probabilities and the ‘node probability’ (classification trees).

```r
where
```
an integer vector of the same length as the number of observations in the root node, containing the row number of frame corresponding to the leaf node that each observation falls into.

```r
call
```
an image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say update(tree).

```r
terms
```
an object of class c("terms", "formula") (see terms.object) summarizing the formula. Used by various methods, but typically not of direct relevance to users.

```r
splits
```
a numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are count, the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), ncat, the number of categories or levels for the variable (+/-1 for a continuous variable), improve, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and index, the numeric split point. The last column adj gives the adjusted concordance for surrogate splits. For a factor, the index column contains the row number of the csplit matrix. For a continuous variable, the sign of ncat determines whether the subset x < cutpoint or x > cutpoint is sent to the left.

```r
csplit
```
an integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the index column of the splits matrix. The columns record 1 if that level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree (or not defined for the factor).

```r
method
```
character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).

```r
cptable
```
a matrix of information on the optimal prunings based on a complexity parameter.
variable.importance
a named numeric vector giving the importance of each variable. (Only present if there are any splits.) When printed by summary.rpart these are rescaled to add to 100.
	numresp integer number of responses; the number of levels for a factor response.

parms, control a record of the arguments supplied, which defaults filled in.

functions the summary, print and text functions for method used.

ordered a named logical vector recording for each variable if it was an ordered factor.

na.action (where relevant) information returned by model.frame on the special handling of NAs derived from the na.action argument.

There may be attributes "xlevels" and "levels" recording the levels of any factor splitting variables and of a factor response respectively.

Optional components include the model frame (model), the matrix of predictors (x) and the response variable (y) used to construct the rpart object.

Structure
The following components must be included in a legitimate rpart object.

See Also
rpart.

rsq.rpart
Plots the Approximate R-Square for the Different Splits

Description
Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

Usage
rsq.rpart(x)

Arguments
x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

Side Effects
Two plots are produced.

Note
The labels are only appropriate for the "anova" method.
Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

---

### snip.rpart

#### Snip Subtrees of an Rpart Object

**Description**

Creates a "snipped" `rpart` object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the `toss` argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

**Usage**

```r
snip.rpart(x, toss)
```

**Arguments**

- `x` fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `toss` an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

**Details**

A dendrogram of `rpart` is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting `rpart` object.

See the documentation for the specific graphics device for details on graphical input techniques.

**Value**

A `rpart` object containing the nodes that remain after specified or selected subtrees have been snipped off.

**Warning**

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

**See Also**

`plot.rpart`
Examples

```r
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree
# can also interactively select the node using the mouse in the
# graphics window
## End(Not run)
```

### solder.balance

#### Description

The `solder.balance` data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

The `solder` data frame is the full version of the data with 900 rows. It is located in both the `rpart` and the `survival` packages.

#### Usage

`solder`

#### Format

This data frame contains the following columns:

- **Opening**: a factor with levels 'L', 'M' and 'S' indicating the amount of clearance around the mounting pad.
- **Solder**: a factor with levels 'Thick' and 'Thin' giving the thickness of the solder used.
- **Mask**: a factor with levels 'A1.5', 'A3', 'B3' and 'B6' indicating the type and thickness of mask used.
- **PadType**: a factor with levels 'D4', 'D6', 'D7', 'L4', 'L6', 'L7', 'L8', 'L9', 'W4' and 'W9' giving the size and geometry of the mounting pad.
- **Panel**: 1:3 indicating the panel on a board being tested.
- **skips**: a numeric vector giving the number of visible solder skips.

#### Source

#### Examples

```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
             data = solder.balance, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```
Stage C Prostate Cancer

Description

A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

Usage

data(stagec)

Format

A data frame with 146 observations on the following 8 variables.

- \texttt{pgtime}\, Time to progression or last follow-up (years)
- \texttt{pgstat}\, 1 = progression observed, 0 = censored
- \texttt{age}\, age in years
- \texttt{eet}\, early endocrine therapy, 1 = no, 2 = yes
- \texttt{g2}\, percent of cells in G2 phase, as found by flow cytometry
- \texttt{grade}\, grade of the tumor, Farrow system
- \texttt{gleason}\, grade of the tumor, Gleason system
- \texttt{ploidy}\, the ploidy status of the tumor, from flow cytometry. Values are ‘diploid’, ‘tetraploid’, and ‘aneuploid’

Details

A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

Examples

```r
require(survival)
rpart(Surv(pgtime, pgstat) ~ ., stagec)
```

summary.rpart

Summarize a Fitted rpart Object

Description

Returns a detailed listing of a fitted \texttt{rpart} object.

Usage

```r
## S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```
text.rpart

Arguments

object  fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits  Number of significant digits to be used in the result.
cp      trim nodes with a complexity of less than cp from the listing.
file    write the output to a given file name. (Full listings of a tree are often quite long).
...     arguments to be passed to or from other methods.

Details

This function is a method for the generic function summary for class "rpart". It can be invoked by calling summary for an object of the appropriate class, or directly by calling summary.rpart regardless of the class of the object.

It prints the call, the table shown by printcp, the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

See Also

summary.rpart, object, printcp.

Examples

## a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

## a classification tree with multiple variables and surrogate splits.
summary(rpart(Kyphosis ~ Age + Number + Start, data = kyphosis))

---

text.rpart  Place Text on a Dendrogram Plot

Description

Labels the current plot of the tree dendrogram with text.

Usage

## S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
     pretty = NULL, digits =getOption("digits") - 3, use.n = FALSE,
     fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
     minlength = 1L, ...)
text.rpart

Arguments

x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
splits logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split.
label For compatibility with rpart2, ignored in this version (with a warning).
FUN the name of a labeling function, e.g. text.
all Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes.
minlength the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', ...... Larger values use abbreviations of the label names. See the labels.rpart function for details.
pretty an alternative to the minlength argument, see labels.rpart.
digits number of significant digits to include in numerical labels.
use.n Logical. If TRUE, adds to label (#events level1/ #events level2/ etc. for class, n for anova, and #events/n for poisson and exp).
fancy Logical. If TRUE, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by yval. The edges connecting the nodes are labeled by left and right splits.
fwidth Relates to option fancy and the width of the ellipses and rectangles. If fwidth < 1 then it is a scaling factor (default = 0.8). If fwidth > 1 then it represents the number of character widths (for current graphical device) to use.
fheight Relates to option fancy and the height of the ellipses and rectangles. If fheight < 1 then it is a scaling factor (default = 0.8). If fheight > 1 then it represents the number of character heights (for current graphical device) to use.
bg The color used to paint the background to annotations if fancy = TRUE.
...
Graphical parameters may also be supplied as arguments to this function (see par). As labels often extend outside the plot region it can be helpful to specify xpd = TRUE.

Side Effects

the current plot of a tree dendrogram is labeled.

See Also

text, plot.rpart, rpart, labels.rpart, abbreviate

Examples

freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)
xpred.rpart  

Return Cross-Validated Predictions

Description

Gives the predicted values for an \texttt{rpart} fit, under cross validation, for a set of complexity parameter values.

Usage

\texttt{xpred.rpart(fit, xval = 10, cp, return.all = FALSE)}

Arguments

- \textit{fit} \hspace{0.5cm} a object of class "\texttt{rpart}".
- \textit{xval} \hspace{0.5cm} number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups.
- \textit{cp} \hspace{0.5cm} the desired list of complexity values. By default it is taken from the \texttt{cptable} component of the fit.
- \textit{return.all} \hspace{0.5cm} if FALSE return only the first element of the prediction

Details

Complexity penalties are actually ranges, not values. If the \textit{cp} values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for \textit{cp} in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.

Value

A matrix with one row for each observation and one column for each complexity value. If \textit{return.all} is TRUE and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; \texttt{result[1,,]} will be the matrix of predicted classes, \texttt{result[2,,]} the matrix of class 1 probabilities, etc.

See Also

- \texttt{rpart}

Examples

\begin{verbatim}
fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum) \# cross-validated error estimate

\# approx same result as rel. error from \texttt{printcp(fit)}
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
\end{verbatim}
Chapter 28

The spatial package

---

**anova.trls**  
Anova tables for fitted trend surface objects

---

Description

Compute analysis of variance tables for one or more fitted trend surface model objects; where anova.trls is called with multiple objects, it passes on the arguments to anovalist.trls.

Usage

```r
## S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

Arguments

- `object`  
  A fitted trend surface model object from surf.ls

- `...`  
  Further objects of the same kind

Value

anova.trls and anovalist.trls return objects corresponding to their printed tabular output.

References

See Also

- `surf.ls`
Examples

library(stats)
data(topo, package="MASS")
topo0 <- surf.ls(0, topo)
topo1 <- surf.ls(1, topo)
topo2 <- surf.ls(2, topo)
topo3 <- surf.ls(3, topo)
topo4 <- surf.ls(4, topo)
anova(topo0, topo1, topo2, topo3, topo4)
summary(topo4)

---

correlogram  
Compute Spatial Correlograms

Description

Compute spatial correlograms of spatial data or residuals.

Usage

correlogram(krig, nint, plotit = TRUE, ...)

Arguments

  krig  trend-surface or kriging object with columns x, y, and z
  nint  number of bins used
  plotit logical for plotting
  ...  parameters for the plot

Details

Divides range of data into nint bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

Value

  x and y coordinates of the correlogram, and cnt, the number of pairs averaged per bin.

Side Effects

  Plots the correlogram if plotit = TRUE.

References

See Also

  variogram
**Examples**

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
correlogram(topo.kr, 25)
d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```

---

**expcov**

*Spatial Covariance Functions*

**Description**

Spatial covariance functions for use with `surf.gls`.

**Usage**

```r
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

**Arguments**

- `r`: vector of distances at which to evaluate the covariance
- `d`: range parameter
- `alpha`: proportion of nugget effect
- `se`: standard deviation at distance zero
- `D`: dimension of spheres.

**Value**

vector of covariance values.

**References**

**See Also**

- `surf.gls`

**Examples**

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
correlogram(topo.kr, 25)
d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```
Kaver  

Average K-functions from Simulations

Description
Forms the average of a series of (usually simulated) K-functions.

Usage
Kaver(fs, nsim, ...)

Arguments
fs full scale for K-fn
nsim number of simulations
... arguments to simulate one point process object

Value
list with components x and y of the average K-fn on L-scale.

References

See Also
Kfn, Kenv1

Examples
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 40), type="b")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")

lines(Kaver(10,25,Strauss(69,0.5,3.5)), col="red")
**Kenvl**

*Compute Envelope and Average of Simulations of K-fns*

**Description**

Computes envelope (upper and lower limits) and average of simulations of K-fns.

**Usage**

```r
Kenvl(fs, nsim, ...)  
```

**Arguments**

- `fs` full scale for K-fn
- `nsim` number of simulations
- `...` arguments to produce one simulation

**Value**

List with components:

- `x` distances
- `lower` min of K-fns
- `upper` max of K-fns
- `aver` average of K-fns

**References**

**See Also**

- `Kfn`, `Kaver`

**Examples**

  towns <- ppinit("towns.dat")
  par(pty="s")
  plot(Kfn(towns, 40), type="b")
  plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
  for(i in 1:10) lines(Kfn(Psim(69), 10))
  lims <- Kenvl(10,100,Psim(69))
  lines(lims$x,lims$lower, lty=2, col="green")
  lines(lims$x,lims$upper, lty=2, col="green")
  lines(Kaver(10,25,Strauss(69,0.5,3.5)), col="red")
```
Compute K-fn of a Point Pattern

Description
Actually computes \( L = \sqrt{K/\pi} \).

Usage
Kfn(pp, fs, k=100)

Arguments
pp a list such as a pp object, including components x and y
fs full scale of the plot
k number of regularly spaced distances in \((0, f_s)\)

Details
relies on the domain D having been set by ppinit or ppregion.

Value
A list with components

x vector of distances
y vector of L-fn values
k number of distances returned – may be less than k if fs is too large
dmin minimum distance between pair of points
lm maximum deviation from \( L(t) = t \)

References

See Also

Examples
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="s", xlab="distance", ylab="L(t)")
**ppgetregion**

*Get Domain for Spatial Point Pattern Analyses*

**Description**

Retrieves the rectangular domain \((x_l, x_u) \times (y_l, y_u)\) from the underlying C code.

**Usage**

`ppgetregion()`

**Value**

A vector of length four with names `c("xl", "xu", "yl", "yu")`.

**References**

**See Also**

`ppregion`

---

**ppinit**

*Read a Point Process Object from a File*

**Description**

Read a file in standard format and create a point process object.

**Usage**

`ppinit(file)`

**Arguments**

- `file` string giving file name

**Details**

The file should contain
- the number of points
- a header (ignored)
- \(x_l\) \(x_u\) \(y_l\) \(y_u\) scale
- \(x\) \(y\) (repeated \(n\) times)

**Value**

class "pp" object with components \(x, y, x_l, x_u, y_l, y_u\)
**Side Effects**

Calls `ppregion` to set the domain.

**References**

**See Also**

`ppregion`

**Examples**

```r
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
```

---

**pplik**  
*Pseudo-likelihood Estimation of a Strauss Spatial Point Process*

**Description**

Pseudo-likelihood estimation of a Strauss spatial point process.

**Usage**

```r
pplik(pp, R, ng=50, trace=FALSE)
```

**Arguments**

- `pp`  
a pp object
- `R`  
the fixed parameter \( R \)
- `ng`  
use a \( ng \times ng \) grid with border \( R \) in the domain for numerical integration.
- `trace`  
logical? Should function evaluations be printed?

**Value**

estimate for \( c \) in the interval \([0, 1]\).

**References**

**See Also**

`Strauss`

**Examples**

```r
pines <- ppinit("pines.dat")
pplik(pines, 0.7)
```
ppregion  Set Domain for Spatial Point Pattern Analyses

Description
Sets the rectangular domain \((x_1, x_u) \times (y_1, y_u)\).

Usage
ppregion(x1 = 0, xu = 1, y1 = 0, yu = 1)

Arguments
- **xl**: Either \(xl\) or a list containing components \(xl, xu, yl, yu\) (such as a point-process object).
- **xu, yl, yu**: Other limits of the rectangle if given separately.

Value
none

Side Effects
initializes variables in the C subroutines.

ppinit, ppgetregion

predict.trls  Predict method for trend surface fits

Description
Predicted values based on trend surface model object

Usage
## S3 method for class 'trls'
predict(object, x, y, ...)

Arguments
- **object**: Fitted trend surface model object returned by surf.ls
- **x**: Vector of prediction location eastings (x coordinates)
- **y**: Vector of prediction location northings (y coordinates)
- **...**: Further arguments passed to or from other methods.
prmat

Evaluate Kriging Surface over a Grid

Description

Evaluate Kriging surface over a grid.

Usage

prmat(obj, xl, xu, yl, yu, n)

Arguments

- **obj**: object returned by `surf.gls`
- **xl**: limits of the rectangle for grid
- **xu**: ditto
- **yl**: ditto
- **yu**: ditto
- **n**: use n x n grid within the rectangle

Value

list with components x, y and z suitable for `contour` and `image`.

References

Examples

data(topo, package="MASS")
topo2 <- surf.ls(2, topo)
topo4 <- surf.ls(4, topo)
x <- c(1.78, 2.21)
y <- c(6.15, 6.15)
z2 <- predict(topo2, x, y)
z4 <- predict(topo4, x, y)
cat("2nd order predictions:", z2, "\n4th order predictions:", z4, "\n")
Psim

Simulate Binomial Spatial Point Process

Description

Simulate Binomial spatial point process.

Usage

Psim(n)

Arguments

n
number of points

Details

relies on the region being set by ppinit or ppregion.

Value

list of vectors of x and y coordinates.

Side Effects

uses the random number generator.

References

See Also

SSI, Strauss

Examples

towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="s", xlab="distance", ylab="L(t)")
for(i in 1:10) lines(Kfn(Psim(69), 10))
Evaluate Kriging Standard Error of Prediction over a Grid

Description
Evaluate Kriging standard error of prediction over a grid.

Usage
semat(obj, xl, xu, yl, yu, n, se)

Arguments
- obj: object returned by `surf.gls`
- xl: limits of the rectangle for grid
- xu: ditto
- yl: ditto
- yu: ditto
- n: use \( n \times n \) grid within the rectangle
- se: standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied.

Value
list with components x, y and z suitable for `contour` and `image`.

References

See Also
- `surf.gls`, `trmat`, `prmat`

Examples
```
data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))

sesurf <- semat(topo.kr, 0, 6.5, 0, 6.5, 30)
contour(sesurf, levels=c(22,25))
```
**Description**

Simulates SSI (sequential spatial inhibition) point process.

**Usage**

SSI(n, r)

**Arguments**

- `n` number of points
- `r` inhibition distance

**Details**

uses the region set by `ppinit` or `ppregion`.

**Value**

list of vectors of x and y coordinates

**Side Effects**

uses the random number generator.

**Warnings**

will never return if `r` is too large and it cannot place `n` points.

**References**

**See Also**

**Examples**

towns <- ppinit("towns.dat")
par(pty = "s")
plot(Kfn(towns, 10), type = "b", xlab = "distance", ylab = "L(t)")
lines(Kaver(10, 25, SSI(69, 1.2)))
Simulates Strauss Spatial Point Process

**Description**
Simulates Strauss spatial point process.

**Usage**
```
Strauss(n, c=0, r)
```

**Arguments**
- `n`: number of points
- `c`: parameter `c` in `[0, 1]`. `c = 0` corresponds to complete inhibition at distances up to `r`.
- `r`: inhibition distance

**Details**
Uses spatial birth-and-death process for `4n` steps, or for `40n` steps starting from a binomial pattern on the first call from another function. Uses the region set by `ppinit` or `ppregion`.

**Value**
List of vectors of `x` and `y` coordinates

**Side Effects**
Uses the random number generator

**References**

**See Also**

lines(Kaver(10, 25, Strauss(69,0.5,3.5)))
```
surf.gls

*Fits a Trend Surface by Generalized Least-squares*

**Description**
Fits a trend surface by generalized least-squares.

**Usage**
surf.gls(np, covmod, x, y, z, nx = 1000, ...)

**Arguments**
- **np**: degree of polynomial surface
- **covmod**: function to evaluate covariance or correlation function
- **x**: x coordinates or a data frame with columns x, y, z
- **y**: y coordinates
- **z**: z coordinates. Will supersede x$z
- **nx**: Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object.
- **...**: parameters for covmod

**Value**
list with components
- **beta**: the coefficients
- **x**:
- **y**:
- **z**: and others for internal use only.

**References**

trsurf <- trmat(topo.kr, 0, 6.5, 0, 6.5, 50)
eqscplot(trsurf, type = "n")
contour(trsurf, add = TRUE)

prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
surf.ls

Fits a Trend Surface by Least-squares

Description

Fits a trend surface by least-squares.

Usage

surf.ls(np, x, y, z)

Arguments

np  degree of polynomial surface
x   x coordinates or a data frame with columns x, y, z
y   y coordinates
z   z coordinates. Will supersede x$z

Value

list with components

beta the coefficients
x
y
z  and others for internal use only.

**trls.influence**

*Regression diagnostics for trend surfaces*

**Description**

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

**Usage**

```r
trls.influence(object)
```

**Arguments**

- `object, x` Fitted trend surface model from `surf.ls`
- `div` scaling factor for influence circle radii in `plot.trls`
- `add` add influence plot to existing graphics if TRUE
- `border, col, pch, cex, ...` additional graphical parameters

**Value**

`trls.influence` returns a list with components:

- `r` raw residuals as given by `residuals.trls`
- `hii` diagonal elements of the Hat matrix
- `stresid` standardised residuals
- `Di` Cook's statistic

variogram

Examples

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
trsurf <- trmat(topo.kr, 0, 6.5, 0, 6.5, 50)
```

---

**Description**

Compute spatial (semi-)variogram of spatial data or residuals.

**Usage**

```r
variogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

- `krig`: trend-surface or kriging object with columns `x`, `y`, and `z`
- `nint`: number of bins used
- `plotit`: logical for plotting
- `...`: parameters for the plot

**Details**

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

**Value**

- `x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

**Side Effects**

Plots the variogram if `plotit = TRUE`

```
variogram
Chapter 29

The survival package

**aareg**

Aalen’s additive regression model for censored data

**Description**

Returns an object of class "aareg" that represents an Aalen model.

**Usage**

```r
aareg(formula, data, weights, subset, na.action,
qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
test = c('aalen', 'variance', 'nrisk'), cluster,
model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

- **formula**: a formula object, with the response on the left of a `~` operator and the terms, separated by `+` operators, on the right. The response must be a `Surv` object. Due to a particular computational approach that is used, the model MUST include an intercept term. If "-1" is used in the model formula the program will ignore it.
- **data**: data frame in which to interpret the variables named in the formula, subset, and weights arguments. This may also be a single number to handle some special cases – see below for details. If data is missing, the variables in the model formula should be in the search path.
- **weights**: vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of weights must be the same as the number of observations. The weights must be nonnegative and it is recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the subset argument instead of zero weights.
- **subset**: expression specifying which subset of observations should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default.
aareg

na.action a function to filter missing data. This is applied to the model.frame after any subset argument has been applied. The default is na.fail, which returns an error if any missing values are found. An alternative is na.exclude, which deletes observations that contain one or more missing values.

qr_tol tolerance for detection of singularity in the QR decomposition

nmin minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when n is small and the calculations can become numerically unstable.

dfbeta should the array of dfbeta residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a cluster term in the model formula.

taper allows for a smoothed variance estimate. Var(x), where x is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point t, it is computed over all subjects who are still at risk at time t. The taper argument allows smoothing these estimates, for example taper=(1:4)/4 would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model.

test selects the weighting to be used, for computing an overall “average” coefficient vector over time and the subsequent test for equality to zero.

cluster the clustering group, optional. The variable will be searched for in the data argument.

model, x, y should copies of the model frame, the x matrix of predictors, or the response vector y be included in the saved result.

Details

The Aalen model assumes that the cumulative hazard H(t) for a subject can be expressed as \( a(t) + X \cdot B(t) \), where \( a(t) \) is a time-dependent intercept term, \( X \) is the vector of covariates for the subject (possibly time-dependent), and \( B(t) \) is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to \( B \) at time t is based on the subjects still at risk at time t. The tolerance and/or nmin parameters may act to truncate the estimate before the last death. The taper argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when n is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

Value

an object of class "aareg" representing the fit, with the following components:

n vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation

times vector of sorted event times, which may contain duplicates

nrisk vector containing the number of subjects at risk, of the same length as times

coefficient matrix of coefficients, with one row per event and one column per covariate

test.statistic the value of the test statistic, a vector with one element per covariate
test.var variance-covariance matrix for the test
test the type of test; a copy of the test argument above
tweight matrix of weights used in the computation, one row per event
call a copy of the call that produced this result

### aeqSurv

**Adjudicate near ties in a Surv object**

**Description**

The check for tied survival times can fail due to floating point imprecision, which can make actual ties appear to be distinct values. Routines that depend on correct identification of ties pairs will then give incorrect results, e.g., a Cox model. This function rectifies these.

**Usage**

```r
aeqSurv(x, tolerance = sqrt(.Machine$double.eps))
```

**Arguments**

- `x`: a Surv object
- `tolerance`: the tolerance used to detect values that will be considered equal

**Details**

This routine is called by both `survfit` and `coxph` to deal with the issue of ties that get incorrectly broken due to floating point imprecision. See the short vignette on tied times for a simple example. Use the `timefix` argument of `survfit` or `coxph.control` to control the option if desired.

The rule for ‘equality’ is identical to that used by the `all.equal` routine. Pairs of values that are within round off error of each other are replaced by the smaller value. An error message is generated if this process causes a 0 length time interval to be created.

**Value**

A Surv object identical to the original, but with ties restored.

**Author(s)**

Terry Therneau

**See Also**

`survfit`, `coxph.control`
For a survfit object containing multiple curves, create average curves over a grouping.

**Usage**

```r
## S3 method for class 'survfit'
aggregate(x, by = NULL, FUN = mean, ...)
```

**Arguments**

- `x`: a survfit object which has a data dimension.
- `by`: an optional list or vector of grouping elements, each as long as `dim(x)['data']`.
- `FUN`: a function to compute the summary statistic of interest.
- `...`: optional further arguments to `FUN`.

**Details**

The primary use of this is to take an average over multiple survival curves that were created from a modeling function. That is, a marginal estimate of the survival. It is primarily used to average over multiple predicted curves from a Cox model.

**Value**

A survfit object of lower dimension.

**See Also**

- `survfit`

**Examples**

```r
cfit <- coxph(Surv(futime, death) ~ sex + age*hgb, data=mgus2)
# marginal effect of sex, after adjusting for the others
dummy <- rbind(mgus2, mgus2)
dummy$sex <- rep(c("F", "M"), each=nrow(mgus2)) # population data set
dummy <- na.omit(dummy) # don't count missing hgb in our "population
csurv <- survfit(cfit, newdata=dummy) # don't count missing hgb in our "population
csurv2 <- aggregate(csurv, dummy$sex)
csurv2 <- aggregate(csurv2, dummy$sex)
```
Description

These are the functions called by coxph that do the actual computation. In certain situations, e.g. a simulation, it may be advantageous to call these directly rather than the usual coxph call using a model formula.

Usage

agreg.fit(x, y, strata, offset, init, control, weights, method, rownames, resid=TRUE, nocenter=NULL)
coxph.fit(x, y, strata, offset, init, control, weights, method, rownames, resid=TRUE, nocenter=NULL)

Arguments

x Matix of predictors. This should not include an intercept.
y a Surv object containing either 2 columns (coxph.fit) or 3 columns (agreg.fit).
strata a vector containing the stratification, or NULL
offset optional offset vector
init initial values for the coefficients
control the result of a call to coxph.control
weights optional vector of weights
method method for handling ties, one of "breslow" or "efron"
rownames this is only needed for a NULL model, in which case it contains the rownames (if any) of the original data.
resid compute and return residuals.
nocenter an optional list of values. Any column of the X matrix whose values lie strictly within that set will not be recentered. Note that the coxph function has (-1, 0, 1) as the default.

Details

This routine does no checking that arguments are the proper length or type. Only use it if you know what you are doing!

The resid and concordance arguments will save some compute time for calling routines that only need the likelihood, the generation of a permutation distribution for instance.

Value

a list containing results of the fit

Author(s)

Terry Therneau
aml

Description
Survival in patients with Acute Myelogenous Leukemia. The question at the time was whether the standard course of chemotherapy should be extended (‘maintenance’) for additional cycles.

Usage
aml
leukemia
data(cancer, package="survival")

Format
time: survival or censoring time
status: censoring status
x: maintenance chemotherapy given? (factor)

Source

anova.coxph

Analysis of Deviance for a Cox model.

Description
Compute an analysis of deviance table for one or more Cox model fits, based on the log partial likelihood.

Usage
## S3 method for class 'coxph'
anova(object, ..., test = 'Chisq')

Arguments
object An object of class coxph
... Further coxph objects
test a character string. The appropriate test is a chisquare, all other choices result in no test being done.
Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model Cox log-partial-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of likelihood values does not make sense (differences no longer have a chi-square distribution), and anova will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models by anova will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

See Also

coxph, anova.

Examples

fit <- coxph(Surv(futime, fustat) ~ resid.ds * rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds + rx + ecog.ps, data=ovarian)
anova(fit2,fit)

attrassign

Create new-style "assign" attribute

Description

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

Usage

attrassign(object, ...)
## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm'
attrassign(object,...)
Arguments

object  model matrix or linear model object
tt  terms object
...  further arguments for other methods

Details

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact form for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as "the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3".

The alternate (S-Plus default) form is a list

```
$( Intercept)  1
$age  2
$sex  3
$factor(ph.ecog)  4 5 6
```

Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

See Also

terms, model.matrix

Examples

```
formula <- Surv(time,status)-factor(ph.ecog)
tt <- terms(formula)
mf <- model.frame(tt,data=lung)
mm <- model.matrix(tt,mf)
  ## a few rows of data
mm[1:3,]
  ## old-style assign attribute
attr(mm,"assign")
  ## alternate style assign attribute
attrassign(mm,tt)
```
basehaz

**Alias for the survfit function**

**Description**

Compute the predicted survival curve for a Cox model.

**Usage**

```r
basehaz(fit, newdata, centered=TRUE)
```

**Arguments**

- `fit`: a `coxph` fit
- `newdata`: a data frame containing one row for each predicted survival curve, said row contains the covariate values for that curve
- `centered`: ignored if the `newdata` argument is present. Otherwise, if `TRUE` return data from a predicted survival curve for the covariate values `fit$mean`, if `FALSE` return a prediction for all covariates equal to zero.

**Details**

This function is simply an alias for `survfit`, which does the actual work and has a richer set of options. The alias exists only because some users look for predicted survival estimates under this name.

The function returns a data frame containing the `time`, `cumhaz` and optionally the `strata` (if the fitted Cox model used a `strata` statement), which are copied the `survfit` result. Results for all covariates =0 are a standard form found in textbooks, however, due to possible overflow in the `exp()` function this can be a very bad idea in practice.

**Value**

a data frame with variable names of `hazard`, `time` and optionally `strata`. The first is actually the cumulative hazard.

**See Also**

`survfit.coxph`
Description

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo, and only the first four recurrences for any patient. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the \( (\text{start, stop}] \) or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects: all those with follow-up beyond their 4th recurrence. This “follow-up” is a side effect of throwing away all events after the fourth while retaining the last follow-up time variable from the original data. The bladder2 data set found here does not make this mistake, but some analyses in the literature have done so; it results in the addition of a small amount of immortal time bias and shrinks the fitted coefficients towards zero.

Usage

```r
bladder1
bladder
bladder2
data(cancer, package="survival")
```

Format

Bladder1

**blogit**

*Bounded link functions*

**Description**

Alternate link functions that impose bounds on the input of their link function

**Usage**

blogit(edge = 0.05)
bprobit(edge= 0.05)
bclgloglog(edge=.05)
blog(edge=.05)

**Arguments**

edge: input values less than the cutpoint are replaces with the cutpoint. For all be blog input values greater than (1-edge) are replaced with (1-edge)
When using survival pseudovalues for binomial regression, the raw data can be outside the range (0,1), yet we want to restrict the predicted values to lie within that range. A natural way to deal with this is to use glm with family = gaussian(link= "logit"). But this will fail. The reason is that the family object has a component linkfun that does not accept values outside of (0,1).

This function is only used to create initial values for the iteration step, however. Mapping the offending input argument into the range of (edge, 1-edge) before computing the link results in starting estimates that are good enough. The final result of the fit will be no different than if explicit starting estimates were given using the etastart or mustart arguments. These functions create copies of the logit, probit, and complimentary log-log families that differ from the standard ones only in this use of a bounded input argument, and are called a "bounded logit" = blogit, etc.

The same argument hold when using RMST (area under the curve) pseudovalues along with a log link to ensure positive predictions, though in this case only the lower boundary needs to be mapped.

Value

a family object of the same form as make.family.

See Also

stats{make.family}

Examples

py <- pseudo(survfit(Surv(time, status) ~1, lung), time=730) #2 year survival
range(py)
pfit <- glm(py ~ ph.ecog, data=lung, family=gaussian(link=blogit()))
# For each +1 change in performance score, the odds of 2 year survival
# are multiplied by 1/2 = exp of the coefficient.

brier  
Compute the Brier score for a Cox model

Description

Compute the Brier score, for a coxph model

Usage

brier(fit, times, newdata, ties = TRUE, detail = FALSE, timefix = TRUE, 
      efron = FALSE)

Arguments

fit        result of a coxph fit
times      time points at which to create the score
newdata    optional, used to validate a prior fit with new data
ties       if TRUE, treat tied event/censoring times properly
detail     if TRUE, the returned object has more detail. This can be useful for debugging or for instruction.
timefix deal with near ties in the data. See the tied times vignette.
efron use the same survival estimate for the NULL model as was used in the coxph call

Details

Far more details are found in the vignette. At any time point tau, the scaled Brier score is essentially the R-squared statistic where y = the 0/1 variable “event at or before tau”, yhat is the probability of an event by tau, as predicted by the model, and the ybar is the predicted probabilitly without covariate, normally from a Kaplan-Meier. If \( R^2 = 1 - \frac{\sum(y - \hat{y})^2}{\sum(y - \mu)^2} \), the Brier score is formally only the numerator of the second term. The rescaled value is much more useful, however.

Many, perhaps even most algorithms do not properly deal with a tied censoring time/event time pair. The tied option is present mostly verify that we get the same answer, when we make the same mistake. The numerical size of the inaccuracy is very small; just large enough to generate concern that this function is incorrect.

A sensible argument can be made that the NULL model should be a coxph call with no covariates, rather than the Kaplan-Meier; but it turns out that the effect is very slight. This is allowed by the efron argument.

Value

a list with components

rsquared the \( R^2 \) value, a scaled Brier score. This will be a vector with one entry for each time point.
brier the brier score, a vector with one entry per time point
times the time points at which the score was computed

brier(cfit, times=c(4,6)*365.25) # values at 4 and 6 years
cch

Fits proportional hazards regression model to case-cohort data

Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

Usage

```r
cch(formula, data, subcoh, id, stratum=NULL, cohort.size, 
method =c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"), 
robust=FALSE)
```

Arguments

- `formula`: A formula object that must have a `Surv` object as the response. The `Surv` object must be of type "right", or of type "counting".
- `subcoh`: Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If `data` is a data frame then `subcoh` may be a one-sided formula.
- `id`: Vector of unique identifiers, or formula specifying such a vector.
- `stratum`: A vector of stratum indicators or a formula specifying such a vector
- `cohort.size`: Vector with size of each stratum original cohort from which subcohort was sampled
- `data`: An optional data frame in which to interpret the variables occurring in the formula.
- `method`: Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".
- `robust`: For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I

Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The `data` argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.
Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

- **coef**: regression coefficients.
- **naive.var**: Self-Prentice model based variance-covariance matrix.
- **var**: Lin-Ying empirical variance-covariance matrix.

cipoisson  Confidence limits for the Poisson

Description

Confidence interval calculation for Poisson rates.

Usage

cipoisson(k, time = 1, p = 0.95, method = c("exact", "anscombe"))

Arguments

k  Number of successes

k  Number of successes

time  Total time on trial

p  Probability level for the (two-sided) interval

method  The method for computing the interval.

Details

The likelihood method is based on equation 10.10 of Feller, which relates poisson probabilities to tail area of the gamma distribution. The Anscombe approximation is based on the fact that $\sqrt{k + 3/8}$ has a nearly constant variance of $1/4$, along with a continuity correction.

There are many other proposed intervals: Patil and Kulkarni list and evaluate 19 different suggestions from the literature!. The exact intervals can be overly broad for very small values of $k$, many of the other approaches try to shrink the lengths, with varying success.

Value

a vector, matrix, or array. If both $k$ and $t$ are single values the result is a vector of length 2 containing the lower an upper limits. If either or both are vectors the result is a matrix with two columns. If $k$ is a matrix or array, the result will be an array with one more dimension; in this case the dimensions and dimnames (if any) of $k$ are preserved.

clogit  

Conditional logistic regression

Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form case.status~exposure+strata(matched.set). The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.

Usage

clogit(formula, data, weights, subset, na.action,
  method=c("exact", "approximate", "efron", "breslow"),
  ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>formula</td>
<td>Model formula</td>
</tr>
<tr>
<td>data</td>
<td>data frame</td>
</tr>
<tr>
<td>weights</td>
<td>optional, names the variable containing case weights</td>
</tr>
<tr>
<td>subset</td>
<td>optional, subset the data</td>
</tr>
<tr>
<td>na.action</td>
<td>optional na.action argument. By default the global option na.action is used.</td>
</tr>
<tr>
<td>method</td>
<td>use the correct (exact) calculation in the conditional likelihood or one of the approximations</td>
</tr>
<tr>
<td>...</td>
<td>optional arguments, which will be passed to coxph.control</td>
</tr>
</tbody>
</table>

Details

It turns out that the loglikelihood for a conditional logistic regression model = loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this ‘trick’ rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is \(\frac{20!}{10! \cdot 10!}\) = 184756 terms. Gail et al describe a fast recursion method which partly ameliorates this; it was incorporated into version 2.36-11 of the survival package. The computation remains infeasible for very large groups of ties, say 100 ties out of 500 subjects, and may even lead to integer overflow for the subscripts – in this latter case the routine will refuse to undertake the task. The Efron approximation is normally a sufficiently accurate substitute.

Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, in which case all of the approximations for ties lead to exactly the same result. The 'approximate' option maps to the Breslow approximation for the Cox model, for historical reasons.

Case weights are not allowed when the exact option is used, as the likelihood is not defined for fractional weights. Even with integer case weights it is not clear how they should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine in this case.

Value

An object of class "clogit", which is a wrapper for a "coxph" object.

cluster

Identify clusters.

Description

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. This style is now discouraged, use the cluster option instead.

Usage

cluster(x)

Arguments

x

A character, factor, or numeric variable.

Details

The function’s only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the “working independence” variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don’t mix.

Value

x

See Also

</tr>
</tbody>
</table>

Note

The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).

Peter Higgins has pointed out a data inconsistency, revealed by `table(colon$nodes, colon$node4)`. We don’t know which of the two variables is actually correct so have elected not to ‘fix’ it. (Real data has warts, why not have some in the example data too?)

**concordance**

Compute the concordance statistic for data or a model

**Description**

The concordance statistic compute the agreement between an observed response and a predictor. It is closely related to Kendall’s tau-a and tau-b, Goodman’s gamma, and Somers’ d, all of which can also be calculated from the results of this function.

**Usage**

```r
concordance(object, ...)  
## S3 method for class 'formula'
concordance(object, data, weights, subset, na.action,  
cluster, ymin, ymax, timewt= c("n", "S", "S/G", "n/G2", "I"),  
influence=0, ranks = FALSE, reverse=FALSE, timefix=TRUE, keepstrata=10, ...)
## S3 method for class 'lm'
concordance(object, ..., newdata, cluster, ymin, ymax,  
influence=0, ranks=FALSE, timefix=TRUE, keepstrata=10)
## S3 method for class 'coxph'
concordance(object, ..., newdata, cluster, ymin, ymax,  
timewt= c("n", "S", "S/G", "n/G2", "I"), influence=0,  
ranks=FALSE, timefix=TRUE, keepstrata=10)
## S3 method for class 'survreg'
concordance(object, ..., newdata, cluster, ymin, ymax,  
timewt= c("n", "S", "S/G", "n/G2", "I"), influence=0,  
ranks=FALSE, timefix=TRUE, keepstrata=10)
```

**Arguments**

- **object** a fitted model or a formula. The formula should be of the form `y ~ x` or `y ~ x + strata(z)` with a single numeric or survival response and a single predictor. Counts of concordant, discordant and tied pairs are computed separately per stratum, and then added.
concordance

data a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument. Only applicable if object is a formula.
weights optional vector of case weights. Only applicable if object is a formula.
subset expression indicating which subset of the rows of data should be used in the fit. Only applicable if object is a formula.
na.action a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action. Only applicable if object is a formula.

... multiple fitted models are allowed. Only applicable if object is a model object.
newdata optional, a new data frame in which to evaluate (but not refit) the models
cluster optional grouping vector for calculating the robust variance
ymin, ymax compute the concordance over the restricted range ymin <= y <= ymax. (For survival data this is a time range.)
timewt the weighting to be applied. The overall statistic is a weighted mean over event times.
influence 1= return the dfbeta vector, 2= return the full influence matrix, 3 = return both ranks if TRUE, return a data frame containing the scaled ranks that make up the overall score.
reverse if TRUE then assume that larger x values predict smaller response values y; a proportional hazards model is the common example of this, larger hazard = shorter survival.
timefix correct for possible rounding error. See the vignette on tied times for more explanation. Essentially, exact ties are an important part of the concordance computation, but "exact" can be a subtle issue with floating point numbers.
keepstrata either TRUE, FALSE, or an integer value. Computations are always done within stratum, then added. If the total number of strata greater than keepstrata, or keepstrata=FALSE, those subtotals are not kept in the output.

Details

The concordance is an estimate of \( Pr(x_i < x_j | y_i < y_j) \), for a model fit replace \( x \) with \( \hat{y} \), the predicted response from the model. For a survival outcome some pairs of values are not comparable, e.g., censored at time 5 and a death at time 6, as we do not know if the first observation will or will not outlive the second. In this case the total number of evaluable pairs is smaller.

Relations to other statistics: For continuous x and y, 2C- 1 is equal to Somers’ d. If the response is binary, C is equal to the area under the receiver operating curve or AUC. For a survival response and binary predictor C is the numerator of the Gehan-Wilcoxon test.

A naive computation requires adding up over all n(n-1)/2 comparisons, which can be quite slow for large data sets. This routine uses an O(n log(n)) algorithm. At each uncensored event time y, compute the rank of x for the subject who had the event as compared to the x values for all others with a longer survival, where the rank has value between 0 and 1. The concordance is a weighted mean of these ranks, determined by the timewt option. The rank vector can be efficiently updated as subjects are added to the risk set. For further details see the vignette.

The variance is based on an infinitesimal jackknife. One advantage of this approach is that it also gives a valid covariance for the covariance based on multiple different predicted values, even if those predictions come from quite different models. See for instance the example below which has a poisson and two non-nested Cox models. This has been useful to compare a machine learning model to a Cox model fit, say. It is absolutely critical, however, that the predicted values line up
exactly, with the same observation in each row; otherwise the result will be nonsense. (Be alert to the impact of missing values.)

The \texttt{timewt} option is only applicable to censored data. In this case the default corresponds to Harrell’s C statistic, which is closely related to the Gehan-Wilcoxon test; \texttt{timewt="S"} corresponds to the Peto-Wilcoxon, \texttt{timewt="S/G"} is suggested by Schemper, and \texttt{timewt="n/G2"} corresponds to Uno’s C. It turns out that the Schemper and Uno weights are computationally identical, we have retained both option labels as a user convenience. The \texttt{timewt=} \texttt{"I"} option is related to the log-rank statistic.

When the number of strata is very large, such as in a conditional logistic regression for instance (\texttt{clogit} function), a much faster computation is available when the individual strata results are not retained; use \texttt{keepstrata=FALSE} or \texttt{keepstrata=} \texttt{0} to do so. In the general case the \texttt{keepstrata=} \texttt{10} default simply keeps the printout manageable: it retains and prints per-strata counts if the number of strata is \texttt{<=} \texttt{10}.

\textbf{Value}

An object of class \texttt{concordance} containing the following components:

\begin{itemize}
  \item \texttt{concordance} the estimated concordance value or values
  \item \texttt{count} a vector containing the number of concordant pairs, discordant, tied on x but not y, tied on y but not x, and tied on both x and y
  \item \texttt{n} the number of observations
  \item \texttt{var} a vector containing the estimated variance of the concordance based on the infinitesimal jackknife (IJ) method. If there are multiple models it contains the estimated variance/covariance matrix.
  \item \texttt{cvar} a vector containing the estimated variance(s) of the concordance values, based on the variance formula for the associated score test from a proportional hazards model. (This was the primary variance used in the \texttt{survConcordance} function.)
  \item \texttt{dfbeta} optional, the vector of leverage estimates for the concordance
  \item \texttt{influence} optional, the matrix of leverage values for each of the counts, one row per observation
  \item \texttt{ranks} optional, a data frame containing the Somers’ d rank at each event time, along with the time weight, and the case weight of the observation. The time weighted sum of the ranks will equal concordant pairs - discordant pairs.
\end{itemize}

\textbf{Note}

A coxph model that has a numeric failure may have undefined predicted values, in which case the concordance will be \texttt{NULL}.

Computation for an existing coxph model along with \texttt{newdata} has some subtleties with respect to extra arguments in the original call. These include

\begin{itemize}
  \item \texttt{tt()} terms in the model. This is not supported with \texttt{newdata}.
  \item \texttt{subset}. Any subset clause in the original call is ignored, i.e., not applied to the new data.
  \item \texttt{strata()} terms in the model. The new data is expected to have the strata variable(s) found in the original data set, with concordance computed within strata. The levels of the strata variable need not be the same as in the original data.
  \item \texttt{id} or \texttt{cluster} directives. This has not yet been sorted out.
\end{itemize}

concordancefit  Compute the concordance

Description
This is the working routine behind the concordance function. It is not meant to be called by users, but is available for other packages to use. Input arguments, for instance, are assumed to all be the correct length and type, and missing values are not allowed: the calling routine is responsible for these things.

Usage
concordancefit(y, x, strata, weights, ymin = NULL, ymax = NULL, timewt = c("n", "S", "S/G", "n/G2", "I"), cluster, influence = 0, ranks = FALSE, reverse = FALSE, timefix = TRUE, keepstrata = 10, std.err = TRUE)

Arguments
y  the response. It can be numeric, factor, or a Surv object
x  the predictor, a numeric vector
strata optional numeric vector that stratifies the data
weights  options vector of case weights
ymin, ymax  restrict the comparison to response values in this range
timewt  the time weighting to be used
cluster, influence, ranks, reverse, timefix  see the help for the concordance function
keepstrata  either TRUE, FALSE, or an integer value. Computations are always done within stratum, then added. If the total number of strata greater than keepstrata, or keepstrata=FALSE, those subtotals are not kept in the output.
std.err  compute the standard error; not doing so saves some compute time.

Details
This function is provided for those who want a “direct” call to the concordance calculations, without using the formula interface. A primary use has been other packages. The routine does minimal checking of its input arguments, under the assumption that this has already been taken care of by the calling routine.

Value
a list containing the results

Author(s)
Terry Therneau

concordance
Description
Test the proportional hazards assumption for a Cox regression model fit (coxph).

Usage
cox.zph(fit, transform="km", terms=TRUE, singledf=FALSE, global=TRUE)

Arguments
- **fit**: the result of fitting a Cox regression model, using the coxph or coxme functions.
- **transform**: a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument.
- **terms**: if TRUE, do a test for each term in the model rather than for each separate covariate. For a factor variable with k levels, for instance, this would lead to a k-1 degree of freedom test. The plot for such variables will be a single curve evaluating the linear predictor over time.
- **sievedf**: use a single degree of freedom test for terms that have multiple coefficients, i.e., the test that corresponds most closely to the plot. If terms=FALSE this argument has no effect.
- **global**: should a global chi-square test be done, in addition to the per-variable or per-term tests tests.

Details
The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in coxph. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient \( \beta(t) \). If the proportional hazards assumption holds then the true \( \beta(t) \) function would be a horizontal line. The table component provides the results of a formal score test for slope=0, a linear fit to the plot would approximate the test.

Random effects terms such as frailty or random effects in a coxme model are not checked for proportional hazards, rather they are treated as a fixed offset in model.

If the model contains strata by covariate interactions, then the y matrix may contain structural zeros, i.e., deaths (rows) that had no role in estimation of a given coefficient (column). These are marked as NA. If an entire row is NA, for instance after subscripting a cox.zph object, that row is removed.

Value
an object of class "cox.zph", with components:
- **table**: a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain a score test of for addition of the time-dependent term, the degrees of freedom, and the two-sided p-value.
- **x**: the transformed time axis.
time the untransformed time values; there is one entry for each event time in the data
strata for a stratified coxph model, the stratum of each of the events
y the matrix of scaled Schoenfeld residuals. There will be one column per term
or per variable (depending on the terms option above), and one row per event.
The row labels are a rounded form of the original times.
var a variance matrix for the covariates, used to create an approximate standard error
band for plots
transform the transform of time that was used
call the calling sequence for the routine.

Note
In versions of the package before survival3.0 the function computed a fast approximation to the
score test. Later versions compute the actual score test.

**coxph**

*Fit Proportional Hazards Regression Model*

**Description**
Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata,
multiple events per subject, and other extensions are incorporated using the counting process for-
mulation of Andersen and Gill.

**Usage**

`coxph(formula, data=, weights, subset,
 na.action, init, control,
 ties=c("efron","breslow","exact"),
 singular.ok=TRUE, robust,
 model=FALSE, x=FALSE, y=TRUE, tt, method=ties,
 id, cluster, istate, statedata, nocenter=c(-1, 0, 1), ...)`
Arguments

- **formula**: a formula object, with the response on the left of a `~` operator, and the terms on the right. The response must be a survival object as returned by the `Surv` function. For a multi-state model the formula may be a list of formulas.

- **data**: a data.frame in which to interpret the variables named in the `formula`, or in the `subset` and the `weights` argument.

- **weights**: vector of case weights, see the note below. For a thorough discussion of these see the book by Therneau and Grambsch.

- **subset**: expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.

- **na.action**: a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is `options()$na.action`.

- **init**: vector of initial values of the iteration. Default initial value is zero for all variables.

- **control**: Object of class `coxph.control` specifying iteration limit and other control options. Default is `coxph.control(...)`.  

- **ties**: a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. The Efron approximation is used as the default, it is more accurate when dealing with tied death times, and is as efficient computationally. (But see below for multi-state models.) The “exact partial likelihood” is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values.

- **singular.ok**: logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.

- **robust**: should a robust variance be computed. The default is TRUE if: there is a `cluster` argument, there are case weights that are not 0 or 1, or there are `id` values with more than one event.

- **id**: optional variable name that identifies subjects. Only necessary when a subject can have multiple rows in the data, and there is more than one event type. This variable will normally be found in `data`.

- **cluster**: optional variable which clusters the observations, for the purposes of a robust variance. If present, it implies robust. This variable will normally be found in `data`.

- **istate**: optional variable giving the current state at the start each interval. This variable will normally be found in `data`.

- **statedata**: optional data set used to describe multistate models.

- **model**: logical value: if TRUE, the model frame is returned in component `model`.

- **x**: logical value: if TRUE, the x matrix is returned in component `x`.

- **y**: logical value: if TRUE, the response vector is returned in component `y`.

- **tt**: optional list of time-transform functions.

- **method**: alternate name for the `ties` argument.

- **nocenter**: columns of the X matrix whose values lie strictly within this set are not recentered. Remember that a factor variable becomes a set of 0/1 columns.

- **...**: Other arguments will be passed to `coxph.control`
Details

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or “observations”, each of which applies to an interval of observation (start, stop).

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. Any column of the X matrix whose values lie within the ncenter list are not recentered. The practical consequence of the default is to not recenter dummy variables corresponding to factors. However, arguments to offset are not scaled since there are situations where a large offset value is a purposefully used. In general, however, users should not avoid very large numeric values for an offset due to possible loss of precision in the estimates.

Value

an object of class coxph representing the fit. See coxph.object and coxphms.object for details.

Side Effects

Depending on the call, the predict, residuals, and survfit routines may need to reconstruct the x matrix created by coxph. It is possible for this to fail, as in the example below in which the predict function is unable to find tform.

```r
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the model=TRUE option to the coxph call to obviate the need for reconstruction, at the expense of a larger fit object.

Case weights

Case weights are treated as replication weights, i.e., a case weight of 2 is equivalent to having 2 copies of that subject's observation. When computers were much smaller grouping like subjects together was a common trick to used to conserve memory. Setting all weights to 2 for instance will give the same coefficient estimate but halve the variance. When the Efron approximation for ties (default) is employed replication of the data will not give exactly the same coefficients as the weights option, and in this case the weighted fit is arguably the correct one.

When the model includes a cluster term or the robust=TRUE option the computed variance treats any weights as sampling weights; setting all weights to 2 will in this case give the same variance as weights of 1.

Special terms

There are three special terms that may be used in the model equation. A strata term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The cluster term is used to compute a robust variance for the model. The term + cluster(id) where each value of id is unique is equivalent to specifying the robust=TRUE argument. If the id variable is not unique, it is assumed that it identifies clusters of correlated observations. The robust estimate arises from many different arguments and thus has had many labels. It is variously known as the Huber sandwich estimator, White’s estimate (linear models/econometrics), the Horvitz-Thompson estimate (survey
sampling), the working independence variance (generalized estimating equations), the infinitesimal jackknife, and the Wei, Lin, Weissfeld (WLW) estimate.

A time-transform term allows variables to vary dynamically in time. In this case the tt argument will be a function or a list of functions (if there are more than one tt() term in the model) giving the appropriate transform. See the examples below.

One user mistake that has recently arisen is to slavishly follow the advice of some coding guides and prepend survival:: onto everthing, including the special terms, e.g.,

```
Survival::coxph(Surv(time, status) ~ age + survival::cluster(inst),
data=lung)
```

First, this is unnecessary: arguments within the coxph call will be evaluated within the survival namespace, so another package’s Surv or cluster function would not be noticed. (Full qualification of the coxph call itself may be protective, however.) Second, and more importantly, the call just above will not give the correct answer. The specials are recognized by their name, and survival::cluster is not the same as cluster; the above model would treat inst as an ordinary variable. A similar issue arises from using stats::offset as a term, in either survival or glm models.

**Convergence**

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to exp becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Most often number 1 is the first to occur.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic = coefficient/se(coefficient) is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

**Ties**

There are three possible choices for handling tied event times. The Breslow approximation is the easiest to program and hence became the first option coded for almost all computer routines. It then ended up as the default option when other options were added in order to "maintain backwards compatability". The Efron option is more accurate if there are a large number of ties, and it is the default option here. In practice the number of ties is usually small, in which case all the methods are statistically indistinguishable.

Using the "exact partial likelihood" approach the Cox partial likelihood is equivalent to that for matched logistic regression. (The clogit function uses the coxph code to do the fit.) It is technically appropriate when the time scale is discrete and has only a few unique values, and some packages refer to this as the "discrete" option. There is also an "exact marginal likelihood" due to Prentice which is not implemented here.

The calculation of the exact partial likelihood is numerically intense. Say for instance 180 subjects are at risk on day 7 of which 15 had an event; then the code needs to compute sums over all 180-choose-15 > 10^43 different possible subsets of size 15. There is an efficient recursive algorithm for this task, but even with this the computation can be insufferably long. With (start, stop) data it is much worse since the recursion needs to start anew for each unique start time.

Multi state models are a more difficult case. First of all, a proper extension of the Efron argument is much more difficult to do, and this author is not yet fully convinced that the resulting algorithm is defensible. Secondly, the current code for Efron case does not consistently compute that extended logic (and extension would require major changes in the code). Due to this complexity, the default is ties="breslow" for the multistate case. If ties="efron" is selected the current code will, in effect, only apply to to tied transitions of the same type.
A separate issue is that of artificial ties due to floating-point imprecision. See the vignette on this topic for a full explanation or the timefix option in \texttt{coxph.control}. Users may need to add \texttt{timefix=FALSE} for simulated data sets.

**Penalized regression**

\texttt{coxph} can maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression (\texttt{ridge}), smoothing splines (\texttt{pspline}), and frailty models (\texttt{frailty}).

coxph.control

Ancillary arguments for controlling coxph fits

Description

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to coxph.

Usage

coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75, 
iter.max = 20, toler.inf = sqrt(eps), outer.max = 10, timefix=TRUE)

Arguments

eps  Iteration continues until the relative change in the log partial likelihood is less than eps, or the absolute change is less than sqrt(eps). Must be positive.
toler.chol  Tolerance for detection of singularity during a Cholesky decomposition of the variance matrix, i.e., for detecting a redundant predictor variable.
iter.max  Maximum number of iterations to attempt for convergence.
toler.inf  Tolerance criteria for the warning message about a possible infinite coefficient value.
outer.max  For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop.
timefix  Resolve any near ties in the time variables.

Details

The convergence tolerances are a balance. Users think they want THE maximum point of the likelihood surface, and for well behaved data sets where this is quadratic near the max a high accuracy is fairly inexpensive: the number of correct digits approximately doubles with each iteration. Conversely, a drop of .0001 from the maximum in any given direction will be correspond to only about 1/20 of a standard error change in the coefficient. Statistically, more precision than this is straining at a gnat. Based on this the author originally had set the tolerance to 1e-5, but relented in the face of multiple "why is the answer different than package X" queries.

Asking for results that are too close to machine precision (double.eps) is a fool’s errand; a reasonable criteria is often the square root of that precision. The Cholesky decomposition needs to be held to a higher standard than the overall convergence criterion, however. The tolerancel.inf value controls a warning message; if it is too small incorrect warnings can appear, if too large some actual cases of an infinite coefficient will not be detected.

The most difficult cases are data sets where the MLE coefficient is infinite; an example is a data set where at each death time, it was the subject with the largest covariate value who perished. In that situation the coefficient increases at each iteration while the log-likelihood asymptotes to a maximum. As iteration proceeds there is a race condition condition for three endpoint: exp(coef) overflows, the Hessian matrix become singular, or the change in loglik is small enough to satisfy
the convergence criterion. The first two are difficult to anticipate and lead to numeric difficulties, which is another argument for moderation in the choice of eps.

See the vignette "Roundoff error and tied times" for a more detailed explanation of the timefix option. In short, when time intervals are created via subtraction then two time intervals that are actually identical can appear to be different due to floating point round off error, which in turn can make coxph and survfit results dependent on things such as the order in which operations were done or the particular computer that they were run on. Such cases are unfortunately not rare in practice. The timefix=TRUE option adds logic similar to all.equal to ensure reliable results. In analysis of simulated data sets, however, where often by definition there can be no duplicates, the option will often need to be set to FALSE to avoid spurious merging of close numeric values.

Value

a list containing the values of each of the above constants

See Also

coxph

coxph.detail
Details of a Cox Model Fit

Description

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

Usage

coxph.detail(object, riskmat=FALSE, rorder=c("data", "time"))

Arguments

object a Cox model object, i.e., the result of coxph.

riskmat include the at-risk indicator matrix in the output?

rorder should the rows of x, y and riskmat be returned in the original data order, or sorted by time within strata.

Details

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

Value

a list with components

time the vector of unique event times

nevent the number of events at each of these time points.
means a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights $\exp(x \%*% fit$coeff).

nrisk number of subjects at risk.
score the contribution to the score vector (first derivative of the log partial likelihood) at each time point.
imat the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.
hazard the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses object$means as the future subject.
varhaz the variance of the hazard increment.
x, y copies of the input data.
strata only present for a stratified Cox model, this is a table giving the number of time points of component time that were contributed by each of the strata.
wtrisk the weighted number at risk
riskmat a matrix with one row for each observation and one column for each unique event time, containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point. Rows are in the order of the original data (after removal of any missings by coxph), or in time order.

See Also
coxph, residuals.coxph

Examples

```r
fit <- coxph(Surv(futime, fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
# There is one Schoenfeld residual for each unique death. It is a # vector (covariates for the subject who died) - (weighted mean covariate # vector at that time). The weighted mean is defined over the subjects # still at risk, with $\exp(X \beta)$ as the weight.

events <- fit$y[,2]==1
etime <- fit$y[events,1]  # the event times --- may have duplicates
indx <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

Description

This class of objects is returned by the coxph class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions print, summary, residuals, predict and survfit.
Arguments

- **coefficients**: the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.
- **var**: the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.
- **naive.var**: this component will be present only if the `robust` option was true. If so, the var component will contain the robust estimate of variance, and this component will contain the ordinary estimate. (A far better name would be `asymp.var` since it contains the model-based asymptotic variance estimate, which is not necessarily "naive"; but that ship has sailed.)
- **loglik**: a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.
- **score**: value of the efficient score test, at the initial value of the coefficients.
- **rscore**: the robust log-rank statistic, if a robust variance was requested.
- **wald.test**: the Wald test of whether the final coefficients differ from the initial values.
- **iter**: number of iterations used.
- **linear.predictors**: the vector of linear predictors, one per subject. Note that this vector has been centered, see `predict.coxph` for more details.
- **residuals**: the martingale residuals.
- **means**: vector of values used as the reference for each covariate. For instance, a later call to `predict(fit, type='risk')` will give the hazard ratio between an observation and this reference. (For most covariates this will contain the mean.)
- **n**: the number of observations used in the fit.
- **nevent**: the number of events (usually deaths) used in the fit.
- **concordance**: a vector of length 6, containing the number of pairs that are concordant, discordant, tied on x, tied on y, and tied on both, followed by the standard error of the concordance statistic.
- **first**: the first derivative vector at the solution.
- **weights**: the vector of case weights, if one was used.
- **method**: the method used for handling tied survival times.
- **na.action**: the na.action attribute, if any, that was returned by the na.action routine.
- **timefix**: the value of the timefix option used in the fit

... The object will also contain the following, for documentation see the `lm` object: `terms`, `assign`, `formula`, `call`, and, optionally, `x`, `y`, and/or `frame`.

Components

The following components must be included in a legitimate coxph object.

See Also

- `coxph`, `coxph.detail`, `cox.zph`, `residuals.coxph`, `survfit`, `survreg`. 
**coxph.wtest**

*Compute a quadratic form*

Description

This function is used internally by several survival routines. It computes a simple quadratic form, while properly dealing with missings.

Usage

```r
coxph.wtest(var, b, toler.chol = 1e-09)
```

Arguments

- `var` variance matrix
- `b` vector
- `toler.chol` tolerance for the internal cholesky decomposition

Details

Compute `b' V-inverse b`. Equivalent to `sum(b * solve(V,b))`, except for the case of redundant covariates in the original model, which lead to NA values in V and b.

Value

a real number

Author(s)

Terry Therneau

---

**coxphms.object**

*Multi-state Proportional Hazards Regression Object*

Description

This class of objects is returned by the `coxph` class of functions to represent a fitted hazards model, when the model has multiple states. The object inherits from the `coxph` class.

Arguments

- `states` a character vector listing the states in the model
- `cmap` the coefficient map. A matrix containing a column for each transition and a row for each coefficient, the value maps that transition/coefficient pair to a position in the coefficient vector. If a particular covariate is not used by a transition the matrix will contain a zero in that position, if two transitions share a coefficient the matrix will contain repeats.
the stratum map. The row labeled '(Baseline)' identifies transitions that do or
do not share a baseline hazard. Further rows correspond to strata() terms in the
model, each of which may apply to some transitions and not others.

rmap mapping for the residuals and linear predictors. A two column matrix with one
row for each element of the vectors and two columns, the first contains the data
row and the second the transition.

Details

In a multi-state model a set of intermediate observations is created during the computation, with a
separate set of data rows for each transition. An observation (id and time interval) that is at risk
for more than one transition will for instance have a linear predictor and residual for each of the
potential transitions. As a result the vector of linear predictors will be longer than the number of
observations. The rmap matrix shows the mapping.

Components

The object has all the components of a coxph object, with the following additions and variations.

coxph, coxph.object

coxsurv.fit A direct interface to the ‘computational engine’ of survfit.coxph

Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a
‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can
lead to unexpected errors if that data is wrong.

Usage

coxsurv.fit(ctype, stype, se.fit, varmat, cluster,
    y, x, wt, risk, position, strata, oldid,
    y2, x2, risk2, strata2, id2, unlist=TRUE)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stype</td>
<td>survival curve computation: 1=direct, 2=exp(-cumulative hazard)</td>
</tr>
<tr>
<td>ctype</td>
<td>cumulative hazard computation: 1=Breslow, 2=Efron</td>
</tr>
<tr>
<td>se.fit</td>
<td>if TRUE, compute standard errors</td>
</tr>
<tr>
<td>varmat</td>
<td>the variance matrix of the coefficients</td>
</tr>
<tr>
<td>cluster</td>
<td>vector to control robust variance</td>
</tr>
<tr>
<td>y</td>
<td>the response variable used in the Cox model. (Missing values removed of course.)</td>
</tr>
<tr>
<td>x</td>
<td>covariate matrix used in the Cox model</td>
</tr>
<tr>
<td>wt</td>
<td>weight vector for the Cox model. If the model was unweighted use a vector of 1s.</td>
</tr>
</tbody>
</table>
**risk**
the risk score \( \exp(X \beta + \text{offset}) \) from the fitted Cox model.

**position**
optional argument controlling what is counted as 'censored'. Due to time dependent covariates, for instance, a subject might have start, stop times of (1,5)(5,30)(30,100). Times 5 and 30 are not 'real' censorings. Position is 1 for a real start, 2 for an actual end, 3 for both, 0 for neither.

**strata**
strata variable used in the Cox model. This will be a factor.

**oldid**
identifier for subjects with multiple rows in the original data.

**y2, x2, risk2, strata2**
variables for the hypothetical subjects, for which prediction is desired

**id2**
optional; if present and not NULL this should be a vector of identifiers of length \( nrow(x2) \). A non-null value signifies that \( x2 \) contains time dependent covariates, in which case this identifies which rows of \( x2 \) go with each subject.

**unlist**
if FALSE the result will be a list with one element for each strata. Otherwise the strata are "unpacked" into the form found in a `survfit` object.

**Value**
a list containing nearly all the components of a `survfit` object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a `coxph` object), and the class.

**Note**
The source code for both this function and `survfit.coxph` is written using noweb. For complete documentation see the `inst/sourcecode.pdf` file.

`survfit.coxph`

---

**diabetic**

**Ddiabetic retinopathy**

**Description**
Partial results from a trial of laser coagulation for the treatment of diabetic retinopathy.

**Usage**
```r
diabetic
data(diabetic, package="survival")
```
Format

A data frame with 394 observations on the following 8 variables.

- **id**  subject id
- **laser**  laser type: xenon or argon
- **age**  age at diagnosis
- **eye**  a factor with levels of left right
- **trt**  treatment: 0 = no treatment, 1= laser
- **risk**  risk group of 6-12
- **time**  time to event or last follow-up
- **status**  status of 0= censored or 1 = visual loss

Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are therefore the actual time to blindness in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

References

Huster, Brookmeyer and Self, Biometrics, 1989.

Examples

```r
# juvenile diabetes is defined as and age less than 20
juvenile <- 1*(diabetic$age < 20)
coxph(Surv(time, status) ~ trt + juvenile, cluster= id, 
data= diabetic)
```

\[ dsurvreg \]

\textit{Distributions available in survreg.}

Description

Density, cumulative distribution function, quantile function and random generation for the set of distributions supported by the \texttt{survreg} function.

Usage

\begin{verbatim}
dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qsurvreg(p, mean, scale=1, distribution='weibull', parms)
r survreg(n, mean, scale=1, distribution='weibull', parms)
\end{verbatim}
Arguments

- **x**: vector of quantiles. Missing values (NAs) are allowed.
- **q**: vector of quantiles. Missing values (NAs) are allowed.
- **p**: vector of probabilities. Missing values (NAs) are allowed.
- **n**: number of random deviates to produce.
- **mean**: vector of location (linear predictor) parameters for the model. This is replicated to be the same length as p, q or n.
- **scale**: vector of (positive) scale factors. This is replicated to be the same length as p, q or n.
- **distribution**: character string giving the name of the distribution. This must be one of the elements of `survreg.distributions`.
- **parms**: optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.

Details

Elements of q or p that are missing will cause the corresponding elements of the result to be missing.

The location and scale values are as they would be for `survreg`. The label "mean" was an unfortunate choice (made in mimicry of qnorm); a more correct label would be "linear predictor". Since almost none of these distributions are symmetric the location parameter is not actually a mean.

The `survreg` routines use the parameterization found in chapter 2 of Kalbfleisch and Prentice. Translation to the usual parameterization found in a textbook is not always obvious. For example, the Weibull distribution has cumulative distribution function \( F(t) = 1 - e^{-(\lambda t)^p} \). The actual fit uses the fact that \( \log(t) \) has an extreme value distribution, with location and scale of \( \alpha, \sigma \), which are the location and scale parameters reported by the `survreg` function. The parameters are related by \( \sigma = 1/p \) and \( \alpha = -\log(\lambda) \). The `stats::dweibull` routine is parameterized in terms of shape and scale parameters which correspond to \( p \) and \( 1/\lambda \) in the K and P notation. Combining these we see that shape = \( 1/\sigma \) and scale = \( \exp \alpha \).

Value

density (`dsurvreg`), probability (`psurvreg`), quantile (`qsurvreg`), or for the requested distribution with mean and scale parameters `mean` and `sd`.

# per the help page for dweibull, the mean is scale * gamma(1 + 1/shape)
c(mean = exp(coef(fit))* gamma(1 + fit$scale))

finegray

Create data for a Fine-Gray model

Description

The Fine-Gray model can be fit by first creating a special data set, and then fitting a weighted Cox model to the result. This routine creates the data set.

Usage

finegray(formula, data, weights, subset, na.action= na.pass, etype,
prefix="fg", count, id, timefix=TRUE)

Arguments

formula a standard model formula, with survival on the left and covariates on the right.
data an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model.
weights optional vector of observation weights
subset: an optional vector specifying a subset of observations to be used in the fitting process.

na.action: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options.

etype: the event type for which a data set will be generated. The default is to use whichever is listed first in the multi-state survival object.

prefix: the routine will add 4 variables to the data set: a start and end time for each interval, status, and a weight for the interval. The default names of these are "fgstart", "fgstop", "fgstatus", and "fgwt"; the prefix argument determines the initial portion of the new names.

count: a variable name in the output data set for an optional variable that will contain the the replication count for each row of the input data. If a row is expanded into multiple lines it will contain 1, 2, etc.

id: optional, the variable name in the data set which identifies subjects.

timefix: process times through the aeqSurv function to eliminate potential roundoff issues.

Details

The function expects a multi-state survival expression or variable as the left hand side of the formula, e.g. Surv(atime, astat) where astat is a factor whose first level represents censoring and remaining levels are states. The output data set will contain simple survival data (status = 0 or 1) for a single endpoint of interest. For exposition call this endpoint A and lump all others as endpoint B. In the output data set subjects who experience endpoint B become censored observations whose times are artificially extended to the right, with a decreasing case weight from interval to interval. The output data set will normally contain many more rows than the input.

The algorithm allows for delayed entry, and only a limited form of time-dependent covariates. That is, when subjects with endpoint B are extended, those future covariate values stay constant; so there is an implicit assumption that no more changes would have occurred if the event had not intervened and follow-up had been longer. For predictable time-dependent covariates the final data set could be further processed to fix this, but this is not included in the function. Geskus for example considers an example with different calendar epochs, corresponding to a change in standard medical practice for the disese, as a covariate. dependent covariates. If there are time dependent covariates or delayed entry, e.g., the input data set had Surv(entry, exit, stat) as the left hand side, then an id statement is required. The program does data checks in this case, and needs to know which rows belong to each subject.

The output data set will often have gaps. Say that there were events at time 50 and 100 (and none between) and censoring at 60, 70, and 80. Formally, a non event subjects at risk from 50 to 100 will have different weights in each of the 3 intervals 50-60, 60-70, and 80-100, but because the middle interval does not span any event times the subsequent Cox model will never use that row. The finegray output omits such rows.

See the competing risks vignette for more details.

Value

a data frame

flchain

Assay of serum free light chain for 7874 subjects.

Description

This is a stratified random sample containing 1/2 of the subjects from a study of the relationship between serum free light chain (FLC) and mortality. The original sample contains samples on approximately 2/3 of the residents of Olmsted County aged 50 or greater.

Usage

flchain
data(flchain, package="survival")

Format

A data frame with 7874 persons containing the following variables.

age  age in years
sex  F=female, M=male
sample.yr the calendar year in which a blood sample was obtained
kappa  serum free light chain, kappa portion
lambda  serum free light chain, lambda portion
flc.grp  the FLC group for the subject, as used in the original analysis
The primary investigator (A Dispenzieri) and statistician (T Therneau) for the study.

References

Examples

data(flchain)
age.grp <- cut(flchain$age, c(49, 54, 59, 64, 69, 74, 79, 89, 110), labels= paste(c(50, 55, 60, 65, 70, 75, 80, 90, 95), sep='-', c(54, 59, 64, 69, 74, 79, 89, 100), sep='-', ))
table(flchain$sex, age.grp)
**random effects terms**

**Description**

The frailty function allows one to add a simple random effects term to a Cox model.

**Usage**

```
frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05,
               method = c("em", "aic", "df", "fixed"), ...)
frailty.gaussian(x, sparse = (nclass > 5), theta, df,
                 method = c("reml", "aic", "df", "fixed"), ...)
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,
          method = c("aic", "df", "fixed"), ...)
```

**Arguments**

- **x** the variable to be entered as a random effect. It is always treated as a factor.
- **distribution** either the gamma, gaussian or t distribution may be specified. The routines `frailty.gamma`, `frailty.gaussian` and `frailty.t` do the actual work.
- **...** Arguments for specific distribution, including (but not limited to) `sparse`
- **sparse** cutoff for using a sparse coding of the data matrix. If the total number of levels of `x` is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership.
- **theta** if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies `method="fixed"`.
- **df** if specified, this fixes the degrees of freedom for the random effect. Specifying this implies `method="df"`. Only one of `theta` or `df` should be specified.
- **method** the method used to select a solution for `theta`, the variance of the random effect. The fixed corresponds to a user-specified value, and no iteration is done. The df selects the variance such that the degrees of freedom for the random effect matches a user specified value. The aic method seeks to maximize Akaike’s information criteria \(2*(partial likelihood - df)\). The em and reml methods are specific to Cox models with gamma and gaussian random effects, respectively. Please see further discussion below.
- **tdf** the degrees of freedom for the t-distribution.
- **eps** convergence criteria for the iteration on theta.
frailty 3577

Details

The frailty plugs into the general penalized modeling framework provided by the coxph and survreg routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a gamma frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a gaussian frailty. Both of these are specific to the Cox model. Use of gamma/ml or gaussian/reml with survreg does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as frailty or pspline, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a frailty term implies a mixed effects model and use of a cluster term implies a GEE approach; these cannot be mixed.

The coxme package has superseded this method. It is faster, more stable, and more flexible.

Value

this function is used in the model statement of either coxph or survreg. It’s results are used internally.

Breast cancer data sets used in Royston and Altman (2013)

Description
The gbsg data set contains patient records from a 1984-1989 trial conducted by the German Breast Cancer Study Group (GBSG) of 720 patients with node positive breast cancer; it retains the 686 patients with complete data for the prognostic variables.

Usage
```
gbsg
data(cancer, package="survival")
```

Format
A data set with 686 observations and 11 variables.
```
  pid  patient identifier
  age  age, years
  menopausal status (0= premenopausal, 1= postmenopausal)
  size  tumor size, mm
  grade  tumor grade
  nodes  number of positive lymph nodes
  pgr  progesterone receptors (fmol/l)
  er  estrogen receptors (fmol/l)
  hormon  hormonal therapy, 0= no, 1= yes
  rfstime  recurrence free survival time; days to first of recurrence, death or last follow-up
  status  0= alive without recurrence, 1= recurrence or death
```

Details
These data sets are used in the paper by Royston and Altman. The Rotterdam data is used to create a fitted model, and the GBSG data for validation of the model. The paper gives references for the data source.

hoel  

**Description**

Days until occurrence of cancer for male mice

**Usage**

`data("cancer")`

**Format**

A data frame with 181 observations on the following 4 variables.

- **trt** treatment assignment: Control or Germ-free
- **days** days until death
- **outcome** outcome: codecensor, thymic lymphoma, reticulum cell sarcoma other causes
- **id** mouse id

**Details**

Two groups of male mice were given 300 rads of radiation and followed for cancer incidence. One group was maintained in a germ free environment. The data set is used as an example of competing risks in Kalbfleisch and Prentice. The germ-free environment has little effect on the rate of occurrence of thymic lymphoma, but significantly delays the other causes of death.

**Note**

The Ontology Search website defines reticulum cell sarcoma as "An antiquated term that refers to a non-Hodgkin lymphoma composed of diffuse infiltrates of large, often anaplastic lymphocytes".

**Source**

The data can be found in appendix I of Kalbfleisch and Prentice.

**References**

**Examples**

```r
hsurv <- survfit(Surv(days, outcome) ~ trt, data = hoel, id= id)
plot(hsurv, lty=1:2, col=rep(1:3, each=2), lwd=2, xscale=30.5,
     xlab="Months", ylab= "Death")
legend("topleft", c("Lymphoma control", "Lymphoma germ free",
                     "Sarcoma control", "Sarcoma germ free",
                     "Other control", "Other germ free"),
       col=rep(1:3, each=2), lty=1:2, lwd=2, bty='n')
hfit <- coxph(Surv(days, outcome) ~ trt, data= hoel, id = id)
```
is.ratetable

Verify that an object is of class ratetable.

Description

The function verifies not only the class attribute, but the structure of the object.

Usage

is.ratetable(x, verbose=FALSE)

Arguments

x
  the object to be verified.
verbose
  if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which x fails to be a proper ratetable object.

Details

Rate tables are used by the pyears and survexp functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the verbose option can help in creating a new rate table.

Value

returns TRUE if x is a ratetable, and FALSE or a description if it is not.

See Also

pyears, survexp.

Examples

is.ratetable(survexp.us)  # True
is.ratetable(lung)       # False

kidney

Kidney catheter data

Description

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.
Usage

kidney
data(cancer, package="survival")

Format

patient: id
time: time
status: event status
age: in years
sex: 1=male, 2=female
disease: disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail: frailty estimate from original paper

Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

Source

Examples

kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time,status) ~ age + sex + disease + frailty(id, dist='gauss'), kidney)

levels.Surv Return the states of a multi-state Surv object

Description

For a multi-state Surv object, this will return the names of the states.

Usage

## S3 method for class 'Surv'
levels(x)

Arguments

x a Surv object
Value

for a multi-state Surv object, the vector of state names (excluding censoring); or NULL for an ordinary Surv object

Examples

```r
y1 <- Surv(c(1, 5, 9, 17, 21, 30),
           factor(c(0, 1, 2, 1, 0, 2), 0:2, c("censored", "progression", "death")))
levels(y1)

y2 <- Surv(1:6, rep(0:1, 3))
y2
levels(y2)
```

lines.survfit  
Add Lines or Points to a Survival Plot

Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with plot.survfit.

Usage

```r
## S3 method for class 'survfit'
lines(x, type="s", pch=3, col=1, lty=1,
       lwd=1, cex=1, mark.time=FALSE, xmax,
       fun, conf.int=FALSE, conf.times, conf.cap=.005, conf.offset=.012,
       conf.type = c("log", "log-log", "plain", "logit", "arcsin"),
       mark, noplot="(s0)", cumhaz=FALSE, ...)

## S3 method for class 'survexp'
lines(x, type="l", ...)

## S3 method for class 'survfit'
points(x, fun, censor=FALSE, col=1, pch,
        noplot="(s0)", cumhaz=FALSE, ...)
```

Arguments

- **x**: a survival object, generated from the survfit or survexp functions.
- **type**: the line type, as described in lines. The default is a step function for survfit objects, and a connected line for survexp objects. All other arguments for lines.survexp are identical to those for lines.survfit.
- **col, lty, lwd, cex**: vectors giving the mark symbol, color, line type, line width and character size for the added curves. Of this set only color is applicable to points.
- **pch**: plotting characters for points, in the style of matplot, i.e., either a single string of characters of which the first will be used for the first curve, etc; or a vector of characters or integers, one element per curve.
- **mark**: a historical alias for pch
censor should censoring times be displayed for the points function?
mark.time controls the labeling of the curves. If FALSE, no labeling is done. If TRUE, then curves are marked at each censoring time. If mark.time is a numeric vector, then curves are marked at the specified time points.
xmax optional cutoff for the right hand of the curves.
fun an arbitrary function defining a transformation of the survival curve. For example fun=log is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the log=T option, "event" plots cumulative events (f(y) = 1-y), "cumhaz" plots the cumulative hazard function (f(y) = -log(y)) and "cloglog" creates a complimentary log-log survival plot (f(y) = log(-log(y))) along with log scale for the x-axis.
conf.int if TRUE, confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot. A numeric value, e.g. conf.int = .90, can be used to
conf.times optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.
conf.cap width of the horizontal cap on top of the confidence bars; only used if conf.times is used. A value of 1 is the width of the plot region.
conf.offset the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve’s bars are offset by this amount from the prior curve’s bars, if it is a vector the values are used directly.
conf.type One of "plain", "log" (the default), "log-log", "logit", or "none". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve +- k *se(curve), where k is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option bases the intervals on the log hazard or log(-log(survival)), and the logit option on log(survival/(1-survival)).
noplot for multi-state models, curves with this label will not be plotted. The default corresponds to an unspecified state.
cumhaz plot the cumulative hazard, rather than the survival or probability in state.
... other graphical parameters

Details
When the `survfit` function creates a multi-state survival curve the resulting object has class ‘survfitms’. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.
If the user set an explicit range in an earlier `plot.survfit` call, e.g. via xlim or xmax, subsequent calls to this function remember the right hand cutoff. This memory can be erased by `options(plot.survfit) <- NULL`.

Value
a list with components x and y, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.
Side Effects

one or more curves are added to the current plot.

See Also

lines, par, plot.survfit, survfit, survexp.

Examples

```r
fit <- survfit(Surv(time, status==2) ~ sex, pbc, subset=1:312)
plot(fit, mark.time=FALSE, xscale=365.25,
     xlab='Years', ylab='Survival')
lines(fit[1], lwd=2)  # darken the first curve and add marks

# Add expected survival curves for the two groups,
# based on the US census data
# The data set does not have entry date, use the midpoint of the study
efit <- survexp(~sex, data=pbc, times= (0:24)*182, ratetable=survexp.us,
     rmap=list(sex=sex, age=age*365.35, year=as.Date('1979/01/01')))
temp <- lines(efit, lty=2, lwd=2:1)
text(temp, c("Male", "Female"), adj=-.1) # labels just past the ends
title(main="Primary Biliary Cirrhosis, Observed and Expected")
```

Description

Intergenerational occupational mobility data with covariates.

Usage

```r
logan
data(logan, package="survival")
```

Format

A data frame with 838 observations on the following 4 variables.

- **occupation**: subject's occupation, a factor with levels farm, operatives, craftsmen, sales, and professional
- **focc**: father's occupation
- **education**: total years of schooling, 0 to 20
- **race**: levels of non-black and black

logLik.coxph

logLik method for a Cox model

Description
The logLik function for survival models

Usage

```r
## S3 method for class 'coxph'
logLik(object, ...)  
## S3 method for class 'survreg'
logLik(object, ...)
```

Arguments

- `object`: the result of a coxph or survreg fit
- `...`: optional arguments for other instances of the method

Details
The logLik function is used by summary functions in R such as AIC. For a Cox model, this method returns the partial likelihood. The number of degrees of freedom (df) used by the fit and the effective number of observations (nobs) are added as attributes. Per Raftery and others, the effective number of observations is taken to be the number of events in the data set.

For a survreg model the proper value for the effective number of observations is still an open question (at least to this author). For right censored data the approach of logLik.coxph is the possible the most sensible, but for interval censored observations the result is unclear. The code currently does not add a nobs attribute.

Value
an object of class logLik

Author(s)
Terry Therneau

logLik
NCCTG Lung Cancer Data

Description

Survival in patients with advanced lung cancer from the North Central Cancer Treatment Group. Performance scores rate how well the patient can perform usual daily activities.

Usage

```r
lung
data(cancer, package="survival")
```

Format

- `inst`: Institution code
- `time`: Survival time in days
- `status`: Censoring status: 1=censored, 2=dead
- `age`: Age in years
- `sex`: Male=1, Female=2
- `ph.ecog`: ECOG performance score as rated by the physician. 0=asymptomatic, 1=symptomatic but completely ambulatory, 2=bedridden
- `ph.karno`: Karnofsky performance score (bad=0, good=100) rated by physician
- `pat.karno`: Karnofsky performance score as rated by patient
- `meal.cal`: Calories consumed at meals
- `wt.loss`: Weight loss in last six months (pounds)

Note

The use of 1/2 for alive/dead instead of the usual 0/1 is a historical footnote. For data contained on punch cards, IBM 360 Fortran treated blank as a zero, which led to a policy within the section of Biostatistics to never use "0" as a data value since one could not distinguish it from a missing value. The policy became a habit, as is often the case; and the 1/2 coding endured long beyond the demise of punch cards and Fortran.

**mgus**  
*Monoclonal gammopathy data*

**Description**

Natural history of 241 subjects with monoclonal gammopathy of undetermined significance (MGUS).

**Usage**

```r
mgus
mgus1
data(cancer, package="survival")
```

**Format**

`mgus`: A data frame with 241 observations on the following 12 variables.

- **id**: subject id
- **age**: age in years at the detection of MGUS
- **sex**: male or female
- **dxyr**: year of diagnosis
- **pcdx**: for subjects who progress to a plasma cell malignancy
  - the subtype of malignancy: multiple myeloma (MM) is the most common, followed by amyloidosis (AM), macroglobulinemia (MA), and other lymphoproliferative disorders (LP)
- **pctime**: days from MGUS until diagnosis of a plasma cell malignancy
- **futime**: days from diagnosis to last follow-up
- **death**: 1= follow-up is until death
- **alb**: albumin level at MGUS diagnosis
- **creat**: creatinine at MGUS diagnosis
- **hgb**: hemoglobin at MGUS diagnosis
- **mspike**: size of the monoclonal protein spike at diagnosis

`mgus1`: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

- **start, stop**: sequential intervals of time for each subject
- **status**: =1 if the interval ends in an event
- **event**: a factor containing the event type: censor, death, or plasma cell malignancy
- **enum**: event number for each subject: 1 or 2

**Details**

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about $10^6$ different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undetermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data
set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural history of such subjects. Due to the diligence of the principle investigator 0 subjects have been lost to follow-up.

Three subjects had MGUS detected on the day of death. In data set mgus1 these subjects have the time to MGUS coded as .5 day before the death in order to avoid tied times.

These data sets were updated in Jan 2015 to correct some small errors.

Examples

```r
# Create the competing risk curves for time to first of death or PCM
sfit <- survfit(Surv(start, stop, event) ~ sex, mgus1, id=id, 
subset=(enum==1))
print(sfit)  # the order of printout is the order in which they plot

plot(sfit, xscale=365.25, lty=c(2,2,1,1), col=c(1,2,1,2),
xlab="Years after MGUS detection", ylab="Proportion")
legend(0, .8, c("Death/male", "Death/female", "PCM/male", "PCM/female"),
lty=c(1,1,2,2), col=c(2,1,2,1), bty='n')

title("Curves for the first of plasma cell malignancy or death")
# The plot shows that males have a higher death rate than females (no
# surprise) but their rates of conversion to PCM are essentially the same.
```

### mgus2 Monoclonal gammopathy data

**Description**

Natural history of 1341 sequential patients with monoclonal gammopathy of undetermined significance (MGUS). This is a superset of the mgus data, at a later point in the accrual process

**Usage**

```r
mgus2
data(cancer, package="survival")
```

**Format**

A data frame with 1384 observations on the following 10 variables.

- id  subject identifier
- age  age at diagnosis, in years
- sex  a factor with levels F M
dxyr  year of diagnosis
hgb  hemoglobin
creat  creatinine
mspike  size of the monoclonal serum spike
ptime  time until progression to a plasma cell malignancy (PCM) or last contact, in months
pstat  occurrence of PCM: 0=no, 1=yes
futime  time until death or last contact, in months
death  occurrence of death: 0=no, 1=yes

Details

This is an extension of the study found in the mgus data set, containing enrollment through 1994 and follow-up through 1999.

Source

Mayo Clinic data courtesy of Dr. Robert Kyle. All patient identifiers have been removed, age rounded to the nearest year, and follow-up times rounded to the nearest month.

References

Value
the model frame used in the original fit, or a parallel one for new data.

Author(s)
Terry Therneau

See Also
model.frame

Description
Reconstruct the model matrix for a cox model.

Usage
## S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg =
object$contrasts, ...)

Arguments
object the result of a coxph model
data optional, a data frame from which to obtain the data
contrast.arg optional, a contrasts object describing how factors should be coded
... other possible argument to model.frame

Details
When there is a data argument this function differs from most of the other model.matrix methods in that the response variable for the original formula is not required to be in the data.

If the data frame contains a terms attribute then it is assumed to be the result of a call to model.frame, otherwise a call to model.frame is applied with the data as an argument.

Value
The model matrix for the fit

Author(s)
Terry Therneau

model.matrix
Examples

```r
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung, x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

myeloid | Acute myeloid leukemia

Description

This simulated data set is based on a trial in acute myeloid leukemia.

Usage

```r
myeloid
data(cancer, package="survival")
```

Format

A data frame with 646 observations on the following 9 variables.

- **id**: subject identifier, 1-646
- **trt**: treatment arm A or B
- **sex**: f=female, m=male
- **futime**: time to death or last follow-up
- **death**: 1 if futime is a death, 0 for censoring
- **txtime**: time to hematopoetic stem cell transplant
- **crtime**: time to complete response
- **rltime**: time to relapse of disease

Details

This data set is used to illustrate multi-state survival curves. The correlation between within-subject event times strongly resembles that from an actual trial, but none of the actual data values are from that source.

References

Examples

```r
coxph(Surv(futime, death) ~ trt, data=myeloid)
# See the mstate vignette for a more complete analysis
```
**myeloma**  
*Survival times of patients with multiple myeloma*

**Description**  
Survival times of 3882 subjects with multiple myeloma, seen at Mayo Clinic from 1947–1996.

**Usage**  
```r
myeloma
data("cancer", package="survival")
```

**Format**  
A data frame with 3882 observations on the following 5 variables.

- **id**  subject identifier  
- **year**  year of entry into the study  
- **entry**  time from diagnosis of MM until entry (days)  
- **futime**  follow up time (days)  
- **death**  status at last follow-up: 0 = alive, 1 = death

**Details**  
Subjects who were diagnosed at Mayo will have `entry = 0`, those who were diagnosed elsewhere and later referred will have positive values.

**References**  

**Examples**

```r
# Incorrect survival curve, which ignores left truncation
fit1 <- survfit(Surv(futime, death) ~ 1, myeloma)
# Correct curve
fit2 <- survfit(Surv(entry, futime, death) ~1, myeloma)
```

**nafld**  
*Non-alcohol fatty liver disease*

**Description**  
Data sets containing the data from a population study of non-alcoholic fatty liver disease (NAFLD). Subjects with the condition and a set of matched control subjects were followed forward for metabolic conditions, cardiac endpoints, and death.
Usage

nafl1d

nafl2d

nafl3d
data(nafl1d, package="survival")

Format

nafl1d1 is a data frame with 17549 observations on the following 10 variables.

id subject identifier
age age at entry to the study
male 0=female, 1=male
weight weight in kg
height height in cm
bmi body mass index
case.id the id of the NAFLD case to whom this subject is matched
futime time to death or last follow-up
status 0= alive at last follow-up, 1=dead

nafl2d is a data frame with 400123 observations and 4 variables containing laboratory data

id subject identifier
days days since index date
test the type of value recorded
value the numeric value

nafl3d is a data frame with 34340 observations and 3 variables containing outcomes

id subject identifier
days days since index date
event the endpoint that occurred

Details

The primary reference for the NAFLD study is Allen (2018). The incidence of non-alcoholic fatty liver disease (NAFLD) has been rising rapidly in the last decade and it is now one of the main drivers of hepatology practice. It is essentially the presence of excess fat in the liver, and parallels the ongoing obesity epidemic. Approximately 20-25% of NAFLD patients will develop the inflammatory state of non-alcoholic steatohepatitis (NASH), leading to fibrosis and eventual end-stage liver disease. NAFLD can be accurately diagnosed by MRI methods, but NASH diagnosis currently requires a biopsy.

The current study constructed a population cohort of all adult NAFLD subjects from 1997 to 2014 along with 4 potential controls for each case. To protect patient confidentiality all time intervals are in days since the index date; none of the dates from the original data were retained. Subject age is their integer age at the index date, and the subject identifier is an arbitrary integer. As a final protection, we include only a 90% random sample of the data. As a consequence analyses results will not exactly match the original paper.

There are 3 data sets: nafl1d1 contains baseline data and has one observation per subject, nafl1d2 has one observation for each (time dependent) continuous measurement, and nafl1d3 has one observation for each yes/no outcome that occurred.
Source

Data obtained from the author.

References

Description

A common task in medical work is to find the closest lab value to some index date, for each subject.

Usage

```r
neardate(id1, id2, y1, y2, best = c("after", "prior"), nomatch = NA_integer_)
```

Arguments

- `id1`: vector of subject identifiers for the index group
- `id2`: vector of identifiers for the reference group
- `y1`: normally a vector of dates for the index group, but any orderable data type is allowed
- `y2`: reference set of dates
- `best`: if `best='prior'` find the index of the first `y2` value less than or equal to the target `y1` value, for each subject. If `best='after'` find the first `y2` value which is greater than or equal to the target `y1` value, for each subject.
- `nomatch`: the value to return for items without a match

Details

This routine is closely related to `match` and to `findInterval`, the first of which finds exact matches and the second closest matches. This finds the closest matching date within sets of exactly matching identifiers. Closest date matching is often needed in clinical studies. For example data set 1 might contain the subject identifier and the date of some procedure and data set 2 has the dates and values for laboratory tests, and the query is to find the first test value after the intervention but no closer than 7 days.

The `id1` and `id2` arguments are similar to `match` in that we are searching for instances of `id1` that will be found in `id2`, and the result is the same length as `id1`. However, instead of returning the first match with `id2` this routine returns the one that best matches with respect to `y1`.

The `y1` and `y2` arguments need not be dates, the function works for any data type such that the expression `c(y1, y2)` gives a sensible, sortable result. Be careful about matching `Date` and `DateTime` values and the impact of time zones, however, see `as.POSIXct`. If `y1` and `y2` are not of the same class the user is on their own. Since there exist pairs of unmatched data types where the result could be sensible, the routine will in this case proceed under the assumption that "the user knows what they are doing". Caveat emptor.
Value

the index of the matching observations in the second data set, or the nomatch value for no successful match

Author(s)

Terry Therneau

indx2 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt,
    best="prior")
ifelse(is.na(indx1), indx2, # none after, take before
    ifelse(is.na(indx2), indx1, #none before
        ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
        abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))

# closest date before or after, but no more than 21 days prior to index
indx2 <- ifelse((data1$entry.dt - data2$lab.dt[indx2]) >21, NA, indx2)
ifelse(is.na(indx1), indx2, # none after, take before
    ifelse(is.na(indx2), indx1, #none before
        ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
        abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1))))
Arguments

- **x**: the predictor variable. Missing values are allowed.
- **df**: degrees of freedom. One can supply df rather than knots; ns() then chooses df - 1 - intercept knots at suitably chosen quantiles of x (which will ignore missing values). The default, df = NULL, sets the number of inner knots as length(knots).
- **knots**: breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on x. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.
- **intercept**: if TRUE, an intercept is included in the basis; default is FALSE
- **b**: default placement of the boundary knots. A value of bs=0 will replicate the default behavior of ns.
- **Boundary.knots**: boundary points at which to impose the natural boundary conditions and anchor the B-spline basis. Beyond these points the function is assumed to be linear. If both knots and Boundary.knots are supplied, the basis parameters do not depend on x. Data can extend beyond Boundary.knots

Details

The nsk function behaves identically to the ns function, with two exceptions. The primary one is that the returned basis is such that coefficients correspond to the value of the fitted function at the knot points. If intercept = FALSE, there will be k-1 coefficients corresponding to the k knots, and they will be the difference in predicted value between knots 2-k and knot 1. The primary advantage to the basis is that the coefficients are directly interpretable. A second is that tests for the linear and non-linear components are simple contrasts.

The second difference with ns is one of opinion with respect to the default position for the boundary knots. The default here is closer to that found in the rms::rcs function.

This function is a trial if a new idea, it’s future inclusion in the package is not yet guaranteed.

Value

A matrix of dimension length(x) * df where either df was supplied or, if knots were supplied, df = length(knots) + 1 + intercept. Attributes are returned that correspond to the arguments to kns, and explicitly give the knots, Boundary.knots etc for use by predict.kns().

Note

A thin flexible metal or wooden strip is called a spline, and is the traditional method for laying out a smooth curve, e.g., for a ship’s hull or an airplane wing. Pins are put into a board and the strip is passed through them, each pin is a ‘knot’.

A mathematical spline is a piecewise function between each knot. A linear spline will be a set of connected line segments, a quadratic spline is a set of connected local quadratic functions, constrained to have a continuous first derivative, a cubic spline is cubic between each knot, constrained to have continuous first and second derivatives, and etc. Mathematical splines are not an exact representation of natural splines: being a physical object the wood or metal strip will have continuous derivatives of all orders. Cubic splines are commonly used because they are sufficiently smooth to look natural to the human eye.

If the mathematical spline is further constrained to be linear beyond the end knots, this is often called a ‘natural spline’, due to the fact that a wooden or metal spline will also be linear beyond the last knots. Another name for the same object is a ‘restricted cubic spline’, since it is achieved in
code by adding further constraints. Given a vector of data points and a set of knots, it is possible to create a basis matrix X with one column per knot, such that ordinary regression of X on y will fit the cubic spline function, hence these are also called 'regression splines'. (One of these three labels is no better or worse than another, in our opinion).

Given a basis matrix X with k columns, the matrix Z = XT for any k by k nonsingular matrix T is also a basis matrix, and will result in identical predicted values, but a new set of coefficients gamma = (T-inverse) beta in place of beta. One can choose the basis functions so that X is easy to construct, to make the regression numerically stable, to make tests easier, or based on other considerations. It seems as though every spline library returns a different basis set, which unfortunately makes fits difficult to compare between packages. This is yet one more basis set, chosen to make the coefficients more interpretable.

**nwtco**  
*Data from the National Wilms’ Tumor Study*

**Description**

Measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

**Usage**

```r
nwtco
data(nwtco, package="survival")
```
**Format**

A data frame with 4028 observations on the following 9 variables.

- `seqno` id number
- `instit` Histology from local institution
- `histol` Histology from central lab
- `stage` Disease stage
- `study` study
- `rel` indicator for relapse
- `edrel` time to relapse
- `age` age in months
- `in.subcohort` Included in the subcohort for the example in the paper

**References**

**Examples**

```r
with(nwtco, table(instit,histol))
anova(coxph(Surv(edrel,rel)~histol+instit,data=nwtco))
anova(coxph(Surv(edrel,rel)~instit+histol,data=nwtco))
```

Mayo Clinic Primary Biliary Cholangitis Data

Description
Primary sclerosing cholangitis is an autoimmune disease leading to destruction of the small bile ducts in the liver. Progression is slow but inexorable, eventually leading to cirrhosis and liver decompensation. The condition has been recognised since at least 1851 and was named "primary biliary cirrhosis" in 1949. Because cirrhosis is a feature only of advanced disease, a change of its name to "primary biliary cholangitis" was proposed by patient advocacy groups in 2014.

This data is from the Mayo Clinic trial in PBC conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

Usage
pbc
data(pbc, package="survival")

Format
age: in years
albumin: serum albumin (g/dl)
alk.phos: alkaline phosphotase (U/liter)
ascites: presence of ascites
ast: aspartate aminotransferase, once called SGOT (U/ml)
bili: serum bilirunbin (mg/dl)
chol: serum cholesterol (mg/dl)
copper: urine copper (ug/day)
edema: 0 no edema, 0.5 untreated or successfully treated
1 edema despite diuretic therapy
hepato: presence of hepatomegaly or enlarged liver
id: case number
platelet: platelet count  
protime: standardised blood clotting time  
sex: m/f  
spiders: blood vessel malformations in the skin  
stage: histologic stage of disease (needs biopsy)  
status: status at endpoint, 0/1/2 for censored, transplant, dead  
time: number of days between registration and the earlier of death, transplantation, or study analysis in July, 1986  
trt: 1/2/NA for D-penicillmain, placebo, not randomised  
trig: triglycerides (mg/dl)

pbcseq

pbcseq  
*Mayo Clinic Primary Biliary Cirrhosis, sequential data*

Description
This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory parameters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

Usage
```r
pbcseq
data(pbc, package="survival")
```

Format
id: case number
age: in years
sex: m/f
trt: 1/2/NA for D-penicillmain, placebo, not randomised
time: number of days between registration and the earlier of death, transplantation, or study analysis in July, 1986
status: status at endpoint, 0/1/2 for censored, transplant, dead
day: number of days between enrollment and this visit date
all measurements below refer to this date
albumin: serum albumin (mg/dl)
alk.phos: alkaline phosphotase (U/liter)
ascites: presence of ascites
ast: aspartate aminotransferase, once called SGOT (U/ml)
bili: serum bilirunbin (mg/dl)
chol: serum cholesterol (mg/dl)
copper: urine copper (ug/day)
edema: 0 no edema, 0.5 untreated or successfully treated
1 edema despite diuretic therapy
hepato: presence of hepatomegaly or enlarged liver
platelet: platelet count
protime: standardised blood clotting time
spiders: blood vessel malformations in the skin
stage: histologic stage of disease (needs biopsy)
trig: triglycerides (mg/dl)

fit1 <- coxph(Surv(time1, time2, event) ~ age + sex + log(bili), pbcseq)
```

---

**plot.aareg**  
*Plot an aareg object.*

**Description**

Plot the estimated coefficient function(s) from a fit of Aalen’s additive regression model.

**Usage**

```r
## S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', ...)
```

**Arguments**

- `x`  
  the result of a call to the `aareg` function
- `se`  
  if TRUE, standard error bands are included on the plot
- `maxtime`  
  upper limit for the x-axis.
- `type`  
  graphical parameter for the type of line, default is "steps".
- `...`  
  other graphical parameters such as line type, color, or axis labels.

**Side Effects**

A plot is produced on the current graphical device.

**References**

**See Also**

aareg

---

**plot.cox.zph**  
*Graphical Test of Proportional Hazards*

**Description**

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

**Usage**

```r
## S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var,  
     xlab="Time", ylab, lty=1:2, col=1, lwd=1, hr=FALSE, ...)
```
Arguments

- **x**: result of the `cox.zph` function.
- **resid**: a logical value, if TRUE the residuals are included on the plot, as well as the smooth fit.
- **se**: a logical value, if TRUE, confidence bands at two standard errors will be added.
- **df**: the degrees of freedom for the fitted natural spline, df=2 leads to a linear fit.
- **nsmo**: number of points to use for the lines.
- **var**: the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below.
- **hr**: if TRUE, label the y-axis using the estimated hazard ratio rather than the estimated coefficient. (The plot does not change, only the axis label.)
- **xlab**: label for the x-axis of the plot.
- **ylab**: optional label for the y-axis of the plot. If missing a default label is provided. This can be a vector of labels.
- **lty, col, lwd**: line type, color, and line width for the overlaid curve. Each of these can be vector of length 2, in which case the second element is used for the confidence interval.
- **...**: additional graphical arguments passed to the `plot` function.

Side Effects

A plot is produced on the current graphics device.

- `coxph`, `cox.zph`.

Examples

```r
vfit <- coxph(Surv(time, status) ~ trt + factor(celltype) + karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=3) # Look at Karnofsy score, old way of doing plot
plot(temp[3]) # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,3] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```
Description

A plot of survival curves is produced, one curve for each strata. The log=T option does extra work to avoid \( \log(0) \), and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

Curves are plotted in the same order as they are listed by print (which gives a 1 line summary of each). This will be the order in which col, lty, etc are used.

Usage

```r
# S3 method for class 'survfit'
plot(x, conf.int=, mark.time=FALSE, pch=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1, xlim, ylim, xmax, fun, xlab="", ylab="", xaxs="r", conf.times, conf.cap=.005, conf.offset=.012, conf.type = c("log", "log-log", "plain", "logit", "arcsin"), mark, noplot="(s0)", cumhaz=FALSE, firstx, ymin, ...)
```

Arguments

- `x`: an object of class `survfit`, usually returned by the `survfit` function.
- `conf.int`: determines whether pointwise confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata, using 95% confidence intervals. Alternatively, this can be a numeric value giving the desired confidence level.
- `mark.time`: controls the labeling of the curves. If set to FALSE, no labeling is done. If TRUE, then curves are marked at each censoring time. If mark is a numeric vector then curves are marked at the specified time points.
- `pch`: vector of characters which will be used to label the curves. The points help file contains examples of the possible marks. A single string such as "abcd" is treated as a vector c("a", "b", "c", "d"). The vector is reused cyclically if it is shorter than the number of curves. If it is present this implies mark.time = TRUE.
- `col`: a vector of integers specifying colors for each curve. The default value is 1.
- `lty`: a vector of integers specifying line types for each curve. The default value is 1.
- `lwd`: a vector of numeric values for line widths. The default value is 1.
- `cex`: a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.
- `log`: a logical value, if TRUE the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.
- `xscale`: a numeric value used like yscale for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.
yscale

A numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with `lines(surv.exp(...))`, say, will perform as it did without the yscale argument.

xlim,ylim

Optional limits for the plotting region.

xmax

The maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the xlim graphical parameter, warning messages about out of bounds points are not generated.

fun

An arbitrary function defining a transformation of the survival (or probability in state, or cumulative hazard) curves. For example `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values), and `fun=sqrt` would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: "S" gives the usual survival curve, "log" is the same as using the log=T option, "event" or "F" plots the empirical CDF \( F(t) = 1 - S(t) \) \( f(y) = 1-y \), and "cloglog" creates a complimentary log-log survival plot \( f(y) = \log(-\log(y)) \) along with log scale for the x-axis. The terms "identity" and "surv" are allowed as synonyms for type="S". The argument "cumhaz" causes the cumulative hazard function to be plotted.

xlab

Label given to the x-axis.

ylab

Label given to the y-axis.

xaxs

Either "S" for a survival curve or a standard x axis style as listed in par; "r" (regular) is the R default. Survival curves have historically been displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally. The "S" style is becoming increasingly less common, however.

conf.times

Optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.

conf.cap

Width of the horizontal cap on top of the confidence bars; only used if conf.times is used. A value of 1 is the width of the plot region.

conf.offset

The offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve’s bars are offset by this amount from the prior curve’s bars, if it is a vector the values are used directly.

conf.type

One of "plain", "log" (the default), "log-log" or "logit". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals \( \pm k \times \text{se(curve)} \), where \( k \) is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option bases the intervals on the log hazard or log(-log(survival)), and the logit option on log(survival)/(1-survival)).

mark

A historical alias for pch.

noplot

For multi-state models, curves with this label will not be plotted. (Also see the istate0 argument in survcheck.)

cumhaz

Plot the cumulative hazard rather than the probability in state or survival. Optionally, this can be a numeric vector specifying which columns of the cumhaz component to plot.
ymin
this will normally be given as part of the ylim argument

firstx
this will normally be given as part of the xlim argument.

... 
other arguments that will be passed forward to the underlying plot method, such as xlab or ylab.

Details

If the object contains a cumulative hazard curve, then fun='cumhaz' will plot that curve, otherwise it will plot -log(S) as an approximation. Theoretically, \( S = \exp(-\Lambda) \) where \( S \) is the survival and \( \Lambda \) is the cumulative hazard. The same relationship holds for estimates of \( S \) and \( \Lambda \) only in special cases, but the approximation is often close.

When the survfit function creates a multi-state survival curve the resulting object also has class 'survfits'. Competing risk curves are a common case. In this situation the fun argument is ignored.

When the conf.times argument is used, the confidence bars are offset by conf.offset units to avoid overlap. The bar on each curve are the confidence interval for the time point at which the bar is drawn, i.e., different time points for each curve. If curves are steep at that point, the visual impact can sometimes substantially differ for positive and negative values of conf.offset.

Value

a list with components x and y, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

Note

In prior versions the behavior of xscale and yscale differed: the first changed the scale both for the plot and for all subsequent actions such as adding a legend, whereas yscale affected only the axis label. This was normalized in version 2-36.4, and both parameters now only affect the labeling.

In versions prior to approximately 2.36 a survfit object did not contain the cumulative hazard as a separate result, and the use of fun="cumhaz" would plot the approximation -log(surv) to the cumulative hazard. When cumulative hazards were added to the object, the cumhaz=TRUE argument to the plotting function was added. In version 2.3-8 the use of fun="cumhaz" became a synonym for cumhaz=TRUE.

Examples

leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
xlab="Months", ylab="Cumulative Hazard")
predict.coxph

Predictions for a Cox model

Description

Compute fitted values and regression terms for a model fitted by coxph

Usage

## S3 method for class 'coxph'
predict(object, newdata,
    type=c("lp", "risk", "expected", "terms", "survival"),
    se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
    reference=c("strata", "sample", "zero"), ...)

Arguments

object the results of a coxph fit.
newdata Optional new data at which to do predictions. If absent predictions are for the
data frame used in the original fit. When coxph has been called with a formula
argument created in another context, i.e., coxph has been called within another
function and the formula was passed as an argument to that function, there can
be problems finding the data set. See the note below.
type the type of predicted value. Choices are the linear predictor ("lp"), the risk
score exp(lp) ("risk"), the expected number of events given the covariates and
follow-up time ("expected"), and the terms of the linear predictor ("terms").
The survival probability for a subject is equal to exp(-expected).
se.fit if TRUE, pointwise standard errors are produced for the predictions.
na.action applies only when the newdata argument is present, and defines the missing
value action for the new data. The default is to include all observations. When
there is no newdata, then the behavior of missing is dictated by the na.action
option of the original fit.
terms if type="terms", this argument can be used to specify which terms should be
included; the default is all.
collapse optional vector of subject identifiers. If specified, the output will contain one
entry per subject rather than one entry per observation.
reference reference for centering predictions, see details below
... For future methods

Details

The Cox model is a relative risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The underlying reason is both statistical and practical. First, a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Second, downstream calculations depend on the risk score exp(linear predictor), which will fall prey to numeric overflow for a linear predictor greater than .Machine$double.max.exp. The coxph routines try to approximately center the predictors out
of self protection. Using the reference="strata" option is the safest centering, since strata occasionally have different means. When the results of predict are used in further calculations it may be desirable to use a single reference level for all observations. Use of reference="sample" will use the overall means, and agrees with the linear.predictors component of the coxph object (which uses the overall mean for backwards compatibility with older code). Predictions of type="terms" are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference. A reference of "zero" causes no centering to be done.

Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the reference option has no effect on these. These values depend on the follow-up time for the future subjects as well as covariates so the newdata argument needs to include both the right and left hand side variables from the formula. (The status variable will not be used, but is required since the underlying code needs to reconstruct the entire formula.)

Models that contain a frailty term are a special case: due to the technical difficulty, when there is a newdata argument the predictions will always be for a random effect of zero.

Value

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the se.fit option is TRUE.

Note

Some predictions can be obtained directly from the coxph object, and for others it is necessary for the routine to have the entirety of the original data set, e.g., for type = terms or if standard errors are requested. This extra information is saved in the coxph object if model=TRUE, if not the original data is reconstructed. If it is known that such residuals will be required overall execution will be slightly faster if the model information is saved.

In some cases the reconstruction can fail. The most common is when coxph has been called inside another function and the formula was passed as one of the arguments to that enclosing function. Another is when the data set has changed between the original call and the time of the prediction call. In each of these the simple solution is to add model=TRUE to the original coxph call.

predict.coxph, termplot

Examples

options(na.action=na.exclude) # retain NA in predictions
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
#lung data set has status coded as 1/2
mresid <- (lung$status-1) - predict(fit, type='expected') #Martingale resid
predict(fit,type="lp")
predict(fit,type="expected")
predict(fit,type="risk",se.fit=TRUE)
predict(fit,type="terms",se.fit=TRUE)

# For someone who demands reference='zero'

pzero <- function(fit)
  predict(fit, reference="sample") + sum(coef(fit) * fit$means, na.rm=TRUE)
Description

Predicted values for a survreg object

Usage

```r
## S3 method for class 'survreg'
predict(object, newdata, 
    type=c("response", "link", "lp", "linear", "terms", "quantile", 
        "uquantile"), 
    se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)
```

Arguments

- `object`: result of a model fit using the `survreg` function.
- `newdata`: data for prediction. If absent predictions are for the subjects used in the original fit.
- `type`: the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical.
- `se.fit`: if TRUE, include the standard errors of the prediction in the result.
- `terms`: subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.
- `p`: vector of percentiles. This is used only for quantile predictions.
- `na.action`: applies only when the `newdata` argument is present, and defines the missing value action for the new data. The default is to include all observations.
- `...`: for future methods

Value

a vector or matrix of predicted values.

Examples

# Draw figure 1 from Escobar and Meeker, 1992.
fit <- survreg(Surv(time,status) ~ age + I(age^2), data=stanford2,
dist='lognormal')
with(stanford2, plot(age, time, xlab='Age', ylab='Days',
xlim=c(0,65), ylim=c(.1, 10^5), log='y', type='n'))
with(stanford2, points(age, time, pch=c(2,4)[status+1], cex=.7))
pred <- predict(fit, newdata=list(age=1:65), type='quantile',
p=c(.1, .5, .9))
matlines(1:65, pred, lty=c(2,1,2), col=1)

# Predicted Weibull survival curve for a lung cancer subject with
# ECOG score of 2
lfit <- survreg(Surv(time, status) ~ ph.ecog, data=lung)
pct <- 1:98/100 # The 100th percentile of predicted survival is at +infinity
ptime <- predict(lfit, newdata=data.frame(ph.ecog=2), type='quantile',
p=pct, se=TRUE)
matplot(cbind(ptime$fit, ptime$fit + 2*ptime$se.fit,
ptime$fit - 2*ptime$se.fit)/30.5, 1-pct,
xlab="Months", ylab="Survival", type='l', lty=c(1,2,2), col=1)

print.aareg

Print an aareg object

Description

Print out a fit of Aalen's additive regression model

Usage

## S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"),scale=1,...)

Arguments

x         the result of a call to the aareg function
maxtime   the upper time point to be used in the test for non-zero slope
test      the weighting to be used in the test for non-zero slope. The default weights are
           based on the variance of each coefficient, as a function of time. The alternative
           weight is proportional to the number of subjects still at risk at each time point.
scale     scales the coefficients. For some data sets, the coefficients of the Aalen model
           will be very small (10^{-4}); this simply multiplies the printed values by a constant,
           say 1e6, to make the printout easier to read.
...       for future methods

Details

The estimated increments in the coefficient estimates can become quite unstable near the end of
follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope
will sometimes be more powerful if this last 'tail' is excluded.
Value

the calling argument is returned.

Side Effects

the results of the fit are displayed.

print.summary.coxph

Print method for summary.coxph objects

Description

Produces a printed summary of a fitted coxph model

Usage

## S3 method for class 'summary.coxph'
print(x, digits=max(getOption("digits") - 3, 3),
      signif.stars = getOption("show.signif.stars"), expand=FALSE, ...)

Arguments

x         the result of a call to summary.coxph
digits    significant digits to print
signif.stars Show stars to highlight small p-values
expand    if the summary is for a multi-state coxph fit, print the results in an expanded format.
...        For future methods
**print.summary.survexp**  
*Print Survexp Summary*

**Description**
Prints the results of `summary.survexp`.

**Usage**
```r
## S3 method for class 'summary.survexp'
print(x, digits = max(options()$digits - 4, 3), ...)
```

**Arguments**
- `x`: an object of class `summary.survexp`.
- `digits`: the number of digits to use in printing the result.
- `...`: for future methods.

**Value**
`x`, with the invisible flag set to prevent further printing.

**Author(s)**
Terry Therneau

**See Also**
- `summary.survexp`, `survexp`

---

**print.summary.survfit**  
*Print Survfit Summary*

**Description**
Prints the result of `summary.survfit`.

**Usage**
```r
## S3 method for class 'summary.survfit'
print(x, digits = max(options()$digits-4, 3), ...)
```

**Arguments**
- `x`: an object of class "summary.survfit", which is the result of the `summary.survfit` function.
- `digits`: the number of digits to use in printing the numbers.
- `...`: for future methods.
Value

x, with the invisible flag set to prevent printing.

Side Effects

prints the summary created by summary.survfit.

See Also

options, print, summary.survfit.

Description

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

Usage

## S3 method for class 'survfit'
print(x, scale=1, digits = max(options()$digits - 4,3),
      print.rmean=getOption("survfit.print.rmean"),
      rmean = getOption("survfit.rmean"),...
)

Arguments

x       the result of a call to the survfit function.
scale   a numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale=365 would scale the printout to years.
digits  Number of digits to print
print.rmean,rmean
       Options for computation and display of the restricted mean.
...     for future results

Details

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches to resolve this, which are selected by the rmean option. The first is to set the upper limit to a constant, e.g., rmean=365. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are "none" (no estimate), "common" and "individual". The "common" option uses the maximum time for all curves in the object as a common upper limit for the auc calculation. For the "individual" options the mean is computed as the area under each curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatatability, as this estimate was the default (only) one in earlier
releases of the code. Note that SAS (as of version 9.3) uses the integral up to the last event time of each individual curve; we consider this the worst of the choices and do not provide an option for that calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. If that line does not intersect the curve, then the median is undefined. The intersection of the line with the lower CI band defines the lower limit for the median’s interval, and similarly for the upper band. If any of the intersections is not a point then we use the center of the intersection interval, e.g., if the survival curve were exactly equal to 0.5 over an interval. When data is uncensored this agrees with the usual definition of a median.

Value

x, with the invisible flag set to prevent printing. (The default for all print functions in R is to return the object passed to them; print.survfit complies with this pattern. If you want to capture these printed results for further processing, see the table component of summary.survfit.)

Side Effects

The number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (rmean) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

summary.survfit, quantile.survfit

pseudo

Pseudo values for survival.

Description

Produce pseudo values from a survival curve.

Usage

pseudo(fit, times, type, addNA=TRUE, data.frame=FALSE, minus1=FALSE, ...)

Arguments

fit a survfit object, or one that inherits that class.
times a vector of time points, at which to evaluate the pseudo values.
type the type of value, either the probability in state pstate, the cumulative hazard cumhaz or the expected sojourn time in the state sojourn.
addNA If any observations were removed due to missing values in the fit object, add those rows (as NA) into the return. This causes the result of pseudo to match the original dataframe.
This function computes pseudo values based on a first order Taylor series, also known as the "infinitesimal jackknife" (IJ) or "dfbeta" residuals. To be completely correct these results could perhaps be called 'IJ pseudo values' or even pseudo psuedo-values. For moderate to large data, however, the resulting values will be almost identical, numerically, to the ordinary jackknife.

A primary advantage of this approach is computational speed. Other features, neither good nor bad, are that they will agree with robust standard errors of other survival package estimates, which are based on the IJ, and that the mean of the estimates, over subjects, is exactly the underlying survival estimate.

For the type variable, surv is an acceptable synonym for pstate, and rmst and rmts are equivalent to sojourn. All of these are case insensitive.

The result from this routine is simply n times the IJ value, where n is the number of subjects. (If the the survfit call included and id option, n is the number of unique id values, otherwise the number of rows in the data set.) IJ values are well defined for all variants of the Aalen-Johansen estimate, as computed by the survfit function; indeed, they are the basis for standard errors of the result. Understanding of the properties of the pseudo-values, however, is still evolving. Validity has been shown for the simplest case (Kaplan-Meier), for competing risks, and for the corresponding sojourn times. On the other hand, one must be careful when the data includes left-truncation (P. K. Andersen, personal communication), and also with pseudo-values for the cumulative hazard. As understanding evolves, treat this routine's results as a reseach tool, not production, for the more complex models.

Value

A vector, matrix, or array. The first dimension is always the number of observations in fit object, in the same order as the original data set (less any missing values that were removed when creating the survfit object); the second, if applicable, corresponds to fit$states, e.g., multi-state survival, and the last dimension to the selected time points. (If there are multiple rows for a given id, there is only one pseudovalue per unique id.)

For the data.frame option, a data frame containing values for id, time, and pseudo. If the original survfit call contained an id statement, then the values in the id column will be taken from that variable. If the id statement has a simple form, e.g., id = patno, then the name of the id column will be 'patno', otherwise it will be named '(id)'.

Note

The code will be slightly faster if the model=TRUE option is used in the survfit call. It may be essential if the survfit/pseudo pair is used inside another function.

residuals.survfit

Examples

```r
fit1 <- survfit(Surv(time, status) ~ 1, data=lung)
yhat <- pseudo(fit1, times=c(365, 730))
dim(yhat)
1fit <- lm(yhat[,1] ~ ph.ecog + age + sex, data=lung)

# Restricted Mean Time in State (RMST)
rms <- pseudo(fit1, times=730, type='RMST') # 2 years
rfit <- lm(rms ~ ph.ecog + sex, data=lung)
rhat <- predict(rfit, newdata=expand.grid(ph.ecog=0:3, sex=1:2), se.fit=TRUE)
# print it out nicely
temp1 <- cbind(matrix(rhat$fit, 4,2))
temp2 <- cbind(matrix(rhat$se.fit, 4, 2))
temp3 <- cbind(temp1[,1], temp2[,1], temp1[,2], temp2[,2])
dimnames(temp3) <- list(paste("ph.ecog", 0:3),
                         c("Male RMST", "(se)", "Female RMST", "(se)"))
```

```
round(temp3, 1)
```

```
# compare this to the fully non-parametric estimate
fit2 <- survfit(Surv(time, status) ~ ph.ecog, data=lung)
print(fit2, rmean=730)
# the estimate for ph.ecog=3 is very unstable (n=1), pseudovalues smooth it.
# # In all the above we should be using the robust variance, e.g., svyglm, but
# # a recommended package can’t depend on external libraries.
# # See the vignette for a more complete exposition.
```

---

**pspline**

**Smoothing splines using a pspline basis**

**Description**

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplification, they refer to the result as a p-spline.

**Usage**

```r
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
        Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, combine, ...)
```

```r
psplineinverse(x)
```
Arguments

- **x**: for psline: a covariate vector. The function does not apply to factor variables. For psplineinverse x will be the result of a pspline call.

- **df**: the desired degrees of freedom. One of the arguments df or theta must be given, but not both. If df=0, then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument 'caic=T' can be used to specify the corrected AIC of Hurvich et. al.

- **theta**: roughness penalty for the fit. It is a monotone function of the degrees of freedom, with theta=1 corresponding to a linear fit and theta=0 to an unconstrained fit of nterm degrees of freedom.

- **nterm**: number of splines in the basis

- **degree**: degree of splines

- **eps**: accuracy for df

- **method**: the method for choosing the tuning parameter theta. If theta is given, then 'fixed' is assumed. If the degrees of freedom is given, then 'df' is assumed. If method='aic' then the degrees of freedom is chosen automatically using Akaike’s information criterion.

- **Boundary.knots**: the spline is linear beyond the boundary knots. These default to the range of the data.

- **intercept**: if TRUE, the basis functions include the intercept.

- **penalty**: if FALSE a large number of attributes having to do with penalized fits are excluded. This is useful to create a pspline basis matrix for other uses.

- **combine**: an optional vector of increasing integers. If two adjacent values of combine are equal, then the corresponding coefficients of the fit are forced to be equal. This is useful for monotone fits, see the vignette for more details.

Value

Object of class pspline, coxph.penalty containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the coxph or survreg functions.

For psplineinverse the original x vector is reconstructed.

<table>
<thead>
<tr>
<th>pyears</th>
<th>Person Years</th>
</tr>
</thead>
</table>

Description

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

Usage

```r
pyears(formula, data, weights, subset, na.action, rmap,
rateetable, scale=365.25, expect=c('event', 'pyears'),
model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

Arguments

- **formula** a formula object. The response variable will be a vector of follow-up times for each subject, or a `Surv` object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by `+` operators (exactly as in `survfit`), time-dependent grouping variables such as `age` (specified with `tcut`), and optionally a `ratetable` term. This latter matches each subject to his/her expected cohort.
- **data** a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.
- **weights** case weights.
- **subset** expression saying that only a subset of the rows of the data should be used in the fit.
- **na.action** a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is `options()`$na.action.
- **rmap** an optional list that maps data set names to the ratetable names. See the details section below.
- **rateetable** a table of event rates, such as `survexp.uswhite`.
- **scale** a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.
- **expect** should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.
- **data.frame** return a data frame rather than a set of arrays.
- **model, x, y** If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.
Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```r
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt),
             ratetable=survexp.us)
```

the natural unit of the ratetable is hazard per day, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The ratetable being used may have different variable names than the user's data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary(survexp.us)` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The sex variable is not mapped, therefore the code assumes that it exists in `mydata` in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that `age` is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0,2,10,25,100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The `print` routine, therefore, is designed to give only a summary of the table.

Value

A list with components:

- `pyears` an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation.
- `n` an array containing the number of subjects who contribute time to each cell of the `pyears` array.
- `event` an array containing the observed number of events. This will be present only if the response variable is a `Surv` object.
- `expected` an array containing the expected number of events (or person years if `expect` = "pyears"). This will be present only if there was a `ratetable` term.
- `data` if the `data.frame` option was set, a data frame containing the variables `n`, `event`, `pyears` and `event` that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays.
- `offtable` the number of person-years of exposure in the cohort that was not part of any cell in the `pyears` array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table.
- `tcut` whether the call included any time-dependent cutpoints.
- `summary` a summary of the rate-table matching. This is also useful as an error check.
quantile.survfit

quantile.survfit

quantile.survfit

Quantiles from a survfit object

Description

Retrieve quantiles and confidence intervals for them from a survfit or Surv object.
Usage

```r
## S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
         scale, tolerance = sqrt(.Machine$double.eps), ...)
## S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
         scale, tolerance = sqrt(.Machine$double.eps), ...)
## S3 method for class 'survfit'
median(x, ...)
```

Arguments

- **x**: a result of the survfit function
- **probs**: numeric vector of probabilities with values in [0,1]
- **conf.int**: should lower and upper confidence limits be returned?
- **scale**: optional scale factor, e.g., `scale=365.25` would return results in years if the fit object were in days.
- **tolerance**: tolerance for checking that the survival curve exactly equals one of the quantiles
- **...**: optional arguments for other methods

Details

The kth quantile for a survival curve S(t) is the location at which a horizontal line at height \( p = 1-k \) intersects the plot of S(t). Since S(t) is a step function, it is possible for the curve to have a horizontal segment at exactly 1-k, in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to 1-k, then that quantile is undefined.

In order to be consistent with other quantile functions, the argument `prob` of this function applies to the cumulative distribution function \( F(t) = 1-S(t) \).

Confidence limits for the values are based on the intersection of the horizontal line at 1-k with the upper and lower limits for the survival curve. Hence confidence limits use the same p-value as was in effect when the curve was created, and will differ depending on the `conf.type` option of `survfit`. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.

When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is \( (19/20)(18/19)(17/18) \ldots (10/11) = 10/20, \) but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than `tolerance` is considered to be an exact match.

Value

The quantiles will be a vector if the `survfit` object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components `quantile`, `lower`, and `upper`, otherwise it is the vector or matrix of quantiles.

ratetable

Allow ratetable() terms in a model

Description
This function supports ratetable() terms in a model statement, within survexp and pyears.

Usage
ratetable(...)

Arguments
...

the named dimensions of a rate table

Details
This way of mapping a rate table’s variable names to a user data frame has been superseded, instead use the rmap argument of the survexp, pyears, or survdiff routines. The function remains only to allow older code to be run.

Author(s)
Terry Therneau
**ratetableDate**  
*Convert date objects to ratetable form*

**Description**  
This method converts dates from various forms into the internal form used in ratetable objects.

**Usage**  
```r  
ratetableDate(x)  
```

**Arguments**  
`x`  
a date. The function currently has methods for Date, date, POSIXt, timeDate, and chron objects.

**Details**  
This function is useful for those who create new ratetables, but is normally invisible to users. It is used internally by the `survexp` and `pyears` functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

**Value**  
a numeric vector, the number of days since 1/1/1960.

rats

3625

Details
survexp.us total United States population, by age and sex, 1940 to 2012.
survexp.usr United States population, by age, sex and race, 1940 to 2014. Race is white or black.
For 1960 and 1970 the black population values were not reported separately, so the nonwhite
values were used. (Over the years, the reported tables have differed wrt reporting non-white
and/or black.)
survexp.mn total Minnesota population, by age and sex, 1970 to 2013.
Each of these tables contains the daily hazard rate for a matched subject from the population, defined
as − log(1 − q)/365.25 where q is the 1 year probability of death as reported in the original tables
from the US Census. For age 25 in 1970, for instance, p = 1 − q is is the probability that a subject
who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in
terms of hazard per day for computational convenience.
Each table is stored as an array, with additional attributes, and can be subset and manipulated as
standard R arrays. See the help page for ratetable for details.
All numeric dimensions of a rate table must be in the same units. The survexp.us rate table
contains daily hazard rates, the age cutpoints are in days, and the calendar year cutpoints are a Date.

rats

Rat treatment data from Mantel et al

Description
Rat treatment data from Mantel et al. Three rats were chosen from each of 100 litters, one of which
was treated with a drug, and then all followed for tumor incidence.
Usage
rats
data(cancer, package="survival")
Format
litter:
rx:
time:
status:
sex:

litter number from 1 to 100
treatment,(1=drug, 0=control)
time to tumor or last follow-up
event status, 1=tumor and 0=censored
male or female


Note

Since only 2/150 of the male rats have a tumor, most analyses use only females (odd numbered litters), e.g. Lee et al.

Source

References

rats2

Rat data from Gail et al.

Description

48 rats were injected with a carcinogen, and then randomized to either drug or placebo. The number of tumors ranges from 0 to 13; all rats were censored at 6 months after randomization.

Usage

rats2
data(cancer, package="survival")

Format

rat: id
trt: treatment,(1=drug, 0=control)
observation: within rat
start: entry time
stop: exit time
status: event status, 1=tumor, 0=censored

Source

Description
A set of data for simple reliability analyses, taken from the book by Meeker and Escobar.

Usage
data(reliability, package="survival")

Details
- capacitor: Data from a factorial experiment on the life of glass capacitors as a function of voltage and operating temperature. There were 8 capacitors at each combination of temperature and voltage. Testing at each combination was terminated after the fourth failure.
  - temperature: temperature in degrees celcius
  - voltage: applied voltage
  - time: time to failure
  - status: 1=failed, 0=censored
- cracks: Data on the time until the development of cracks in a set of 167 identical turbine parts. The parts were inspected at 8 selected times.
  - day: time of inspection
  - fail: number of fans found to have cracks, at this inspection
- Data set genfan: Time to failure of 70 diesel engine fans.
  - hours: hours of service
  - status: 1=failure, 0=censored
- Data set ifluid: A data frame with two variables describing the time to electrical breakdown of an insulating fluid.
  - time: hours to breakdown
  - voltage: test voltage in kV
- Data set imotor: Breakdown of motor insulation as a function of temperature.
  - temp: temperature of the test
  - time: time to failure or censoring
  - status: 0=censored, 1=failed
- Data set turbine: Each of 432 turbine wheels was inspected once to determine whether a crack had developed in the wheel or not.
  - hours: time of inspection (100s of hours)
  - inspected: number that were inspected
  - failed: number that failed
- Data set valveSeat: Time to replacement of valve seats for 41 diesel engines. More than one seat may be replaced at a particular service, leading to duplicate times in the data set. The final inspection time for each engine will have status=0.
  - id: engine identifier
  - time: time of the inspection, in days
  - status: 1=replacement occured, 0= not

survreg(Surv(time, status) ~ temperature + voltage, capacitor)

residuals.coxph Calculate Residuals for a ‘coxph’ Fit

Description

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

Usage

## S3 method for class 'coxph'
residuals(object, 
  type=c("martingale", "deviance", "score", "schoenfeld", 
  "dfbeta", "dfbetas", "scaledsch","partial"), 
  collapse=FALSE, weighted= (type %in% c("dfbeta", "dfbetas")), ...)
## S3 method for class 'coxphms'
residuals(object, 
  type=c("martingale", "score", "schoenfeld", 
  "dfbeta", "dfbetas", "scaledsch"), 
  collapse=FALSE, weighted= FALSE, ...)
## S3 method for class 'coxph.null'
residuals(object, 
  type=c("martingale", "deviance","score","schoenfeld"), 
  collapse=FALSE, weighted= FALSE, ...)

Arguments

object an object inheriting from class coxph, representing a fitted Cox regression model. Typically this is the output from the coxph function.

type character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", "scaledsch" and "partial". Only enough of the string to determine a unique match is required.

collapse vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then collapse=c(1,1,1,2, 3,3,4,4,4,4) could be used to obtain per subject rather than per observation residuals.

weighted if TRUE and the model was fit with case weights, then the weighted residuals are returned.

... other unused arguments
Value

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute strata is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the \texttt{cox.zph} function.

The score residuals are each individual’s contribution to the score vector. Two transformations of this are often more useful: \texttt{dfbeta} is the approximate change in the coefficient vector if that observation were dropped, and \texttt{dfbetas} is the approximate change in the coefficients, scaled by the standard error for the coefficients.

NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

\end{verbatim}

\texttt{residuals.survfit} \hspace{1cm} \textit{II residuals from a survfit object.}

Description

Return infinitesimal jackknife residuals from a survfit object, for the survival, cumulative hazard, or restricted mean time in state (RMTS).

Usage

\begin{verbatim}
## S3 method for class 'survfit'
residuals(object, times, 
        type="pstate", collapse, weighted=FALSE, 
        method=1, ...)
\end{verbatim}
Arguments

object
a survfit object

times
a vector of times at which the residuals are desired

type
the type of residual, see below

collapse
add the residuals for all subjects in a cluster. If the survfit object used an id statement, the default is to collapse over that variable.

weighted
weight the residuals by each observation’s weight

method
controls a choice of algorithm. Current an internal debugging option.

... arguments for other methods

Details

This function is designed to efficiently compute the residuals at a small number of time points, also known as the infinitesimal jackknife (IJ). Primary usages are the creation of pseudo-values and IJ estimates of variance. If the residuals at all time points are needed, e.g. to compute a robust pointwise confidence interval for the survival curve, then this can be done more efficiently using the influence argument of the underlying survfit function. But be aware that such matrices can get very large.

The residuals are the impact of each observation or cluster on the resulting probability in state curves at the given time points, the cumulative hazard curve at those time points, or the expected sojourn time in each state up to the given time points. For a simple Kaplan-Meier the survfit object contains only the probability in the “initial” state, i.e., the survival fraction. For the KM case the sojourn time, the expected amount of time spent in the initial state, up to the specified endpoint, is more commonly known as the restricted mean survival time (RMST). For a multistate model this same quantity is also referred to as the restricted mean time in state (RMTS). It can be computed as the area under the respective probability in state curve. The program allows any of pstate, surv, cumhaz, chaz, sojourn, rmst, rmts or auc for the type argument, ignoring upper/lowercase, so users can choose whichever abbreviation they like best.

When collapse=TRUE the result has the cluster identifier (which defaults to the id variable) as the dimname for the first dimension. If the fit object contains more than one curve, and the same identifier is reused in two different curves this approach does not work and the routine will stop with an error. In principle this is not necessary, e.g., the result could contain two rows with the same label, showing the separate effect on each curve, but this was deemed too confusing.

Value

A matrix or array with one row per observation or cluster, and one column for each value in times. For a multi-state model the three dimensions are observation, time and state. For cumulative hazard, the last dimension is the set of transitions. (A competing risks model for instance has 3 states and 2 transitions.)

Examples

fit <- survfit(Surv(time, status) ~ x, aml)
resid(fit, times=c(24, 48), type="RMTS")
residuals.survreg

Compute Residuals for 'survreg' Objects

Description

This is a method for the function residuals for objects inheriting from class survreg.

Usage

## S3 method for class 'survreg'
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE, collapse=FALSE, weighted=FALSE, ...)

Arguments

- **object**: an object inheriting from class survreg.
- **type**: type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", and "matrix".
- **rsigma**: include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).
- **collapse**: optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.
- **weighted**: give weighted residuals? Normally residuals are unweighted.
- **...**: other unused arguments

Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the ith row gives the approximate change in the coefficients due to the addition of subject i. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let $L$ be the log-likelihood, $p$ be the linear predictor $X \beta$, and $s$ be $\log(\sigma)$. Then the 6 columns of the matrix are $L$, $dL/dp$, $\partial^2 L/\partial p^2$, $dL/ds$, $\partial^2 L/\partial s^2$ and $\partial^2 L/\partial p \partial s$. Diagnostics based on these quantities are discussed in the book and article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (ldcase), the response value (ldresp), and the shape.

For a transformed distribution such as the log-normal or Weibull, matrix residuals are based on the log-likelihood of the transformed data $\log(y)$. For a monotone function $f$ the density of $f(X)$ is the density of $X$ divided by the derivative of $f$ (the Jacobian), so subtract $\log(\text{derivative})$ from each uncensored observation’s loglik value in order to match the loglik component of the result. The other columns of the matrix residual are unchanged by the transformation.

References

retinopathy

Description

A trial of laser coagulation as a treatment to delay diabetic retinopathy.

Usage

retinopathy
data(retinopathy, package="survival")

Format

A data frame with 394 observations on the following 9 variables.

- id numeric subject id
- laser type of laser used: xenon argon
- eye which eye was treated: right left
- age age at diagnosis of diabetes
- type type of diabetes: juvenile adult, (diagnosis before age 20)
- trt 0 = control eye, 1 = treated eye
- futime time to loss of vision or last follow-up
- status 0 = censored, 1 = loss of vision in this eye
- risk a risk score for the eye. This high risk subset is defined as a score of 6 or greater in at least one eye.

Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment, and has two observations in the data set. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are the actual time to vision loss in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

---

rhDNase

**rhDNASE data set**

Description

Results of a randomized trial of rhDNase for the treatment of cystic fibrosis.

Usage

rhDNase
data(rhDNase, package="survival")

Format

A data frame with 767 observations on the following 8 variables.

- id: subject id
- inst: enrolling institution
- trt: treatment arm: 0=placebo, 1= rhDNase
- entry.dt: date of entry into the study
- end.dt: date of last follow-up
- fev: forced expiratory volume at enrollment, a measure of lung capacity
- ivstart: days from enrollment to the start of IV antibiotics
- ivstop: days from enrollment to the cessation of IV antibiotics

Details

In patients with cystic fibrosis, extracellular DNA is released by leukocytes that accumulate in the airways in response to chronic bacterial infection. This excess DNA thickens the mucus, which then cannot be cleared from the lung by the cilia. The accumulation leads to exacerbations of respiratory symptoms and progressive deterioration of lung function. At the time of this study more than 90% of cystic fibrosis patients eventually died of lung disease.

Deoxyribonuclease I (DNase I) is a human enzyme normally present in the mucus of human lungs that digests extracellular DNA. Genentech, Inc. cloned a highly purified recombinant DNase I (rhDNase or Pulmozyme) which when delivered to the lungs in an aerosolized form cuts extracellular DNA, reducing the viscoelasticity of airway secretions and improving clearance. In 1992 the company conducted a randomized double-blind trial comparing rhDNase to placebo. Patients were then monitored for pulmonary exacerbations, along with measures of lung volume and flow. The primary
The definition of an exacerbation was an infection that required the use of intravenous (IV) antibiotics. Subjects had 0–5 such episodes during the trial, those with more than one have multiple rows in the data set, those with none have NA for the IV start and end times. A few subjects were infected at the time of enrollment, subject 173 for instance has a first infection interval of -21 to 7. We do not count this first infection as an "event", and the subject first enters the risk set at day 7. Subjects who have an event are not considered to be at risk for another event during the course of antibiotics, nor for an additional 6 days after they end. (If the symptoms reappear immediately after cessation then from a medical standpoint this would not be a new infection.)

This data set reproduces the data in Therneau and Grambsch, it does not exactly reproduce those in Therneau and Hamilton due to data set updates.

**References**

**Examples**

```r
# Build the start-stop data set for analysis, and
# replicate line 2 of table 8.13 in the book
first <- subset(rhDNase, !duplicated(id)) # first row for each subject
dnase <- tmerge(first, first, id=id, tstop=as.numeric(end.dt - entry.dt))

# Subjects whose fu ended during the 6 day window are the reason for
# this next line
temp.end <- with(rhDNase, pmin(ivstop+6, end.dt - entry.dt))
dnase <- tmerge(dnase, rhDNase, id=id,
               infect=event(ivstart),
               end= event(temp.end))

# toss out the non-at-risk intervals, and extra variables
# 3 subjects had an event on their last day of fu, infect=1 and end=1
dnase <- subset(dnase, (infect==1 | end==0), c(id:trt, fev:infect))
agfit <- coxph(Surv(tstart, tstop, infect) ~ trt + fev, cluster=id,
               data=dnase)
```

---

**ridge**

*Ridge regression*

**Description**

When used in a `coxph` or `survreg` model formula, specifies a ridge regression term. The likelihood is penalised by $\theta/2$ time the sum of squared coefficients. If `scale=T` the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If `df` is specified then $\theta$ is chosen based on an approximate degrees of freedom.

**Usage**

```r
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```
Arguments

... predictors to be ridged
theta penalty is theta/2 time sum of squared coefficients
df Approximate degrees of freedom
eps Accuracy required for df
scale Scale variables before applying penalty?

Value

An object of class coxph.penalty containing the data and control functions.

Note

If the expression ridge(x1, x2, x3, ...) is too many characters long then the internal terms() function will add newlines to the variable name and then the coxph routine simply gets lost. (Some labels will have the newline and some won’t.) One solution is to bundle all of the variables into a single matrix and use that matrix as the argument to ridge so as to shorten the call, e.g. mdata$many <- as.matrix(mydata[,5:53]).

lfit3 <- survreg(Surv(time, status) ~ sex + age + ph.ecog, lung)

rotterdam

Breast cancer data set used in Royston and Altman (2013)

Description

The rotterdam data set includes 2982 primary breast cancers patients whose records were included in the Rotterdam tumor bank.

Usage

rotterdam
data(cancer, package="survival")
Format

A data frame with 2982 observations on the following 15 variables.

- **pid**  patient identifier
- **year**  year of surgery
- **age**  age at surgery
- **meno**  menopausal status (0= premenopausal, 1= postmenopausal)
- **size**  tumor size, a factor with levels <=20 20-50 >50
- **grade**  differentiation grade
- **nodes**  number of positive lymph nodes
- **pgr**  progesterone receptors (fmol/l)
- **er**  estrogen receptors (fmol/l)
- **hormon**  hormonal treatment (0=no, 1=yes)
- **chemo**  chemotherapy
- **rtime**  days to relapse or last follow-up
- **recur**  0= no relapse, 1= relapse
- **dtime**  days to death or last follow-up
- **death**  0= alive, 1= dead

Details

These data sets are used in the paper by Royston and Altman that is referenced below. The Rotterdam data is used to create a fitted model, and the GBSG data for validation of the model. The paper gives references for the data source.

There are 43 subjects who have died without recurrence, but whose death time is greater than the censoring time for recurrence. A common way that this happens is that a death date is updated in the health record sometime after the research study ended, and said value is then picked up when a study data set is created. Vital status information can come from many sources: a patient visit for another condition, correspondence, financial transactions, or social media. But this raises serious questions about censoring. For instance subject 40 is censored for recurrence at 4.2 years and died at 6.6 years; when creating the endpoint of recurrence free survival (earlier of recurrence or death), treating them as a death at 6.6 years implicitly assumes that they were recurrence free just before death. For this to be true we would have to assume that if they had progressed in the 2.4 year interval before death (while off study), that this information would also have been noted in their general medical record, and would also be captured in the study data set. However, that may be unlikely. Death information is often in a centralized location in electronic health records, easily accessed by a programmer and merged with the study data, while recurrence may require manual review. How best to address this is an open issue.

---

royston

**Compute Royston’s D for a Cox model**

Description

Compute the D statistic proposed by Royston and Sauerbrei along with several pseudo- R square values.

Usage

royston(fit, newdata, ties = TRUE, adjust = FALSE)

Arguments

- **fit**: a coxph fit
- **newdata**: optional validation data set
- **ties**: make a correction for ties in the risk score
- **adjust**: adjust for possible overfitting

Details

These values are called pseudo R-squared since they involve only the linear predictor, and not the outcome. R.D is the value that corresponds to the Royston and Sauerbrei D statistic. R.KO is the value proposed by Kent and O’Quigley. R.N is the value proposed by Nagelkerke, and C.GH corresponds to Goen and Heller’s concordance measure.

An adjustment for D is based on the ratio r= (number of events)/(number of coefficients). For models which have sufficient sample size (r>20) the adjustment will be small.

The Nagelkerke value is the Cox-Snell R-squared divided by a scaling constant. The two separate values are present in the result of summary.coxph as a 2 element vector rsq, and were listed as "Rsqare" and "max possible" in older versions of the print routine. (Since superseded in the default printout by the concordance.) The Nagelkerke estimate is not returned when newdata is present.
Value

A vector containing the value of D, the estimated standard error of D, and three or four pseudo R-squared values.

royston(cfit)

rttright

Compute redistribute-to-the-right weights

Description

For many survival estimands, one approach is to redistribute each censored observation’s weight to those other observations with a longer survival time (think of distributing an estate to the heirs). Then compute on the remaining, uncensored data.

Usage

rttright(formula, data, weights, subset, na.action, times, id, timefix = TRUE, renorm= TRUE)

Arguments

formula a formula object, which must have a Surv object as the response on the left of the ~ operator and, if desired, terms separated by + operators on the right. Each unique combination of predictors will define a separate strata.
data a data frame in which to interpret the variables named in the formula, subset and weights arguments.
weights The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the subset argument.
subset expression saying that only a subset of the rows of the data should be used in the fit.
na.action a missing-data filter function, applied to the model frame, after any subset argument has been used. Default is options()$na.action.
times a vector of time points, for which to return updated weights. If missing, a time after the largest time in the data is assumed.

id optional: if the data set has multiple rows per subject, a variable containing the subject identifier of each row.

timefix correct for possible round-off error

renorm the resulting weights sum to 1 within each group

Details

The formula argument is treated exactly the same as in the survfit function.

Redistribution is recursive: redistribute the weight of the first censored observation to all those with longer time, which may include other censored observations. Then redistribute the next smallest and etc. up to the specified time value. After re-distributing the weight for a censored observation to other observations that are not censored, ordinary non-censored methods can often be applied. For example, redistribution of the weights, followed by computation of the weighted cumulative distribution function, reprises the Kaplan-Meier estimator.

A primary use of this routine is illustration of methods or exploration of new methods. Methods that use RTTR directly, such as the Brier score, will often do these computations internally.

A covariate on the right hand side of the formula causes redistribution to occur within group; a censoring in group 1 redistributes weights to others in group 1, etc. This is appropriate when the censoring pattern depends upon group.

Value

a vector or matrix of weights, with one column for each requested time

See Also

survfit

Examples

afit <- survfit(Surv(time, status) ~1, data=aml)
rtwt <- rttright(Surv(time, status) ~1, data=aml)
# Reproduce a Kaplan-Meier
index <- order(aml$time)
cdf <- cumsum(rwt[index]) # weighted CDF
cdf <- cdf[!duplicated(aml$time[index], fromLast=TRUE)] # remove duplicate times
cbind(time=afit$time, KM= afit$surv, RTTR= 1-cdf)

# Hormonal patients have a different censoring pattern
wt2 <- rttright(Surv(dtime, death) ~ hormon, rotterdam, times= 365*c(3, 5))
dim(wt2)
solder

Data from a soldering experiment

Description

In 1988 an experiment was designed and implemented at one of AT&T’s factories to investigate alternatives in the "wave soldering" procedure for mounting electronic components to printed circuit boards. The experiment varied a number of factors relevant to the process. The response, measured by eye, is the number of visible solder skips.

Usage

solder
data(solder, package="survival")

Format

A data frame with 900 observations on the following 6 variables.

Opening the amount of clearance around the mounting pad (3 levels)
Solder the amount of solder (Thick or Thin)
Mask type and thickness of the material used for the solder mask (A1.5, A3, A6, B3, B6)
PadType the geometry and size of the mounting pad (10 levels)
Panel each board was divided into 3 panels
skips the number of skips

Details

This data set is used as a detailed example in chapter 1 of Chambers and Hastie. Observations 1-360 and 541-900 form a balanced design of 3*2*10*3= 180 observations for four of the pad types (A1.5, A3, B3, B6), while rows 361-540 match 3 of the 6 Solder*Opening combinations with pad type A6 and the other 3 with pad type A3.

References

Examples

# The balanced subset used by Chambers and Hastie
# contains the first 180 of each mask and deletes mask A6.
index <- 1 + (1:nrow(solder)) - match(solder$Mask, solder$Mask)
solder.balance <- droplevels(subset(solder, Mask != "A6" & index <= 180))

More Stanford Heart Transplant data

Description

This contains the Stanford Heart Transplant data in a different format. The main data set is in `heart`.

Usage

```
stanford2
```

Format

```
id: ID number
time: survival or censoring time
status: censoring status
age: in years
t5: T5 mismatch score
```

Source

See Also

`predict.survreg`, `heart`

Draw a state space figure.

Description

For multi-state survival models it is useful to have a figure that shows the states and the possible transitions between them. This function creates a simple "box and arrows" figure. It’s goal was simplicity.

Usage

```
statefig(layout, connect, margin = 0.03, box = TRUE, cex = 1, col = 1,
        lwd=1, lty=1, bcol=col, acol=col, alwd=lwd, alty=lty, offset=0)
```
Arguments

layout describes the layout of the boxes on the page. See the detailed description below.

connect a square matrix with one row for each state. If connect[i,j] ! = 0 then an arrow is drawn from state i to state j. The row names of the matrix are used as the labels for the states.

margin the fraction of white space between the label and the surrounding box, and between the box and the arrows, as a function of the plot region size.

box should boxes be drawn? TRUE or FALSE.

cex, col, lty, lwd default graphical parameters used for the text and boxes. The last 3 can be a vector of values.

bcol color for the box, if it differs from that used for the text.

acol, alwd, alty color, line type and line width for the arrows.

offset used to slight offset the arrows between two boxes x and y if there is a transition in both directions. The default of 0 leads to a double headed arrow in this case – to arrows are drawn but they coincide. A positive value causes each arrow to shift to the left, from the view of someone standing at the foot of a arrow and looking towards the arrowhead, a negative offset shifts to the right. A value of 1 corresponds to the size of the plotting region.

Details

The arguments for color, line type and line width can all be vectors, in which case they are recycled as needed. Boxes and text are drawn in the order of the rownames of connect, and arrows are drawn in the usual R matrix order.

The layout argument is normally a vector of integers, e.g., the vector (1, 3, 2) describes a layout with 3 columns. The first has a single state, the second column has 3 states and the third has 2. The coordinates of the plotting region are 0 to 1 for both x and y. Within a column the centers of the boxes are evenly spaced, with 1/2 a space between the boxes and the margin, e.g., 4 boxes would be at 1/8, 3/8, 5/8 and 7/8. If layout were a 1 column matrix with values of (1, 3, 2) then the layout will have three rows with 1, 3, and 2 boxes per row, respectively. Alternatively, the user can supply a 2 column matrix that directly gives the centers.

The values of the connect matrix should be 0 for pairs of states that do not have a transition and values between 0 and 2 for those that do. States are connected by an arc that passes through the centers of the two boxes and a third point that is between them. Specifically, consider a line segment joining the two centers and erect a second segment at right angles to the midpoint of length d times the distance from center to midpoint. The arc passes through this point. A value of d=0 gives a straight line, d=1 a right hand half circle centered on the midpoint and d= -1 a left hand half circle. The connect matrix contains values of d+1 with -1 < d < 1.

The connecting arrow are drawn from (center of box 1 + offset) to (center of box 2 + offset), where the the amount of offset (white space) is determined by the box and margin parameters. If a pair of states are too close together this can result in an arrow that points the wrong way.

Value

a matrix containing the centers of the boxes, with the invisible attribute set.
Note

The goal of this function is to make “good enough” figures as simply as possible, and thereby to encourage users to draw them. The layout argument was inspired by the `diagram` package, which can draw more complex and well decorated figures, e.g., many different shapes, shading, multiple types of connecting lines, etc., but at the price of greater complexity.

Because curved lines are drawn as a set of short line segments, line types have almost no effect for that case.

Author(s)

Terry Therneau

Examples

# Draw a simple competing risks figure
states <- c("Entry", "Complete response", "Relapse", "Death")
connect <- matrix(0, 4, 4, dimnames=list(states, states))
connect[1, -1] <- c(1.1, 1, 0.9)
statefig(c(1, 3), connect)

---

**strata**

*Identify Stratification Variables*

Description

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

Usage

strata(..., na.group=FALSE, shortlabel, sep=", ")

Arguments

... any number of variables. All must be the same length.

na.group a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.

shortlabel if TRUE omit variable names from resulting factor labels. The default action is to omit the names if all of the arguments are factors, and none of them was named.

sep the character used to separate groups, in the created label

Details

When used outside of a `coxph` formula the result of the function is essentially identical to the `interaction` function, though the labels from `strata` are often more verbose.

Value

a new factor, whose levels are all possible combinations of the factors supplied as arguments.
See Also
coxph, interaction

Examples

```r
a <- factor(rep(1:3,4), labels=c("low", "medium", "high"))
b <- factor(rep(1:4,3))
levels(strata(b))
levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```

---

**summary.aareg**

**Summarize an aareg fit**

**Description**

Creates the overall test statistics for an Aalen additive regression model

**Usage**

```r
## S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

**Arguments**

- `object` the result of a call to the aareg function
- `maxtime` truncate the input to the model at time "maxtime"
- `test` the relative time weights that will be used to compute the test
- `scale` scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10^{-4}); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
- `...` for future methods

**Details**

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The `maxtime` parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in lieu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.
Value

A list is returned with the following components:

- `table`: A matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, its standard error, the z-score, and a p-value.
- `test`: The time weighting used for computing the test statistics.
- `test.statistic`: The vector of test statistics.
- `test.var`: The model-based variance matrix for the test statistic.
- `test.var2`: Optionally, a robust variance matrix for the test statistic.
- `chisq`: The overall test (ignoring the intercept term) for significance of any variable.
- `n`: A vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times.

```
Description

Produces a summary of a fitted coxph model

Usage

## S3 method for class 'coxph'
summary(object, conf.int=0.95, scale=1,...)

Arguments

  object     the result of a coxph fit
  conf.int   level for computation of the confidence intervals. If set to FALSE no confidence
              intervals are printed
  scale      vector of scale factors for the coefficients, defaults to 1. The printed coefficients,
              se, and confidence intervals will be associated with one scale unit.
  ...        for future methods

Value

An object of class summary.coxph, with components:

  n, nevent  number of observations and number of events, respectively, in the fit
  loglik     the log partial likelihood at the initial and final values
  coefficients a matrix with one row for each coefficient, and columns containing the coefficient,
                the hazard ratio exp(coef), standard error, Wald statistic, and P value.
  conf.int   a matrix with one row for each coefficient, containing the confidence limits for
                exp(coef)
  logtest, sctest, waldtest  the overall likelihood ratio, score, and Wald test statistics for the model
  concordance the concordance statistic and its standard error
  used.robust whether an asymptotic or robust variance was used
  rsq         an approximate R^2 based on Nagelkerke (Biometrika 1991).
  fail        a message, if the underlying coxph call failed
  call        a copy of the call
  na.action   information on missing values

Note

The pseudo r-squared of Nagelkerke is attractive because it is simple, but further work has shown
that it has poor properties and it is now deprecated. The value is no longer printed by default, and
will eventually be removed from the object.

```

## summary.pyears

### Summary function for pyears objects

**Description**

Create a printable table of a person-years result.

**Usage**

```r
## S3 method for class 'pyears'
summary(object, header = TRUE, call = header, n = TRUE,
event = TRUE, pyears = TRUE, expected = TRUE, rate = FALSE, rr = expected,
ci.r = FALSE, ci.rr = FALSE, totals=FALSE, legend = TRUE, vline = FALSE,
vertical= TRUE, nastring=".", conf.level = 0.95,
scale = 1, ...)```

**Arguments**

- `object`: a pyears object
- `header`: print out a header giving the total number of observations, events, person-years, and total time (if any) omitted from the table
- `call`: print out a copy of the call
- `n, event, pyears, expected`: logical arguments: should these elements be printed in the table?
- `rate, ci.r`: logical arguments: should the incidence rate and/or its confidence interval be given in the table?
- `rr, ci.rr`: logical arguments: should the hazard ratio and/or its confidence interval be given in the table?
- `totals`: should row and column totals be added?
- `legend`: should a legend be included in the printout?
- `vline`: should vertical lines be included in the printed tables?
- `vertical`: when there is only a single predictor, should the table be printed with the predictor on the left (vertical=TRUE) or across the top (vertical=FALSE)?
- `nastring`: what to use for missing values in the table. Some of these are structural, e.g., risk ratios for a cell with no follow-up time.
- `conf.level`: confidence level for any confidence intervals
- `scale`: a scaling factor for printed rates
- `...`: optional arguments which will be passed to the `format` function; common choices would be `digits=2` or `nsmall=1`.
Details

The \texttt{pyears} function is often used to create initial descriptions of a survival or time-to-event variable; the type of material that is often found in "table 1" of a paper. The summary routine prints this information out using one of pandoc table styles. A primary reason for choosing this style is that Rstudio is then able to automatically render the results in multiple formats: html, rtf, latex, etc.

If the \texttt{pyears} call has only a single covariate then the table will have that covariate as one margin and the statistics of interest as the other. If the \texttt{pyears} call has two predictors then those two predictors are used as margins of the table, while each cell of the table contains the statistics of interest as multiple rows within the cell. If there are more than two predictors then multiple tables are produced, in the same order as the standard R printout for an array.

The "N" entry of a \texttt{pyears} object is the number of observations which contributed to a particular cell. When the original call includes \texttt{tcut} objects then a single observation may contribute to multiple cells.

Value

a copy of the object

Notes

The pandoc system has four table types: with or without vertical bars, and with single or multiple rows of data in each cell. This routine produces all 4 styles depending on options, but currently not all of them are recognized by the Rstudio-pandoc pipeline. (And we don’t yet see why.)

summary.survexp Summary function for a survexp object

Description

Returns a list containing the values of the survival at specified times.

Usage

```r
## S3 method for class 'survexp'
summary(object, times, scale = 1, ...)
```

Arguments

- \texttt{object} the result of a call to the \texttt{survexp} function
- \texttt{times} vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed.
- \texttt{scale} numeric value to rescale the survival time, e.g., if the input data to \texttt{survfit} were in days, \texttt{scale = 365.25} would scale the output to years.
- \texttt{...} For future methods
Details

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

Value

a list with the following components:

- `surv`: the estimate of survival at time t.
- `time`: the timepoints on the curve.
- `n.risk`: In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation.

Author(s)

`survexp`

Description

Returns a list containing the survival curve, confidence limits for the curve, and other information.

Usage

```r
## S3 method for class 'survfit'
summary(object, times, censored=FALSE, scale=1, 
extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

Arguments

- `object`: the result of a call to the `survfit` function.
- `times`: vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If `censored=TRUE`, the default `times` vector contains all the unique times in `fit`, otherwise the default `times` vector uses only the event (death) times.
- `censored`: logical value: should the censoring times be included in the output? This is ignored if the `times` argument is present.
- `scale`: numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, `scale = 365.25` would scale the output to years.
extend
logical value: if TRUE, prints information for all specified times, even if there are no subjects left at the end of the specified times. This is only used if the times argument is present.

rmean
Show restricted mean: see print.survfit for details

... for future methods

Value
a list with the following components:

surv
the estimate of survival at time t+0.
time
the timepoints on the curve.
n.risk
the number of subjects at risk at time t-0 (but see the comments on weights in the survfit help file).
n.event
if the times argument is missing, then this column is the number of events that occurred at time t. Otherwise, it is the cumulative number of events that have occurred since the last time listed until time t+0.
n.entered
This is present only for counting process survival data. If the times argument is missing, this column is the number of subjects that entered at time t. Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time t.
n.exit.censored
if the times argument is missing, this column is the number of subjects that left without an event at time t. Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time t+0. This is only present for counting process survival data.

std.err
the standard error of the survival value.
conf.int
level of confidence for the confidence intervals of survival.
lower
lower confidence limits for the curve.
upper
upper confidence limits for the curve.
strata
indicates stratification of curve estimation. If strata is not NULL, there are multiple curves in the result and the surv, time, n.risk, etc. vectors will contain multiple curves, pasted end to end. The levels of strata (a factor) are the labels for the curves.
call
the statement used to create the fit object.
na.action
same as for fit, if present.
table
table of information that is returned from print.survfit function.
type
type of data censoring. Passed through from the fit object.

Details
This routine has two uses: printing out a survival curve at specified time points (often yearly), or extracting the values at specified time points for further processing. In the first case we normally want extend=FALSE, i.e., don’t print out data past the end of the curve. If the times option only contains values beyond the last point in the curve then there is nothing to print and an error message will result. For the second usage we almost always want extend=TRUE, so that the results will have a predictable length.

The survfit object itself will have a row of information at each censoring or event time, it does not save information on each unique entry time. For printout at two time points t1, t2, this function
Surv will give the number at risk at the smallest event times that are \( \geq t_1 \) and \( \geq t_2 \), respectively, the survival curve at the largest recorded times \( \leq t_1 \) and \( \leq t_2 \), and the number of events and censorings in the interval \( t_1 < t \leq t_2 \).

When the routine is called with counting process data many users are confused by counts that are too large. For example, \( \text{Surv}(c(0,0, 5, 5), c(2, 3, 8, 10), c(1, 0, 1, 0)) \) followed by a request for the values at time 4. The \texttt{survfit} object has entries only at times 2, 3, 8, and 10; there are 2 subjects at risk at time 8, so that is what will be printed.

\end{verbatim}

---

Create a Survival Object

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

Usage

\( \text{Surv}(\text{time}, \text{time2}, \text{event}, \text{type}=c(\text{'right'}, \text{'left'}, \text{'interval'}, \text{'counting'}, \text{'interval2'}, \text{'mstate'}), \text{origin}=0) \)

\textit{is.Surv}(x)

Arguments

- \textit{time} for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.
- \textit{event} The status indicator, normally 0=alive, 1=dead. Other choices are \texttt{TRUE}/\texttt{FALSE} (\texttt{TRUE} = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. For multiple endpoint data the event variable will be a factor, whose first level is treated as censoring. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event.
- \textit{time2} ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, \texttt{(start, end)}. For counting process data, \textit{event} indicates whether an event occurred at the end of the interval.
- \textit{type} character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", "interval2" or "mstate".
for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful.

\(x\) any R object.

**Details**

When the type argument is missing the code assumes a type based on the following rules:

- If there are two unnamed arguments, they will match time and event in that order. If there are three unnamed arguments they match time, time2 and event.
- If the event variable is a factor then type mstate is assumed. Otherwise type right if there is no time2 argument, and type counting if there is.

As a consequence the type argument will normally be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level of the factor is taken to represent censoring and remaining ones a transition to the given state. (If the status variable is a factor then mstate is assumed.)

Interval censored data can be represented in two ways. For the first use type = "interval" and the codes shown above. In that usage the value of the time2 argument is ignored unless event=3. The second approach is to think of each observation as a time interval with (-infinity, t2) for left censored, (t1, infinity) for right censored, (t1, t2) for exact and (t1, t2) for an interval. This is the approach used for type = interval2. Infinite values can be represented either by actual infinity (Inf) or NA. The second form has proven to be the more useful one.

Presently, the only methods allowing interval censored data are the parametric models computed by survreg and survival curves computed by survfit; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for censored data via the condition if (max(status)==2). If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., Surv(time, status==3) would indicate that ‘3’ is the code for an event. For multi-state survival the status variable will be a factor, whose first level is assumed to correspond to censoring.

Surv objects can be subscripted either as a vector, e.g. \(x[1:3]\) using a single subscript, in which case the drop argument is ignored and the result will be a survival object; or as a matrix by using two subscripts. If the second subscript is missing and drop=F (the default), the result of the subscripting will be a Surv object, e.g., \(x[1:3,,drop=F]\), otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

**Value**

An object of class Surv. There are methods for print, is.na, and subscripting survival objects. Surv objects are implemented as a matrix of 2 or 3 columns that has further attributes. These include the type (left censored, right censored, counting process, etc.) and labels for the states for multi-state objects. Any attributes of the input arguments are also preserved in inputAttributes. This may be useful for other packages that have attached further information to data items such as labels; none of the routines in the survival package make use of these values, however.

In the case of is.Surv, a logical value TRUE if \(x\) inherits from class "Surv", otherwise an FALSE.
Note
The use of 1/2 coding for status is an interesting historical artifact. For data contained on punch cards, IBM 360 Fortran treated blank as a zero, which led to a policy within the Mayo Clinic section of Biostatistics to never use "0" as a data value since one could not distinguish it from a missing value. Policy became habit, as is often the case, and the use of 1/2 coding for alive/dead endured long after the demise of the punch cards that had sired the practice. At the time Surv was written many Mayo data sets still used this obsolete convention, e.g., the lung data set found in the package.

rev(x)
## S3 method for class 'Surv'
t(x)
## S3 method for class 'Surv'
tail(x, ...)
## S3 method for class 'Surv'
unique(x, ...)

Arguments

- **x**  
a Surv object
- **probs**  
a vector of probabilities
- **na.rm**  
remove missing values from the calculation
- **value**  
a character vector of up to the same length as x, or NULL
- **...**  
other arguments to the method

Details

These functions extend the standard methods to Surv objects. The arguments and results from these are mostly as expected, with the following further details:

- The as.character function uses "5+" for right censored at time 5, "5-" for left censored at time 5, "[2,7]" for an observation that was interval censored between 2 and 7, "(1,6]" for a counting process data denoting an observation which was at risk from time 1 to 6, with an event at time 6, and "(1,6+]" for an observation over the same interval but not ending with an event. For a multi-state survival object the type of event is appended to the event time using ":type".
- The print and format methods make use of as.character.
- The as.numeric and as.integer methods perform these actions on the survival times, but do not affect the censoring indicator.
- The as.matrix and t methods return a matrix
• The length of a Surv object is the number of survival times it contains, not the number of items required to encode it, e.g., \( x \leftarrow \text{Surv}(1:4, 5:9, c(1,0,1,0)) \); length(x) has a value of 4. Likewise names(x) will be NULL or a vector of length 4. (For technical reasons, any names are actually stored in the rownames attribute of the object.)

• For a multi-state survival object levels returns the names of the endpoints, otherwise it is NULL.

• The median, quantile and plot methods first construct a survival curve using survfit, then apply the appropriate method to that curve.

• The concatenation method \( c() \) is asymmetric, its first argument determines the execution path. For instance \( c(\text{Surv}(1:4), \text{Surv}(5:6)) \) will concatenate the two objects, \( c(\text{Surv}(1:4), 5:6) \) will give an error, and \( c(5:6, \text{Surv}(1:4)) \) is equivalent to \( c(5:6, \text{as.vector}(%23{}\text{Surv}(1:4))) \).

Surv

---

**Surv2**  
*Create a survival object*

**Description**

Create a survival object from a timeline style data set. This will almost always be the response variable in a formula.

**Usage**

`Surv2(time, event, repeated=FALSE)`

**Arguments**

- `time`  
a timeline variable, such as age, time from enrollment, date, etc.
- `event`  
the outcome at that time. This can be a 0/1 variable, TRUE/FALSE, or a factor. If the latter, the first level of the factor corresponds to ‘no event was observed at this time’.
- `repeated`  
if the same level of the outcome repeats, without an intervening event of another type, should this be treated as a new event?

**Details**

This function is still experimental.

When used in a coxph or survfit model, Surv2 acts as a trigger to internally convert a timeline style data set into counting process style data, which is then acted on by the routine.

The repeated argument controls how repeated instances of the same event code are treated. If TRUE, they are treated as new events, an example where this might be desired is repeated infections in a subject. If FALSE, then repeats are not a new event. An example would be a data set where we wanted to use diabetes, say, as an endpoint, but this is repeated at each medical visit.
An object of class Surv2. There are methods for print, is.na and subscripting.

Surv2data, coxph, survfit

Surv2data  Convert data from timecourse to (time1,time2) style

Description
The multi-state survival functions coxph and survfit allow for two forms of input data. This routine converts between them. The function is normally called behind the scenes when Surv2 is as the response.

Usage
Surv2data(formula, data, subset, id)

Arguments
formula  a model formula
data     a data frame
subset   optional, selects rows of the data to be retained
id       a variable that identified multiple rows for the same subject, normally found in the referenced data set

Details
For timeline style data, each row is uniquely identified by an (identifier, time) pair. The time could be a date, time from entry to a study, age, etc, (there may often be more than one time variable). The identifier and time cannot be missing. The remaining covariates represent values that were observed at that time point. Often, a given covariate is observed at only a subset of times and is missing at others. At the time of death, in particular, often only the identifier, time, and status indicator are known.

In the resulting data set missing covariates are replaced by their last known value, and the response y will be a Surv(time1, time2, endpoint) object.

Value
a list with elements
mf     an updated model frame (fewer rows, unchanged columns)
S2.y   the constructed response variable
S2.state the current state for each of the rows
**survcheck**

*Checks of a survival data set*

**Description**

Perform a set of consistency checks on survival data

**Usage**

```r
survcheck(formula, data, subset, na.action, id, istate, istate0="(s0)",
timefix=TRUE,...)
```

**Arguments**

- `formula`: a model formula with a `Surv` object as the response
- `data`: data frame in which to find the `id`, `istate` and `formula` variables
- `subset`: expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
- `na.action`: a missing-data filter function. This is applied to the model frame after any subset argument has been used. Default is `options()$na.action`.
- `id`: an identifier that labels unique subjects
- `istate`: an optional vector giving the current state at the start of each interval
- `istate0`: default label for the initial state of each subject (at their first interval) when `istate` is missing
- `timefix`: process times through the `aeqSurv` function to eliminate potential roundoff issues.
- `...`: other arguments, which are ignored (but won’t give an error if someone added weights for instance)

**Details**

This routine will examine a multi-state data set for consistency of the data. The basic rules are that if a subject is at risk they have to be somewhere, can not be two states at once, and should make sensible transitions from state to state. It reports the number of instances of the following conditions:

- **overlap**: two observations for the same subject that overlap in time, e.g. intervals of (0, 100) and (90, 120). If `y` is simple (time, status) survival observation intervals implicitly start at 0, so in that case any duplicate identifiers will generate an overlap.
- **jump**: a hole in a subject’s timeline, where they are in one state at the end of the prior interval, but a new state in the at the start subsequent interval.
- **gap**: one or more gaps in a subject’s timeline; they are presumably in the same state at their return as when they left.
- **teleport**: two adjacent intervals for a subject, with the first interval ending in one state and the subsequent interval starting in another. They have instantaneously changed states with experiencing a transition.

The total number of occurrences of each is present in the `flags` vector. Optional components give the location and identifiers of the flagged observations.
survcondense

Value

a list with components

- **states**: the vector of possible states
- **transitions**: a matrix giving the count of transitions from one state to another
- **statecount**: table of the number of visits per state, e.g., 18 subjects had 2 visits to the "infection" state
- **flags**: a vector giving the counts of each check
- **istate**: a copy of the istate vector, if it was supplied; otherwise a constructed istate that satisfies all the checks
- **overlap**: a list with the row number and id of overlaps (not present if there are no overlaps)
- **gaps**: a list with the row number and id of gaps (not present if there are no gaps)
- **teleport**: a list with the row number and id of inconsistent rows (not present if there are none)
- **jumps**: a list with the row number and id of jumps (not present if there are no jumps)

Note

For data sets with time-dependent covariates, a given subject will often have intermediate rows with a status of 'no event at this time'. (numeric value of 0). For instance a subject who started in state 1 at time 0, transitioned to state 2 at time 10, had a covariate \( x \) change from 135 to 156 at time 20, and a final transition to state 3 at time 30. The response would be \( \text{Surv}(c(0, 10, 20), c(10, 20, 30), c(2, 0, 3)) \): the status variable records changes in state, and there was no change at time 20. The istate variable would be \((1, 2, 2)\); it contains the current state, and so the value is unchanged when status = censored.

Thus, when there are intermediate observations istate is not simply a lagged version of the status, and may be more challenging to create. One approach is to let survcheck do the work: call it with an istate argument that is correct for the first row of each subject, or no istate argument at all, and then insert the returned value into ones data frame.

survcondense

**Shorten a (timel, time2) survival dataset**

Description

Counting process data sets can sometimes grow to be unwieldy, this can be used to compact one.

Usage

```
survcondense(formula, data, subset, weights, na.action= na.pass, id,
             start = "tstart", end = "tstop", event = "event")
```
Arguments

formula

a formula object, with the response on the left of a ~ operator, and the terms on the right. The response must be a survival object as returned by the Surv function.

data

a data.frame in which to interpret the variables named in the formula and the id argument argument.

subset

optional subset expression to apply to the data set

weights

optional variable name for case weights

na.action

optional removal of missing values

id

variable name that identifies subjects

start

optional character string, giving the name of the start time variable in the result

day

optional character string, giving the name of the stop time variable in the result

event

optional character string, giving the name of the event variable in the result

Details

Through the use of the survSplit and tmerge functions, a counting process data set will gain more and more rows of data. Occasionally it is useful to collapse this surplus back down, e.g., when interest is to be focused on only a few covariates, or for debugging. The right hand side of formula will often have only a few variables, in this use.

If a row of data is censored, and represents the same covariates and identifier as the row below it, then the two rows can be merged together using a single (time1, time2) interval. The compression can sometimes be large.

The start, stop and end options are used when the left hand side of the formula has expressions that are not a simple name, e.g. Surv(time1, time2, death | progression) would be a case where event is used to set the outcome variable’s name.

Value

a data frame

   cut=c(10, 20, 30), id="newid")
dim(test1)

# remove the added rows
test2 <- survcondense(Surv(tstart, time, status) ~ x, test1, id=newid)
dim(test2)
survdiff

Test Survival Curve Differences

Description

Tests if there is a difference between two or more survival curves using the $G^p$ family of tests, or for a single curve against a known alternative.

Usage

survdiff(formula, data, subset, na.action, rho=0, timefix=TRUE)

Arguments

- **formula**: a formula expression as for other survival models, of the form `Surv(time, status) ~ predictors`. For a one-sample test, the predictors must consist of a single `offset(sp)` term, where `sp` is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A `strata` term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `strata` function with its `na.group=T` argument.

- **data**: an optional data frame in which to interpret the variables occurring in the formula.

- **subset**: expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.

- **na.action**: a missing-data filter function. This is applied to the `model.frame` after any subset argument has been used. Default is `options()$na.action`.

- **rho**: a scalar parameter that controls the type of test.

- **timefix**: process times through the `aeqSurv` function to eliminate potential roundoff issues.

Value

A list with components:

- **n**: the number of subjects in each group.
- **obs**: the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum.
- **exp**: the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum.
- **chisq**: the chisquare statistic for a test of equality.
- **var**: the variance matrix of the test.
- **strata**: optionally, the number of subjects contained in each stratum.
- **pvalue**: the p-value corresponding to the Chisquare statistic.
**Description**

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of \( S(t)^\rho \), where \( S(t) \) is the Kaplan-Meier estimate of survival. With \( \rho = 0 \) this is the log-rank or Mantel-Haenszel test, and with \( \rho = 1 \) it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

Peto and Peto show that the Gehan-Wilcoxon test can be badly biased if the two groups have different censoring patterns, and proposed an alternative. Prentice and Marek later showed an actual example where this issue occurs. For most data sets the Gehan-Wilcoxon and Peto-Peto-Prentice variant will hardly differ, however.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument to recode the righthand-side covariate.

**References**

**Examples**

```r
## Two-sample test
survdiff(Surv(futime, fustat) ~ rx, data=ovarian)
```

```r
## Stratified 7-sample test
survdiff(Surv(time, status) ~ pat.karno + strata(inst), data=lung)
```

```r
## Expected survival for heart transplant patients based on
## US mortality tables
expect <- survexp(futime ~ 1, data=jasa, cohort=FALSE,
                 rmap=list(age=(accept.dt - birth.dt), sex=1, year=accept.dt),
                 ratetable=survexp.us)
```

```r
## actual survival is much worse (no surprise)
survdiff(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

```r
# The free light chain data set is close to the population.
e2 <- survexp(futime ~ 1, data=flchain, cohort=FALSE,
              rmap=list(age=age*365.25, sex=sex,
                        year=as.Date(paste0(sample.yr, "-07-01"))),
              ratetable= survexp.mn)
survdiff(Surv(futime, death) ~ offset(e2), flchain)
```

---

**survexp**  
*Compute Expected Survival*
**Description**

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

**Usage**

```r
survexp(formula, data, weights, subset, na.action, rmap, times,
    method=c("ederer", "hakulinen", "conditional", "individual.h",
             "individual.s"),
    cohort=TRUE, conditional=FALSE,
    ratetable=survival::survexp.us, scale=1,
    se.fit, model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

- `formula`: formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the `+` operator (as in `survfit`), and is often `~1`, i.e., expected survival for the entire group.
- `data`: data frame in which to interpret the variables named in the `formula`, `subset` and `weights` arguments.
- `weights`: case weights. This is most useful when conditional survival for a known population is desired, e.g., the data set would contain all unique age/sex combinations and the weights would be the proportion of each.
- `subset`: expression indicating a subset of the rows of `data` to be used in the fit.
- `na.action`: function to filter missing data. This is applied to the model frame after `subset` has been applied. Default is `options()$na.action`.
- `rmap`: an optional list that maps data set names to the ratetable names. See the details section below.
- `times`: vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of times supplied in the response value of the `formula`.
- `method`: computational method for the creating the survival curves. The `individual` option does not create a curve, rather it retrieves the predicted survival `individual.s` or cumulative hazard `individual.h` for each subject. The default is to use `method='ederer'` if the formula has no response, and `method='hakulinen'` otherwise.
- `cohort`: logical value. This argument has been superseded by the `method` argument. To maintain backwards compatibility, if is present and `FALSE`, it implies `method='individual.s'`.
- `conditional`: logical value. This argument has been superseded by the `method` argument. To maintain backwards compatibility, if it is present and `TRUE` it implies `method='conditional'`.
- `ratetable`: a table of event rates, such as `survexp.mn`, or a fitted Cox model. Note the `survival::` prefix in the default argument is present to avoid the (rare) case of a user who expects the default table but just happens to have an object named "survexp.us" in their own directory.
- `scale`: numeric value to scale the results. If `ratetable` is in units/day, `scale = 365.25` causes the output to be reported in years.
survexp

se.fit compute the standard error of the predicted survival. This argument is currently ignored. Standard errors are not a defined concept for population rate tables (they are treated as coming from a complete census), and for Cox models the calculation is hard. Despite good intentions standard errors for this latter case have not been coded and validated.

model,x,y flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.

Details

Individual expected survival is usually used in models or testing, to 'correct' for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study, sex and actual survival time are all known for a group of subjects. The survexp.us population tables contain expected death rates based on calendar year, sex and age. Then

```r
haz <- survexp(fu.time ~ 1, data=mydata,
               rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),
               method='individual.h'))
```

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable fu.time) This probability can be used as a rescaled time value in models:

```r
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)
```

In the first model, a test for intercept=0 is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable x after adjustment for age and sex.

The ratetable being used may have different variable names than the user's data set, this is dealt with by the rmap argument. The rate table for the above calculation was survexp.us, a call to summary(survexp.us) reveals that it expects to have variables age = age in days, sex, and year = the date of study entry, we create them in the rmap line. The sex variable was not mapped, therefore the function assumes that it exists in mydata in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored, for this case no response variable is required in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

Value

if cohort=TRUE an object of class survexp, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time. The cohort survival is the hypothetical survival for a cohort of subjects enrolled from the population at large, but matching the data set on the factors found in the rate table.

Examples

```r
# # Stanford heart transplant data
# # We don't have sex in the data set, but know it to be nearly all males.
# # Estimate of conditional survival
# fit1 <- survexp(futime ~ 1, rmap=list(sex="male", year=accept.dt,
# age=(accept.dt-birth.dt)), method='conditional', data=jasa)
# summary(fit1, times=1:10*182.5, scale=365) #expected survival by 1/2 years
#
# # Estimate of expected survival stratified by prior surgery
# survexp(~ surgery, rmap= list(sex="male", year=accept.dt,
# age=(accept.dt-birth.dt)), method='ederer', data=jasa,
# times=1:10 * 182.5)
#
# ## Compare the survival curves for the Mayo PBC data to Cox model fit
# ## pfit <- coxph(Surv(time,status>0) ~ trt + log(bili) + log(protime) + age +
# platelet, data=pbc)
# plot(survfit(Surv(time, status>0) ~ trt, data=pbc), mark.time=FALSE)
# lines(survexp(~ trt, ratetable=pfit, data=pbc), col='purple')
```

survexp.fit

**Compute Expected Survival**

**Description**

Compute expected survival times.

**Usage**

`survexp.fit(group, x, y, times, death, ratetable)`
**Arguments**

- **group**
  - if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer.

- **x**
  - A matrix whose columns match the dimensions of the `ratetable`, in the correct order.

- **y**
  - the follow up time for each subject.

- **times**
  - the vector of times at which a result will be computed.

- **death**
  - a logical value, if `TRUE` the conditional survival is computed, if `FALSE` the cohort survival is computed. See `survexp` for more details.

- **ratetable**
  - a rate table, such as `survexp.uswhite`.

**Details**

For conditional survival `y` must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate `times` should be a superset of `y`, so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the `times` spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are > .99.

For a subgroup of size 1 and `times > y`, the conditional method reduces to exp(-h) where h is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

**Value**

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

**Warning**

Most users will call the higher level routine `survexp`. Consequently, this function has very few error checks on its input arguments.

**See Also**

- `survexp`, `survexp.us`.

---

**survexp.object  Expected Survival Curve Object**

**Description**

This class of objects is returned by the `survexp` class of functions to represent a fitted survival curve.

Objects of this class have methods for `summary`, and inherit the `print`, `plot`, `points` and `lines` methods from `survfit`. 
survfit

Arguments

surv  the estimate of survival at time t+0. This may be a vector or a matrix.
n.risk the number of subjects who contribute at this time.
time  the time points at which the curve has a step.
std.err the standard error of the cumulative hazard or -log(survival).
strata if there are multiple curves, this component gives the number of elements of the
time etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
method the estimation method used. One of "Ederer", "Hakulinen", or "conditional".
na.action the returned value from the na.action function, if any. It will be used in the
printout of the curve, e.g., the number of observations deleted due to missing
values.
call  an image of the call that produced the object.

Structure

The following components must be included in a legitimate survfit object.

Subscripts

Survexp objects that contain multiple survival curves can be subscripted. This is most often used to
plot a subset of the curves.

Details

In expected survival each subject from the data set is matched to a hypothetical person from the
parent population, matched on the characteristics of the parent population. The number at risk
printed here is the number of those hypothetical subject who are still part of the calculation. In
particular, for the Ederer method all hypotheticals are retained for all time, so n.risk will be a
constant.

survfit  Create survival curves

Description

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously
fitted Cox model, or a previously fitted accelerated failure time model.

Usage

survfit(formula, ...)
**survfit.coxph**

Arguments

- **formula**: either a formula or a previously fitted model
- **...**: other arguments to the specific method

Details

A survival curve is based on a tabulation of the number at risk and number of events at each unique death time. When time is a floating point number the definition of "unique" is subject to interpretation. The code uses factor() to define the set. For further details see the documentation for the appropriate method, i.e., ?survfit.formula or ?survfit.coxph.

A survfit object may contain a single curve, a set of curves (vector), a matrix of curves, or even a 3 way array: dim(fit) will reveal the dimensions. Predicted curves from a coxph model have one row for each stratum in the Cox model fit and one column for each specified covariate set. Curves from a multi-state model have one row for each stratum and a column for each state, the strata correspond to predictors on the right hand side of the equation. The default printing and plotting order for curves is by column, as with other matrices.

Value

An object of class survfit containing one or more survival curves.

Note

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., survfit(Surv(time, status)), in which case the formula argument is not actually a formula. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

**survfit.coxph**

Compute a Survival Curve from a Cox model

Description

Computes the predicted survivor function for a Cox proportional hazards model.
### S3 method for class 'coxph'

survfit(formula, newdata,
  se.fit=TRUE, conf.int=.95, individual=FALSE, stype=2, ctype,
  conf.type=c("log","log-log","plain","none", "logit", "arcsin"),
  censor=TRUE, start.time, id, influence=FALSE,
  na.action=na.pass, type, ...)

### S3 method for class 'coxphms'

survfit(formula, newdata,
  se.fit=FALSE, conf.int=.95, individual=FALSE, stype=2, ctype,
  conf.type=c("log","log-log","plain","none", "logit", "arcsin"),
  censor=TRUE, start.time, id, influence=FALSE,
  na.action=na.pass, type, p0=NULL, ...)

#### Arguments

- **formula**: A coxph object.
- **newdata**: A data frame with the same variable names as those that appear in the coxph formula. One curve is produced per row. The curve(s) produced will be representative of a cohort whose covariates correspond to the values in newdata.
- **se.fit**: a logical value indicating whether standard errors should be computed. Default is TRUE for standard models, FALSE for multi-state (code not yet present for that case.)
- **conf.int**: the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.
- **individual**: deprecated argument, replaced by the general id
- **stype**: computation of the survival curve, 1=direct, 2= exponential of the cumulative hazard.
- **ctype**: whether the cumulative hazard computation should have a correction for ties, 1=no, 2=yes.
- **conf.type**: One of "none", "plain", "log" (the default), "log-log" or "logit". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve +/- k *se(curve), where k is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option uses the log hazard or log(-log(survival)), and the logit log(survival/(1-survival)).
- **censor**: if FALSE time points at which there are no events (only censoring) are not included in the result.
- **id**: optional variable name of subject identifiers. If this is present, it will be search for in the newdata data frame. Each group of rows in newdata with the same subject id represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the coxph fit had strata then that must also be specified in newdata. If newid is not present, then each individual row of newdata is presumed to represent a distinct subject.
- **start.time**: optional starting time, a single numeric value. If present the returned curve contains survival after start.time conditional on surviving to start.time.
- **influence**: option to return the influence values
- **na.action**: the na.action to be used on the newdata argument
Details

This routine produces Pr(state) curves based on a coxph model fit. For single state models it produces the single curve for S(t) = Pr(remain in initial state at time t), known as the survival curve; for multi-state models a matrix giving probabilities for all states. The stype argument states the type of estimate, and defaults to the exponential of the cumulative hazard, better known as the Breslow estimate. For a multi-state Cox model this involves the exponential of a matrix. The argument stype=1 uses a non-exponential or ‘direct’ estimate. For a single endpoint coxph model the code evaluates the Kalbfleisch-Prentice estimate, and for a multi-state model it uses an analog of the Aalen-Johansen estimator. The latter approach is the default in the mstate package.

The ctype option affects the estimated cumulative hazard, and if stype=2 the estimated Pr(state) curves as well. If not present it is chosen so as to be concordant with the ties option in the coxph call. (For multistate coxphms objects only ctype=1 is currently implemented.) Likewise the choice between a model based and robust variance estimate for the curve will mirror the choice made in the coxph call, any clustering is also inherited from the parent model.

If the newdata argument is missing, then a curve is produced for a single "pseudo" subject with covariate values equal to the means component of the fit. The resulting curve(s) almost never make sense, but the default remains due to an unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about equal numbers of observations for each. The “mean” covariate level will be 0.5 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with age*sex. The “mean” value for the age:sex interaction term will be about 30, a value that does not occur in the data. Users are strongly advised to use the newdata argument. For these reasons predictions from a multistate coxph model require the newdata argument.

If the coxph model contained an offset term, then the data set in the newdata argument should also contain that variable.

When the original model contains time-dependent covariates, then the path of that covariate through time needs to be specified in order to obtain a predicted curve. This requires newdata to contain multiple lines for each hypothetical subject which gives the covariate values, time interval, and strata for each line (a subject can change strata), along with an id variable which demarks which rows belong to each subject. The time interval must have the same (start, stop, status) variables as the original model: although the status variable is not used and thus can be set to a dummy value of 0 or 1, it is necessary for the response to be recognized as a Surv object. Last, although predictions with a time-dependent covariate path can be useful, it is very easy to create a prediction that is senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When a model contains strata but no time-dependent covariates the user of this routine has a choice. If newdata argument does not contain strata variables then the returned object will be a matrix of survival curves with one row for each strata in the model and one column for each row in newdata. (This is the historical behavior of the routine.) If newdata does contain strata variables, then the result will contain one curve per row of newdata, based on the indicated stratum of the original model. In the rare case of a model with strata by covariate interactions the strata variable must be included in newdata, the routine does not allow it to be omitted (predictions become too confusing).

(Note that the model Surv(time, status) ~ age*strata(sex) expands internally to strata(sex) + age:sex; the sex variable is needed for the second term of the model.)
See `survfit` for more details about the counts (number of events, number at risk, etc.)

**Value**

an object of class "survfit". See `survfit.object` for details. Methods defined for survfit objects are `print`, `plot`, `lines`, and `points`.

**Notes**

If the following pair of lines is used inside of another function then the `model=TRUE` argument must be added to the coxph call: `fit <- coxph(...); survfit(fit)`. This is a consequence of the non-standard evaluation process used by the `model.frame` function when a formula is involved.

Let \( \log[S(t; z)] \) be the log of the survival curve for a fixed covariate vector \( z \), then \( \log[S(t; x)] = e^{(x-z)\beta} \log[S(t; z)] \) is the log of the curve for any new covariate vector \( x \). There is an unfortunate tendency to refer to the reference curve with \( z = 0 \) as ‘THE’ baseline hazard. However, any \( z \) can be used as the reference point, and more importantly, if \( x - z \) is large the computation can suffer severe roundoff error. It is always safest to provide the desired \( x \) values directly via `newdata`.

**survfit.formula**

*Compute a Survival Curve for Censored Data*

**Description**

Computes an estimate of a survival curve for censored data using the Aalen-Johansen estimator. For ordinary (single event) survival this reduces to the Kaplan-Meier estimate.

**Usage**

```r
## S3 method for class 'formula'
survfit(formula, data, weights, subset, na.action,
    stype=1, ctype=1, id, cluster, robust, istance, timefix=TRUE,
    etype, model=FALSE, error, ...)
```
Arguments

formula

a formula object, which must have a Surv object as the response on the left of
the ~ operator and, if desired, terms separated by + operators on the right. One
of the terms may be a strata object. For a single survival curve the right hand
side should be ~ 1.

data

a data frame in which to interpret the variables named in the formula, subset
and weights arguments.

weights

The weights must be nonnegative and it is strongly recommended that they
be strictly positive, since zero weights are ambiguous, compared to use of the
subset argument.

subset

expression saying that only a subset of the rows of the data should be used in the
fit.

na.action

a missing-data filter function, applied to the model frame, after any subset arg-
ument has been used. Default is options()$na.action.

stype

the method to be used estimation of the survival curve: 1 = direct, 2 =
exp(cumulative hazard).

cctype

the method to be used for estimation of the cumulative hazard: 1 = Nelson-Aalen
formula, 2 = Fleming-Harrington correction for tied events.

id

identifies individual subjects, when a given person can have multiple lines of
data.

cluster

used to group observations for the infinitesimal jackknife variance estimate, de-
defaults to the value of id.

robust

logical, should the function compute a robust variance. For multi-state survival
curves this is true by default. For single state data see details, below.

istate

for multi-state models, identifies the initial state of each subject or observation
timefix

process times through the aeqSurv function to eliminate potential roundoff is-
issues.

etype

a variable giving the type of event. This has been superseded by multi-state Surv
objects and is deprecated; see example below.

model

include a copy of the model frame in the output

error

this argument is no longer used

... The following additional arguments are passed to internal functions called by
survfit.

se.fit

logical value, default is TRUE. If FALSE then standard error computa-
tions are omitted.

conf.type One of "none", "plain", "log" (the default), "log-log", "logit"
or "arcsin". Only enough of the string to uniquely identify it is necessary.
The first option causes confidence intervals not to be generated. The sec-
ond causes the standard intervals curve + k * se(curve), where k is de-
termined from conf.int. The log option calculates intervals based on the
cumulative hazard or log(survival). The log-log option bases the intervals
on the log hazard or log(-log(survival)), the logit option on log(survival)/(1-
survival)) and arcsin on arcsin(survival).

conf.lower a character string to specify modified lower limits to the curve, the
upper limit remains unchanged. Possible values are "usual" (unmodified),
"peto", and "modified". The modified lower limit is based on an "effect-
ive n" argument. The confidence bands will agree with the usual calcula-
tion at each death time, but unlike the usual bands the confidence interval
becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor \( m/n \), where \( n \) is the number currently at risk and \( m \) is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.

The Peto lower limit is based on the same "effective n" argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

**start.time** numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to \( \text{start.time} \).

**conf.int** the level for a two-sided confidence interval on the survival curve(s).

Default is 0.95.

**se.fit** a logical value indicating whether standard errors should be computed. Default is TRUE.

**influence** a logical value indicating whether to return the infinitesimal jackknife (influence) values for each subject. These contain the values of the derivative of each value with respect to the case weights of each subject \( i: \frac{\partial p}{\partial w_i} \), evaluated at the vector of weights. The resulting object will contain influence.surv and influence.chaz components. Alternatively, options of influence=1 or influence=2 will return values for only the survival or hazard curves, respectively.

**p0** this applies only to multi-state curves. An optional vector giving the initial probability across the states. If this is missing, then \( p0 \) is estimated using the frequency of the starting states of all observations at risk at \( \text{start.time} \), or if that is not specified, at the time of the first event.

**type** an older argument that combined stype and ctype, now deprecated. Legal values were "kaplan-meier" which is equivalent to stype=1, ctype=1, "fleming-harrington" which is equivalent to stype=2, ctype=1, and "fh2" which is equivalent to stype=2, ctype=2.

**Details**

If there is a data argument, then variables in the formula, weights, subset, id, cluster and istate arguments will be searched for in that data set.

The routine returns both an estimated probability in state and an estimated cumulative hazard estimate. The cumulative hazard estimate is the Nelson-Aalen (NA) estimate or the Fleming-Harrington (FH) estimate, the latter includes a correction for tied event times. The estimated probability in state can estimated either using the exponential of the cumulative hazard, or as a direct estimate using the Aalen-Johansen approach. For single state data the AJ estimate reduces to the Kaplan-Meier and the probability in state to the survival curve; for competing risks data the AJ reduces to the cumulative incidence (CI) estimator. For backward compatability the type argument can be used instead.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. Currently this algorithm is very slow, only a survival curve is produced, and it does not support a robust variance.

Robust variance: If a robust is TRUE, or for multi-state curves, then the standard errors of the results will be based on an infinitesimal jackknife (IJ) estimate, otherwise the standard model based estimate will be used. For single state curves, the default for robust will be TRUE if one of: there is a cluster argument, there are non-integer weights, or there is a id statement and at least one of the id values has multiple events, and FALSE otherwise. The default represents our best guess about
when one would most often desire a robust variance. When there are non-integer case weights and (time1, time2) survival data the routine is at an impasse: a robust variance likely is called for, but requires either id or cluster information to be done correctly; it will default to robust=FALSE.

One unanticipated side effect of defaulting to a robust variance when there are non-integer case weights is that a fit using interval censored data, which iterates an underlying KM using an updated weight vector, now returns a robust variance by default. Based on Sun (2001) this may be preferred, as the naive estimate ignores the estimation of the weights. The prior behavior can be obtained with robust=FALSE.

With the IJ estimate, the leverage values themselves can be returned as arrays with dimensions: number of subjects, number of unique times, and for a multi-state model, the number of unique states. Be forewarned that these arrays can be huge. If there is a cluster argument this first dimension will be the number of clusters and the variance will be a grouped IJ estimate; this can be an important tool for reducing the size. A numeric value for the influence argument allows finer control: 0= return neither (same as FALSE), 1= return the influence array for probability in state, 2= return the influence array for the cumulative hazard, 3= return both (same as TRUE).

Value

an object of class "survfit". See survfit.object for details. Methods defined for survfit objects are print, plot, lines, and points.

## End(Not run)

survfit.matrix Create Aalen-Johansen estimates of multi-state survival from a matrix of hazards.

Description

This allows one to create the Aalen-Johansen estimate of P, a matrix with one column per state and one row per time, starting with the individual hazard estimates. Each row of P will sum to 1. Note
that this routine has been superseded by the use of multi-state Cox models, and will eventually be removed.

Usage

```r
## S3 method for class 'matrix'
survfit(formula, p0, method = c("discrete", "matexp"),
        start.time, ...)
```

Arguments

- `formula`: a matrix of lists, each element of which is either NULL or a survival curve object.
- `p0`: the initial state vector. The names of this vector are used as the names of the states in the output object. If there are multiple curves then `p0` can be a matrix with one row per curve.
- `method`: use a product of discrete hazards, or a product of matrix exponentials. See details below.
- `start.time`: optional; start the calculations at a given starting point
- `...`: further arguments used by other `survfit` methods

Details

On input the matrix should contain a set of predicted curves for each possible transition, and NULL in other positions. Each of the predictions will have been obtained from the relevant Cox model. This approach for multistate curves is easy to use but has some caveats. First, the input curves must be consistent. The routine checks as best it can, but can easy be fooled. For instance, if one were to fit two Cox models, obtain predictions for males and females from one, and for treatment A and B from the other, this routine will create two curves but they are not meaningful. A second issue is that standard errors are not produced.

The names of the resulting states are taken from the names of the vector of initial state probabilities. If they are missing, then the dimnames of the input matrix are used, and lacking that the labels ‘1’, ‘2’, etc. are used.

For the usual Aalen-Johansen estimator the multiplier at each event time is the matrix of hazards $H$ (also written as $I + dA$). When using predicted survival curves from a Cox model, however, it is possible to get predicted hazards that are greater than 1, which leads to probabilities less than 0. If the `method` argument is not supplied and the input curves are derived from a Cox model this routine instead uses the approximation $\expm(H-I)$ as the multiplier, which always gives valid probabilities. (This is also the standard approach for ordinary survival curves from a Cox model.)

Value

- a `survfitms` object

Note

- The R syntax for creating a matrix of lists is very fussy.

Author(s)

- Terry Therneau
survfit.object

Survival Curve Object

Description

This class of objects is returned by the survfit class of functions to represent a fitted survival curve. For a multi-state model the object has class c('survfitms', 'survfit').

Objects of this class have methods for the functions print, summary, plot, points and lines. The print.survfit method does more computation than is typical for a print method and is documented on a separate page.

Arguments

n total number of subjects in each curve.

time the time points at which the curve has a step.

n.risk the number of subjects at risk at t.

n.event the number of events that occur at time t.

n.enter for counting process data only, and only if there was an id argument, the number of subjects that enter the risk set during the current interval. If there are event/censoring times at 1, 3, 5 for instance, someone who enters at time 1 is counted in the \([1, 3]\) interval, i.e., appears in the row for time 3.

n.censor for counting process data only, the number of subjects who exit the risk set, without an event, at time t. (For right censored data, this number can be computed from the successive values of the number at risk).
	surv the estimate of survival at time t+0. This may be a vector or a matrix. The latter occurs when a set of survival curves is created from a single Cox model, in which case there is one column for each covariate set.

survfit

Examples

etime <- with(mgus2, ifelse(pstat==0, futime, ptime))
event <- with(mgus2, ifelse(pstat==0, 2*death, 1))
event <- factor(event, 0:2, labels=c("censor", "pcm", "death"))

cfit1 <- coxph(Surv(etime, event=="pcm") ~ age + sex, mgus2)
cfit2 <- coxph(Surv(etime, event=="death") ~ age + sex, mgus2)

# predicted competing risk curves for a 72 year old with mspike of 1.2
# (median values), male and female.
# The survfit call is a bit faster without standard errors.
newdata <- expand.grid(sex=c("F", "M"), age=72, mspike=1.2)

AJmat <- matrix(list(), 3,3)
AJmat[1,2] <- list(survfit(cfit1, newdata, std.err=FALSE))
AJmat[1,3] <- list(survfit(cfit2, newdata, std.err=FALSE))

csurv <- survfit(AJmat, p0 = c(entry=1, PCM=0, death=0))
survfit.object

pstate a multi-state survival will have the pstate component instead of surv. It will be a matrix containing the estimated probability of each state at each time, one column per state.

std.err for a survival curve this contains standard error of the cumulative hazard or -log(survival), for a multi-state curve it contains the standard error of prev. This difference is a reflection of the fact that each is the natural calculation for that case.

cumhaz optional. Contains the cumulative hazard for each possible transition.

strata if there are multiple curves, this component gives the number of elements of the time vector corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.

upper optional upper confidence limit for the survival curve or pstate

lower options lower confidence limit for the survival curve or pstate

start.time optional, the starting time for the curve if other than 0

p0, sp0 for a multistate object, the distribution of starting states. If the curve has a strata dimension, this will be a matrix one row per stratum. The sp0 element has the standard error of p0, if p0 was estimated.

newdata for survival curves from a fitted model, this contains the covariate values for the curves

n.all the total number of observations that were available For counting process data, and any time that the start.time argument was used, not all may have been used in creating the curve, in which case this value will be larger than n above. The print and plot routines in the package do no use this value, it is for information only.

conf.type the approximation used to compute the confidence limits.

conf.int the level of the confidence limits, e.g. 90 or 95%.

transitions for multi-state data, the total number of transitions of each type.

na.action the returned value from the na.action function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.

call an image of the call that produced the object.

type type of survival censoring.

influence.p, influence.c optional influence matrices for the pstate (or surv) and for the cumhaz estimates. A list with one element per stratum, each element of the list is an array indexed by subject, time, state.

version the version of the object. Will be missing, 2, or 3

Structure

The following components must be included in a legitimate survfit or survfitsms object.

Subscripts

Survfit objects can be subscripted. This is often used to plot a subset of the curves, for instance. From the user’s point of view the survfit object appears to be a vector, matrix, or array of curves. The first dimension is always the underlying number of curves or “strata”; for multi-state models the state is always the last dimension. Predicted curves from a Cox model can have a second dimension which is the number of different covariate prediction vectors.
Details

The `survfit` object has evolved over time: when first created there was no thought of multi-state models for instance. This evolution has almost entirely been accomplished by the addition of new elements. One change in survival version 3 is the addition of a `survfitconf` routine which will compute confidence intervals for a `survfit` object. This allows the computation of CI intervals to be deferred until later, if desired, rather than making them a permanent part of the object. Later iterations of the base routines may omit the confidence intervals.

The `survfit` object starts at the first observation time, but survival curves are normally plotted from time 0. A helper routine `survfit0` can be used to add this first time point and align the data.

---

**survfit0**

Convert the format of a `survfit` object.

Description

Add the point for a starting time (time 0) to a `survfit` object’s elements. This is useful for plotting.

Usage

```
survfit0(x, start.time=0)
```

Arguments

- `x` a `survfit` object
- `start.time` the desired starting time; see details below.

Details

Survival curves are traditionally plotted forward from time 0, but since the true starting time is not known as a part of the data, the `survfit` routine does not include a time 0 value in the resulting object. Someone might look at cumulative mortgage defaults versus calendar year, for instance, with the ‘time’ value a Date object. The plotted curve probably should not start at 0 = 1970/01/01. Due to this uncertainty, it was decided not to include a “time 0” as part of a `survfit` object. If the original `survfit` call included a `start.time` argument, that value is of course retained.

Whether that (1989) decision was wise or foolish, it is now far too late to change it. (We tried it once as a trial, resulting in over 20 errors in the survival test suite. We extrapolate that it might break 1/2 - 2/3 of the other CRAN packages that depend on survival, if made a default.) If the original `survfit` call included a `start.time` argument, that value is of course retained.

One problem with this choice is that some functions must choose a starting point, plots for example. This utility function is used by `plot.survfit` and `summary.survfit` to do so, adding a new time point at the front of each curve in a consistent way: the optional argument to the `survfit0` function as the first choice (if supplied), then the user’s `start.time` if present, otherwise `min(0, x$time)`. The resulting object is not guaranteed to work with functions that further manipulate a `survfit` object such as subcripting, aggregation, pseudovalues, etc. (remember the 20 errors). Rather it is intended as a penultimate step, most often when creating a plot.
**Value**

A reformulated version of the object with an initial data point at start.time added. The time, surv, pstate, cumhaz, std.err, std.cumhaz and other components will all be aligned, so as to make plots and summaries easier to produce.

**Description**

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a 'data' level rather than a 'user' level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

**Usage**

survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype, vartype, varmat, id, y2, strata2, unlist=TRUE)

**Arguments**

- **y**: the response variable used in the Cox model. (Missing values removed of course.)
- **x**: covariate matrix used in the Cox model
- **wt**: weight vector for the Cox model. If the model was unweighted use a vector of 1s.
- **x2**: matrix describing the hypothetical subjects for which a curve is desired. Must have the same number of columns as x.
- **risk**: the risk score exp(X beta) from the fitted Cox model. If the model had an offset, include it in the argument to exp.
- **newrisk**: risk scores for the hypothetical subjects
- **strata**: strata variable used in the Cox model. This will be a factor.
- **se.fit**: if TRUE the standard errors of the curve(s) are returned
- **survtype**: 1=Kalbfleisch-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for 'exact', N-A for 'breslow' and Efron for 'efron'.
- **vartype**: 1=Greenwood, 2=Aalen, 3=Efron
- **varmat**: the variance matrix of the coefficients
- **id**: optional; if present and not NULL this should be a vector of identifiers of length nrow(x2). A non-null value signifies that x2 contains time dependent covariates, in which case this identifies which rows of x2 go with each subject.
- **y2**: survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of x2. Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however.
- **strata2**: vector of strata indicators for x2. This must be a factor.
- **unlist**: if FALSE the result will be a list with one element for each strata. Otherwise the strata are “unpacked” into the form found in a survfit object.
Value

a list containing nearly all the components of a `survfit` object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a `coxph` object), and the class.

Note

The source code for for both this function and `survfit.coxph` is written using noweb. For complete documentation see the `inst/sourcecode.pdf` file.

`survfit.coxph`

---

**Description**

These functions are temporarily retained for compatability with older programs, and may transition to defunct status.

**Usage**

```r
survConcordance(formula, data, weights, subset, na.action)  # use concordance
survConcordance.fit(y, x, strata, weight)  # use concordancefit
```

**Arguments**

- `formula` a formula object, with the response on the left of a `~` operator, and the terms on the right. The response must be a survival object as returned by the `Surv` function.
- `data` a data frame
- `weights,subset,na.action` as for `coxph`
- `x, y, strata, weight` predictor, response, strata, and weight vectors for the direct call

**See Also**

*Deprecated*
Description

Peter O’Brien’s test for association of a single variable with survival This test is proposed in Bio-
metrics, June 1978.

Usage

survobrien(formula, data, subset, na.action, transform)

Arguments

formula a valid formula for a cox model.
data a data.frame in which to interpret the variables named in the formula, or in the
subset and the weights argument.
subset expression indicating which subset of the rows of data should be used in the fit.
All observations are included by default.
na.action a missing-data filter function. This is applied to the model.frame after any subset
argument has been used. Default is options()$na.action.
transform the transformation function to be applied at each time point. The default is
O’Brien’s suggestion logit(tr) where tr = (rank(x)- 1/2)/ length(x) is the rank
shifted to the range 0-1 and logit(x) = log(x/(1-x)) is the logit transform.

Value

a new data frame. The response variables will be column names returned by the Surv function,
i.e., "time" and "status" for simple survival data, or "start", "stop", "status" for counting process
data. Each individual event time is identified by the value of the variable .strata.. Other variables
retain their original names. If a predictor variable is a factor or is protected with I(), it is retained
as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows that the original data, approximately the original
number of rows * number of deaths/2.

Method

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally
proposed, is equivalent to single variable score tests from the time-dependent model. This equiva-
ience is the rationale for using the time dependent model as a multivariate extension of the original
paper.

In O’Brien’s method, the x variables are re-ranked at each death time. A simpler method, proposed
by Prentice, ranks the data only once at the start. The results are usually similar.

Note

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that
strategy does not work if the original formula has a strata statement. This new data set will be the
same size, but the coxph routine will process it slightly faster.

coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
```

---

**survreg Regression for a Parametric Survival Model**

**Description**

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

**Usage**

```r
survreg(formula, data, weights, subset, na.action, dist="weibull", init=NULL, scale=0,
control parms=NULL, model=FALSE, x=FALSE, y=TRUE, robust=FALSE, cluster, score=FALSE, ...)
```

**Arguments**

- `formula`: a formula expression as for other regression models. The response is usually a survival object as returned by the `Surv` function. See the documentation for `Surv`, `lm` and `formula` for details.
- `data`: a data frame in which to interpret the variables named in the formula, weights or the subset arguments.
- `weights`: optional vector of case weights
- `subset`: subset of the observations to be used in the fit
- `na.action`: a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is `options()$na.action`.
- `dist`: assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from `survreg.distributions`. These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in `survreg.distributions`.
- `parms`: a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.
init optional vector of initial values for the parameters.

scale optional fixed value for the scale. If set to \(\leq 0\) then the scale is estimated.

control a list of control values, in the format produced by \texttt{survreg.control}. The default value is \texttt{survreg.control()}

model, x, y flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.

score return the score vector. (This is expected to be zero upon successful convergence.)

robust Use robust sandwich error instead of the asymptotic formula. Defaults to TRUE if there is a \texttt{cluster} argument.

cluster Optional variable that identifies groups of subjects, used in computing the robust variance. Like \texttt{model} variables, this is searched for in the dataset pointed to by the data argument.

... other arguments which will be passed to \texttt{survreg.control}.

Details

All the distributions are cast into a location-scale framework, based on chapter 2.2 of Kalbfleisch and Prentice. The resulting parameterization of the distributions is sometimes (e.g. gaussian) identical to the usual form found in statistics textbooks, but other times (e.g. Weibull) it is not. See the book for detailed formulas.

When using weights be aware of the difference between replication weights and sampling weights. In the former, a weight of '2' means that there are two identical observations, which have been combined into a single row of data. With sampling weights there is a single observed value, with a weight used to achieve balance with respect to some population. To get proper variance with replication weights use the default variance, for sampling weights use the robust variance. Replication weights were once common (when computer memory was much smaller) but are now rare.

Value

an object of class \texttt{survreg} is returned.

Examples

# Fit an exponential model: the two fits are the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist="weibull",
        scale=1)

survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian,
        dist="exponential")

# # A model with different baseline survival shapes for two groups, i.e.,
# two different scale parameters
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

# There are multiple ways to parameterize a Weibull distribution. The survreg
# function embeds it in a general location-scale family, which is a
# different parameterization than the rweibull function, and often leads
# to confusion.
# survreg's scale = 1/(rweibull shape)
# survreg's intercept = log(rweibull scale)
# For the log-likelihood all parameterizations lead to the same value.
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")

# Economists fit a model called 'tobit regression', which is a standard
# linear regression with Gaussian errors, and left censored data.
tobinfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant, 
data=tobin, dist='gaussian')

---

survreg.control

Package options for survreg and coxph

Description

This function checks and packages the fitting options for survreg

Usage

survreg.control(maxiter=30, rel.tolerance=1e-09, 
toler.chol=1e-10, iter.max, debug=0, outer.max=10)

Arguments

- maxiter: maximum number of iterations
- rel.tolerance: relative tolerance to declare convergence
- toler.chol: Tolerance to declare Cholesky decomposition singular
- iter.max: same as maxiter
- debug: print debugging information
- outer.max: maximum number of outer iterations for choosing penalty parameters

Value

A list with the same elements as the input

See Also

survreg
survreg.distributions  Parametric Survival Distributions

Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf $F$ and density $f$ of a canonical member of the family.

Usage

survreg.distributions

Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

name: name of distribution
variance: function(parms) returning the variance (currently unused)
init(x,weights,...): Function returning an initial estimate of the mean and variance (used for initial values in the iteration)
density(x,parms): Function returning a matrix with columns $F$, $1 - F$, $f$, $f'/f$, and $f''/f$
quantile(p,parms): Quantile function
scale: Optional fixed value for the scale parameter
parms: Vector of default values and names for any additional parameters
deviance(y,scale,parms): Function returning the deviance for a saturated model; used only for deviance residuals.

and to define one distribution in terms of another

name: name of distribution
dist: name of parent distribution
trans: transformation (eg log)
dtrans: derivative of transformation
itrans: inverse of transformation
scale: Optional fixed value for scale parameter

Details

There are four basic distributions: extreme, gaussian, logistic and t. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

$$F = 1 - e^{-e^t}.$$  

When the logarithm of survival time has one of the first three distributions we obtain respectively weibull, lognormal, and loglogistic. The location-scale parameterization of a Weibull distribution found in survreg is not the same as the parameterization of rweibull.
The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of survreg.distributions with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying survreg.distributions a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

Examples

# time transformation
survreg(Surv(time, status) ~ ph.ecog + sex, dist="weibull", data=lung)
# change the transformation to work in years
# intercept changes by log(365), everything else stays the same
my.weibull <- survreg.distributions$weibull
my.weibull$trans <- function(y) log(y/365)
my.weibull$itrans <- function(y) 365*exp(y)
survreg(Surv(time, status) ~ ph.ecog + sex, lung, dist=my.weibull)

# Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y)-1, dist="weibull")
# survreg scale parameter maps to 1/shape, linear predictor to log(scale)

# Cauchy fit
mycauchy <- list(name='Cauchy',
   init= function(x, weights, ...) {c(median(x), mad(x)), density= function(x, parms) {
   temp <- 1/(1 + x^2)
   cbind(.5 + atan(x)/pi, .5+ atan(-x)/pi, temp/pi, -2 *x*temp, 2*temp*(4*x^2*temp -1))},
   quantile= function(p, parms) tan((p-.5)*pi),
   deviance= function(...) stop('deviance residuals not defined'))
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)
COMPONENTS

The following components must be included in a legitimate survreg object.

**coefficients** the coefficients of the linear.predictors, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

**icoef** coefficients of the baseline model, which will contain the intercept and log(scale), or multiple scale factors for a stratified model.

**var** the variance-covariance matrix for the parameters, including the log(scale) parameter(s).

**loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.

**iter** the number of iterations required

**linear.predictors** the linear predictor for each subject.

**df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

**scale** the scale factor(s), with length equal to the number of strata.

**idf** degrees of freedom for the initial model.

**means** a vector of the column means of the coefficient matrix.

**dist** the distribution used in the fit.

**weights** included for a weighted fit.

The object will also have the following components found in other model results (some are optional): linear.predictors, weights, x, y, model, call, terms and formula. See `lm`.

---

**survregDtest** Verify a survreg distribution

Description

This routine is called by survreg to verify that a distribution object is valid.

Usage

survregDtest(dlist, verbose = F)

Arguments

dlist the list describing a survival distribution

verbose return a simple TRUE/FALSE from the test for validity (the default), or a verbose description of any flaws.
survSplit

Split a survival data set at specified times

Description

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

Usage

```
survSplit(formula, data, subset, na.action=na.pass, 
cut, start="tstart", id, zero=0, episode, 
end="tstop", event="event")
```

Details

If the `survreg` function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

Value

TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

Author(s)

Terry Therneau

See Also

`survreg.distributions`, `survreg`

Examples

```r
# An invalid distribution (it should have "init =" on line 2)
# survreg would give an error message
mycauchy <- list(name='Cauchy',
    init<- function(x, weights, ...)
        c(median(x), mad(x)),
    density= function(x, parms) {
        temp <- 1/(1 + x^2)
        cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
            temp/pi, -2 *x*temp, 2*temp^2*(4*x^2*temp -1))
    },
    quantile= function(p, parms) tan((p-.5)*pi),
    deviance= function(...) stop('deviance residuals not defined')
)
survregDtest(mycauchy, TRUE)
```
Arguments

- **formula**: a model formula
- **data**: a data frame
- **subset, na.action**: rows of the data to be retained
- **cut**: the vector of timepoints to cut at
- **start**: character string with the name of a start time variable (will be created if needed)
- **id**: character string with the name of new id variable to create (optional). This can be useful if the data set does not already contain an identifier.
- **zero**: If start doesn’t already exist, this is the time that the original records start.
- **episode**: character string with the name of new episode variable (optional)
- **end**: character string with the name of event time variable
- **event**: character string with the name of censoring indicator

Details

Each interval in the original data is cut at the given points; if an original row were (15, 60] with a cut vector of (10,30, 40) the resulting data set would have intervals of (15,30], (30,40] and (40, 60]. Each row in the final data set will lie completely within one of the cut intervals. Which interval for each row of the output is shown by the episode variable, where 1= less than the first cutpoint, 2= between the first and the second, etc. For the example above the values would be 2, 3, and 4.

The routine is called with a formula as the first argument. The right hand side of the formula can be used to delimit variables that should be retained; normally one will use ~ . as a shorthand to retain them all. The routine will try to retain variable names, e.g. Surv(adam, joe, fred)~. will result in a data set with those same variable names for tstart, end, and event options rather than the defaults. Any user specified values for these options will be used if they are present, of course. However, the routine is not sophisticated; it only does this substitution for simple names. A call of Surv(time, stat==2) for instance will not retain “stat” as the name of the event variable.

Rows of data with a missing time or status are copied across unchanged, unless the na.action argument is changed from its default value of na.pass. But in the latter case any row that is missing for any variable will be removed, which is rarely what is desired.

Value

New, longer, data frame.

Surv, cut, reshape

Examples

```r
fit1 <- coxph(Surv(time, status) ~ karno + age + trt, veteran)
plot(cox.zph(fit1)[1])
# a cox.zph plot of the data suggests that the effect of Karnofsky score
# begins to diminish by 60 days and has faded away by 120 days.
# Fit a model with separate coefficients for the three intervals.
#
vet2 <- survSplit(Surv(time, status) ~., veteran,
  cut=c(60, 120), episode ="timegroup")
```
fit2 <- coxph(Surv(tstart, time, status) ~ karno* strata(timegroup) + age + trt, data= vet2)
c(overall= coef(fit1)[1],
t0_60 = coef(fit2)[1],
t60_120= sum(coef(fit2)[c(1,4)]),
t120 = sum(coef(fit2)[c(1,5)]))

**tcut**

Factors for person-year calculations

Description

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

Usage

```r
tcut(x, breaks, labels, scale=1)
```

## S3 method for class 'tcut'

```r
levels(x)
```

Arguments

- `x` numeric/date variable
- `breaks` breaks between categories, which are right-continuous
- `labels` labels for categories
- `scale` Multiply `x` and `breaks` by this.

Value

An object of class `tcut`

See Also

`cut`, `pyears`

Examples

# For pyears, all time variable need to be on the same scale; but # futime is in months and age is in years test <- mgus2

test$years <- test$futime/30.5  # follow-up in years

# first grouping based on years from starting age (= current age) # second based on years since enrollment (all start at 0)
test$agegrp <- tcut(test$age, c(0,60, 70, 80, 100),
c("<=60", "60-70", "70-80", ">80")
test$fgrp <- tcut(rep(0, nrow(test)), c(0, 1, 5, 10, 100),
c("0-1yr", "1-5yr", "5-10yr", ">10yr")

# death rates per 1000, by age group
pfit1 <- pyears(Surv(years, death) ~ agegrp, scale =1000, data=test)
round(pfit1$event/ pfit1$pyears)
# Death rates per 100, by follow-up year and age
# There are excess deaths in the first year, within each age stratum
pfit2 <- pyears(Surv(years, death) ~ fgrp + agegrp, scale = 1000, data = test)
round(pfit2$event / pfit2$pyears)

---

**tmerge**

**Time based merge for survival data**

**Description**

A common task in survival analysis is the creation of start, stop data sets which have multiple intervals for each subject, along with the covariate values that apply over that interval. This function aids in the creation of such data sets.

**Usage**

```r
tmerge(data1, data2, id, ..., tstart, tstop, options)
```

**Arguments**

- `data1`: the primary data set, to which new variables and/or observation will be added
- `data2`: second data set in which all the other arguments will be found
- `id`: subject identifier
- `...`: operations that add new variables or intervals, see below
- `tstart`: optional variable to define the valid time range for each subject, only used on an initial call
- `tstop`: optional variable to define the valid time range for each subject, only used on an initial call
- `options`: a list of options. Valid ones are idname, tstartname, tstopname, delay, na.rm, and tdcstart. See the explanation below.

**Details**

The program is often run in multiple passes, the first of which defines the basic structure, and subsequent ones that add new variables to that structure. For a more complete explanation of how this routine works refer to the vignette on time-dependent variables.

There are 4 types of operational arguments: a time dependent covariate (tdc), cumulative count (cumtdc), event (event) or cumulative event (cumevent). Time dependent covariates change their values before an event, events are outcomes.

- `newname = tdc(y, x, init)` A new time dependent covariate variable will created. The argument `y` is assumed to be on the scale of the start and end time, and each instance describes the occurrence of a "condition" at that time. The second argument `x` is optional. In the case where `x` is missing the count variable starts at 0 for each subject and becomes 1 at the time of the event. If `x` is present the value of the time dependent covariate is initialized to value of `init`, if present, or the tdcstart option otherwise, and is updated to the value of `x` at each observation. If the option na.rm=TRUE missing values of `x` are first removed, i.e., the update will not create missing values.
newname = cumtdc(y,x, init) Similar to tdc, except that the event count is accumulated over time for each subject. The variable x must be numeric.

newname = event(y,x) Mark an event at time y. In the usual case that x is missing the new 0/1 variable will be similar to the 0/1 status variable of a survival time.

newname = cumevent(y,x) Cumulative events.

The function adds three new variables to the output data set: tstart, tstop, and id. The options argument can be used to change these names. If, in the first call, the id argument is a simple name, that variable name will be used as the default for the idname option. If data1 contains the tstart variable then that is used as the starting point for the created time intervals, otherwise the initial interval for each id will begin at 0 by default. This will lead to an invalid interval and subsequent error if say a death time were <= 0.

The na.rm option affects creation of time-dependent covariates. Should a data row in data2 that has a missing value for the variable be ignored or should it generate an observation with a value of NA? The default of TRUE causes the last non-missing value to be carried forward. The delay option causes a time-dependent covariate’s new value to be delayed, see the vignette for an example.

Value

a data frame with two extra attributes tm.retain and tcount. The first contains the names of the key variables, and which names correspond to tdc or event variables. The tcount variable contains counts of the match types. New time values that occur before the first interval for a subject are "early", those after the last interval for a subject are "late", and those that fall into a gap are of type "gap". All these are are considered to be outside the specified time frame for the given subject. An event of this type will be discarded. An observation in data2 whose identifier matches no rows in data1 is of type "missid" and is also discarded. A time-dependent covariate value will be applied to later intervals but will not generate a new time point in the output.

The most common type will usually be "within", corresponding to those new times that fall inside an existing interval and cause it to be split into two. Observations that fall exactly on the edge of an interval but within the (min, max] time for a subject are counted as being on a "leading" edge, "trailing" edge or "boundary". The first corresponds for instance to an occurrence at 17 for someone with an intervals of (0,15] and (17, 35]. A tdc at time 17 will affect this interval but an event at 17 would be ignored. An event occurrence at 15 would count in the (0,15] interval. The last case is where the main data set has touching intervals for a subject, e.g. (17, 28] and (28,35] and a new occurrence lands at the join. Events will go to the earlier interval and counts to the latter one. A last column shows the number of additions where the id and time point were identical. When this occurs, the tdc and event operators will use the final value in the data (last edit wins), but ignoring missing, while cumtdc and cumevent operators add up the values.

These extra attributes are ephemeral and will be discarded if the data frame is modified. This is intentional, since they will become invalid if for instance a subset were selected.

# The pbc data set contains baseline data and follow-up status
# for a set of subjects with primary biliary cirrhosis, while the
The `tobin` data set contains repeated laboratory values for those subjects.

The first data set contains data on 312 subjects in a clinical trial plus 106 that agreed to be followed off protocol, the second data set has data only on the trial subjects.

```r
temp <- subset(pbc, id <= 312, select=c(id:sex, stage))  # baseline data
pbc2 <- tmerge(temp, temp, id=id, endpt = event(time, status))
pbc2 <- tmerge(pbc2, pbcseq, id=id, ascites = tdc(day, ascites),
               bili = tdc(day, bili), albumin = tdc(day, albumin),
               protime = tdc(day, protime), alk.phos = tdc(day, alk.phos))
fit <- coxph(Surv(tstart, tstop, endpt==2) ~ protime + log(bili), data=pbc2)
```

---

tobin

### Tobin’s Tobit data

#### Description

Economists fit a parametric censored data model called the ‘tobit’. These data are from Tobin’s original paper.

#### Usage

```r
tobin
data(tobin, package="survival")
```

#### Format

A data frame with 20 observations on the following 3 variables.

- **durable**: Durable goods purchase
- **age**: Age in years
- **quant**: Liquidity ratio (x 1000)

#### Source

#### Examples

```r
tfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
data=tobin, dist='gaussian')
predict(tfit,type='response')
```
transplant  

**Liver transplant waiting list**

**Description**

Subjects on a liver transplant waiting list from 1990-1999, and their disposition: received a transplant, died while waiting, withdrew from the list, or censored.

**Usage**

```r
transplant
data(transplant, package="survival")
```

**Format**

A data frame with 815 (transplant) observations on the following 6 variables.

- **age**: age at addition to the waiting list
- **sex**: m or f
- **abo**: blood type: A, B, AB or O
- **year**: year in which they entered the waiting list
- **futime**: time from entry to final disposition
- **event**: final disposition: censored, death, ltx or withdraw

**Details**

This represents the transplant experience in a particular region, over a time period in which liver transplant became much more widely recognized as a viable treatment modality. The number of liver transplants rises over the period, but the number of subjects added to the liver transplant waiting list grew much faster. Important questions addressed by the data are the change in waiting time, who waits, and whether there was an consequent increase in deaths while on the list.

Blood type is an important consideration. Donor livers from subjects with blood type O can be used by patients with A, B, AB or O blood types, whereas an AB liver can only be used by an AB recipient. Thus type O subjects on the waiting list are at a disadvantage, since the pool of competitors is larger for type O donor livers.

This data is of historical interest and provides a useful example of competing risks, but it has little relevance to current practice. Liver allocation policies have evolved and now depend directly on each individual patient’s risk and need, assessments of which are regularly updated while a patient is on the waiting list. The overall organ shortage remains acute, however.

The `transplant` data set was a version used early in the analysis, `transplant2` has several additions and corrections, and was the final data set and matches the paper.

**References**

Examples

# since event is a factor, survfit creates competing risk curves
pfit <- survfit(Surv(futime, event) ~ abo, transplant)
pfit[,2] # time to liver transplant, by blood type

     xscale=30.5, xlab="Months", ylab="Fraction transplanted",
     xaxt = 'n')
temp <- c(0, 6, 12, 18, 24)
axis(1, temp*30.5, temp)
legend(450, .35, levels(transplant$abo), lty=1, col=1:4, lwd=2)

# competing risks for type O
plot(pfit[4,], xscale=30.5, xmax=735, col=1:3, lwd=2)
legend(450, .4, c("Death", "Transplant", "Withdrawal"), col=1:3, lwd=2)

udca

Data from a trial of Ursodeoxycholic acid

Description

Data from a trial of ursodeoxycholic acid (UDCA) in patients with primary biliary cirrhosis (PBC).

Usage

udca
udca2
data(udca, package="survival")

Format

A data frame with 170 observations on the following 15 variables.

id subject identifier
trt treatment of 0=placebo, 1=UDCA
entry.dt date of entry into the study
last.dt date of last on-study visit
stage stage of disease
bili bilirubin value at entry
riskscore the Mayo PBC risk score at entry
death.dt date of death
tx.dt date of liver transplant
hprogress.dt date of histologic progression
varices.dt appearance of esophageal varices
ascites.dt appearance of ascites
enceph.dt appearance of encephalopathy
double.dt doubling of initial bilirubin
worsen.dt worsening of symptoms by two stages
Details

This data set is used in the Therneau and Grambsch. The udca1 data set contains the baseline variables along with the time until the first endpoint (any of death, transplant, . . . , worsening). The udca2 data set treats all of the endpoints as parallel events and has a stratum for each.

References

Examples

# values found in table 8.3 of the book
fit1 <- coxph(Surv(futime, status) ~ trt + log(bili) + stage,
              cluster =id , data=udca1)
fit2 <- coxph(Surv(futime, status) ~ trt + log(bili) + stage +
              strata(endpoint), cluster=id, data=udca2)

untangle.specials

Help Process the ‘specials’ Argument of the ‘terms’ Function.

Description

Given a terms structure and a desired special name, this returns an index appropriate for subscripting the terms structure and another appropriate for the data frame.

Usage

untangle.specials(tt, special, order=1)

Arguments

- **tt**: a terms object.
- **special**: the name of a special function, presumably used in the terms object.
- **order**: the order of the desired terms. If set to 2, interactions with the special function will be included.

Value

A list with two components:

- **vars**: a vector of variable names, as would be found in the data frame, of the specials.
- **terms**: a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special.
Examples

```r
formula <- Surv(tt,ss) ~ x + z*strata(id)
tms <- terms(formula, specials="strata")
## the specials attribute
attr(tms, "specials")
## main effects
untangle.specials(tms, "strata")
## and interactions
untangle.specials(tms, "strata", order=1:2)
```

---

### uspop2

**Projected US Population**

**Description**

US population by age and sex, for 2000 through 2020

**Format**

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

**Details**

This data is often used as a "standardized" population for epidemiology studies.

**Source**

**See Also**

`uspop`

**Examples**

```r
us50 <- uspop2[51:101,, "2000"]  # US 2000 population, 50 and over
age <- as.integer(dimnames(us50)[[1]])
smat <- model.matrix(~ factor(floor(age/5)) -1)
ustot <- t(smat) %*% us50  # totals by 5 year age groups
temp <- c(50,55, 60, 65, 70, 75, 80, 85, 90, 95)
dimnames(ustot) <- list(c(paste(temp, temp+4, sep="-"), "100+"),
                       c("male", "female"))
```
vcov.coxph  Variance-covariance matrix

Description

Extract and return the variance-covariance matrix.

Usage

## S3 method for class 'coxph'
vcov(object, complete=TRUE, ...)
## S3 method for class 'survreg'
vcov(object, complete=TRUE, ...)

Arguments

- object  a fitted model object
- complete  logical indicating if the full variance-covariance matrix should be returned.
  This has an effect only for an over-determined fit where some of the coefficients are undefined, and coef(object) contains corresponding NA values. If complete=TRUE the returned matrix will have row/column for each coefficient, if FALSE it will contain rows/columns corresponding to the non-missing coefficients. The coef() function has a similar complete argument.
- ...  additional arguments for method functions

Details

For the coxph and survreg functions the returned matrix is a particular generalized inverse: the row and column corresponding to any NA coefficients will be zero. This is a side effect of the generalized cholesky decomposition used in the underlying computation.

Value

a matrix

veteran  Veterans’ Administration Lung Cancer study

Description

xtfrm.Surv | Sorting order for Surv objects

Description

Sort survival objects into a partial order, which is the same one used internally for many of the calculations.

Usage

```r
## S3 method for class 'Surv'
xtfrm(x)
```

Arguments

- `x`: a `Surv` object

Details

This creates a partial ordering of survival objects. The result is sorted in time order, for tied pairs of times right censored events come after observed events (censor after death), and left censored events are sorted before observed events. For counting process data (`tstart, tstop, status`) the ordering is by stop time, status, and start time, again with censoring last. Interval censored data is sorted using the midpoint of each interval.

The `xtfrm` routine is used internally by `order` and `sort`, so these results carry over to those routines.

Value

A vector of integers which will have the same sort order as `x`.

Author(s)

Terry Therneau
See Also

sort, order

Examples

test <- c(Surv(c(10, 9, 9, 8, 8, 7, 5, 5, 4), rep(1:0, 5)), Surv(6.2, NA))
test
sort(test)

yates Population prediction

Description

Compute population marginal means (PMM) from a model fit, for a chosen population and statistic.

Usage

yates(fit, term, population = c("data", "factorial", "sas"),
levels, test = c("global", "trend", "pairwise"), predict = "linear",
options, nsim = 200, method = c("direct", "sgtt"))

Arguments

fit a model fit. Examples using lm, glm, and coxph objects are given in the vignette.
term the term from the model whic is to be evaluated. This can be written as a character string or as a formula.
population the population to be used for the adjusting variables. User can supply their own data frame or select one of the built in choices. The argument also allows "empirical" and "yates" as aliases for data and factorial, respectively, and ignores case.
levels optional, what values for term should be used.
test the test for comparing the population predictions.
predict what to predict. For a glm model this might be the 'link' or 'response'. For a coxph model it can be linear, risk, or survival. User written functions are allowed.
options optional arguments for the prediction method.
nsim number of simulations used to compute a variance for the predictions. This is not needed for the linear predictor.
method the computational approach for testing equality of the population predictions. Either the direct approach or the algorithm used by the SAS glim procedure for "type 3" tests.

Details

The many options and details of this function are best described in a vignette on population prediction.
Value

an object of class `yates` with components of

- **estimate**
  a data frame with one row for each level of the term, and columns containing the level, the mean population predicted value (mppv) and its standard deviation.

- **tests**
  a matrix giving the test statistics

- **mvar**
  the full variance-covariance matrix of the mppv values

- **summary**
  optional: any further summary if the values provided by the prediction method.

Author(s)

Terry Therneau

Examples

```r
fit1 <- lm(skips ~ Solder*Opening + Mask, data = solder)
yates(fit1, ~Opening, population = "factorial")

fit2 <- coxph(Surv(time, status) ~ factor(ph.ecog)*sex + age, lung)
yates(fit2, ~ ph.ecog, predict="risk") # hazard ratio
```

Description

This is a method which is called by the `yates` function, in order to setup the code to handle a particular model type. Methods for glm, coxph, and default are part of the survival package.

Usage

```r
yates_setup(fit, 
```

Arguments

- **fit**
  a fitted model object

- **...**
  optional arguments for some methods

Details

If the predicted value should be the linear predictor, the function should return NULL. The `yates` routine has particularly efficient code for this case. Otherwise it should return a prediction function or a list of two elements containing the prediction function and a summary function. The prediction function will be passed the linear predictor as a single argument and should return a vector of predicted values.

Note

See the vignette on population prediction for more details.
