Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.
as.matrix.corStruct

Usage

## S3 method for class 'corStruct'
as.matrix(x, ...)  

Arguments

x an object inheriting from class corStruct, representing a correlation structure.

... further arguments passed from other methods.

Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

AsTable

Bioassay on Cell Culture Plate

Description

The Assay data frame has 60 rows and 4 columns.

Format

This data frame contains the following columns:

- **Block**: an ordered factor with levels 2 < 1 identifying the block where the wells are measured.
- **sample**: a factor with levels a to f identifying the sample corresponding to the well.
- **dilut**: a factor with levels 1 to 5 indicating the dilution applied to the well.
- **logDens**: a numeric vector of the log-optical density.

Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

Source

asTable

Convert groupedData to a matrix

Description

Create a tabular representation of the response in a balanced groupedData object.

Usage

asTable(object)

Arguments

- **object**: A balanced groupedData object
A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Predicted values are obtained at the specified values of primary. If object has a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. If level has more than one element, predictions are obtained for each level of the max(level) grouping factor. If other covariates besides primary are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

```r
augPred(object, primary, minimum, maximum, length.out, ...)  # S3 method for class 'lme'
```

```r
groupedData, isBalanced, balancedGrouped
```
Arguments

object  a fitted model object from which predictions can be extracted, using a predict method.
primary  an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate object (using getCovariate), it will be used as primary.
minimum  an optional lower limit for the primary covariate. Defaults to min(primary).
maximum  an optional upper limit for the primary covariate. Defaults to max(primary).
length.out  an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
level  an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

...  some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: original for the observed values and predicted (single or no grouping factor) or predict.groupVar (multiple levels of grouping), with groupVar replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class "augPred".

Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

balancedGrouped

Create a groupedData object from a matrix

Description
Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

Usage

balancedGrouped(form, data, labels=NULL, units=NULL)

Arguments

form  
A formula of the form \( y \sim x | g \) giving the name of the response, the primary covariate, and the grouping factor.

data  
A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate.

labels  
an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named \( x \) and that for the response is named \( y \). Either label can be omitted.

units  
an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named \( x \) and that for the response is named \( y \). Either units string can be omitted.

Value
A balanced groupedData object.

**bdf**

**Language scores**

**Description**

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

**Usage**

data(bdf)

**Format**

- schoolNR: a factor denoting the school.
- pupilNR: a factor denoting the pupil.
- IQ.verb: a numeric vector of verbal IQ scores
- IQ.perf: a numeric vector of IQ scores.
- sex: Sex of the student.
- Minority: a factor indicating if the student is a member of a minority group.
- repeatgr: an ordered factor indicating if one or more grades have been repeated.
- aritPRET: a numeric vector
- classNR: a numeric vector
- aritPOST: a numeric vector
- langPRET: a numeric vector
- langPOST: a numeric vector
- ses: a numeric vector of socioeconomic status indicators.
- denomina: a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.
- schoolSES: a numeric vector
- satiprin: a numeric vector
- natitest: a factor with levels 0 and 1
- meetings: a numeric vector
- currmeet: a numeric vector
- mixedgra: a factor indicating if the class is a mixed-grade class.
- percmino: a numeric vector
- aritdiff: a numeric vector
- homework: a numeric vector
- classsiz: a numeric vector
- groupsiz: a numeric vector

<table>
<thead>
<tr>
<th>BodyWeight</th>
<th>Rat weight over time for different diets</th>
</tr>
</thead>
</table>

**Description**

The BodyWeight data frame has 176 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **weight**: a numeric vector giving the body weight of the rat (grams).
- **Time**: a numeric vector giving the time at which the measurement is made (days).
- **Rat**: an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.
- **Diet**: a factor with levels 1 to 3 indicating the diet that the rat receives.

**Details**

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before "day 1." There are three groups of rats, each on a different diet.

Cefamandole  Pharmacokinetics of Cefamandole

Description
The Cefamandole data frame has 84 rows and 3 columns.

Format
This data frame contains the following columns:

- **Subject** a factor giving the subject from which the sample was drawn.
- **Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).
- **conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

Details
Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

summary(fml)
```

Assign Values to Coefficients

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "pdMat", "corStruct" and "varFunc" classes, "reStruct", and "modelStruct".

Usage
```
coef(object, ...) <- value
```
coef.corStruct

Arguments

object: any object representing a fitted model, or, by default, any object with a \texttt{coef} component.

...: some methods for this generic function may require additional arguments.

value: a value to be assigned to the coefficients associated with \texttt{object}.

Value

will depend on the method function; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{coef}

Examples

## see the method function documentation

---

\texttt{coef.corStruct} \hspace{1cm} \textit{Coefficients of a corStruct Object}

Description

This method function extracts the coefficients associated with the correlation structure represented by \texttt{object}.

Usage

## S3 method for class 'corStruct'
coef(object, unconstrained, ...)

## S3 replacement method for class 'corStruct'
coef(object, ...) <- value

Arguments

object: an object inheriting from class "\texttt{corStruct}"$, representing a correlation structure.

unconstrained: a logical value. If \texttt{TRUE} the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If \texttt{FALSE} the coefficients are returned in "natural", possibly constrained, form. Defaults to \texttt{TRUE}.

value: a vector with the replacement values for the coefficients associated with \texttt{object}. It must be a vector with the same length of \texttt{coef(object)} and must be given in unconstrained form.

...: some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using Initialize) before new values can be assigned to its coefficients.

Author(s)

José Pinheiro and Douglas Bates

cst1 <- corARMA(p = 1, q = 1)
coef(cst1)

coef.gnls

Extract gnls Coefficients

Description

The estimated coefficients for the nonlinear model represented by object are extracted.

Usage

## S3 method for class 'gnls'
coef(object, ...)

Arguments

object

an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the estimated coefficients for the nonlinear model represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
The estimated coefficients at level \( i \) are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to \( i \). The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

**Usage**

```r
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
     omitGroupingFactor, subset, ...)
```

**Arguments**

- `object` an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `augFrame` an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `level` an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
- `data` an optional data frame with the variables to be used for augmenting the returned data frame when `augFrame = TRUE`. Defaults to the data frame used to fit object.
- `which` an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
- `FUN` an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both factor and ordered. The `Mode` function,
defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor
an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset
an optional expression specifying a subset

... some methods for this generic require additional arguments. None are used in this method.

Value
a data frame inheriting from class "coef.lme" with the estimated coefficients at level level and, optionally, other covariates summarized over groups. The returned object also inherits from classes "ranef.lme" and "data.frame".

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

describe
Arguments

object
an object inheriting from class "lmList", representing a list of lm objects with
a common model.

augFrame
an optional logical value. If TRUE, the returned data frame is augmented with
variables defined in the data frame used to produce object; else, if FALSE, only
the coefficients are returned. Defaults to FALSE.

data
an optional data frame with the variables to be used for augmenting the returned
data frame when augFrame = TRUE. Defaults to the data frame used to fit object.

which
an optional positive integer or character vector specifying which columns of the
data frame used to produce object should be used in the augmentation of the
returned data frame. Defaults to all variables in the data.

FUN
an optional summary function or a list of summary functions to be applied to
group-varying variables, when collapsing the data by groups. Group-invariant
variables are always summarized by the unique value that they assume within
that group. If FUN is a single function it will be applied to each non-invariant
variable by group to produce the summary for that variable. If FUN is a list
of functions, the names in the list should designate classes of variables in the
frame such as ordered, factor, or numeric. The indicated function will be
applied to any group-varying variables of that class. The default functions to
be used are mean for numeric factors, and Mode for both factor and ordered.
The Mode function, defined internally in gsummary, returns the modal or most
popular value of the variable. It is different from the mode function that returns
the S-language mode of the variable.

omitGroupingFactor
an optional logical value. When TRUE the grouping factor itself will be omitted
from the group-wise summary of data but the levels of the grouping factor will
continue to be used as the row names for the returned data frame. Defaults to
FALSE.

...some methods for this generic require additional arguments. None are used in
this method.

Value

a data frame inheriting from class "coef.lmList" with the estimated coefficients for each "lm"
component of object and, optionally, other covariates summarized over the groups correspond-
ing to the "lm" components. The returned object also inherits from classes "ranef.lmList" and
"data.frame".

Examples

```r
fm1 <- lmList(distance ~ age|Subject, data = Orthodont)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

### Description

This method function extracts the coefficients associated with each component of the `modelStruct` list.

### Usage

```r
## S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

### Arguments

- `object`: an object inheriting from class "modelStruct", representing a list of model components, such as "corStruct" and "varFunc" objects.
- `unconstrained`: a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...`: some methods for this generic require additional arguments. None are used in this method.

### Value

A vector with all coefficients corresponding to the components of `object`.

### SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

### Author(s)

### coef.pdMat

**pdMat Object Coefficients**

**Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

**Usage**

```r
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

**Arguments**

- `object`: an object inheriting from class "pdMat", representing a positive-definite matrix.
- `unconstrained`: a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to TRUE.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

coef(vf1) <- 2
```

Description

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a groupedData method is available.

Usage

```r
collapse(object, ...)
```

Arguments

- `object` an object to be collapsed, usually a data frame.
- `...` some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `collapse.groupedData`

Examples

```r
## see the method function documentation
```
collapse.groupedData  

Collapse a groupedData Object

Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

Usage

```r
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel, 
    outer, inner, preserve, FUN, subset, ...)
```

Arguments

- `object`: an object inheriting from class groupedData, generally with multiple grouping factors.
- `collapseLevel`: an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
- `displayLevel`: an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is `collapseLevel`.
- `outer`: an optional logical value or one-sided formula, indicating covariates that are outer to the `displayLevel` grouping factor. If equal to `TRUE`, the `displayLevel` element `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.
- `inner`: an optional logical value or one-sided formula, indicating a covariate that is inner to the `displayLevel` grouping factor. If equal to `TRUE`, `attr(object, "outer")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.
- `preserve`: an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the `collapseLevel` grouping factor. The collapsing factor is obtained by pasting together the levels of the `collapseLevel` grouping factor and the values of the covariate to be preserved. Default is `NULL`, meaning that no covariates need to be preserved.
- `FUN`: an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by `collapseLevel`. Invariant variables are always summarized by group using the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables.
in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

subset

an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used.

... some methods for this generic require additional arguments. None are used in this method.

Value

a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

groupedData, plot.nmGroupedData

Examples

# collapsing by Dog
collapse(Pixel, collapse = 1) # same as collapse(Pixel, collapse = "Dog")
Value

A three-dimensional array, with the third dimension given by the number of unique column names in either object1 or object2. To each column name there corresponds a matrix with as many rows as the rows in object1 and two columns, corresponding to object1 and object2. The returned object inherits from class compareFits.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

plot.compareFits, pairs.compareFits, comparePred, coef, random.effects

Examples

fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
(cF12 <- compareFits(coef(fm1), coef(fm2)))

Description

Predicted values are obtained at the specified values of primary for each object. If either object1 or object2 have a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides primary are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

comparePred(object1, object2, primary, minimum, maximum, length.out, level, ...)

Arguments

object1, object2
fitted model objects, from which predictions can be extracted using the predict method.

primary
an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using getCovariate), it will be used as primary.

minimum
an optional lower limit for the primary covariate. Defaults to min(primary), after primary is evaluated in the data used in fitting object1.

maximum
an optional upper limit for the primary covariate. Defaults to max(primary), after primary is evaluated in the data used in fitting object1.
length.out  an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.

level  an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.

... some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects’ names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes comparePred and augPred.

Note

This function is generic: method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

corAR1  

AR(1) Correlation Structure

Description

This function is a constructor for the corAR1 class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corAR1(value, form, fixed)
Arguments

value the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).

form a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corAR1, representing an autocorrelation structure of order 1.

corARMA

**ARMA(p,q) Correlation Structure**

**Description**

This function is a constructor for the corARMA class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate initialize method.

**Usage**

```r
corARMA(value, form, p, q, fixed)
```

**Arguments**

- **value**: a vector with the values of the autoregressive and moving average parameters, which must have length p + q and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.

- **form**: a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **p, q**: non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.
corARMA

Value

Continuous AR(1) Correlation Structure

Description
This function is a constructor for the corCAR1 class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate Initialize method.

Usage

corCAR1(value, form, fixed)

Arguments

value
the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.

form
a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. Covariates for this correlation structure need not be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corCAR1, representing an autocorrelation structure of order 1, with a continuous time covariate.

fm1Ovar.lme <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time),
                   data = Ovary, random = pdDiag(~sin(2*pi*Time)))
fm4Ovar.lme <- update(fm1Ovar.lme,
                       correlation = corCAR1(form = ~Time))
```

### corClasses

**Correlation Structure Classes**

#### Description

Standard classes of correlation structures (corStruct) available in the nlme package.

#### Value

Available standard classes:

- `corAR1`: autoregressive process of order 1.
- `corARMA`: autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components.
- `corCAR1`: continuous autoregressive process (AR(1) process for a continuous time covariate).
- `corCompSymm`: compound symmetry structure corresponding to a constant correlation.
- `corExp`: exponential spatial correlation.
- `corGaus`: Gaussian spatial correlation.
- `corLin`: linear spatial correlation.
- `corRatio`: Rational quadratics spatial correlation.
- `corSpher`: spherical spatial correlation.
- `corSymm`: general correlation matrix, with no additional structure.

#### Note

Users may define their own corStruct classes by specifying a constructor function and, at a minimum, methods for the functions corMatrix and coef. For examples of these functions, see the methods for classes corSymm and corAR1.

corCompSymm

Compound Symmetry Correlation Structure

Description

This function is a constructor for the corCompSymm class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corCompSymm(value, form, fixed)

Arguments

value the correlation between any two correlated observations. Defaults to 0.
form a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corCompSymm, representing a compound symmetry correlation structure.

fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight, 
    random = ~ Time)
# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())
# p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)

corMatrix(cs1CompSymm)

## Print/Summary methods for the empty case:
(cCS <- corCompSymm()) # Uninitialized correlation struct..
summary(cCS) # (ditto)
```

### corExp

**Exponential Correlation Structure**

**Description**

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-r/d)$ when no nugget effect is present and $(1-n)\exp(-r/d)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```r
corExp(value, form, nugget, metric, fixed)
```

**Arguments**

- `value`: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, value can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- `form`: a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget

an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric

an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed

an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

corFactor

Factor of a Correlation Matrix

description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

usage

```
corfactor(object, ...)
```

arguments

- **object**: an object from which a correlation matrix can be extracted.
- **...**: some methods for this generic function require additional arguments.

value

will depend on the method function used; see the appropriate documentation.

author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

see also

```
corfactor.corStruct, recalc.corStruct
```

examples

```r
## see the method function documentation
```
Factor of a corStruct Object Matrix

Description
This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by object. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L' L$. This method extracts $L^{-t}$.

Usage
```r
## S3 method for class 'corStruct'
corFactor(object, ...)
```

Arguments
- `object`: an object inheriting from class "corStruct" representing a correlation structure, which must have been initialized (using Initialize).
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value
If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with object stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

Note
This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The corMatrix method function can be used to obtain transpose inverse square-root factors in matrix form.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corFactor, corMatrix.corStruct, recalc.corStruct, Initialize.corStruct

Examples
```r
cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```
General Gaussian Correlation Structure

**Description**

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( \exp(- (r/d)^2) \) when no nugget effect is present and \( (1 - n) \exp(- (r/d)^2) \) when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```r
corGaus(value, form, nugget, metric, fixed)
```

**Arguments**

- `value`: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- `form`: a one sided formula of the form \( \sim S_1 + \ldots + S_p \) or \( \sim S_1 + \ldots + S_p | g \), specifying spatial covariates \( S_1 \) through \( S_p \) and, optionally, a grouping factor \( g \). When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \( \sim 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- `nugget`: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

- `metric`: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- `fixed`: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

an object of class `corGaus`, also inheriting from class `corSpatial`, representing a Gaussian spatial correlation structure.
corLin

Linear Correlation Structure

Description

This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r < d \) apart is \( 1 - \frac{r}{d} \) when no nugget effect is present and \( (1 - n)(1 - \frac{r}{d}) \) when a nugget effect is assumed. If \( r \geq d \) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corLin(value, form, nugget, metric, fixed)
Arguments

value: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form: a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corLin, also inheriting from class corSpatial, representing a linear spatial correlation structure.

corMatrix  Extract Correlation Matrix

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

Usage

```r
corMatrix(object, ...)
```

Arguments

- `object` an object for which a correlation matrix can be extracted.
- `...` some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- corMatrix.corStruct, corMatrix.pdMat

Examples

```r
## see the method function documentation
```
corMatrix.corStruct

Matrix of a corStruct Object

Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to covariate and object. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. When $corr = FALSE$, this method extracts $L^{-1}$.

Usage

```r
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

Arguments

- `object`: an object inheriting from class "corStruct" representing a correlation structure.
- `covariate`: an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.
- `corr`: a logical value. If `TRUE` the function returns the correlation matrix, or list of correlation matrices, represented by `object`. If `FALSE` the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the covariate is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of covariate.

**corMatrix.pdMat**

*Extract Correlation Matrix from a pdMat Object*

**Description**

The correlation matrix corresponding to the positive-definite matrix represented by `object` is obtained.

**Usage**

```r
## S3 method for class 'pdMat'
corMatrix(object, ...)
```

**Arguments**

- `object` an object inheriting from class "pdMat", representing a positive definite matrix.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

the correlation matrix corresponding to the positive-definite matrix represented by `object`.

corMatrix.reStruct  Extract Correlation Matrix from Components of an reStruct Object

Description
This method function extracts the correlation matrices corresponding to the pdMat elements of object.

Usage
## S3 method for class 'reStruct'
corMatrix(object, ...)

Arguments
object

an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.

...
some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by the correlation matrices corresponding to the elements of object.

corNatural

General correlation in natural parameterization

Description

This function is a constructor for the corNatural class, representing a general correlation structure in the “natural” parameterization, which is described under pdNatural. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corNatural(value, form, fixed)

Arguments

value an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corNatural representing a general correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
corRatio

Rational Quadratic Correlation Structure

Description

This function is a constructor for the corRatio class, representing a rational quadratic spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \( 1/(1+(r/d)^2) \) when no nugget effect is present and \( (1-n)/(1+(r/d)^2) \) when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate Initialize method.

Usage

corRatio(value, form, nugget, metric, fixed)

Arguments

- **value**: an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form \(~ S1+...+Sp\), or \(~ S1+...+Sp \mid g\), specifying spatial covariates \( S1 \) through \( Sp \) and, optionally, a grouping factor \( g \). When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corRatio, also inheriting from class corSpatial, representing a rational quadratic spatial correlation structure.

# p. 249
fm5BW.lme <- update(fm3BW.lme, correlation =
                     corRatio(form = ~ Time))

# example gls(..., corRatio ...)
# Pinheiro and Bates, pp. 261, 263
fm1Wheat2 <- gls(yield ~ variety - 1, Wheat2)
# p. 263
fm3Wheat2 <- update(fm1Wheat2, corr =
                     corRatio(c(12.5, 0.2),
                              form = ~ latitude + longitude,
                              nugget = TRUE))
corSpatial

Usage

corSpatial(value, form, nugget, type, metric, fixed)

Arguments

value  an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the “range” of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the “range” and the second the “nugget effect” (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form  a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget  an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

type  an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions corSpher, corExp, corGaus, corLin, and corRatio for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".

metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class determined by the type argument and also inheriting from class corSpatial, representing a spatial correlation structure.

```

corSpher | Spherical Correlation Structure
---------|-----------------------------

Description
This function is a constructor for the corSpher class, representing a spherical spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r < d \) apart is \( 1 - 1.5(r/d) + 0.5(r/d)^3 \) when no nugget effect is present and \( (1-n)(1-1.5(r/d) + 0.5(r/d)^3) \) when a nugget effect is assumed. If \( r \geq d \) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage
```r
corSpher(value, form, nugget, metric, fixed)
```

Arguments
- **value**: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.
- **form**: a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp | g`, specifying spatial covariates `S1` through `Sp` and, optionally, a grouping factor `g`. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`. 

**metric**
an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

**fixed**
an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

**Value**
an object of class corSpher, also inheriting from class corSpatial, representing a spherical spatial correlation structure.

fm2Wheat2 <- update(fm1Wheat2, corr = 
    corSpher(c(28, 0.2), 
    form = ~ latitude + longitude, nugget = TRUE))
```
**corSymm**

*General Correlation Structure*

**Description**

This function is a constructor for the `corSymm` class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSymm(value, form, fixed)
```

**Arguments**

- **value**
  - an optional vector with the parameter values. Default is `numeric(0)`, which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

- **form**
  - a one sided formula of the form `~ t`, or `~ t | g`, specifying a time covariate `t` and, optionally, a grouping factor `g`. A covariate for this correlation structure must be integer valued. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **fixed**
  - an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

an object of class `corSymm` representing a general correlation structure.

**Covariate Assign Covariate Values**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "varFunc" classes.

**Usage**

```r
covariate(object) <- value
```

**Arguments**

- `object` any object with a covariate component.
- `value` a value to be assigned to the covariate associated with object.

**Value**

will depend on the method function; see the appropriate documentation.

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
getCovariate

Examples
## see the method function documentation

---

**Covariate.varFunc**

Assign varFunc Covariate

Description
The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

Usage
## S3 replacement method for class 'varFunc'
covariate(object) <- value

Arguments
object an object inheriting from class "varFunc", representing a variance function structure.
value a value to be assigned to the covariate associated with object.

Value
a varFunc object similar to object, but with its covariate attribute replaced by value.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
getCovariate.varFunc

Examples
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont["age"]
**Description**

The Dialyzer data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject.
- **QB**: a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- **pressure**: a numeric vector giving the transmembrane pressure (dmHg).
- **rate**: the hemodialyzer ultrafiltration rate (mL/hr).
- **index**: index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

**Dim**

**Extract Dimensions from an Object**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: "corSpatial", "corStruct", "pdCompSymm", "pdDiag", "pdIdent", "pdMat", and "pdSymm".

**Usage**

```
Dim(object, ...)
```
Arguments

object  any object for which dimensions can be extracted.

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Note

If `dim` allowed more than one argument, there would be no need for this generic function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Dim.corSpatial**

*Dimensions of a corSpatial Object*

**Description**

If `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```r
## S3 method for class 'corSpatial'
Dim(object, groups, ...)
```

**Arguments**

- **object**: an object inheriting from class "corSpatial", representing a spatial correlation structure.
- **groups**: an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
- **...**: further arguments to be passed to or from methods.
**Value**

a list with components:

- **N** length of groups
- **M** number of groups
- **spClass** an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin
- **sumLenSq** sum of the squares of the number of observations per group
- **len** an integer vector with the number of observations per group
- **start** an integer vector with the starting position for the distance vectors in each group, beginning from zero

Dim(cs1ARMA)

---

**Description**

if `groups` is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```r
## S3 method for class 'corStruct'
Dim(object, groups, ...)
```

**Arguments**

- **object** an object inheriting from class "corStruct", representing a correlation structure.
- **groups** an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
- **...** some methods for this generic require additional arguments. None are used in this method.
**Value**

a list with components:

- **N**: length of groups
- **M**: number of groups
- **maxLen**: maximum number of observations in a group
- **sumLenSq**: sum of the squares of the number of observations per group
- **len**: an integer vector with the number of observations per group
- **start**: an integer vector with the starting position for the observations in each group, beginning from zero

## S3 method for class 'pdMat'
Dim(object, ...)
```

**Arguments**

- **object**: an object inheriting from class "pdMat", representing a positive-definite matrix.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

an integer vector with the number of rows and columns of the matrix represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
The *Earthquake* data frame has 182 rows and 5 columns.

### Format

This data frame contains the following columns:

- **Quake** an ordered factor with levels `20 < 16 < 14 < 10 < 8 < 3 < 2 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11` indicating the earthquake on which the measurements were made.
- **Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.
- **distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).
- **soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.
- **accel** maximum horizontal acceleration observed (g).

### Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

### Source

ergoStool  
Ergometrics experiment with stool types

Description

The ergoStool data frame has 36 rows and 3 columns.

Format

This data frame contains the following columns:

- **effort**: a numeric vector giving the effort (Borg scale) required to arise from a stool.
- **Type**: a factor with levels T1, T2, T3, and T4 giving the stool type.
- **Subject**: an ordered factor giving a unique identifier for the subject in the experiment.

Details

Devore (2000) cites data from an article in Ergometrics (1993, pp. 519-535) on "The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity."

Source

Examples

```r
fm1 <- lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fm1 )
```

Fatigue  
Cracks caused by metal fatigue

Description

The Fatigue data frame has 262 rows and 3 columns.

Format

This data frame contains the following columns:

- **Path**: an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.
- **cycles**: number of test cycles at which the measurement is made (millions of cycles).
- **relLength**: relative crack length (dimensionless).
Details

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

**fdHess**

*Finite difference Hessian*

**Description**

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

**Usage**

```r
fdHess(pars, fun, ..., 
    .relStep = .Machine$double.eps^(1/3), minAbsPar = 0)
```

**Arguments**

- `pars` the numeric values of the parameters at which to evaluate the function `fun` and its derivatives.
- `fun` a function depending on the parameters `pars` that returns a numeric scalar.
- `...` Optional additional arguments to `fun`
- `.relStep` The relative step size to use in the finite differences. It defaults to the cube root of `.Machine$double.eps`
- `minAbsPar` The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero.

**Details**

This function uses a second-order response surface design known as a “Koschal design” to determine the parameter values at which the function is evaluated.

**Value**

A list with components

- `mean` the value of function `fun` evaluated at the parameter values `pars`
- `gradient` an approximate gradient (of length `length(pars)`).
- `Hessian` a matrix whose upper triangle contains an approximate Hessian.
fitted.glsStruct

Calculate glsStruct Fitted Values

Description

The fitted values for the linear model represented by object are extracted.

Usage

## S3 method for class 'glsStruct'
fitted(object, glsFit, ...)

Arguments

- **object**: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.
- **glsFit**: an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit").
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

A vector with the fitted values for the linear model represented by object.

Note

This method function is generally only used inside gls and fitted.gls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, residuals.glsStruct
fitted.gnlsStruct  
Calculate gnlsStruct Fitted Values

Description

The fitted values for the nonlinear model represented by object are extracted.

Usage

```r
## S3 method for class 'gnlsStruct'
fitted(object, ...)
```

Arguments

- `object`: an object inheriting from class "gnlsStruct", representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A vector with the fitted values for the nonlinear model represented by object.

Note

This method function is generally only used inside `gnls` and `fitted.gnls`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `gnls`, `residuals.gnlsStruct`

fitted.lme  
Extract lme Fitted Values

Description

The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$.

Usage

```r
## S3 method for class 'lme'
fitted(object, level, asList, ...)
```
Arguments

- **object**: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- **asList**: an optional logical value. If `TRUE` and a single value is given in `level`, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of `level`. Defaults to `FALSE`.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

If a single level of grouping is specified in `level`, the returned value is either a list with the fitted values split by groups (`asList = TRUE`) or a vector with the fitted values (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the `napredict` method is applied.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fitted(fm1, level = 0:1)
```

---

**fitted.lmeStruct**

*Calculate lmeStruct Fitted Values*

**Description**

The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$. 
Usage

```r
## S3 method for class 'lmeStruct'
fitted(object, level, conLin, lmeFit, ...)
```

Arguments

- `object`: an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
- `level`: an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`.
- `lmeFit`: an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to `attr(object, "lmeFit")`.
- `...`: some methods for this generic accept other optional arguments.

Value

- if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside `lme` and `fitted.lme`.

## S3 method for class 'lmList'
fitted(object, subset, asList, ...)

Description

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

Usage

```r
## S3 method for class 'lmList'
fitted(object, subset, asList, ...)
```
**fitted.nlmeStruct**

**Arguments**

- **object**
  - an object inheriting from class "**lmList**", representing a list of **lm** objects with a common model.

- **subset**
  - an optional character or integer vector naming the **lm** components of **object** from which the fitted values are to be extracted. Default is **NULL**, in which case all components are used.

- **asList**
  - an optional logical value. If **TRUE**, the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to **FALSE**.

- **...**
  - some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by the fitted values of each **lm** component of **object**, or a vector with the fitted values for all **lm** components of **object**.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**lmList**, **residuals.lmList**

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fitted(fm1)
```

---

**Description**

The fitted values at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level $i$.

**Usage**

```r
## S3 method for class 'nlmeStruct'
fitted(object, level, conLin, ...)
```
fixed.effects

Arguments

object an object inheriting from class "nlmeStruct", representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects, plus attributes specifying the underlying nonlinear model and the response variable.

level an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

conLin an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nlme model. Defaults to attr(object, "conLin").

... additional arguments that could be given to this method. None are used.

Value

if a single level of grouping is specified in level, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside nlme and fitted.nlme.

fixed.effects Extract Fixed Effects

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include lmList and lme.

Usage

fixed.effects(object, ...)
fixef(object, ...)
fixef.lmList

Arguments

object any fitted model object from which fixed effects estimates can be extracted.

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

References

See Also

fixef.lmList

Examples

## see the method function documentation

---

fixef.lmList Extract lmList Fixed Effects

Description

The average of the coefficients corresponding to the \texttt{lm} components of \texttt{object} is calculated.

Usage

## S3 method for class 'lmList'
fixef(object, ...)

Arguments

object an object inheriting from class "\texttt{lmList}" representing a list of \texttt{lm} objects with a common model.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the average of the individual \texttt{lm} coefficients in \texttt{object}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{lmList}, \texttt{random.effects.lmList}
Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fixed.effects(fm1)
```

---

**formula.pdBlocked**

**Extract pdBlocked Formula**

**Description**

The `formula` attributes of the `pdMat` elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the `pdMat` elements do not have a `formula` attribute, a `NULL` value is returned.

**Usage**

```r
## S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

**Arguments**

- `x` an object inheriting from class "pdBlocked", representing a positive definite block diagonal matrix.
- `asList` an optional logical value. If TRUE, a list with the formulas for the individual block diagonal elements of `x` is returned; else, if FALSE, a one-sided formula combining all individual formulas is returned. Defaults to FALSE.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list of one-sided formulas, or a single one-sided formula, or `NULL`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`pdBlocked`, `pdMat`

**Examples**

```r
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```
Description

This method function extracts the formula associated with a pdMat object, in which the column and row names are specified.

Usage

```r
## S3 method for class 'pdMat'
formula(x, asList, ...)
```

Arguments

- `x` an object inheriting from class "pdMat", representing a positive definite matrix.
- `asList` logical. Should the asList argument be applied to each of the components? Never used.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

If `x` has a `formula` attribute, its value is returned, else `NULL` is returned.

Note

Because factors may be present in `formula(x)`, the pdMat object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `pdMat`

Examples

```r
pd1 <- pdSymm(~Sex*age)
formula(pd1)
```
### formula.reStruct

**Extract reStruct Object Formula**

**Description**

This method function extracts a formula from each of the components of x, returning a list of formulas.

**Usage**

```r
## S3 method for class 'reStruct'
formula(x, asList, ...)
```

**Arguments**

- `x`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- `asList`: logical. Should the asList argument be applied to each of the components?
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with the formulas of each component of x.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`formula`

**Examples**

```r
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

---

### gapply

**Apply a Function by Groups**

**Description**

Applies the function to the distinct sets of rows of the data frame defined by groups.

**Usage**

```r
gapply(object, which, FUN, form, level, groups, ...)
```
Arguments

object  
an object to which the function will be applied - usually a groupedData object or a data.frame. Must inherit from class "data.frame".

which  
an optional character or positive integer vector specifying which columns of object should be used with FUN. Defaults to all columns in object.

FUN  
function to apply to the distinct sets of rows of the data frame object defined by the values of groups.

form  
an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

level  
an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

groups  
an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

...  
optional additional arguments to the summary function FUN. Often it is helpful to specify na.rm = TRUE.

Value

Returns a data frame with as many rows as there are levels in the groups argument.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

## Find number of non-missing "conc" observations for each Subject
gapply( Phenobarb, FUN = function(x) sum(!is.na(x$conc)) )

# Pinheiro and Bates, p. 127
table( gapply(Quinidine, "conc", function(x) sum(!is.na(x))) )
changeRecords <- gapply( Quinidine, FUN = function(frm)
  any(is.na(frm["conc"])) & is.na(frm["dose"]) )
Description

The Gasoline data frame has 32 rows and 6 columns.

Format

This data frame contains the following columns:

- **yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation
- **endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized
- **Sample** an ordered factor giving the inferred crude oil sample number
- **API** a numeric vector giving the crude oil gravity (degrees API)
- **vapor** a numeric vector giving the vapor pressure of the crude oil (lbf/in²)
- **ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

Source

covariate

Extract Covariate from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, corSpatial, data.frame, and varFunc.
Usage

getCovariate(object, form, data)

Arguments

object      any object with a covariate component
form       an optional one-sided formula specifying the covariate(s) to be extracted. De-
            faults to formula(object).
data       a data frame in which to evaluate the variables defined in form.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

getcovariate.corStruct, getcovariate.data.frame, getcovariate.varFunc,
getcovariateFormula

Examples

## see the method function documentation

getcovariate.corStruct

Extract corStruct Object Covariate

Description

This method function extracts the covariate(s) associated with object.

Usage

## S3 method for class 'corStruct'
getcovariate(object, form, data)

Arguments

object      an object inheriting from class corStruct representing a correlation structure.
form       this argument is included to make the method function compatible with the
generic. It will be assigned the value of formula(object) and should not be modified.
data       an optional data frame in which to evaluate the variables defined in form, in case
            object is not initialized and the covariate needs to be evaluated.
when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with object. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

### Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

### See Also
getCovariate

### Examples
```r
cs1 <- corAR1(form = ~ 1 | Subject)
getCovariate(cs1, data = Orthodont)
```

---

**Extract Data Frame Covariate**

### Description
The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

### Usage
```r
## S3 method for class 'data.frame'
getCovariate(object, form, data)
```

### Arguments
- **object**: an object inheriting from class `data.frame`.
- **form**: an optional formula specifying the covariate to be evaluated in `object`. Defaults to `formula(object)`.
- **data**: some methods for this generic require a separate data frame. Not used in this method.

### Value
the value of the right hand side of `form`, stripped of any conditional expression, evaluated in `object`.

### Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
getCovariate.varFunc

See Also
getcovariateFormula

Examples
getcovariate(Orthodont)

Description
This method function extracts the covariate(s) associated with the variance function represented by object, if any is present.

Usage
## S3 method for class 'varFunc'
getcovariate(object, form, data)

Arguments
  object    an object inheriting from class varFunc, representing a variance function structure.
  form      an optional formula specifying the covariate to be evaluated in object. Defaults to formula(object).
  data      some methods for this generic require a data object. Not used in this method.

Value
if object has a covariate attribute, its value is returned; else NULL is returned.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
covariate<-.varFunc

Examples
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
getcovariate(vf1)
getCovariateFormula  Extract Covariates Formula

Description

The right hand side of formula(object), without any conditioning expressions (i.e. any expressions after a \(|\) operator) is returned as a one-sided formula.

Usage

getCovariateFormula(object)

Arguments

object any object from which a formula can be extracted.

Value

a one-sided formula describing the covariates associated with formula(object).

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

ggetCovariate

Examples

getCovariateFormula(y ~ x | g)
ggetCovariateFormula(y ~ x)

ggetData  Extract Data from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include gls, lme, and lmList.

Usage

ggetData(object)

Arguments

object an object from which a data.frame can be extracted, generally a fitted model object.
Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

glsls, getData.lme, getData.lmList

Examples

## see the method function documentation

glsls

Extract gls Object Data

Description

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

Usage

## S3 method for class 'gls'
getData(object)

Arguments

object

an object inheriting from class gls, representing a generalized least squares fitted linear model.

Value

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, getData

Examples

fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
correlation = corAR1(form = ~ 1 | Mare))
getData(fm1)
getData.lme

Extract lme Object Data

Description

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

Usage

## S3 method for class 'lme'
getData(object)

Arguments

object

an object inheriting from class lme, representing a linear mixed-effects fitted model.

Value

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if na.action = na.omit, and does not omit at all if na.action = na.exclude. That is generally what is wanted for plotting, the main use of this function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lme, getData

Examples

fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
            random = ~ sin(2*pi*Time))
getData(fm1)
**getGroups**

**Extract Grouping Factors from an Object**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, data.frame, gls, lme, lmList, and varFunc.

**Usage**

```r
getGroups(object, form, level, data, sep)
```

**getGroups.lmList**

**Extract lmList Object Data**

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```r
## S3 method for class 'lmList'
getData(object)
```

**Arguments**

- **object**: an object inheriting from class lmList, representing a list of lm objects with a common model.

**Value**

If a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

lmList.getData

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
getData(fm1)
```
getGroups.corStruct

Arguments

object any object
form an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object).
level a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting.
data a data frame in which to interpret the variables named in form. Optional for most methods.
sep character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

getGroupsFormula, getGroups.data.frame, getGroups.gls, getGroups.lmList, getGroups.lme

Examples

## see the method function documentation

---

getGroups.corStruct Extract corStruct Groups

Description

This method function extracts the grouping factor associated with object, if any is present.

Usage

## S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
Arguments

object  
an object inheriting from class corStruct representing a correlation structure.

form  
this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified.

level  
this argument is included to make the method function compatible with the generic and is not used.

data  
an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the grouping factor needs to be evaluated.

sep  
character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.

Value

if a grouping factor is present in the correlation structure represented by object, the function returns the corresponding factor vector; else the function returns NULL.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

groups

Examples

cs1 <- corAR1(form = ~ 1 | Subject)
groups(cs1, data = Orthodont)

Description

Each variable named in the expression after the | operator on the right hand side of form is evaluated in object. If more than one variable is indicated in level they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in form and level > 1, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to level, to ensure their uniqueness.

Usage

## S3 method for class 'data.frame'
groups(object, form, level, data, sep)
Arguments

object an object inheriting from class data.frame.
form an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object).
level a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.
data unused
sep character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.

Value

either a data frame with columns given by the grouping factors indicated in level, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

groupsFormula

Examples

getGroups(Pixel)
getGroups(Pixel, level = 2)

Description

If present, the grouping factor associated to the correlation structure for the linear model represented by object is extracted.

Usage

## S3 method for class 'gls'
getGroups(object, form, level, data, sep)
getGroups.lme

Arguments

object  an object inheriting from class gls, representing a generalized least squares fitted linear model.
form    an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to formula(object). Not used.
level   a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
data    a data frame in which to interpret the variables named in form. Optional for most methods. Not used.
sep     character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used.

Value

if the linear model represented by object incorporates a correlation structure and the corresponding corStruct object has a grouping factor, a vector with the group values is returned; else, NULL is returned.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, corClasses

Examples

fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, correlation = corAR1(form = ~ 1 | Mare))
getGroups(fm1)

Description

The grouping factors corresponding to the linear mixed-effects model represented by object are extracted. If more than one level is indicated in level, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

Usage

## S3 method for class 'lme'
getGroups(object, form, level, data, sep)
Arguments

object an object inheriting from class \texttt{lme}, representing a fitted linear mixed-effects model.
form this argument is included to make the method function compatible with the generic and is ignored in this method.
level an optional integer vector giving the level(s) of grouping to be extracted from \texttt{object}. Defaults to the highest or innermost level of grouping.
data unused
sep character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.

Value

either a data frame with columns given by the grouping factors indicated in \texttt{level}, or, when a single level is requested, a factor representing the selected grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

\texttt{lme}

Examples

\begin{verbatim}
fm1 <- lme(pixel ~ day + day^2, Pixel, 
random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
\end{verbatim}

---

**Description**

The grouping factor determining the partitioning of the observations used to produce the \texttt{lme} components of \texttt{object} is extracted.

**Usage**

```r
## S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```
getGroups.varFunc

**Arguments**

- **object**: an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.
- **form**: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used.
- **level**: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
- **data**: a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. Not used.

**Value**

a vector with the grouping factor corresponding to the `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates `<bates@stat.wisc.edu>`

**See Also**

`lmList`

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
getGroups(fm1)
```

---

**Description**

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

**Usage**

```r
## S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```
**Arguments**

- **object**: an object inheriting from class `varFunc`, representing a variance function structure.
- **form**: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used.
- **level**: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
- **data**: a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`. Not used.

**Value**

If `object` has a `groups` attribute, its value is returned; else `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```r
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

**Description**

The conditioning expression associated with `formula(object)` (i.e. the expression after the `|` operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of `asList`. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

**Usage**

```r
getGroupsFormula(object, asList, sep)
```

**Arguments**

- **object**: any object from which a formula can be extracted.
- **asList**: an optional logical value. If `TRUE` the returned value will be a list of formulas; else, if `FALSE` the returned value will be a one-sided formula. Defaults to `FALSE`.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`.
getResponse

Value

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with formula(object). If no conditioning expression is present in formula(object) a NULL value is returned.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples
getResponse(Orthodont)
getResponseFormula

**Extract Formula Specifying Response Variable**

**Description**

The left hand side of `formula(object)` is returned as a one-sided formula.

**Usage**

`getResponseFormula(object)`

**Arguments**

- `object` any object from which a formula can be extracted.

**Value**

a one-sided formula with the response variable associated with `formula(object)`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

gVarCov

**Extract variance-covariance matrix**

**Description**

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

**Usage**

```r
gVarCov(obj, ...)
## S3 method for class 'lme'
gVarCov(obj, individuals, type = c("random.effects", "conditional", "marginal"), ...)
## S3 method for class 'gls'
gVarCov(obj, individual = 1, ...)
```
Arguments

obj A fitted model. Methods are available for models fit by \texttt{lme} and by \texttt{gls}

individuals For models fit by \texttt{lme} a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.

individual For models fit by \texttt{gls} the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument \texttt{individual} specifies the group of responses.

type For models fit by \texttt{lme} the \texttt{type} argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional. variance-covariance of the responses or "marginal" for the the marginal variance-covariance of the responses.

... Optional arguments for some methods, as described above

Value

A variance-covariance matrix or a list of variance-covariance matrices.

Author(s)

Mary Lindstrom <lindstro@biostat.wisc.edu>

correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
\end{verbatim}

\section*{gls}

\textit{Fit Linear Model Using Generalized Least Squares}

Description

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage

\begin{verbatim}
gls(model, data, correlation, weights, subset, method, na.action, control, verbose)  
## S3 method for class 'gls'
update(object, model., ..., evaluate = TRUE)
\end{verbatim}
Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted linear model.

model a two-sided linear formula object describing the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right.

model. Changes to the model – see update.formula for details.

data an optional data frame containing the variables named in model, correlation, weights, and subset. By default the variables are taken from the environment from which gls is called.

correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gls to print an error message and terminate if there are any incomplete observations.

control a list of control values for the estimation algorithm to replace the default values returned by the function glsControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Details

offset terms in model are an error since 3.1-157 (2022-03): previously they were silently ignored.

Value

an object of class "gls" representing the linear model fit. Generic functions such as print, plot, and summary have methods to show the results of the fit. See glsObject for the components of the fit. The functions resid, coef and fitted, can be used to extract some of its components.

Examples

# AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())

glsControl

Control Values for gls Fit

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gls function.

Usage

glsControl(maxIter, msMaxIter, tolerance, msTol, msVerbose,
singular.ok, returnObject = FALSE, apVar, .relStep,
          opt = c("nlminb", "optim"), optimMethod,
          minAbsParApVar, natural, sigma = NULL)
Arguments

maxIter maximum number of iterations for the gls optimization algorithm. Default is 50.

msMaxIter maximum number of iterations for the optimization step inside the gls optimization. Default is 50.

tolerance tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.

msTol tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.

msVerbose a logical value passed as the trace control value to the chosen optimizer (see documentation on that function). Default is FALSE.

singular.ok a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE.

returnObject a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.

apVar a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

opt the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default).

optim Method character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".

minAbsParApVar numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

natural logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.

sigma optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

**glsObject**

### Fitted gls Object

#### Description

An object returned by the `gls` function, inheriting from class "gls" and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

#### Value

The following components must be included in a legitimate "gls" object.

- **apVar**
  - an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the list of control values used in the call to `gls`, this component is equal to `NULL`.

- **call**
  - a list containing an image of the `gls` call that produced the object.

- **coefficients**
  - a vector with the estimated linear model coefficients.

- **contrasts**
  - a list of the contrast matrices used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.

- **dims**
  - a list with basic dimensions used in the model fit, including the components `N` - the number of observations in the data and `p` - the number of coefficients in the linear model.

- **fitted**
  - a vector with the fitted values.

- **modelStruct**
  - an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.

- **groups**
  - a vector with the correlation structure grouping factor, if any is present.

- **logLik**
  - the log-likelihood at convergence.

- **method**
  - the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

- **numIter**
  - the number of iterations used in the iterative algorithm.

- **residuals**
  - a vector with the residuals.

- **sigma**
  - the estimated residual standard error.

- **varBeta**
  - an approximate covariance matrix of the coefficients estimates.

#### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

#### See Also

`gls`, `glsStruct`
A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A `glsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `glsStruct` list.

**Usage**

```r
glsStruct(corStruct, varStruct)
```

**Arguments**

- `corStruct`: an optional `corStruct` object, representing a correlation structure. Default is `NULL`.
- `varStruct`: an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- `corClasses`, `gls`, `residuals.glsStruct`, `varFunc`

**Examples**

```r
gls1 <- glsStruct(corAR1(), varPower())
```

---

The Glucose data frame has 378 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4
- **Time**: a numeric vector
- **conc**: a numeric vector of glucose levels
- **Meal**: an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

### Glucose2

*Glucose Levels Following Alcohol Ingestion*

#### Description

The Glucose2 data frame has 196 rows and 4 columns.

#### Format

This data frame contains the following columns:

- **Subject**: a factor with levels 1 to 7 identifying the subject whose glucose level is measured.
- **Date**: a factor with levels 1 2 indicating the occasion in which the experiment was conducted.
- **Time**: a numeric vector giving the time since alcohol ingestion (in min/10).
- **glucose**: a numeric vector giving the blood glucose level (in mg/dl).

#### Details

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

### gnlS

*Fit Nonlinear Model Using Generalized Least Squares*

#### Description

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

#### Usage

```
   gnlS(model, data, params, start, correlation, weights, subset, 
        na.action, naPattern, control, verbose)
```
Arguments

model an two-sided formula object describing the model, with the response on the left of a ~ operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame.

data an optional data frame containing the variables named in model, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which gnls is called.

params an optional two-sided linear formula of the form p1+...+pn~x1+...+xm, or list of two-sided formulas of the form p1~x1+...+xm, with possibly different models for each parameter. The p1,...,pn represent parameters included on the right hand side of model and x1+...+xm define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of start.

start an optional named list, or numeric vector, with the initial values for the parameters in model. It can be omitted when a selfStarting function is used in model, in which case the starting estimates will be obtained from a single call to the nls function.

correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gnls to print an error message and terminate if there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be regarded as missing.

control a list of control values for the estimation algorithm to replace the default values returned by the function gnlsControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

Value

an object of class gnls, also inheriting from class gls, representing the nonlinear model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See
gnlsControl

Values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gnls function.

Examples

# variance increases with a power of the absolute fitted values
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean, weights = varPower())
summary(fm1)
Usage

gnlsControl(maxIter = 50, nlsMaxIter = 7, msMaxIter = 50, minScale = 0.001,
tolerance = 1e-6, nlsTol = 0.001, msTol = 1e-7,
returnObject = FALSE, msVerbose = FALSE,
apVar = TRUE, .relStep =,
  opt = c("nlminb", "optim"), optimMethod = "BFGS",
  minAbsParApVar = 0.05, sigma = NULL)

Arguments

maxIter maximum number of iterations for the gnls optimization algorithm. Default is 50.
nlsMaxIter maximum number of iterations for the nls optimization step inside the gnls optimization. Default is 7.
msMaxIter maximum number of iterations for the optimization step inside the gnls optimization. Default is 50.
minScale minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the nls step. Default 0.001.
tolerance tolerance for the convergence criterion in the gnls algorithm. Default is 1e-6.
nlsTol tolerance for the convergence criterion in nls step. Default is 1e-3.
msTol tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.
returnObject a logical value indicating whether the fitted object should be returned with a warning (instead of an error via stop()) when the maximum number of iterations is reached without convergence of the algorithm.
msVerbose a logical value passed as the trace argument to the optimizer chosen by opt; see documentation on that. Default is FALSE.
apVar a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.relStep relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3) (about 6e-6).
opt the optimizer to be used, either "nlminb" (the current default) or "optim" (the previous default).
optimMethod character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
minAbsParApVar numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
sigma optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.
Fitted gnls Object

Description
An object returned by the `gnls` function, inheriting from class "gnls" and also from class "gls", and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

Value
The following components must be included in a legitimate "gnls" object.

- `apVar` an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the control values used in the call to `gnls`, this component is equal to `NULL`.
- `call` a list containing an image of the `gnls` call that produced the object.
- `coefficients` a vector with the estimated nonlinear model coefficients.
- `contrasts` a list of the contrast matrices used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
- `dims` a list with basic dimensions used in the model fit, including the components `N` - the number of observations used in the fit and `p` - the number of coefficients in the nonlinear model.
- `fitted` a vector with the fitted values.
- `modelStruct` an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.
- `groups` a vector with the correlation structure grouping factor, if any is present.
- `logLik` the log-likelihood at convergence.
- `numIter` the number of iterations used in the iterative algorithm.
- `plist` a vector with the residuals.
- `pmap` the estimated residual standard error.
- `varBeta` an approximate covariance matrix of the coefficients estimates.
GNLS STRUCT

Description

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A gnlsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the gnlsStruct list.

Usage

gnlsStruct(corStruct, varStruct)

Arguments

corStruct an optional corStruct object, representing a correlation structure. Default is NULL.

varStruct an optional varFunc object, representing a variance function structure. Default is NULL.

Value

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

gnls1 <- gnlsStruct(corAR1(), varPower())
groupedData

Construct a groupedData Object

Description

An object of the groupedData class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of outer, inner, labels, and units that are given. If order.groups is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: nfnGroupedData - numeric covariate, single level of nesting; nffGroupedData - factor covariate, single level of nesting; and nmGroupedData - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a groupedData object to construct default plots and models.

Usage

groupedData(formula, data, order.groups, FUN, outer, inner, labels, units)

## S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN, outer, inner, labels, units, ...)

Arguments

object an object inheriting from class groupedData.
formula a formula of the form resp ~ cov | group where resp is the response, cov is the primary covariate, and group is the grouping factor. The expression 1 can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the / symbol as in fact1/fact2. In an expression like this the fact2 factor is nested within the fact1 factor.
data a data frame in which the expressions in formula can be evaluated. The resulting groupedData object will consist of the same data values in the same order but with additional attributes.
order.groups an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function FUN applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE.
FUN an optional summary function that will be applied to the values of the response for each level of the grouping factor, when order.groups = TRUE, to determine the ordering. Defaults to the max function.
groupedData

outer

an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument outer = TRUE causes the panels to be determined by the outer formula. The points within the panels are associated by level of the grouping factor. Defaults to NULL, meaning that no outer covariates are present.

inner

an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to NULL, meaning that no inner covariates are present.

labels

an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.

units

an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.

... some methods for this generic require additional arguments. None are used in this method.

Value

an object of one of the classes nfnGroupedData, nffGroupedData, or nmGroupedData, and also inheriting from classes groupedData and data.frame.

gsummary( Orth.new ) # apply summary by Subject
fm1 <- lme( Orth.new ) # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)

gsummary

Summarize by Groups

Description

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a groupedData object to examine the variables by group.

Usage

gsummary(object, FUN, omitGroupingFactor, form, level,
        groups, invariantsOnly, ...)

Arguments

object
    an object to be summarized - usually a groupedData object or a data.frame.

FUN
    an optional summary function or a list of summary functions to be applied to
    each variable in the frame. The function or functions are applied only to vari-
    ables in object that vary within the groups defined by groups. Invariant vari-
    ables are always summarized by group using the unique value that they assume
    within that group. If FUN is a single function it will be applied to each non-
    invariant variable by group to produce the summary for that variable. If FUN
    is a list of functions, the names in the list should designate classes of variables in
    the frame such as ordered, factor, or numeric. The indicated function will be
    applied to any non-invariant variables of that class. The default functions to
    be used are mean for numeric factors, and Mode for both factor and ordered.
    The Mode function, defined internally in gsummary, returns the modal or most
    popular value of the variable. It is different from the mode function that returns
    the S-language mode of the variable.

omitGroupingFactor
    an optional logical value. When TRUE the grouping factor itself will be omitted
    from the group-wise summary but the levels of the grouping factor will continue
    to be used as the row names for the data frame that is produced by the summary.
    Defaults to FALSE.
form  an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

level  an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

groups  an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

invariantsOnly  an optional logical value. When TRUE only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in object. By definition, the grouping factor itself must be an invariant. When combined with omitGroupingFactor = TRUE, this option can be used to discover is there are invariant covariates in the data frame. Defaults to FALSE.

Value
A data.frame with one row for each level of the grouping factor. The number of columns is at most the number of columns in object.

Examples
gsummary(Orthodont)  # default summary by Subject
## gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
## determines whether there are covariates like Sex that are invariant
## within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
**Gun**  
*Methods for firing naval guns*

**Description**

The Gun data frame has 36 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **rounds** a numeric vector
- **Method** a factor with levels M1 M2
- **Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H
- **Physique** an ordered factor with levels Slight < Average < Heavy

**Details**

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

**IGF**  
*Radioimmunoassay of IGF-I Protein*

**Description**

The IGF data frame has 237 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Lot** an ordered factor giving the radioactive tracer lot.
- **age** a numeric vector giving the age (in days) of the radioactive tracer.
- **conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

**Details**

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `lmeStruct`, `reStruct`, and `varFunc`.

**Usage**

Initialize(object, data, ...)

**Arguments**

- `object`: any object requiring initialization, e.g. "plug-in" structures such as `corStruct` and `varFunc` objects.
- `data`: a data frame to be used in the initialization procedure.
- `...`: some methods for this generic function require additional arguments.

**Value**

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`Initialize.corStruct`, `Initialize.lmeStruct`, `Initialize.glsStruct`, `Initialize.varFunc`, `isInitialized`

**Examples**

## see the method function documentation
Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

Usage

```r
## S3 method for class 'corStruct'
Initialize(object, data, ...)
```

Arguments

- `object`: an object inheriting from class "corStruct" representing a correlation structure.
- `data`: a data frame in which to evaluate the variables defined in `formula(object)`.
- `...`: this argument is included to make this method compatible with the generic.

Value

an initialized object with the same class as object representing a correlation structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

`Dim.corStruct`

Examples

```r
cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```
Initialize.glsStruct  Initialize a glsStruct Object

Description
The individual linear model components of the glsStruct list are initialized.

Usage
## S3 method for class 'glsStruct'
Initialize(object, data, control, ...)

Arguments
- object: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and varFunc objects.
- data: a data frame in which to evaluate the variables defined in formula(object).
- control: an optional list with control parameters for the initialization and optimization algorithms used in gls. Defaults to list(singular.ok = FALSE), implying that linear dependencies are not allowed in the model.
- ... some methods for this generic require additional arguments. None are used in this method.

Value
a glsStruct object similar to object, but with initialized model components.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
gls, Initialize.corStruct, Initialize.varFunc, Initialize

Initialize.lmeStruct  Initialize an lmeStruct Object

Description
The individual linear mixed-effects model components of the lmeStruct list are initialized.

Usage
## S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)

Initialize.reStruct

Arguments

object an object inheriting from class "lmeStruct", representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
data a data frame in which to evaluate the variables defined in formula(object).
groups a data frame with the grouping factors corresponding to the lme model associated with object as columns, sorted from innermost to outermost grouping level.
conLin an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object, "conLin").
control an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to list(niterEM=20, gradHess=TRUE), implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the reStruct component of object and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm.
... some methods for this generic require additional arguments. None are used in this method.

Value

an lmeStruct object similar to object, but with initialized model components.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lme, Initialize.reStruct, Initialize.corStruct, Initialize.varFunc, Initialize

Description

Initial estimates for the parameters in the pdMat objects forming object, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in control.

Usage

## S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)

Initialize.reStruct  Initialize reStruct Object
Arguments

object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
data a data frame in which to evaluate the variables defined in formula(object).
conLin a condensed linear model object, consisting of a list with components "Xy" corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
control an optional list with a single component niterEM controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other Initialize methods. Defaults to list(niterEM = 20).

Value

an reStruct object similar to object, but with all pdMat components initialized.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

reStruct, pdMat, Initialize

Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data; determining if the covariate(s) need to be updated when the values of the coefficients associated with object change; initializing the log-likelihood and the weights associated with object; and assigning initial values for the coefficients in object, if none were present. The covariate(s) will only be initialized if no update is needed when coef(object) changes.

Usage

## S3 method for class 'varFunc'
Initialize(object, data, ...)

Arguments

object an object inheriting from class "varFunc", representing a variance function structure.
data a data frame in which to evaluate the variables named in formula(object).
... this argument is included to make this method compatible with the generic.
Value

an initialized object with the same class as object representing a variance function structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Initialize

Examples

vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )

intervals

Confidence Intervals on Coefficients

Description

Confidence intervals on the parameters associated with the model represented by object are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

Usage

intervals(object, level, ...)

Arguments

object a fitted model object from which parameter estimates can be extracted.
level an optional numeric value for the interval confidence level. Defaults to 0.95.
... some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

### see the method documentation
Confidence Intervals on gls Parameters

Description

Approximate confidence intervals for the parameters in the linear model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

Usage

## S3 method for class 'gls'
intervals(object, level, which, ...)

Arguments

- **object**: an object inheriting from class "gls", representing a generalized least squares fitted linear model.
- **level**: an optional numeric value for the interval confidence level. Defaults to 0.95.
- **which**: an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all".
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- **coef**: linear model coefficients, only present when which is not equal to "var-cov".
- **corStruct**: correlation parameters, only present when which is not equal to "coef" and a correlation structure is used in object.
- **varFunc**: variance function parameters, only present when which is not equal to "coef" and a variance function structure is used in object.
- **sigma**: residual standard error.

intervals.lme  Confidence Intervals on lme Parameters

Description
  
Approximate confidence intervals for the parameters in the linear mixed-effects model represented
by object are obtained, using a normal approximation to the distribution of the (restricted) maxi-
mum likelihood estimators (the estimators are assumed to have a normal distribution centered at the
true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the
(restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained
in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to
the constrained scale. The pdNatural parametrization is used for general positive-definite matrices.

Usage
  
## S3 method for class 'lme'
intervals(object, level = 0.95,
         which = c("all", "var-cov", "fixed"), ...)

Arguments
  
oobject an object inheriting from class "lme", representing a fitted linear mixed-effects
  model.
oplevel an optional numeric value with the confidence level for the intervals. Defaults
to 0.95.
which an optional character string specifying the subset of parameters for which to
construct the confidence intervals. Possible values are "all" for all parameters,
"var-cov" for the variance-covariance parameters only, and "fixed" for the
fixed effects only. Defaults to "all".
...
some methods for this generic require additional arguments. None are used in
this method.

Value
  
a list with components given by data frames with rows corresponding to parameters and columns
lower, est., and upper representing respectively lower confidence limits, the estimated values,
and upper confidence limits for the parameters. Possible components are:

fixed fixed effects, only present when which is not equal to "var-cov".
reStruct random effects variance-covariance parameters, only present when which is not
equal to "fixed".
**intervals.lmList**

- **corStruct**: within-group correlation parameters, only present when which is not equal to "fixed" and a correlation structure is used in object.
- **varFunc**: within-group variance function parameters, only present when which is not equal to "fixed" and a variance function structure is used in object.
- **sigma**: within-group standard deviation.

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
intervals(fm1)
```

---

**intervals.lmList**

Confidence Intervals on lmList Coefficients

**Description**

Confidence intervals on the linear model coefficients are obtained for each lm component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by `lower`, `est.`, and `upper` corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

**Usage**

```r
## S3 method for class 'lmList'
intervals(object, level = 0.95, pool = attr(object, "pool"), ...)
```

**Arguments**

- **object**: an object inheriting from class "lmList", representing a list of lm objects with a common model.
- **level**: an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
- **pool**: an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`.
- **...**: some methods for this generic require additional arguments. None are used in this method.
Value

A three-dimensional array with the confidence intervals and estimates for the coefficients of each \( \text{lm} \) component of \( \text{object} \).

Author(s)

José Pinheiro and Douglas Bates &lt;bates@stat.wisc.edu&gt;

\texttt{lmList}, \texttt{intervals}, \texttt{plot.intervals.lmList}

Examples

\begin{verbatim}
fm1 <- lmList(distance ~ age | Subject, Orthodont)
intervals(fm1)
\end{verbatim}

Description

Check a Design for Balance

Usage

\begin{verbatim}
isBalanced(object, countOnly, level)
\end{verbatim}

Arguments

\begin{itemize}
\item \textbf{object} \hspace{1cm} A \texttt{groupedData} object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.
\item \textbf{countOnly} \hspace{1cm} A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to \texttt{FALSE}.
\item \textbf{level} \hspace{1cm} an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.
\end{itemize}

Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If \texttt{countOnly} is \texttt{FALSE} the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.
isInitialized

Check if Object is Initialized

Description
Checks if object has been initialized (generally through a call to Initialize), by searching for components and attributes which are modified during initialization.

Usage
isInitialized(object)

Arguments
object any object requiring initialization.

Value
a logical value indicating whether object has been initialized.

Author(s)
José Pinheiro and Douglas Bates

See Also
Initialize

Examples
pd1 <- pdDiag(~age)
isInitialized(pd1)
LDEsysMat

Generate system matrix for LDEs

Description

Generate the system matrix for the linear differential equations determined by a compartment model.

Usage

LDEsysMat(pars, incidence)

Arguments

pars a numeric vector of parameter values.
incidence an integer matrix with columns named From, To, and Par. Values in the Par column must be in the range 1 to length(pars). Values in the From column must be between 1 and the number of compartments. Values in the To column must be between 0 and the number of compartments.

Details

A compartment model describes material transfer between \( k \) in a system of \( k \) compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

Value

A \( k \) by \( k \) numeric matrix.

Author(s)

Douglas Bates <bates@stat.wisc.edu>

References

Examples

# incidence matrix for a two compartment open system incidence <- matrix(c(1,1,2,2,1,3,2,0), ncol = 3, byrow = TRUE, dimnames = list(NULL, c("Par", "From", "To"))) incidence LDEsysMat(c(1.2, 0.3, 0.4), incidence)
**lme**  
*Linear Mixed-Effects Models*

**Description**

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

The methods `lme.lmList` and `lme.groupedData` are documented separately.

**Usage**

```r
lme(fixed, data, random, correlation, weights, subset, method,  
na.action, control, contrasts = NULL, keep.data = TRUE)
```

**Arguments**

- `object` an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `fixed` a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a `~` operator and the terms, separated by `+` operators, on the right, an "lmList" object, or a "groupedData" object. There is limited support for formulae such as `resp ~ 1` and `resp ~ 0`, and less prior to version ‘3.1-112’.
- `fixed.` Changes to the fixed-effects formula – see `update.formula` for details.
- `data` an optional data frame containing the variables named in `fixed`, `random`, `correlation`, `weights`, and `subset`. By default the variables are taken from the environment from which `lme` is called.
- `random` optionally, any of the following: (i) a one-sided formula of the form `~ x1 + ... + xn | g1/.../gm`, with `x1 + ... + xn` specifying the model for the random effects and `g1/.../gm` the grouping structure (`n` may be equal to 1, in which case `g` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form `~ x1 + ... + xn | g`, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form `~ x1 + ... + xn`, or a `pdMat` object with a formula (i.e. a non-NULL value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class "groupedData"; (iv) a named list of formulas or `pdMat` objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to a formula consisting of the right hand side of `fixed`. 

---

## S3 method for class 'lme'

```r
update(object, fixed., ..., evaluate = TRUE)
```

## Examples

```r
lme(fixed, data, random, correlation, weights, subset, method,  
na.action, control, contrasts = NULL, keep.data = TRUE)
```
correlation  an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

weights  an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset  an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method  a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action  a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations.

control  a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list.

contrasts  an optional list. See the contrasts.arg of model.matrix.default.

keep.data  logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

...  some methods for this generic require additional arguments. None are used in this method.

evaluate  If TRUE evaluate the new call else return the call.

Details

offset terms in fixed are an error since 3.1-157 (2022-03): previously they were silently ignored.

Value

An object of class "lme" representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

summary(fm1)
summary(fm2)
```

---

**lme.groupedData**  
*LME fit from groupedData Object*

**Description**

The response variable and primary covariate in `formula(fixed)` are used to construct the fixed effects model formula. This formula and the groupedData object are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.
Usage

## S3 method for class 'groupedData'

lme(fixed, data, random, correlation, weights,
       subset, method, na.action, control, contrasts, keep.data = TRUE)

Arguments

fixed     a data frame inheriting from class "groupedData".
data      this argument is included for consistency with the generic function. It is ignored in this method function.
random    optionally, any of the following: (i) a one-sided formula of the form ~x1+...+xn | g1/.../gm, with x1+...+xn specifying the model for the random effects and g1/.../gm the grouping structure (m may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form ~x1+...+xn | g, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form ~x1+...+xn, or a pdMat object with a formula (i.e. a non-NULL value for formula(object)), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an reStruct object. See the documentation on pdClasses for a description of the available pdMat classes. Defaults to a formula consisting of the right hand side of fixed.
correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.
weights    an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.
subset    an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
method    a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations.
control   a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list.
contrasts an optional list. See the contrasts.arg of model.matrix.default.
keep.data logical: should the data argument (if supplied and a data frame) be saved as part of the model object?
Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

lme, groupedData, lmeObject

Examples

fm1 <- lme(Orthodont)
summary(fm1)
**Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the fixed and data arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

**Usage**

```r
## S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts, keep.data)
```

**Arguments**

- `fixed` an object inheriting from class "`lmList`." representing a list of `lm` fits with a common model.
- `data` this argument is included for consistency with the generic function. It is ignored in this method function.
- `random` an optional one-sided linear formula with no conditioning expression, or a `pdMat` object with a `formula` attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of `formula(fixed)``.
- `correlation` an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations.
- `weights` an optional `varFunc` object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to `varFixed`, corresponding to fixed variance weights. See the documentation on `varClasses` for a description of the available `varFunc` classes. Defaults to `NULL`, corresponding to homoscedastic within-group errors.
- `subset` an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `method` a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
- `na.action` a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `lme` to print an error message and terminate if there are any incomplete observations.
- `control` a list of control values for the estimation algorithm to replace the default values returned by the function `lmeControl`. Defaults to an empty list.
contrasts an optional list. See the contrasts.arg of model.matrix.default.

keep.data logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

lme, lmList, lmeObject

Examples

fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
summary(fm1)
summary(fm2)
### Description

The values supplied in the `lmeControl()` call replace the defaults, and a list with all settings (i.e., values for all possible arguments) is returned. The returned list is used as the control argument to the `lme` function.

### Usage

```r
lmeControl(maxIter = 50, msMaxIter = 50, tolerance = 1e-6, niterEM = 25,
           msMaxEval = 200,
           msTol = 1e-7, msVerbose = FALSE,
           returnObject = FALSE, gradHess = TRUE, apVar = TRUE,
           .relStep = .Machine$double.eps^(1/3), minAbsParApVar = 0.05,
           opt = c("nlminb", "optim"),
           optimMethod = "BFGS", natural = TRUE,
           sigma = NULL,
           allow.n.lt.q = FALSE,
           ...)```

### Arguments

- **maxIter**: maximum number of iterations for the `lme` optimization algorithm. Default is 50.
- **msMaxIter**: maximum number of iterations for the optimization step inside the `lme` optimization. Default is 50.
- **tolerance**: tolerance for the convergence criterion in the `lme` algorithm. Default is 1e-6.
- **niterEM**: number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
- **msMaxEval**: maximum number of evaluations of the objective function permitted for `nlminb`. Default is 200.
- **msTol**: tolerance for the convergence criterion on the first iteration when `optim` is used. Default is 1e-7.
- **msVerbose**: a logical value passed as the `trace` argument to `nlminb` or `optim`. Default is FALSE.
- **returnObject**: a logical value indicating whether the fitted object should be returned with a warning (instead of an error via `stop()`) when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
- **gradHess**: a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure (`corStruct`) and the variance function structure (`varFunc`) have no "varying" parameters and the `pdMat` classes used in the random effects structure are `pdSymm` (general positive-definite), `pdDiag` (diagonal), `pdIdent` (multiple of the identity), or `pdCompSymm` (compound symmetry). Default is TRUE.
- **apVar**: a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.relStep  relative step for numerical derivatives calculations. Default is 
.Machine$double.eps^((1/3)).

opt  the optimizer to be used, either "nlminb" (the default) or "optim".

optimMethod  character - the optimization method to be used with the opt optimizer. The 
default is "BFGS". An alternative is "L-BFGS-B".

minAbsParApVar  numeric value - minimum absolute parameter value in the approximate variance 
calculation. The default is 0.05.

natural  a logical value indicating whether the pdNatural parametrization should be 
used for general positive-definite matrices (pdSymm) in reStruct, when the ap-
proximate covariance matrix of the estimators is calculated. Default is TRUE.

sigma  optionally a positive number to fix the residual error at. If NULL, as by default, 
or 0, sigma is estimated.

allow.n.lt.q  logical indicating if it is ok to have less observations than random effects for 
each group. The default, FALSE signals an error; if NA, such a situation only 
gives a warning, as in nlme versions prior to 2019; if true, no message is given 
at all.

...  further named control arguments to be passed, depending on opt, to nlminb 
(those from abs.tol down) or optim (those except trace and maxit; reltol 
is used only from the second iteration).

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp 
and Bert van Willigen.

lme, nlminb, optim

Examples

# decrease the maximum number iterations in the ms call and 
# request that information on the evolution of the ms iterations be printed 
str(lCtr <- lmeControl(msMaxIter = 20, msVerbose = TRUE))
## This should always work: 
do.call(lmeControl, lCtr)
Value

The following components must be included in a legitimate "lme" object.

- **apVar**: an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to lme, this component is NULL.

- **call**: a list containing an image of the lme call that produced the object.

- **coefficients**: a list with two components, fixed and random, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the random list, the columns refer to the random effects and the rows to the groups.

- **contrasts**: a list of the contrast matrices used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the lme model, this component will be an empty list.

- **dims**: a list with basic dimensions used in the lme fit, including the components N - the number of observations in the data, Q - the number of grouping levels, qvec - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), ngrps - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and ncol - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

- **fitted**: a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.

- **fixDF**: a list with components X and terms specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.

- **groups**: a data frame with the grouping factors as columns. The grouping level increases from left to right.

- **logLik**: the (restricted) log-likelihood at convergence.

- **method**: the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

- **modelStruct**: an object inheriting from class lmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.

- **numIter**: the number of iterations used in the iterative algorithm.

- **residuals**: a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.

- **terms**: the terms, including formula, see also terms.object.

- **sigma**: the estimated within-group error standard deviation.

- **varFix**: an approximate covariance matrix of the fixed effects estimates.

\begin{verbatim}
\texttt{lmeStruct} \texttt{(reStruct, corStruct, varStruct)}
\end{verbatim}

\textbf{Description}

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An \texttt{lmeStruct} list must contain at least a \texttt{reStruct} object, but may also contain \texttt{corStruct} and \texttt{varFunc} objects. NULL arguments are not included in the \texttt{lmeStruct} list.

\textbf{Usage}

\begin{verbatim}
lmeStruct(reStruct, corStruct, varStruct)
\end{verbatim}

\textbf{Arguments}

- \texttt{reStruct} \hfill a \texttt{reStruct} representing a random effects structure.
- \texttt{corStruct} \hfill an optional \texttt{corStruct} object, representing a correlation structure. Default is NULL.
- \texttt{varStruct} \hfill an optional \texttt{varFunc} object, representing a variance function structure. Default is NULL.

\textbf{Value}

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

\textbf{Author(s)}

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

\end{verbatim}
**lmList**

List of lm Objects with a Common Model

**Description**

Data is partitioned according to the levels of the grouping factor g and individual lm fits are obtained for each data partition, using the model defined in object.

**Usage**

```r
lmList(object, data, level, subset, na.action = na.fail, 
       pool = TRUE, warn.lm = TRUE)
```

## S3 method for class 'lmList'

update(object, formula., ..., evaluate = TRUE)

## S3 method for class 'lmList'

print(x, pool, ...)```

**Arguments**

- **object**
  For lmList, either a linear formula object of the form `y ~ x1+...+xn | g` or a groupedData object. In the formula object, `y` represents the response, `x1,...,xn` the covariates, and `g` the grouping factor specifying the partitioning of the data according to which different lm fits should be performed. The grouping factor `g` may be omitted from the formula, in which case the grouping structure will be obtained from `data`, which must inherit from class groupedData. The method function `lmList.groupedData` is documented separately. For the method `update.lmList`, `object` is an object inheriting from class `lmList`.

- **formula**
  (used in `update.lmList` only) a two-sided linear formula with the common model for the individuals lm fits.

- **formula.**
  Changes to the formula – see `update.formula` for details.

- **data**
  a data frame in which to interpret the variables named in object.

- **level**
  an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.

- **subset**
  an optional expression indicating which subset of the rows of `data` should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

- **na.action**
  a function that indicates what should happen when the data contain NAs. The default action (`na.fail`) causes `lmList` to print an error message and terminate if there are any incomplete observations.

- **pool**
  an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.

- **warn.lm**
  logical indicating if `lm()` errors (all of which are caught by `tryCatch`) should be signalled as a "summarizing" warning.

- **x**
  an object inheriting from class `lmList` to be printed.

- **...**
  some methods for this generic require additional arguments. None are used in this method.

- **evaluate**
  If TRUE evaluate the new call else return the call.
Value

A list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

References

See Also

`lm`, `lme.lmList`, `plot.lmList`, `pooledSD`, `predict.lmList`, `residuals.lmList`, `summary.lmList`

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

Description

The response variable and primary covariate in `formula(object)` are used to construct the linear model formula. This formula and the `groupedData` object are passed as the `object` and `data` arguments to `lmList.formula`, together with any other additional arguments in the function call. See the documentation on `lmList.formula` for a description of that function.

Usage

```r
## S3 method for class 'groupedData'

lmList(object, data, level, subset, na.action = na.fail, pool = TRUE, warn.lm = TRUE)
```

Arguments

- `object`: a data frame inheriting from class "`groupedData`".
- `data`: this argument is included for consistency with the generic function. It is ignored in this method function.
- `level`: an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
- `subset`: an optional expression indicating which subset of the rows of `data` should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `lmList` to print an error message and terminate if there are any incomplete observations.
- `pool`, `warn.lm`: optional `logicals`, see `lmList`.
logDet

Value

A list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

See Also

groupedData, lm, lme.lmList, lmList, lmList.formula

Examples

fm1 <- lmList(Orthodont)
summary(fm1)

logDet

Extract the Logarithm of the Determinant

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, several pdMat classes, and reStruct.

Usage

logDet(object, ...)

Arguments

object any object from which a matrix, or list of matrices, can be extracted
... some methods for this generic function require additional arguments.

Value

The value will depend on the method function used; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

logLik, logDet.corStruct, logDet.pdMat, logDet.reStruct

Examples

# see the method function documentation
**logDet.corStruct**

**Extract corStruct Log-Determinant**

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

**Usage**

```r
## S3 method for class 'corStruct'
logDet(object, covariate, ...)
```

**Arguments**

- `object`: an object inheriting from class "corStruct", representing a correlation structure.
- `covariate`: an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`logLik.corStruct`, `corMatrix.corStruct`, `logDet`

**Examples**

```r
cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```
logDet.pdMat

Extract Log-Determinant from a pdMat Object

Description
This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by object.

Usage
## S3 method for class 'pdMat'
logDet(object, ...)

Arguments
object an object inheriting from class "pdMat", representing a positive definite matrix.
...
some methods for this generic require additional arguments. None are used in this method.

Value
the log-determinant of a square-root factor of the positive-definite matrix represented by object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
pdMat, logDet

Examples
pd1 <- pdSymm(diag(1:3))
logDet(pd1)

logDet.reStruct

Extract reStruct Log-Determinants

Description
Calculates, for each of the pdMat components of object, the logarithm of the determinant of a square-root factor.

Usage
## S3 method for class 'reStruct'
logDet(object, ...)

Examples
Arguments

object

an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the log-determinants of square-root factors of the pdMat components of object.

Author(s)

José Pinheiro

See Also

reStruct, pdMat, logDet

Examples

rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
                  B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)

logLik.corStruct

Extract corStruct Log-Likelihood

Description

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by object.

Usage

## S3 method for class 'corStruct'
logLik(object, data, ...)

Arguments

object

an object inheriting from class "corStruct", representing a correlation structure.

data

this argument is included to make this method function compatible with other logLik methods and will be ignored.

... some methods for this generic require additional arguments. None are used in this method.

Value

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by object.
Description

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

Usage

```r
## S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

Arguments

- `object`: an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.
- `Pars`: the parameter values at which the (restricted) log-likelihood is to be evaluated.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to attr(object, "conLin").
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the (restricted) log-likelihood for the linear model described by object, evaluated at Pars.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, glsStruct, logLik.lme
logLik.gnls

Log-Likelihood of a gnls Object

Description
Returns the log-likelihood value of the nonlinear model represented by object evaluated at the estimated coefficients.

Usage
```r
## S3 method for class 'gnls'
logLik(object, REML, ...)
```

Arguments
- `object`: an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
- `REML`: an logical value for consistency with logLik.gls, but only FALSE is accepted.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value
the log-likelihood of the linear model represented by object evaluated at the estimated coefficients.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
gnls, logLik.lme

Examples
```r
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
weights = varPower())
logLik(fm1)
```

logLik.gnlsStruct

Log-Likelihood of a gnlsStruct Object

Description
Pars is used to update the coefficients of the model components of object and the individual log-likelihood contributions of each component are added together.

Usage
```r
## S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)
```
Arguments

- **object**: an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.
- **Pars**: the parameter values at which the log-likelihood is to be evaluated.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to `attr(object, "conLin")`.

Value

the log-likelihood for the linear model described by `object`, evaluated at `Pars`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gnls, gnlsStruct, logLik.gnls

Description

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by `object` evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

Usage

```r
## S3 method for class 'lme'
logLik(object, REML, ...)
```

Arguments

- **object**: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- **REML**: an optional logical value. If `TRUE` the restricted log-likelihood is returned, else, if `FALSE`, the log-likelihood is returned. Defaults to the method of estimation used, that is `TRUE` if and only if `object` was fitted with method = "REML" (the default for these fitting functions).

... some methods for this generic require additional arguments. None are used in this method.
Value

the (restricted) log-likelihood of the model represented by object evaluated at the estimated coefficients.

Author(s)

José Pinheiro and Douglas Bates

---

**logLik.lmList**

*Log-Likelihood of an lmList Object*

Description

If pool=FALSE, the (restricted) log-likelihoods of the lm components of object are summed together. Else, the (restricted) log-likelihood of the lm fit with different coefficients for each level of the grouping factor associated with the partitioning of the object components is obtained.

Usage

```r
## S3 method for class 'lmList'
logLik(object, REML, pool, ...)
```

Arguments

- `object` an object inheriting from class "lmList", representing a list of lm objects with a common model.
- `REML` an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.
- `pool` an optional logical value indicating whether all lm components of object may be assumed to have the same error variance. Default is attr(object, "pool").
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

either the sum of the (restricted) log-likelihoods of each lm component in object, or the (restricted) log-likelihood for the lm fit with separate coefficients for each component of object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

logLik(fm1)  # returns NA when it should not
```

### logLik.reStruct

**Calculate reStruct Log-Likelihood**

**Description**

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The settings attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

**Usage**

```r
## S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

**Arguments**

- `object`: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of `pdMat` objects.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef(object)`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `pdMat`, `logLik.lme`
Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by object, which is equal to the sum of the logarithms of the corresponding weights.

Usage

## S3 method for class 'varFunc'
logLik(object, data, ...)

Arguments

object an object inheriting from class "varFunc", representing a variance function structure.
data this argument is included to make this method function compatible with other logLik methods and will be ignored.
... some methods for this generic require additional arguments. None are used in this method.

Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

logLik.lme

Examples

vf1 <- varPower(form = ~age)
vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.1
logLik(vf1)
**Machines**

*Productivity Scores for Machines and Workers*

**Description**

The Machines data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Worker**: an ordered factor giving the unique identifier for the worker.
- **Machine**: a factor with levels A, B, and C identifying the machine brand.
- **score**: a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

**MathAchieve**

*Mathematics achievement scores*

**Description**

The MathAchieve data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

- **School**: an ordered factor identifying the school that the student attends
- **Minority**: a factor with levels No Yes indicating if the student is a member of a minority racial group.
- **Sex**: a factor with levels Male Female
- **SES**: a numeric vector of socio-economic status.
- **MathAch**: a numeric vector of mathematics achievement scores.
- **MEANSES**: a numeric vector of the mean SES for the school.
Details

Each row in this data frame contains the data for one student.

Examples

summary(MathAchieve)

MathAchSchool  School demographic data for MathAchieve

Description

The MathAchSchool data frame has 160 rows and 7 columns.

Format

This data frame contains the following columns:

- **School**: a factor giving the school on which the measurement is made.
- **Size**: a numeric vector giving the number of students in the school.
- **Sector**: a factor with levels Public Catholic.
- **PRACAD**: a numeric vector giving the percentage of students on the academic track.
- **DISCLIM**: a numeric vector measuring the discrimination climate.
- **HIMINTY**: a factor with levels 0 1.
- **MEANSES**: a numeric vector giving the mean SES score.

Details

These variables give the school-level demographic data to accompany the MathAchieve data.

Matrix

Assign Matrix Values

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include pdMat, pdBlocked, and reStruct.

Usage

matrix(object) <- value

Arguments

- **object**: any object to which as.matrix can be applied.
- **value**: a matrix, or list of matrices, with the same dimensions as as.matrix(object) with the new values to be assigned to the matrix associated with object.
Matrix.pdMat

Assign Matrix to a pdMat or pdBlocked Object

Description
The positive-definite matrix represented by object is replaced by value. If the original matrix had row and/or column names, the corresponding names for value can either be NULL, or a permutation of the original names.

Usage
## S3 replacement method for class 'pdMat'
matrix(object) <- value
## S3 replacement method for class 'pdBlocked'
matrix(object) <- value

Arguments

object
an object inheriting from class "pdMat", representing a positive definite matrix.

value
a matrix with the new values to be assigned to the positive-definite matrix represented by object. Must have the same dimensions as as.matrix(object).

Value
a pdMat or pdBlocked object similar to object, but with its coefficients modified to produce the matrix in value.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
pdMat,"matrix<-"

Examples
class(pd1 <- pdSymm(diag(3))) # "pdSymm" "pdMat"
matrix(pd1) <- diag(1:3)
pd1
Matrix.reStruct  Assign reStruct Matrices

Description

The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

Usage

```R
## S3 replacement method for class 'reStruct'
matrix(object) <- value
```

Arguments

- **object**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **value**: a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object.

Value

an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

reStruct, pdMat,"matrix<-"

Examples

matrix(rs1) <- list(diag(2), 3)
```

Meat  Tenderness of meat

Description

The Meat data frame has 30 rows and 4 columns.
**Format**

This data frame contains the following columns:

- **Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)
- **score** a numeric vector giving the tenderness score of beef roast.
- **Block** an ordered factor identifying the muscle from which the roast was extracted with levels II \(<\ V <\ 1 <\ III <\ IV
- **Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < \ldots < IV-1

**Details**

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

**Milk**

*Protein content of cows’ milk*

**Description**

The *Milk* data frame has 1337 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **protein** a numeric vector giving the protein content of the milk.
- **Time** a numeric vector giving the time since calving (weeks).
- **Cow** an ordered factor giving a unique identifier for each cow.
- **Diet** a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

**Details**

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows’ milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

**Source**

model.matrix.reStruct  

reStruct Model Matrix

Description

The model matrices for each element of formula(object), calculated using data, are bound together column-wise. When multiple grouping levels are present (i.e. when length(object) > 1), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

Usage

## S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)

Arguments

- **object**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **data**: a data frame in which to evaluate the variables defined in formula(object).
- **contrast**: an optional named list specifying the contrasts to be used for representing the factor variables in data. The components names should match the names of the variables in data for which the contrasts are to be specified. The components of this list will be used as the contrasts attribute of the corresponding factor. If missing, the default contrast specification is used.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a matrix obtained by binding together, column-wise, the model matrices for each element of formula(object).

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

model.matrix, contrasts.reStruct, formula.reStruct

rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
Muscle

Contraction of heart muscle sections

Description

The Muscle data frame has 60 rows and 3 columns.

Format

This data frame contains the following columns:

- **Strip**: an ordered factor indicating the strip of muscle being measured.
- **conc**: a numeric vector giving the concentration of CaCl₂
- **length**: a numeric vector giving the shortening of the heart muscle strip.

Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl₂ solution. The muscle strips are taken from the left auricle of a rat’s heart.

Source

Names

Names Associated with an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

Usage

```r
Names(object, ...) = value
```

Arguments

- **object**: any object for which names can be extracted and/or assigned.
- **...**: some methods for this generic function require additional arguments.
- **value**: names to be assigned to object.

Value

will depend on the method function used; see the appropriate documentation.
SIDE EFFECTS

On the left side of an assignment, sets the names associated with object to value, which must have an appropriate length.

Note

If names were generic, there would be no need for this generic function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Names.formula, Names.pdMat

Examples

## see the method function documentation

```r
Names.formula
```

Description

This method function returns the names of the terms corresponding to the right hand side of object (treated as a linear formula), obtained as the column names of the corresponding model.matrix.

Usage

```r
## S3 method for class 'formula'
Names(object, data, exclude, ...)  
```

Arguments

- `object`: an object inheriting from class "formula".
- `data`: an optional data frame containing the variables specified in object. By default the variables are taken from the environment from which Names.formula is called.
- `exclude`: an optional character vector with names to be excluded from the returned value. Default is `c("pi",".")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a character vector with the column names of the model.matrix corresponding to the right hand side of object which are not listed in excluded.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
See Also

model.matrix, terms, Names

Examples

Names(distance ~ Sex * age, data = Orthodont)

Names.pdBlocked

Names of a pdBlocked Object

Description

This method function extracts the first element of the Dimnames attribute, which contains the column names, for each block diagonal element in the matrix represented by object.

Usage

## S3 method for class 'pdBlocked'
Names(object, asList, ...)

Arguments

object an object inheriting from class "pdBlocked" representing a positive-definite matrix with block diagonal structure

asList a logical value. If TRUE a list with the names for each block diagonal element is returned. If FALSE a character vector with all column names is returned. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

if asList is FALSE, a character vector with column names of the matrix represented by object; otherwise, if asList is TRUE, a list with components given by the column names of the individual block diagonal elements in the matrix represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

Names, Names.pdMat

Examples

pd1 <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(pd1)
Names.pdMat

Names of a pdMat Object

Description

This method function returns the first element of the Dimnames attribute of object, which contains the column names of the matrix represented by object.

Usage

```r
## S3 method for class 'pdMat'
Names(object, ...)

## S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class "pdMat", representing a positive-definite matrix.
- `value`: a character vector with the replacement values for the column and row names of the matrix represented by object. It must have length equal to the dimension of the matrix represented by object and, if names have been previously assigned to object, it must correspond to a permutation of the original names.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

- if `object` has a Dimnames attribute then the first element of this attribute is returned; otherwise NULL.

SIDE EFFECTS

On the left side of an assignment, sets the Dimnames attribute of object to list(value, value).

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`Names`, `Names.pdBlocked`

Examples

```r
pd1 <- pdSymm(~age, data = Orthodont)
Names(pd1)
```
Description

This method function extracts the column names of each of the positive-definite matrices represented the \( \text{pdMat} \) elements of \( \text{object} \).

Usage

```r
## S3 method for class 'reStruct'
Names(object, ...)
## S3 replacement method for class 'reStruct'
Names(object, ...) <- value
```

Arguments

- **object**: an object inheriting from class "\text{reStruct}". representing a random effects structure and consisting of a list of \( \text{pdMat} \) objects.
- **value**: a list of character vectors with the replacement values for the names of the individual \( \text{pdMat} \) objects that form \( \text{object} \). It must have the same length as \( \text{object} \).
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a list containing the column names of each of the positive-definite matrices represented by the \( \text{pdMat} \) elements of \( \text{object} \).

SIDE EFFECTS

On the left side of an assignment, sets the Names of the \( \text{pdMat} \) elements of \( \text{object} \) to the corresponding element of \( \text{value} \).

Names(rs1)
```
needUpdate

Description

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of `object`. If this is NULL or FALSE it returns FALSE; else it returns TRUE. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage

```r
needUpdate(object)
```

Arguments

- `object`: any object

Value

a logical value indicating whether `object` needs to be updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `needUpdate.modelStruct`

Examples

```r
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

needUpdate.modelStruct

Description

This method function checks if any of the elements of `object` needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage

```r
## S3 method for class 'modelStruct'
needUpdate(object)
```
Arguments

object an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.

Value

a logical value indicating whether any element of object needs to be updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

needUpdate

Examples

lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
  varStruct = varPower(form = ~age))
needUpdate(lms1)

Nitrendipene Assay of nitrendipene

Description

The Nitrendipene data frame has 89 rows and 4 columns.

Format

This data frame contains the following columns:

  activity a numeric vector
  NIF a numeric vector
  Tissue an ordered factor with levels 2 < 1 < 3 < 4
  log.NIF a numeric vector

Source

Description

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

Usage

```
nlme(model, data, fixed, random, groups, start, correlation, weights, 
     subset, method, na.action, naPattern, control, verbose)
```

Arguments

- **model**: a nonlinear model formula, with the response on the left of a `~` operator and an expression involving parameters and covariates on the right, or an `nlsList` object. If `data` is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function `nlme.nlsList` is documented separately.

- **data**: an optional data frame containing the variables named in `model`, `fixed`, `random`, `correlation`, `weights`, `subset`, and `naPattern`. By default the variables are taken from the environment from which `nlme` is called.

- **fixed**: a two-sided linear formula of the form `f1+...+fn~x1+...+xm`, or a list of two-sided formulas of the form `f1~x1+...+xm`, with possibly different models for different parameters. The `f1`, `..., fn` are the names of parameters included on the right hand side of `model` and the `x1+...+xm` expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A `1` on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).

- **random**: optionally, any of the following: (i) a two-sided formula of the form `r1+...+rn~x1+...+xm | g1/.../gQ`, with `r1, ..., rn` naming parameters included on the right hand side of `model`, `x1+...+xm` specifying the random-effects model for these parameters and `g1/.../gQ` the grouping structure (`Q` may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form `r1+...+rn~x1+...+xm`, a list of two-sided formulas of the form `r1~x1+...+xm`, with possibly different random-effects models for different parameters, a `pdMat` object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for `formula(random)`), or a list of `pdMat` objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in `groups`, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class `groupedData`; (iii) a named list of formulas, lists of formulas, or `pdMat` objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (iv) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to `fixed`, resulting in all fixed effects having also random effects.
groups an optional one-sided formula of the form \(~g1\) (single level of nesting) or \(~g1/\ldots/gQ\) (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. $g_1, \ldots, g_Q$ must evaluate to factors in `data`. The order of nesting, when multiple levels are present, is taken from left to right (i.e. $g_1$ is the first level, $g_2$ the second, etc.).

start an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component fixed, given by the vector. The fixed component is required, unless the model function inherits from class `selfStart`, in which case initial values will be derived from a call to `nlsList`. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.

correlation an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations.

weights an optional `varFunc` object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to `varFixed`, corresponding to fixed variance weights. See the documentation on `varClasses` for a description of the available `varFunc` classes. Defaults to `NULL`, corresponding to homoscedastic within-group errors.

subset an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `nlme` to print an error message and terminate if there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be regarded as missing.

control a list of control values for the estimation algorithm to replace the default values returned by the function `nlmeControl`. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is `FALSE`.

Value

an object of class `nlme` representing the nonlinear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

\texttt{nlme.nlsList} \hspace{1cm} \textit{NLME fit from nlsList Object}

Description
If the random effects names defined in \texttt{random} are a subset of the \texttt{lmList} object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in \texttt{random}). \texttt{formula(fixed)} and the \texttt{data} argument in the calling sequence used to obtain \texttt{fixed} are passed as the \texttt{fixed} and \texttt{data} arguments to \texttt{nlme.formula}, together with any other additional arguments in the function call. See the documentation on \texttt{nlme.formula} for a description of that function.

Usage
\begin{verbatim}
## S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
\end{verbatim}
Arguments

model an object inheriting from class "nlsList", representing a list of \texttt{nls} fits with a common model.
data this argument is included for consistency with the generic function. It is ignored in this method function.
fixed this argument is included for consistency with the generic function. It is ignored in this method function.
random an optional one-sided linear formula with no conditioning expression, or a \texttt{pdMat} object with a \texttt{formula} attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of \texttt{formula(fixed)}.
groups an optional one-sided formula of the form \(~g_1\) (single level of nesting) or \(~g_1/\ldots/g_Q\) (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. \(g_1,\ldots,g_Q\) must evaluate to factors in \texttt{data}. The order of nesting, when multiple levels are present, is taken from left to right (i.e. \(g_1\) is the first level, \(g_2\) the second, etc.).
start an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component \texttt{fixed}, given by the vector. The \texttt{fixed} component is required, unless the model function inherits from class \texttt{selfStart}, in which case initial values will be derived from a call to \texttt{nlsList}. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
correlation an optional \texttt{corStruct} object describing the within-group correlation structure. See the documentation of \texttt{corClasses} for a description of the available \texttt{corStruct} classes. Defaults to \texttt{NULL}, corresponding to no within-group correlations.
weights an optional \texttt{varFunc} object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to \texttt{varFixed}, corresponding to fixed variance weights. See the documentation on \texttt{varClasses} for a description of the available \texttt{varFunc} classes. Defaults to \texttt{NULL}, corresponding to homoscedastic within-group errors.
subset an optional expression indicating the subset of the rows of \texttt{data} that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".
na.action a function that indicates what should happen when the data contain NAs. The default action (\texttt{na.fail}) causes \texttt{nlme} to print an error message and terminate if there are any incomplete observations.
naPattern an expression or formula object, specifying which returned values are to be regarded as missing.
control a list of control values for the estimation algorithm to replace the default values returned by the function \texttt{nlmeControl}. Defaults to an empty list.
verbose an optional logical value. If \texttt{TRUE} information on the evolution of the iterative algorithm is printed. Default is \texttt{FALSE}. 
Value

an object of class \texttt{nlme} representing the linear mixed-effects model fit. Generic functions such as \texttt{print}, \texttt{plot} and \texttt{summary} have methods to show the results of the fit. See \texttt{nlmeObject} for the components of the fit. The functions \texttt{resid}, \texttt{coef}, \texttt{fitted}, \texttt{fixed.effects}, and \texttt{random.effects} can be used to extract some of its components.

Examples

\begin{verbatim}
fm1 <- nlsList(SSasymp, data = Loblolly)
fm2 <- nlme(fm1, random = Asym ~ 1)
summary(fm1)
summary(fm2)
\end{verbatim}
**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `nlme` function.

**Usage**

```r
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
             tolerance, niterEM, pnlsTol, msTol,
             returnObject, msVerbose, msWarnNoConv,
             gradHess, apVar, relStep, minAbsParApVar = 0.05,
             opt = c("nlminb", "nlm"), natural = TRUE, sigma = NULL, ...)
```

**Arguments**

- `maxIter`: maximum number of iterations for the `nlme` optimization algorithm. Default is 50.
- `pnlsMaxIter`: maximum number of iterations for the PNLS optimization step inside the `nlme` optimization. Default is 7.
- `msMaxIter`: maximum number of iterations for `nlminb` (`iter.max`) or the `nlm` (`iterlim`, from the 10-th step) optimization step inside the `nlme` optimization. Default is 50 (which may be too small for e.g. overparametrized cases).
- `minScale`: minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.
- `tolerance`: tolerance for the convergence criterion in the `nlme` algorithm. Default is 1e-6.
- `niterEM`: number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
- `pnlsTol`: tolerance for the convergence criterion in PNLS step. Default is 1e-3.
- `msTol`: tolerance for the convergence criterion in `nlm`, passed as the `gradtol` argument to the function (see documentation on `nlm`). Default is 1e-7.
- `returnObject`: a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is `FALSE`.
- `msVerbose`: a logical value passed as the `trace` to `nlminb`(..., control=list(trace = *, ...)) or as argument `print.level` to `nlm()`. Default is `FALSE`.
- `msWarnNoConv`: logical indicating if a `warning` should be signalled whenever the minimization (by `opt`) in the LME step does not converge; defaults to `TRUE`.
- `gradHess`: a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the `nlm` optimization. This option is only available when the correlation structure (`corStruct`) and the variance function structure (`varFunc`) have no "varying" parameters and the `pdMat` classes used in the random effects structure are `pdSymm` (general positive-definite), `pdDiag` (diagonal), `pdIdent` (multiple of the identity), or `pdCompSymm` (compound symmetry). Default is `TRUE`. 

apVar  a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

minAbsParApVar  numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

opt  the optimizer to be used, either "nlminb" (the default) or "nlm".

natural  a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

sigma  optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.

...  Further, named control arguments to be passed to nlminb (apart from trace and iter.max mentioned above), where used (eval.max and those from abs.tol down).

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

nlmeObject  

Fitted nlme Object

Description

An object returned by the nlme function, inheriting from class "nlme", also inheriting from class "lme", and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, summary, and update.
The following components must be included in a legitimate "nlme" object.

**apVar**
- an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the control values used in the call to `nlme`, this component is `NULL`.

**call**
- a list containing an image of the `nlme` call that produced the object.

**coefficients**
- a list with two components, `fixed` and `random`, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the `random` list, the columns refer to the random effects and the rows to the groups.

**contrasts**
- a list of the contrast matrices used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the `nlme` model, this component will be an empty list.

**dims**
- a list with basic dimensions used in the `nlme` fit, including the components `N` - the number of observations in the data, `Q` - the number of grouping levels, `qvec` - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), `ngrps` - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and `ncol` - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

**fitted**
- a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.

**fixDF**
- a list with components `X` and `terms` specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.

**groups**
- a data frame with the grouping factors as columns. The grouping level increases from left to right.

**logLik**
- the (restricted) log-likelihood at convergence.

**map**
- a list with components `fmap`, `rmap`, `rmapRel`, and `bmap`, specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.

**method**
- the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

**modelStruct**
- an object inheriting from class `nlmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.

**numIter**
- the number of iterations used in the iterative algorithm.

**residuals**
- a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.

**sigma**
- the estimated within-group error standard deviation.

**varFix**
- an approximate covariance matrix of the fixed effects estimates.
nlmeStruct

Nonlinear Mixed-Effects Structure

Description

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An nlmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the nlmeStruct list.

Usage

nlmeStruct(reStruct, corStruct, varStruct)

Arguments

reStruct a reStruct representing a random effects structure.
corStruct an optional corStruct object, representing a correlation structure. Default is NULL.
varStruct an optional varFunc object, representing a variance function structure. Default is NULL.

Value

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corClasses, nlme, residuals.nlmeStruct, reStruct, varFunc

Examples

nlms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
**nlsList**

*List of nls Objects with a Common Model*

**Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual `nls` fits are obtained for each data partition, using the model defined in `model`.

**Usage**

```r
nlsList(model, data, start, control, level, subset, 
    na.action = na.fail, pool = TRUE, warn.nls = NA)
```

## S3 method for class 'nlsList'

update(object, model., ..., evaluate = TRUE)

**Arguments**

- `object` an object inheriting from class `nlsList`, representing a list of fitted `nls` objects.
- `model` either a nonlinear model formula, with the response on the left of a `~` operator and an expression involving parameters, covariates, and a grouping factor separated by the `|` operator on the right, or a `selfStart` function. The method function `nlsList.selfStart` is documented separately.
- `model.` changes to the model – see `update.formula` for details.
- `data` a data frame in which to interpret the variables named in `model`.
- `start` an optional named list with initial values for the parameters to be estimated in `model`. It is passed as the `start` argument to each `nls` call and is required when the nonlinear function in `model` does not inherit from class `selfStart`.
- `control` a list of control values passed as the `control` argument to `nls`. Defaults to an empty list.
- `level` an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
- `subset` an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `na.action` a function that indicates what should happen when the data contain NAs. The default action (`na.fail`) causes `nlsList` to print an error message and terminate if there are any incomplete observations.
- `pool` an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for `pool` in calculations of standard deviations or standard errors for summaries.
- `warn.nls` logical indicating if `nls()` errors (all of which are caught by `tryCatch`) should be signalled as a "summarizing" warning.
- `...` some methods for this generic require additional arguments. None are used in this method.
- `evaluate` If `TRUE` evaluate the new call else return the call.
Details

As \texttt{nls(.)} is called on each sub group, and convergence of these may be problematic, these calls happen with error catching.

Since \texttt{nlme} version 3.1-127 (2016-04), all the errors are caught (via \texttt{tryCatch}) and if present, a "summarizing" \texttt{warning} is stored as attribute of the resulting \texttt{"nlsList"} object and signalled unless suppressed by \texttt{warn.nls = FALSE} or currently also when \texttt{warn.nls = NA} (default) \texttt{and getOption("show.error.messages")} is false.

\texttt{nlsList()} originally had used \texttt{try(\*\*)} (with its default \texttt{silent=FALSE}) and hence all errors were printed to the console \texttt{unless} the global option \texttt{show.error.messages} was set to true. This still works, but has been \texttt{deprecated}.

Value

a list of \texttt{nls} objects with as many components as the number of groups defined by the grouping factor. Generic functions such as \texttt{coef}, \texttt{fixed.effects}, \texttt{lme}, \texttt{pairs}, \texttt{plot}, \texttt{predict}, \texttt{random.effects}, \texttt{summary}, and \texttt{update} have methods that can be applied to an \texttt{nlsList} object.

Examples

\begin{verbatim}
fm1 <- nlsList(uptake ~ SSasympOff(conc, Asym, lrc, c0),
               data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
cfm1 <- confint(fm1) # via profiling each % FIXME: only *one* message instead of one *each*
mat.class <- class(matrix(1)) # ("matrix", "array") for R >= 4.0.0; ("matrix" in older R)
i.ok <- which(vapply(cfm1,
               function(r) identical(class(r), mat.class), NA))
stopifnot(length(i.ok) > 0, !anyNA(match(c(2:4, 6:9, 12), i.ok)))
## where as (some of) the others gave errors during profile re-fitting :
str(cfm1[- i.ok])
\end{verbatim}

\texttt{nlsList.selfStart} \hspace{1cm} \texttt{nlsList Fit from a selfStart Function}

Description

The response variable and primary covariate in \texttt{formula(data)} are used together with \texttt{model} to construct the nonlinear model formula. This is used in the \texttt{nls} calls and, because a \texttt{selfStarting} model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

Usage

\begin{verbatim}
## S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset,
          na.action = na.fail, pool = TRUE, warn.nls = NA)
\end{verbatim}
Arguments

model a "selfStart" model function, which calculates initial estimates for the model parameters from data.
data a data frame in which to interpret the variables in model. Because no grouping factor can be specified in model, data must inherit from class "groupedData".start an optional named list with initial values for the parameters to be estimated in model. It is passed as the start argument to each nls call and is required when the nonlinear function in model does not inherit from class selfStart.control a list of control values passed as the control argument to nls. Defaults to an empty list.level an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlsList to print an error message and terminate if there are any incomplete observations.pool, warn.nls optional logicals, see nlsList.

Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. A NULL value is assigned to the components corresponding to clusters for which the nls algorithm failed to converge. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an nlsList object.

Oats

Split-plot Experiment on Varieties of Oats

Description

The Oats data frame has 72 rows and 4 columns.
### Orthodont

**Description**

The Orthodont data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

**Format**

This data frame contains the following columns:

- **distance**: a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.
- **age**: a numeric vector of ages of the subject (yr).
- **Subject**: an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.
- **Sex**: a factor with levels Male and Female

**Details**

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

<table>
<thead>
<tr>
<th>Ovary</th>
<th>Counts of Ovarian Follicles</th>
</tr>
</thead>
</table>

Description

The *Ovary* data frame has 308 rows and 3 columns.

Format

This data frame contains the following columns:

- **Mare** an ordered factor indicating the mare on which the measurement is made.
- **Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the oovulations for each mare occur at times 0 and 1.
- **follicles** the number of ovarian follicles greater than 10 mm in diameter.

Details

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

Source

**Oxboys**

*Heights of Boys in Oxford*

**Description**

The Oxboys data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Subject**: an ordered factor giving a unique identifier for each boy in the experiment
- **age**: a numeric vector giving the standardized age (dimensionless)
- **height**: a numeric vector giving the height of the boy (cm)
- **Occasion**: an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

**Details**

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

**Source**

---

**Oxide**

*Variability in Semiconductor Manufacturing*

**Description**

The Oxide data frame has 72 rows and 5 columns.

**Format**

This data frame contains the following columns:

- **Source**: a factor with levels 1 and 2
- **Lot**: a factor giving a unique identifier for each lot.
- **Wafer**: a factor giving a unique identifier for each wafer within a lot.
- **Site**: a factor with levels 1, 2, and 3
- **Thickness**: a numeric vector giving the thickness of the oxide layer.
Details

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

pairs.compareFits  
*Pairs Plot of compareFits Object*

Description

Scatter plots of the values being compared are generated for each pair of coefficients in x. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the `trellis` function `xyplot` is used; otherwise the `trellis` function `splom` is used.

Usage

```r
## S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

Arguments

- **x**: an object of class `compareFits`.
- **subset**: an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used.
- **key**: an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (`splom` or `xyplot`). Defaults to `TRUE`.
- **...**: optional arguments passed down to the `trellis` function generating the plots.

Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

Author(s)

José Pinheiro and Douglas Bates
pairs.lme

See Also

compareFits.plot.compareFits.pairs.lme.pairs.lmList.xyplot.splom

Examples

example(compareFits) # cF12 <- compareFits(coef(lmList(Orthodont)), .. lme(*))
pairs(cF12)

Description

Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a | operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function xyplot is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function splom is used).

Usage

## S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)

Arguments

x an object inheriting from class "lme", representing a fitted linear mixed-effects model.
form an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form, and to the left of the | operator, must evaluate to a data frame with at least two columns. Default is ~ coef(.), corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting.
label an optional character vector of labels for the variables in the pairs plot.
id an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the 1 − value percentile of the appropriate chi-square distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.
pairs.lmList

idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted
to character and used to label the points identified according to id. If given
as a one-sided formula, its right hand side must evaluate to a vector which is
converted to character and used to label the identified points. Default is the
innermost grouping factor.

grid
an optional logical value indicating whether a grid should be added to plot. De-
default is FALSE.

optional arguments passed to the Trellis plot function.

Value
a diagnostic Trellis plot.

Effect of Phenylbiguanide on Blood Pressure

Description

The PBG data frame has 60 rows and 5 columns.

Format

This data frame contains the following columns:

- **deltaBP**: a numeric vector
- **dose**: a numeric vector
- **Run**: an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1
- **Treatment**: a factor with levels MDL 72222 Placebo
- **Rabbit**: an ordered factor with levels 5 < 3 < 2 < 4 < 1

Details

Data on an experiment to examine the effect of an antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

Source

Positive-Definite Block Diagonal Matrix

Description

This function is a constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.
Usage

```
pdBlocked(value, form, nam, data, pdClass)
```

Arguments

- **value**: an optional list with elements to be used as the value argument to other `pdMat` constructors. These include: `pdMat` objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to `numeric(0)`, corresponding to an uninitialized object.

- **form**: an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by `object`. Because factors may be present in `form`, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when `value` is a list of one-sided formulas. Defaults to `NULL`.

- **nam**: an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by `object`. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when `value` is a list of vector of character strings. Defaults to `NULL`.

- **data**: an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.

- **pdClass**: an optional vector of character strings naming the `pdMat` classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when `value` is missing, or its elements are not `pdMat` objects. Defaults to "pdSymm".

Value

- a `pdBlocked` object representing a positive-definite block-diagonal matrix, also inheriting from class `pdMat`.

**pdClasses**

**Positive-Definite Matrix Classes**

**Description**

Standard classes of positive-definite matrices (pdMat) structures available in the nlme package.

**Value**

Available standard classes:

- `pdSymm`: general positive-definite matrix, with no additional structure
- `pdLogChol`: general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization
- `pdDiag`: diagonal
- `pdIdent`: multiple of an identity
- `pdCompSymm`: compound symmetry structure (constant diagonal and constant off-diagonal elements)
- `pdBlocked`: block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class
- `pdNatural`: general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization.

**Note**

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions `pdConstruct`, `pdMatrix` and `coef`. For examples of these functions, see the methods for classes `pdSymm` and `pdDiag`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`pdBlocked`, `pdCompSymm`, `pdDiag`, `pdFactor`, `pdIdent`, `pdMat`, `pdMatrix`, `pdNatural`, `pdSymm`, `pdLogChol`
**Description**

This function is a constructor for the `pdCompSymm` class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdCompSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```r
pdCompSymm(value, form, nam, data)
```

**Arguments**

- `value`: an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector of length 2. Defaults to `numeric(0)`, corresponding to an uninitialized object.
- `form`: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.
- `nam`: an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`.
- `data`: an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

- a `pdCompSymm` object representing a positive-definite matrix with compound symmetry structure, also inheriting from class `pdMat`.

pd1

pdConstruct  Construct pdMat Objects

Description

This function is an alternative constructor for the pdMat class associated with object and is mostly
used internally in other functions. See the documentation on the principal constructor function,
generally with the same name as the pdMat class of object.

Usage

pdConstruct(object, value, form, nam, data, ...)

Arguments

object  an object inheriting from class pdMat, representing a positive definite matrix.

value  an optional initialization value, which can be any of the following: a pdMat ob-

ject, a positive-definite matrix, a one-sided linear formula (with variables sepa-

rated by +), a vector of character strings, or a numeric vector. Defaults to

numeric(0), corresponding to an uninitialized object.

form  an optional one-sided linear formula specifying the row/column names for the

matrix represented by object. Because factors may be present in form, the

formula needs to be evaluated on a data.frame to resolve the names it defines.

This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam  an optional vector of character strings specifying the row/column names for the

matrix represented by object. It must have length equal to the dimension of the

underlying positive-definite matrix and unreplicated elements. This argument is

ignored when value is a vector of character strings. Defaults to NULL.

data  an optional data frame in which to evaluate the variables named in value and

form. It is used to obtain the levels for factors, which affect the dimensions

and the row/column names of the underlying matrix. If NULL, no attempt is

made to obtain information on factors appearing in the formulas. Defaults to

the parent frame from which the function was called.

...

optional arguments for some methods.

Value

a pdMat object representing a positive-definite matrix, inheriting from the same classes as object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>
See Also

`pdCompSymm, pdDiag, pdIdent, pdNatural, pdSymm`

Examples

```r
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```
pdDiag

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

pdClass an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

... some methods for this generic require additional arguments. None are used in this method.

Value a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

Author(s) José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also as.matrix.pdMat, coef.pdMat, pdBlocked, pdClasses, pdConstruct, matrix<-.pdMat

Examples

```
pd1 <- pdBlocked(list(c("A", "B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

Description This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension n, it is represented by n unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

Usage

```
pdDiag(value, form, nam, data)
```
Arguments

value: an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to numeric(0), corresponding to an uninitialized object.

form: an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam: an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data: an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdDiag object representing a diagonal positive-definite matrix, also inheriting from class pdMat.

pdFactor

The square-root factor of a positive-definite matrix

Description

A square-root factor of the positive-definite matrix represented by object is obtained. Letting \( \Sigma \) denote a positive-definite matrix, a square-root factor of \( \Sigma \) is any square matrix \( L \) such that \( \Sigma = L'L \). This function extracts \( L \).
pdFactor.reStruct

Usage

pdFactor(object)

Arguments

object an object inheriting from class pdMat, representing a positive definite matrix, which must have been initialized (i.e. length(coef(object)) > 0).

Value

a vector with a square-root factor of the positive-definite matrix associated with object stacked column-wise.

Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The pdMatrix function can be used to obtain square-root factors in matrix form.

pdFactor.reStruct

Extract Square-Root Factor from Components of an reStruct Object

Description

This method function extracts square-root factors of the positive-definite matrices corresponding to the pdMat elements of object.

Usage

## S3 method for class 'reStruct'
pdFactor(object)

Arguments

object an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
Value

a vector with square-root factors of the positive-definite matrices corresponding to the elements of object stacked column-wise.

Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The pdMatrix function can be used to obtain square-root factors in matrix form.

Examples

rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
pdFactor(rs1)

Description

This function is a constructor for the pdIdent class, representing a multiple of the identity positive-definite matrix. The matrix associated with object is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdIdent object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

Usage

pdIdent(value, form, nam, data)
pdLogChol

Arguments

value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric value. Defaults to numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdIdent object representing a multiple of the identity positive-definite matrix, also inheriting from class pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

pdLogChol | General Positive-Definite Matrix

---
Description

This function is a constructor for the `pdLogChol` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension \( n \), it is represented by \( n(n+1)/2 \) unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996).

- When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a character vector, `object` is returned as an `uninitialized` `pdLogChol` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions.
- If `value` is an `initialized` `pdMat` object, `object` will be constructed from `as.matrix(value)`.
- Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

Usage

```r
pdLogChol(value, form, nam, data)
```

Arguments

- `value` an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector. Defaults to `numeric(0)`, corresponding to an uninitialized object.
- `form` an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.
- `nam` an optional character vector specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a character vector. Defaults to `NULL`.
- `data` an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Details

Internally, the `pdLogChol` representation of a symmetric positive definite matrix is a vector starting with the logarithms of the diagonal of the Choleski factorization of that matrix followed by its upper triangular portion.

Value

- a `pdLogChol` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

pd4c[upper.tri(pd4c)]
log(diag(pd4c)) # 1 2 3

pdMat

Positive-Definite Matrix

Description

This function gives an alternative way of constructing an object inheriting from the pdMat class named in pdClass, or from data.class(object) if object inherits from pdMat, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

Usage

pdMat(value, form, nam, data, pdClass)

Arguments

value

an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.

form

an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam

an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data

an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
pdClass

an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to "pdSymm".

Value

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

pdMatrix

Extract Matrix or Square-Root Factor from a pdMat Object

Description

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting Σ denote a positive-definite matrix, a square-root factor of Σ is any square matrix L such that Σ = L'L. This function extracts Σ or L.

Usage

pdMatrix(object, factor)

Arguments

object

an object inheriting from class pdMat, representing a positive definite matrix.

factor

an optional logical value. If TRUE, a square-root factor of the positive-definite matrix represented by object is returned; else, if FALSE, the positive-definite matrix is returned. Defaults to FALSE.

Value

if factor is FALSE the positive-definite matrix represented by object is returned; else a square-root of the positive-definite matrix is returned.
pdMatrix.reStruct

as.matrix.reStruct, reStruct, pdMat, pdMatrix, pdMatrix.pdMat

Examples

rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
pdMatrix(rs1)

Description

This function is a constructor for the pdNatural class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with object is of dimension n, it is represented by n(n + 1)/2 parameters. Letting σ_{ij} denote the ij-th element of the underlying positive definite matrix and ρ_{ij} = σ_{ij}/√{σ_{ii}σ_{jj}}, i ≠ j denote the associated "correlations", the "natural" parameters are given by √{σ_{ii}, i = 1, . . . , n and log((1 + ρ_{ij})/(1 − ρ_{ij})), i ≠ j. Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

Usage

pdNatural(value, form, nam, data)

Arguments

value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
**Value**

A `pdNatural` object representing a general positive-definite matrix in natural parametrization, also inheriting from class `pdMat`.

**pdSymm**

*General Positive-Definite Matrix*

**Description**

This function is a constructor for the `pdSymm` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension \( n \), it is represented by \( n(n + 1)/2 \) unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```r
pdSymm(value, form, nam, data)
```

**Arguments**

- `value`: an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector. Defaults to `numeric(0)`, corresponding to an uninitialized object.
- `form`: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a `data.frame` to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`. 
Phenobarb

nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdSymm object representing a general positive-definite matrix, also inheriting from class pdMat.

Phenobarb

Phenobarbitol Kinetics

Description

The Phenobarb data frame has 744 rows and 7 columns.

Format

This data frame contains the following columns:

Subject an ordered factor identifying the infant.
Wt a numeric vector giving the birth weight of the infant (kg).
Apgar an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.
ApgarInd a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.
time a numeric vector giving the time when the sample is drawn or drug administered (hr).
dose a numeric vector giving the dose of drug administered (μg/kg).
conc a numeric vector giving the phenobarbital concentration in the serum (μg/L).
Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn (1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

Source

Grasela and Donn (1985), Neonatal population pharmacokinetics of phenobarbital derived from routine clinical data, *Developmental Pharmacology and Therapeutics*, 8, 374-383.

Description

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

Usage

```r
phenoModel(Subject, time, dose, lCl, lV)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subject</td>
<td>an integer vector of subject identifiers. These should be sorted in increasing order.</td>
</tr>
<tr>
<td>time</td>
<td>numeric. A vector of the times at which the sample was drawn or the drug administered (hr).</td>
</tr>
<tr>
<td>dose</td>
<td>numeric. A vector of doses of drug administered (ug/kg).</td>
</tr>
<tr>
<td>lCl</td>
<td>numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.</td>
</tr>
<tr>
<td>lV</td>
<td>numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.</td>
</tr>
</tbody>
</table>

Details

See the details section of *Phenobarb* for a description of the model function that `phenoModel` evaluates.
Pixel

Value

a numeric vector of predicted phenobarbital concentrations.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

Description

The Pixel data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time.

Format

This data frame contains the following columns:

- **Dog** a factor with levels 1 to 10 designating the dog on which the scan was made
- **Side** a factor with levels L and R designating the side of the dog being scanned
- **day** a numeric vector giving the day post injection of the contrast on which the scan was made
- **pixel** a numeric vector of pixel intensities

Source

Examples

```r
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
            random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```
Description

an xplot of the autocorrelations versus the lags, with type = "h", is produced. If alpha > 0, curves representing the critical limits for a two-sided test of level alpha for the autocorrelations are added to the plot.

Usage

## S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)

Arguments

x an object inheriting from class ACF, consisting of a data frame with two columns named lag and ACF, representing the autocorrelation values and the corresponding lags.

alpha an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level alpha are added to the plot. Default is 0, in which case no lines are plotted.

xlab,ylab optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".

grid an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

... optional arguments passed to the xyplot function.

Value

an xyplot Trellis plot.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

ACF, xyplot

Examples

fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
plot.augPred

Plot an augPred Object

Description

A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

Usage

```r
## S3 method for class 'augPred'
plot(x, key, grid, ...)
```

Arguments

- `x`: an object of class "augPred".
- `key`: an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE.
- `grid`: an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- `...`: optional arguments passed down to the trellis function generating the plots.

Value

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `augPred`, `xyplot`

Examples

```r
fm1 <- lme(Orthodont)
plot(augPred(fm1, level = 0:1, length.out = 2))
```
plot.compareFits

Plot a compareFits Object

Description

A Trellis dotplot of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

Usage

```r
## S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)
```

Arguments

- `x`: an object of class "compareFits".
- `subset`: an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used.
- `key`: an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (dotplot). Defaults to TRUE.
- `mark`: an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.
- `...`: optional arguments passed down to the `trellis` function generating the plots.

Value

A Trellis dotplot of the values being compared, with rows determined by the groups and panels by the coefficients.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

- `compareFits`
- `pairs.compareFits`
- `dotplot`

Examples

```r
example(compareFits) # cF12 <- compareFits(coef(lmList(Orthodont)), .. lme(*))
plot(cF12)
```
Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

### S3 method for class 'gls'
```
plot(x, form, abline, id, idLabels, idResType, grid, ...)  
```

- **Arguments**
  - **x**: an object inheriting from class "gls", representing a generalized least squares fitted linear model.
  - **form**: an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. Default is `resid(., type = "p") ~ fitted(.)`, corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.
  - **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
  - **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the `1 - value/2` quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
  - **idLabels**: an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.
  - **idResType**: an optional character string specifying the type of residuals to be used in identifying outliers, when `id` is a numeric value. If "pearson", the standardized
residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

... optional arguments passed to the Trellis plot function.

Value
a diagnostic Trellis plot.

correlation = corAR1(form = ~ 1 | Mare))
# standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") - fitted(.) ~ Mare, abline = 0)
# box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.
))
# observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))

plot.intervals.lmList  Plot lmList Confidence Intervals

Description
A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the lm components of the lmList object used to produce x. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+".
This is based on function dotplot() from package lattice.

Usage
## S3 method for class 'intervals.lmList'
plot(x, xlab = "", ylab = attr(x, "groupsName"),
    strip = function(...) strip.default(..., style = 1),
    ...)

Arguments

- **x**: an object inheriting from class "intervals.lmList", representing confidence intervals and estimates for the coefficients in the lm components of the lmList object used to produce x.
- **xlab, ylab**: axis labels, each with a sensible default.
- **strip**: a function or FALSE, see dotplot() from package lattice.
- **...**: optional arguments passed to the dotplot function (see above).

Value

A Trellis plot with the confidence intervals on the coefficients of the individual lm components of the lmList that generated x.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**plot.lme**

Plot an lme or nls object

Description

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function histogram is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if `form` is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

```r
# S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
# S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```
Arguments

x
an object inheriting from class "lme", representing a fitted linear mixed-effects model, or from nls, representing an fitted nonlinear least squares model.

form
an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "p") ~ fitted(.,), corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.

abline
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

idResType
an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid
an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

...optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot.

# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

plot.lmList

Plot an lmList Object

Description

Diagnostic plots for the linear model fits corresponding to the x components are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

```r
## S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

Arguments

- **x**: an object inheriting from class "lmList", representing a list of lm objects with a common model.
- **form**: an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "pool") ~ fitted(.), corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.
- **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
- **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the 1 - value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is getGroups(x).

grid
an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

... optional arguments passed to the Trellis plot function.

Value
a diagnostic Trellis plot.

Examples
fm1 <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
plot.nffGroupedData

Arguments

x an object inheriting from class \texttt{nffGroupedData}, representing a \texttt{groupedData} object with a factor primary covariate and a single grouping level.

outer an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, \texttt{attr(object, \"outer\")} is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.

inner an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, \texttt{attr(object, \"inner\")} is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.

innerGroups an optional one-sided formula specifying a factor to be used for grouping the levels of the \texttt{inner} covariate. Different colors, or symbols, are used for each level of the \texttt{innerGroups} factor. Default is NULL, meaning that no \texttt{innerGroups} covariate is present.

xlab an optional character string with the label for the horizontal axis. Default is the \texttt{y} elements of \texttt{attr(object, \"labels\")} and \texttt{attr(object, \"units\")} pasted together.

ylab an optional character string with the label for the vertical axis. Default is the grouping factor name.

strip an optional function passed as the \texttt{strip} argument to the \texttt{dotplot} function. Default is \texttt{strip.default(..., style = 1)} (see \texttt{trellis.args}).

panel an optional function used to generate the individual panels in the Trellis display, passed as the \texttt{panel} argument to the \texttt{dotplot} function.

key an optional logical function or function. If TRUE and either \texttt{inner} or \texttt{innerGroups} are non-NULL, a legend for the different \texttt{inner} (\texttt{innerGroups}) levels is included at the top of the plot. If given as a function, it is passed as the key argument to the \texttt{dotplot} function. Default is TRUE if either \texttt{inner} or \texttt{innerGroups} are non-NULL and FALSE otherwise.

grid this argument is included for consistency with the \texttt{plot.nfnGroupedData} method calling sequence. It is ignored in this method function.

... optional arguments passed to the \texttt{dotplot} function.

Value

a Trellis dot-plot of the response by group.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

plot.nfnGroupedData

See Also
groupedData, dotplot

Examples

plot(Machines)
plot(Machines, inner = TRUE)

plot.nfnGroupedData  Plot an nfnGroupedData Object

Description

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

Usage

```r
## S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
     key, grid, ...)
```

Arguments

- `x`: an object inheriting from class `nfnGroupedData`, representing a groupedData object with a numeric primary covariate and a single grouping level.
- `outer`: an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to `TRUE`, `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.
- `inner`: an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to `TRUE`, `attr(object, "inner")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.
- `innerGroups`: an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or line types, are used for each level of the `innerGroups` factor. Default is `NULL`, meaning that no `innerGroups` covariate is present.
- `xlab, ylab`: optional character strings with the labels for the plot. Default is the corresponding elements of `attr(object, "labels")` and `attr(object, "units")` pasted together.
strip
an optional function passed as the strip argument to the xyplot function. Default is strip.default(..., style = 1) (see trellis.args).

aspect
an optional character string indicating the aspect ratio for the plot passed as the aspect argument to the xyplot function. Default is "xy" (see trellis.args).

panel
an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the xyplot function.

key
an optional logical function or function. If TRUE and innerGroups is non-NULL, a legend for the different innerGroups levels is included at the top of the plot. If given as a function, it is passed as the key argument to the xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE otherwise.

grid
an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

... optional arguments passed to the xyplot function.

Value
a Trellis plot of the response versus the primary covariate.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

groupedData, xyplot

Examples

# different panels per Subject
plot(Orthodont)
# different panels per gender
plot(Orthodont, outer = TRUE)
Usage

## S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
    preserve, FUN, subset, key, grid, ...)

Arguments

x an object inheriting from class nmGroupedData, representing a groupedData
    object with multiple grouping factors.
collapseLevel an optional positive integer or character string indicating the grouping level to
    use when collapsing the data. Level values increase from outermost to innermost
    grouping. Default is the highest or innermost level of grouping.
displayLevel an optional positive integer or character string indicating the grouping level to
    use for determining the panels in the Trellis display, when outer is missing.
    Default is collapseLevel.
outer an optional logical value or one-sided formula, indicating covariates that are
    outer to the displayLevel grouping factor, which are used to determine
    the panels of the Trellis plot. If equal to TRUE, the displayLevel element
    attr(object, "outer") is used to indicate the outer covariates. An outer co-
    variate is invariant within the sets of rows defined by the grouping factor. Order-
    ing of the groups is done in such a way as to preserve adjacency of groups with
    the same value of the outer variables. Defaults to NULL, meaning that no outer
    covariates are to be used.
inner an optional logical value or one-sided formula, indicating a covariate that is
    inner to the displayLevel grouping factor, which is used to associate points
    within each panel of the Trellis plot. If equal to TRUE, attr(object, "outer")
    is used to indicate the inner covariate. An inner covariate can change within the
    sets of rows defined by the grouping factor. Defaults to NULL, meaning that no
    inner covariate is present.
preserve an optional one-sided formula indicating a covariate whose levels should be
    preserved when collapsing the data according to the collapseLevel grouping
    factor. The collapsing factor is obtained by pasting together the levels of the
    collapseLevel grouping factor and the values of the covariate to be preserved.
    Default is NULL, meaning that no covariates need to be preserved.
FUN an optional summary function or a list of summary functions to be used for
    collapsing the data. The function or functions are applied only to variables in
    object that vary within the groups defined by collapseLevel. Invariant vari-
    ables are always summarized by group using the unique value that they assume
    within that group. If FUN is a single function it will be applied to each non-
    invariant variable by group to produce the summary for that variable. If FUN
    is a list of functions, the names in the list should designate classes of variables
    in the data such as ordered, factor, or numeric. The indicated function will
    be applied to any non-invariant variables of that class. The default functions to
    be used are mean for numeric factors, and Mode for both factor and ordered.
    The Mode function, defined internally in gsummary, returns the modal or most
    popular value of the variable. It is different from the mode function that returns
    the S-language mode of the variable.
subset an optional named list. Names can be either positive integers representing
    grouping levels, or names of grouping factors. Each element in the list is a
    vector indicating the levels of the corresponding grouping factor to be used for
    plotting the data. Default is NULL, meaning that all levels are used.
key: an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE.

grid: an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

...: optional arguments passed to the Trellis plot function.

Value

A Trellis display of the data collapsed over the values of the collapseLevel grouping factor and grouped according to the displayLevel grouping factor.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### S3 method for class 'ranef.lme'

Plot a ranef.lme Object

Description

Plots (class "Trellis" from package lattice) of the random effects from linear mixed effects model, i.e., the result of ranef(lme(*)) (of class "ranef.lme").

Usage

## S3 method for class 'ranef.lme'
plot(x, form = NULL, omitFixed = TRUE, level = Q, grid = TRUE, control, xlab, ylab, strip, ...)

plot.ranef.lme
Arguments

- **x**: an object inheriting from class "ranef.lme", representing the estimated coefficients or estimated random effects for the lme object from which it was produced.

- **form**: an optional formula specifying the desired type of plot.
  - If given as a one-sided formula, a `dotplot()` of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned.
  - If given as a two-sided formula (or by default, NULL), an `xyplot()` Trellis display of the random effect (coefficient) versus the named covariates is returned. In NULL case the row names of the random effects (coefficients) are used (as covariates).

See also 'Details':

- **omitFixed**: an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is TRUE.

- **level**: an optional integer value giving the level of grouping to be used for `x`. Only used when `x` is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.

- **grid**: an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is TRUE.

- **control**: an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); `span.loess`, used as the span argument in the call to `panel.loess` (default is 2/3); `degree.loess`, used as the degree argument in the call to `panel.loess` (default is 1); `cex.axis`, the character expansion factor for the x-axis (default is 0.8); `srt.axis`, the rotation factor for the x-axis (default is 0); and `mgp.axis`, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

- **xlab**, **ylab**: axis labels, each with a sensible default.

- **strip**: a function or FALSE, see `dotplot()` from package lattice.

- **...**: optional arguments passed to the Trellis dotplot function.

Details

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot (via `dotplot()` from pkg lattice) of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). Single factors (~g) or crossed factors (~g1*g2) are allowed. For a single factor, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula.

If `form` is a two-sided formula, the left hand side must be a single random effect (coefficient) and the right hand side is formed by covariates in `x` separated by +. An `xyplot()` Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (Factor or ordered) variables.
Value

A Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

ranef.lme, lme, dotplot.

Examples

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex) # "connected" boxplots
display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used.

**grid**
an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is FALSE.

**control**
an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); `span.loess`, used as the span argument in the call to `panel.loess` (default is 2/3); `degree.loess`, used as the degree argument in the call to `panel.loess` (default is 1); `cex.axis`, the character expansion factor for the x-axis (default is 0.8); `srt.axis`, the rotation factor for the x-axis (default is 0); and `mgp.axis`, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

... optional arguments passed to the Trellis `dotplot` function.

**Value**
a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex)
```

---

**plot.Variogram**

**Plot a Variogram Object**

**Description**
an `xypplot` of the semi-variogram versus the distances is produced. If `smooth` = TRUE, a loess smoother is added to the plot. If `showModel` = TRUE and `x` includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

**Usage**

```r
## S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab, ylab, type, ylim, grid, ...)
```
Arguments

- **x**: an object inheriting from class "Variogram", consisting of a data frame with two columns named `variog` and `dist`, representing the semi-variogram values and the corresponding distances.
- **smooth**: an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to `TRUE`, when `showModel` is `FALSE`.
- **showModel**: an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of `x`, if any is present, should be added to the plot. Defaults to `TRUE`, when the "modelVariog" attribute is present.
- **sigma**: an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is `NULL`, implying that no horizontal line is drawn.
- **span**: an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.
- **xlab, ylab**: optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".
- **type**: an optional character indicating the type of plot. Defaults to "p".
- **ylim**: an optional numeric vector with the limits for the y-axis. Defaults to `c(0, max(x$variog))`.
- **grid**: an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`.
- **...**: optional arguments passed to the Trellis `xyplot` function.

Value

- an `xyplot` Trellis plot.

```

pooledSD  Extract Pooled Standard Deviation

Description

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of `object`, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.
**predict.gls**

**Usage**

```r
pooledSD(object)
```

**Arguments**

- `object` an object inheriting from class `lmList`.

**Value**

The pooled standard deviation for the non-null elements of `object`, with an attribute `df` with the number of degrees-of-freedom used in the estimation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`lmList`, `lm`

**Examples**

```r
fm1 <- lmList(Orthodont)
pooledSD(fm1)
```

**predict.gls**  
**Predictions from a gls Object**

**Description**

The predictions for the linear model represented by `object` are obtained at the covariate values defined in `newdata`.

**Usage**

```r
## S3 method for class 'gls'
predict(object, newdata, na.action, ...)
```

**Arguments**

- `object` an object inheriting from class "gls", representing a generalized least squares fitted linear model.
- `newdata` an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.
- `na.action` a function that indicates what should happen when `newdata` contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- `...` some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the predicted values.

predict.gnls  Predictions from a gnls Object

Description

The predictions for the nonlinear model represented by `object` are obtained at the covariate values defined in `newdata`.

Usage

```r
## S3 method for class 'gnls'
predict(object, newdata, na.action, naPattern, ...)
```

Arguments

- `object`: an object inheriting from class "gnls", representing a generalized nonlinear least squares fitted model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned.
- `na.action`: a function that indicates what should happen when `newdata` contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- `naPattern`: an expression or formula object, specifying which returned values are to be regarded as missing.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the predicted values.
predict.lme

Predictions from an lme Object

Description

The predictions at level \( i \) are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to \( i \). The resulting values estimate the best linear unbiased predictions (BLUPs) at level \( i \). If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

Usage

```r
## S3 method for class 'lme'
predict(object, newdata, level = Q, asList = FALSE, na.action = na.fail, ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
- `level`: an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
- `asList`: an optional logical value. If TRUE and a single value is given in `level`, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of `level`.
- `na.action`: a function that indicates what should happen when `newdata` contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- `...`: some methods for this generic require additional arguments. None are used in this method.
predict.lmList

Predictions from an lmList Object

Description

If the grouping factor corresponding to object is included in newdata, the data frame is partitioned according to the grouping factor levels; else, newdata is repeated for all lm components. The predictions and, optionally, the standard errors for the predictions, are obtained for each lm component of object, using the corresponding element of the partitioned newdata, and arranged into a list with as many components as object, or combined into a single vector or data frame (if se.fit=TRUE).

Usage

## S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...) 

Arguments

object 
an object inheriting from class "lmList", representing a list of lm objects with a common model.

newdata 
an optional data frame to be used for obtaining the predictions. All variables used in the object model formula must be present in the data frame. If missing, the same data frame used to produce object is used.

subset 
an optional character or integer vector naming the lm components of object from which the predictions are to be extracted. Default is NULL, in which case all components are used.

asList 
an optional logical value. If TRUE, the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to FALSE.
predict.nlme

pool an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").

se.fit an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each lm component of object, a vector with the predictions from all lm components of object, or a data frame with columns given by the predictions and their corresponding standard errors.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

lmList, predict.lm

Examples

fm1 <- lmList(distance ~ age | Subject, Orthodont)
predict(fm1, se.fit = TRUE)

Predictions from an nlme Object

Description

The predictions at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

Usage

## S3 method for class 'nlme'
predict(object, newdata, level = Q, asList = FALSE, na.action = na.fail, naPattern = NULL, ...)

Arguments

object an object inheriting from class "nlme", representing a fitted nonlinear mixed-effects model.

newdata an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
level

an optional integer vector giving the level(s) of grouping to be used in obtaining
the predictions. Level values increase from outermost to innermost grouping,
with level zero corresponding to the population predictions. Defaults to the
highest or innermost level of grouping (and is object$dims$Q).

asList

an optional logical value. If TRUE and a single value is given in level, the
returned object is a list with the predictions split by groups; else the returned
value is either a vector or a data frame, according to the length of level.

na.action

a function that indicates what should happen when newdata contains NAs. The
default action (na.fail) causes the function to print an error message and ter-
minate if there are any incomplete observations.

naPattern

an expression or formula object, specifying which returned values are to be re-
garded as missing.

... some methods for this generic require additional arguments. None are used in
this method.

Value

if a single level of grouping is specified in level, the returned value is either a list with the predic-
tions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when
multiple grouping levels are specified in level, the returned object is a data frame with columns
given by the predictions at different levels and the grouping factors.

all.equal(p301[,"predict.fixed"],
p329[,"predict.fixed"])

## and differ by the 'Seed' effect at level 1 :

predict.nlme
print.summary.pdMat

Description

The standard deviations and correlations associated with the positive-definite matrix represented by object (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated with object, if any are present.

Usage

```r
## S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)
```

Arguments

- `x` an object inheriting from class "summary.pdMat", generally resulting from applying `summary` to an object inheriting from class "pdMat".
- `sigma` an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by object (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
- `rdig` an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.
- `Level` an optional character string with a description of the grouping level associated with object (generally corresponding to levels of grouping in a mixed-effects model). Defaults to NULL.
- `resid` an optional logical value. If TRUE an extra row with the "residual" standard deviation given in sigma will be included in the output. Defaults to FALSE.
- `...` optional arguments passed to `print.default`; see the documentation on that method function.

vf1 <- Initialize(vf1, Orthodont)
print(vf1)
```

---

**qqnorm.gls**  
*Normal Plot of Residuals from a gls Object*

**Description**

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```r
## S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```
Arguments

y
an object inheriting from class "gls", representing a generalized least squares fitted model.

form
an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form and to the left of a | operator must evaluate to a residuals vector. Default is ~ resid(. , type = "p"), corresponding to a normal plot of the standardized residuals.

abline
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

grid
an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

Value
a diagnostic Trellis plot for assessing normality of residuals.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
qqnorm.lme

Normal Plot of Residuals or Random Effects from an lme Object

Description

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

Usage

## S3 method for class 'lme'

qqnorm(y, form, abline, id, idLabels, grid, ...)

Arguments

y
an object inheriting from class "lme", representing a fitted linear mixed-effects model or from class "lmList", representing a list of lm objects, or from class "lm", representing a fitted linear model, or from class "nls", representing a nonlinear least squares fitted model.

form
an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain y can be referenced. In addition, y itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form and to the left of a | operator must evaluate to a residuals vector, or a random effects matrix. Default is resid(. , type = "p"), corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting.

abline
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

grid
an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

... optional arguments passed to the Trellis plot function.
Quinidine

Value

a diagnostic Trellis plot for assessing normality of residuals or random effects.

lme, plot.lme

Examples

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
## normal plot of standardized residuals by gender
qqnorm(fm1, ~ resid(., type = "p") | Sex, abline = c(0, 1))
## normal plots of random effects
qqnorm(fm1, ~ranef(.))

Quinidine Kinetics

Description

The Quinidine data frame has 1471 rows and 14 columns.

Format

This data frame contains the following columns:

- **Subject**  a factor identifying the patient on whom the data were collected.
- **time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.
- **conc** a numeric vector giving the serum quinidine concentration (mg/L).
- **dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.
- **interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.
- **Age** a numeric vector giving the age of the subject on entry to the study (yr).
- **Height** a numeric vector giving the height of the subject on entry to the study (in.).
- **Weight** a numeric vector giving the body weight of the subject (kg).
- **Race** a factor with levels Caucasian, Latin, and Black identifying the race of the subject.
- **Smoke** a factor with levels no and yes giving smoking status at the time of the measurement.
- **Ethanol** a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.
- **Heart** a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.
- **Creatinine** an ordered factor with levels < 50 < = 50 indicating the creatinine clearance (mg/min).
- **glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.
Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation or ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

**Source**

**quinModel**

Model function for the Quinidine data

**Description**

A model function for a model used with the Quinidine data. This function calls compiled C code.

**Usage**

`quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)`

**Arguments**

- **Subject**
  
a factor identifying the patient on whom the data were collected.

- **time**
  
a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

- **conc**
  
a numeric vector giving the serum quinidine concentration (mg/L).

- **dose**
  
a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

- **interval**
  
a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

- **lV**
  
umERIC. A vector of values of the natural log of the effective volume of distribution according to Subject and time.

- **lKa**
  
umERIC. A vector of values of the natural log of the absorption rate constant according to Subject and time.

- **lCl**
  
umERIC. A vector of values of the natural log of the clearance parameter according to Subject and time.
Details

See the details section of Quinidine for a description of the model function that quinModel evaluates.

Value

a numeric vector of predicted quinidine concentrations.

Rail

Evaluation of Stress in Railway Rails

Description

The Rail data frame has 18 rows and 2 columns.

Format

This data frame contains the following columns:

- **Rail**: an ordered factor identifying the rail on which the measurement was made.
- **travel**: a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds). The value given is the original travel time minus 36,100 nanoseconds.

Details

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

random.effects  

Extract Random Effects

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include \texttt{lmList} and \texttt{lme}.

Usage

\begin{verbatim}
random.effects(object, ...)  
ranef(object, ...)
\end{verbatim}

Arguments

\begin{verbatim}
object  
any fitted model object from which random effects estimates can be extracted.

...

some methods for this generic function require additional arguments.
\end{verbatim}

Value

will depend on the method function used; see the appropriate documentation.

References

See Also

\texttt{ranef.lmList}, \texttt{ranef.lme}

Examples

\begin{verbatim}
## see the method function documentation
\end{verbatim}

ranef.lme  

Extract \texttt{lme} Random Effects

Description

The estimated random effects at level \( i \) are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

Usage

\begin{verbatim}
## S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,  
standard, omitGroupingFactor, subset, ...)
\end{verbatim}
Arguments

object an object inheriting from class "lme", representing a fitted linear mixed-effects model.

augFrame an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.

level an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.

data an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.

which an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.

FUN an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

standard an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to FALSE.

omitGroupingFactor an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset an optional expression indicating for which rows the random effects should be extracted.

... some methods for this generic require additional arguments. None are used in this method.

Value

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in level and, optionally, other covariates summarized over groups. The returned object inherits from classes random.effects.lme and data.frame.

ranef.lmList

Extract lmList Random Effects

Description
The difference between the individual lm components coefficients and their average is calculated.

Usage
## S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard, omitGroupingFactor, ...)

Arguments
object an object inheriting from class "lmList", representing a list of lm objects with a common model.
augFrame an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
data an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.
which an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
FUN an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
standard an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.

omitGroupingFactor an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

RatPupWeight

The weight of rat pups

Description

The RatPupWeight data frame has 322 rows and 5 columns.

Format

This data frame contains the following columns:

weight a numeric vector
sex a factor with levels Male Female
Litter an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12
Lsize a numeric vector
Treatment an ordered factor with levels Control < Low < High
Recalculation of a Condensed Linear Model Object

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, modelStruct, reStruct, and varFunc.

Usage
recalc(object, conLin, ...)

Arguments
- object: any object which induces a recalculation of the condensed linear model object conLin.
- conLin: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- ...: some methods for this generic can take additional arguments.

Value
the recalculated condensed linear model object.

Note
This function is only used inside model fitting functions, such as lme and gls, that require recalculation of a condensed linear model object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
recalc.corStruct, recalc.modelStruct, recalc.reStruct, recalc.varFunc

Examples
## see the method function documentation
recalc.corStruct

Recalculate for corStruct Object

Description

This method function pre-multiples the "Xy" component of conLin by the transpose square-root factor(s) of the correlation matrix (matrices) associated with object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

Usage

## S3 method for class 'corStruct'
recalc(object, conLin, ...)

Arguments

object an object inheriting from class "corStruct", representing a correlation structure.

conLin a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.

... some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as lme and gls, that allow correlated error terms.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

corFactor, logLik.corStruct
Recalculate for a modelStruct Object

Description

This method function recalculates the condensed linear model object using each element of object sequentially from last to first.

Usage

```r
# S3 method for class 'modelStruct'
recalc(object, conLin, ...)
```

Arguments

- **object**: an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to attr(object, "conLin").
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is generally only used inside model fitting functions, such as lme and gls, that allow model components, such as correlated error terms and variance functions.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

recalc.corStruct, recalc.reStruct, recalc.varFunc
### Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by object and conLin (assuming spherical within-group covariance structure), evaluated at coef(object) is calculated and added to the logLik component of conLin. The settings attribute of object determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

### Usage

```
## S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

### Arguments

- **object**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **conLin**: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- **...**: some methods for this generic require additional arguments. None are used in this method.

### Value

the condensed linear model with its logLik component updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

- `logLik`, `lme`, `recalc`, `reStruct`

---

### Description

This method function pre-multiples the "Xy" component of conLin by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.
Usage

```r
## S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

Arguments

- **object**: an object inheriting from class "varFunc", representing a variance function structure.
- **conLin**: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as lme and gls, that allow heteroscedastic error terms.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Relaxin

Assay for Relaxin

Description

The Relaxin data frame has 198 rows and 3 columns.

Format

This data frame contains the following columns:

- **Run**: an ordered factor with levels 5 < 8 < 9 < 3 < 4 < 2 < 7 < 1 < 6
- **conc**: a numeric vector
- **cAMP**: a numeric vector

Source

Remifentanil

Pharmacokinetics of Remifentanil

Description

Intravenous infusion of remifentanil (a strong analgesic) in different rates over varying time periods was applied to a total of 65 patients. Concentration measurements of remifentanil were taken along with several covariates resulting in the Remifentanil data frame with 2107 rows and 12 columns.

Usage

data("Remifentanil", package = "nlme")

Format

This data frame (of class "groupedData", specifically "nfnGroupedData") contains the following columns:

- ID: numerical (patient) IDs.
- Subject: an ordered factor with 65 levels (of the IDs): 30 < 21 < 25 < 23 < 29 < ... < 36 < 6 < 5 < 10 < 9.
- Time: time from beginning of infusion in minutes (numeric).
- conc: remifentanil concentration in [ng / ml] (numeric).
- Rate: infusion rate in [µg / min].
- Amt: amount of remifentanil given in the current time interval in [µg].
- Age: age of the patient in years.
- Sex: gender of the patient, a factor with levels Female and Male.
- Ht: height of the patient in cm.
- Wt: weight of the patient in kg.
- BSA: body surface area (DuBois and DuBois 1916): \( BSA := Wt^{0.425} \cdot Ht^{0.725} \cdot 0.007184 \).
- LBM: lean body mass (James 1976), with slightly different formula for men \( LBM_m := 1.1Wt - 128(Wt/Ht)^2 \), and women \( LBM_f := 1.07Wt - 148(Wt/Ht)^2 \).

Examples

plot(Remifentanil, type = "l", lwd = 2) # shows the 65 patients' remi profiles

## The same on log-log scale (*more* sensible for modeling?):
plot(Remifentanil, type = "l", lwd = 2, scales = list(log=TRUE))

str(Remifentanil)
summary(Remifentanil)

plot(xtabs(~Subject, Remifentanil))
summary(unclass(table(Remifentanil$Subject)))
## between 20 and 54 measurements per patient (median: 24; mean: 32.42)

## Only first measurement of each patient:
dim(Remi.1 <- Remifentanil[!duplicated(Remifentanil[,"ID"]],]) # 65 x 12

LBMfn <- function(Wt, Ht, Sex) ifelse(Sex == "Female",
  1.07 * Wt - 148*(Wt/Ht)^2,
  1.1 * Wt - 128*(Wt/Ht)^2)

with(Remi.1,
  stopifnot(all.equal(BSA, Wt^{0.425} * Ht^{0.725} * 0.007184, tol = 1.5e-5),
    all.equal(LBM, LBMfn(Wt, Ht, Sex), tol = 7e-7))

## Rate: typically 3 µg / kg body weight, but:
sunflowerplot(Rate ~ Wt, Remifentanil)
abline(0,3, lty=2, col=adjustcolor("black", 0.5))

residuals.gls

Extract gls Residuals

Description

The residuals for the linear model represented by object are extracted.

Usage

## S3 method for class 'gls'
residuals(object, type, ...)
residuals.glsStruct

Arguments

- **object**: an object inheriting from class "gls", representing a generalized least squares fitted linear model, or from class gnls, representing a generalized nonlinear least squares fitted linear model.

- **type**: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response".

... some methods for this generic function require additional arguments. None are used in this method.

Value

A vector with the residuals for the linear model represented by object.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

- gls

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
          correlation = corAR1(form = ~ 1 | Mare))
residuals(fm1)
```

---

**residuals.glsStruct**  
*Calculate glsStruct Residuals*

Description

The residuals for the linear model represented by object are extracted.

Usage

```r
## S3 method for class 'glsStruct'
residuals(object, glsFit, ...)
```
Arguments

object an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.

glsFit an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit").

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the residuals for the linear model represented by object.

Note

This method function is primarily used inside gls and residuals.gls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gls, glsStruct, residuals.gls, fitted.glsStruct

residuals.gnlsStruct

Calculate gnlsStruct Residuals

Description

The residuals for the nonlinear model represented by object are extracted.

Usage

## S3 method for class 'gnlsStruct'
residuals(object, ...)

Arguments

object an object inheriting from class "gnlsStruct", representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the residuals for the nonlinear model represented by object.
Note

This method function is primarily used inside gnls and residuals.gnls.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

gnls, residuals.gnls, fitted.gnlsStruct

residuals.lme

Extract lme Residuals

Description

The residuals at level \( i \) are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if type="pearson"). The fitted values at level \( i \) are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to \( i \).

Usage

```r
## S3 method for class 'lme'
residuals(object, level = Q,
        type = c("response", "pearson", "normalized"), asList = FALSE, ...)
```

Arguments

- **object**: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.
- **type**: an optional character string specifying the type of residuals to be used. If "response", as by default, the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided.
- **asList**: an optional logical value. If TRUE and a single value is given in `level`, the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of `level`. Defaults to FALSE.
- **...**: some methods for this generic require additional arguments. None are used in this method.
Value

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`lme`, `fitted.lme`

Examples

```r
fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
head(residuals(fm1, level = 0:1))
summary(residuals(fm1) /
        residuals(fm1, type = "p")) # constant scaling factor 1.432
```

Description

The residuals at level `i` are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level `i` are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to `i`.

Usage

```r
## S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

Arguments

- `object`: an object inheriting from class "`lmeStruct`", representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- `level`: an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- `conLin`: an optional condensed linear model object, consisting of a list with components "`Xy`", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to `attr(object, "conLin")`.
- `lmeFit`: an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to `attr(object, "lmeFit")`.
- `...`: some methods for this generic accept optional arguments.
Value

if a single level of grouping is specified in level, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in level, the returned object is a matrix with columns given by the residuals at different levels.

Note

This method function is primarily used within the lme function.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

residuals.lmList

Extract lmList Residuals

Description

The residuals are extracted from each lm component of object and arranged into a list with as many components as object, or combined into a single vector.

Usage

## S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)

Arguments

object an object inheriting from class "lmList", representing a list of lm objects with a common model.

subset an optional character or integer vector naming the lm components of object from which the residuals are to be extracted. Default is NULL, in which case all components are used.

type an optional character string specifying the type of residuals to be extracted. Options include "response" for the "raw" residuals (observed - fitted), "pearson" for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each lm fit, and "pooled.pearson" for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response".

asList an optional logical value. If TRUE, the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.
Value

a list with components given by the residuals of each \texttt{lm} component of \texttt{object}, or a vector with the residuals for all \texttt{lm} components of \texttt{object}.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

residuals.nlmeStruct \hspace{1cm} \textit{Calculate nlmeStruct Residuals}

Description

The residuals at level \(i\) are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level \(i\) are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to \(i\) and evaluating the model function at the resulting estimated parameters.

Usage

\begin{verbatim}
## S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
\end{verbatim}

Arguments

- \texttt{object} an object inheriting from class "\texttt{nlmeStruct}"\texttt{'}, representing a list of mixed-effects model components, such as \texttt{reStruct}, \texttt{corStruct}, and \texttt{varFunc} objects.
- \texttt{level} an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from \texttt{object}. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- \texttt{conLin} an optional condensed linear model object, consisting of a list with components "\texttt{Xy}"\texttt{'}, corresponding to a regression matrix (\(X\)) combined with a response vector (\(y\)), and "\texttt{logLik}\texttt{'}", corresponding to the log-likelihood of the underlying \texttt{nlme} model. Defaults to \texttt{attr(object, "conLin")}.
- \texttt{...} optional arguments to the residuals generic. Not used.

Value

if a single level of grouping is specified in \texttt{level}, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in \texttt{level}, the returned object is a matrix with columns given by the residuals at different levels.
reStruct

Note

This method function is primarily used within the nlme function.

reStruct

Random Effects Structure

Description

This function is a constructor for the reStruct class, representing a random effects structure and consisting of a list of pdMat objects, plus a settings attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

Usage

reStruct(object, pdClass, REML, data)

## S3 method for class 'reStruct'

print(x, sigma, reEstimates, verbose, ...)

Arguments

object any of the following: (i) a one-sided formula of the form ~x1+...+xn | g1/.../gm, with x1+...+xn specifying the model for the random effects and g1/.../gm the grouping structure (m may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form ~x1+...+xn | g, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form ~x1+...+xn, or a pdMat object with a formula (i.e. a non-NULL value for formula(object)), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an reStruct object.

pdClass an optional character string with the name of the pdMat class to be used for the formulas in object. Defaults to "pdLogChol" which corresponds to a general positive-definite matrix (Log-Cholesky parametrization).
**REML**
an optional logical value. If **TRUE**, the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if **FALSE**, maximum likelihood will be used. Defaults to **FALSE**.

**data**
an optional data frame in which to evaluate the variables used in the random effects formulas in object. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying pdMat objects. If **NULL**, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

**x**
an object inheriting from class `reStruct` to be printed.

**sigma**
an optional numeric value used as a multiplier for the square-root factors of the pdMat components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.

**reEstimates**
an optional list with the random effects estimates for each level of grouping. Only used when `verbose = TRUE`.

**verbose**
an optional logical value determining if the random effects estimates should be printed. Defaults to **FALSE**.

**...**
Optional arguments can be given to other methods for this generic. None are used in this method.

**Value**
an object inheriting from class `reStruct`, representing a random effects structure.

**Author(s)**
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**
groupedData, lme, pdMat, solve.reStruct, summary.reStruct, update.reStruct

**Examples**
```r
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
rs1 # 2 entries "Uninitialized"
str(rs1) # a bit more
```

**Description**
The model object is fit to the data. Using the fitted values of the parameters, `nsim` new data vectors from this model are simulated. Both `object` and `m2` are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

**Usage**
```r
## S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2,
        method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)
```
Arguments

**object**
an object inheriting from class "lme", representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to lme. This argument defines the null model.

**m2**
an "lme" object or a list, like object containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model object and m2 need to be specified.

**seed**
an optional integer that is passed to set.seed. Defaults to a random integer.

**method**
an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to c("REML", "ML"), in which case both methods are used.

**nsim**
an optional positive integer specifying the number of simulations to perform. Defaults to 1. This has changed. Previously the default was 1000.

**niterEM**
an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the object and m2 to each simulated set of data. Defaults to c(40, 200).

**useGen**
an optional logical value. If TRUE, the nlminb optimizer is used with numerical derivatives of the log-likelihood. If FALSE, the nlm algorithm is used with an analytic gradient. The default depends on the "pdMat" classes used in object and m2: if both are standard classes (see pdClasses) then defaults to FALSE, otherwise defaults to TRUE.

... optional additional arguments. None are used.

Value

an object of class simulate.lme with components null and alt. Each of these has components ML and/or REML which are matrices. An attribute called seed contains the seed that was used for the random number generator.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

solve.pdMat

Calculate Inverse of a Positive-Definite Matrix

Description

The positive-definite matrix represented by a is inverted and assigned to a.

Usage

## S3 method for class 'pdMat'
solve(a, b, ...)

Arguments

a 
an object inheriting from class "pdMat", representing a positive definite matrix.
b 
this argument is only included for consistency with the generic function and is not used in this method function.
... 
some methods for this generic require additional arguments. None are used in this method.

Value

a pdMat object similar to a, but with coefficients corresponding to the inverse of the positive-definite matrix represented by a.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

pdMat

Examples

    pd1 <- pdCompSymm(3 * diag(3) + 1)
    solve(pd1)

solve.reStruct

Apply Solve to an reStruct Object

Description

Solve is applied to each pdMat component of a, which results in inverting the positive-definite matrices they represent.

Usage

## S3 method for class 'reStruct'
solve(a, b, ...)
Arguments

- **a**: an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- **b**: this argument is only included for consistency with the generic function and is not used in this method function.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

an reStruct object similar to a, but with the pdMat components representing the inverses of the matrices represented by the components of a.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

solve.pdMat.reStruct

Examples

```r
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
                    B = pdDiag(2 * diag(4), form = ~Educ)))
solve(rs1)
```

Soybean Growth of soybean plants

Description

The Soybean data frame has 412 rows and 5 columns.

Format

This data frame contains the following columns:

- **Plot**: a factor giving a unique identifier for each plot.
- **Variety**: a factor indicating the variety: Forrest (F) or Plant Introduction #416937 (P).
- **Year**: a factor indicating the year the plot was planted.
- **Time**: a numeric vector giving the time the sample was taken (days after planting).
- **weight**: a numeric vector giving the average leaf weight per plant (g).

Details

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction #416937 (P), an experimental strain, and Forrest (F), a commercial variety.”
Source

Examples

```r
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

### splitFormula

#### Split a Formula

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

#### Usage

```r
splitFormula(form, sep)
```

#### Arguments

- **form**: a formula object.
- **sep**: an optional character string specifying the separator to be used for splitting the formula. Defaults to `"/"`.

#### Value

A list of formulas, corresponding to the split of `form` according to `sep`.

#### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

#### See Also

`formula`

#### Examples

```r
splitFormula(~ g1/g2/g3)
```
Spruce  

Growth of Spruce Trees

Description

The Spruce data frame has 1027 rows and 4 columns.

Format

This data frame contains the following columns:

- **Tree**: a factor giving a unique identifier for each tree.
- **days**: a numeric vector giving the number of days since the beginning of the experiment.
- **logSize**: a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.
- **plot**: a factor identifying the plot in which the tree was grown.

Details

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

Source

summary.corStruct  

Summarize a corStruct Object

Description

This method function prepares object to be printed using the print.summary method, by changing its class and adding a structName attribute to it.

Usage

```r
## S3 method for class 'corStruct'
summary(object, structName, ...)
```

Arguments

- **object**: an object inheriting from class "corStruct", representing a correlation structure.
- **structName**: an optional character string defining the type of correlation structure associated with object, to be used in the print.summary method. Defaults to class(object)[1].
- **...**: some methods for this generic require additional arguments. None are used in this method.
Value

An object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

Author(s)

José Pinheiro and Douglas Bates

summary.gls

---

`summary.gls` *Summarize a Generalized Least Squares gls Object*

Description

Additional information about the linear model fit represented by `object` is extracted and included as components of `object`.

Usage

```r
## S3 method for class 'gls'
summary(object, verbose, ...)
```

Arguments

- `object`: an object inheriting from class "gls", representing a generalized least squares fitted linear model.
- `verbose`: an optional logical value used to control the amount of output when the object is printed. Defaults to FALSE.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

An object inheriting from class `summary.gls` with all components included in `object` (see `glsObject` for a full description of the components) plus the following components:

- `corBeta`: approximate correlation matrix for the coefficients estimates
- `tTable`: a matrix with columns `Value`, `Std. Error`, `t-value`, and `p-value` representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a t approximation. Rows correspond to the different coefficients.
summary.lme

residuals if more than five observations are used in the gls fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.

AIC the Akaike Information Criterion corresponding to object.
BIC the Bayesian Information Criterion corresponding to object.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also
AIC, BIC, gls, summary

Examples

fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary, correlation = corAR1(form = ~ 1 | Mare))

coef(summary(fm1)) # "the matrix"

summary.lme Summarize an lme Object

Description
Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object has a print and a coef method, the latter returning the coefficient’s tTtable.

Usage

## S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
## S3 method for class 'summary.lme'
print(x, verbose = FALSE, ...)

Arguments

object an object inheriting from class "lme", representing a fitted linear mixed-effects model.
adjustSigma an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by \(\sqrt{\frac{n_{\text{obs}}}{n_{\text{obs}} - n_{\text{par}}}}\), converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
verbose an optional logical value used to control the amount of output in the print.summary.lme method. Defaults to FALSE.
... additional optional arguments passed to methods, mainly for the print method.
x a "summary.lme" object.
**summary.lmList**

**Value**

an object inheriting from class `summary.lme` with all components included in `object` (see `lmeObject` for a full description of the components) plus the following components:

- `corFixed`: approximate correlation matrix for the fixed effects estimates.
- `tTable`: a matrix with columns named `Value`, `Std. Error`, `DF`, `t-value`, and `p-value` representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects.
- `residuals`: if more than five observations are used in the `lme` fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.
- `AIC`: the Akaike Information Criterion corresponding to `object`.
- `BIC`: the Bayesian Information Criterion corresponding to `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`AIC`, `BIC`, `lme`.

**Examples**

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
(s1 <- summary(fm1))
coef(s1) # the (coef | Std.E | t | P-v ) matrix
```

---

**summary.lmList**  
*Summarize an lmList Object*

**Description**

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

**Usage**

```r
## S3 method for class 'lmList'
summary(object, pool, ...)
```

**Arguments**

- `object`: an object inheriting from class "`lmList`", representing a list of `lm` fitted objects.
- `pool`: an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.
Value

a list with summary statistics obtained by applying summary.lm to the elements of object, inheriting from class summary.lmList. The components of value are:

call

a list containing an image of the lmList call that produced object.

coefficients

a three dimensional array with summary information on the lm coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.

correlation

a three dimensional array with the correlations between the individual lm coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by lm component.

cov.unscaled

a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by lm component.

df

an array with the number of degrees of freedom for the model and for residuals, for each lm component.

df.residual

the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all lm components.

fstatistics

an array with the F test statistics and corresponding degrees of freedom, for each lm component.

pool

the value of the pool argument to the function.

r.squared

a vector with the multiple R-squared statistics for each lm component.

residuals

a list with components given by the residuals from individual lm fits.

RSE

the pooled estimate of the residual standard error.

sigma

a vector with the residual standard error estimates for the individual lm fits.

terms

the terms object used in fitting the individual lm components.

### summary.modelStruct

**Summary a modelStruct Object**

**Description**

This method function applies summary to each element of object.

**Usage**

```r
## S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

- `object` an object inheriting from class "modelStruct", representing a list of model components, such as `reStruct`, `corStruct` and `varFunc` objects.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with elements given by the summarized components of object. The returned value is of class `summary.modelStruct`, also inheriting from the same classes as object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `summary`

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                   corStruct = corAR1(0.3))
summary(lms1)
```

### summary.nlsList

**Summarize an nlsList Object**

**Description**

The `summary` function is applied to each nls component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.nlsList` method.

**Usage**

```r
## S3 method for class 'nlsList'
summary(object, ...)
```

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                   corStruct = corAR1(0.3))
summary(lms1)
```
Arguments

object      an object inheriting from class "nlsList", representing a list of nls fitted objects.
...                  optional arguments to the summary.lmList method. One such optional argument is pool, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").

Value

a list with summary statistics obtained by applying summary to the elements of object, inheriting from class summary.nlsList. The components of value are:

  call a list containing an image of the nlsList call that produced object.
  parameters a three dimensional array with summary information on the nls coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
  correlation a three dimensional array with the correlations between the individual nls coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by nls component.
  cov.unscaled a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by nls component.
  df an array with the number of degrees of freedom for the model and for residuals, for each nls component.
  df.residual the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all nls components.
  pool the value of the pool argument to the function.
  RSE the pooled estimate of the residual standard error.
  sigma a vector with the residual standard error estimates for the individual lm fits.

nlsList, summary

Examples

fm1 <- nlsList(SSasymp, Loblolly)
summary(fm1)
Description

Attributes structName and noCorrelation, with the values of the corresponding arguments to the method function, are appended to object and its class is changed to summary.pdMat.

Usage

```r
## S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

Arguments

- **object**: an object inheriting from class "pdMat", representing a positive definite matrix.
- **structName**: an optional character string with a description of the pdMat class. Default depends on the method function: "Blocked" for pdBlocked, "Compound Symmetry" for pdCompSymm, "Diagonal" for pdDiag, "Multiple of an Identity" for pdIdent, "General Positive-Definite, Natural Parametrization" for pdNatural, "General Positive-Definite" for pdSymm, and data.class(object) for pdMat.
- **noCorrelation**: an optional logical value indicating whether correlations are to be printed in print.summary.pdMat. Default depends on the method function: FALSE for pdDiag and pdIdent, and TRUE for all other classes.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

an object similar to object, with additional attributes structName and noCorrelation, inheriting from class summary.pdMat.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
**summary.varFunc**

*Summarize "varFunc" Object*

**Description**

A `structName` attribute, with the value of corresponding argument, is appended to object and its class is changed to `summary.varFunc`.

**Usage**

```r
## S3 method for class 'varFunc'
summary(object, structName, ...)
```

**Arguments**

- `object` an object inheriting from class "varFunc", representing a variance function structure.
- `structName` an optional character string with a description of the `varFunc` class. Default depends on the method function:
  - for `varComb`: "Combination of variance functions",
  - for `varConstPower`: "Constant plus power of variance covariate",
  - for `varConstProp`: "Constant plus proportion of variance covariate",
  - for `varExp`: "Exponential of variance covariate",
  - for `varIdent`: "Different standard deviations per stratum",
  - for `varPower`: "Power of variance covariate",
  - for `varFunc`: `data.class(object)`.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object`, with an additional attribute `structName`, inheriting from class `summary.varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

- **Formulation**: a factor with levels Berkmycin tetramycin

Source

update.modelStruct  
Update a modelStruct Object

Description

This method function updates each element of object, allowing the access to data.

Usage

```r
## S3 method for class 'modelStruct'
update(object, data, ...)
```

Arguments

- `object`: an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.
- `data`: a data frame in which to evaluate the variables needed for updating the elements of object.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

an object similar to object (same class, length, and names), but with updated elements.

Note

This method function is primarily used within model fitting functions, such as lme and gls, that allow model components such as variance functions.

update.varFunc  
Update varFunc Object

Description

If the formula(object) includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.
Usage

```r
## S3 method for class 'varFunc'
update(object, data, ...)
```

Arguments

- `object`: an object inheriting from class "varFunc", representing a variance function structure.
- `data`: a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s).
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

If `formula(object)` includes a "." term, an `varFunc` object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

### varClasses

#### Variance Function Classes

Description

Standard classes of variance function structures (varFunc) available in the nlme package. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

Value

Available standard classes:

- `varExp`: exponential of a variance covariate.
- `varPower`: power of a variance covariate.
- `varConstPower`: constant plus power of a variance covariate.
- `varConstProp`: constant plus proportion of a variance covariate.
- `varIdent`: constant variance(s), generally used to allow different variances according to the levels of a classification factor.
- `varFixed`: fixed weights, determined by a variance covariate.
- `varComb`: combination of variance functions.
**Note**

Users may define their own varFunc classes by specifying a constructor function and, at a minimum, methods for the functions coef, coef<-, and initialize. For examples of these functions, see the methods for class varPower.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

varComb, varConstPower, varConstProp, varExp, varFixed, varIdent, varPower, summary.varFunc

---

**Description**

This function is a constructor for the varComb class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the varFunc objects listed in . . .

**Usage**

varComb(...)

**Arguments**

... objects inheriting from class varFunc representing variance function structures.

**Value**

a varComb object representing a combination of variance functions, also inheriting from class varFunc.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

varClasses, varWeights.varComb, coef.varComb
Examples

```r
vf1 <- varComb(varIdent(form = ~1|Sex), varPower())
```

---

**varConstPower**

*Constant Plus Power Variance Function*

**Description**

This function is a constructor for the varConstPower class, representing a constant plus power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the constant plus power variance function is defined as $\sigma^2(v) = (\theta_1 + |v|^{\theta_2})^2$, where $\theta_1, \theta_2$ are the variance function coefficients. When a grouping factor is present, different $\theta_1, \theta_2$ are used for each factor level.

**Usage**

```r
varConstPower(const, power, form, fixed)
```

**Arguments**

- `const, power` optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in `form`. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for `const`. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- `form` an optional one-sided formula of the form ~ v, or ~ v | g, specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, as in ~ v | g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ fitted(.) representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- `fixed` an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.
Value

- A `varConstPower` object representing a constant plus power variance function structure, also inheriting from class `varFunc`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

See Also

`varClasses`, `varWeights`, `varFunc`, `coef.varConstPower`

Examples

```R
vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)
```
to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, as in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

`fixed` an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

Value

a `varConstProp` object representing a constant plus proportion variance function structure, also inheriting from class `varFunc`.

Note

The error model underlying this variance function structure can be understood to result from two uncorrelated sequences of standardized random variables (Lavielle, M. (2015), p. 55) and has been proposed for use in analytical chemistry (Werner et al. (1978), Wilson et al. (2004)) and chemical degradation kinetics (Ranke and Meinecke (2019)). Note that the two-component error model proposed by Rocke and Lorenzato (1995) assumed a log-normal distribution of residuals at high absolute values, which is not compatible with the `varFunc` structures in package `nlme`.

Author(s)

José Pinheiro and Douglas Bates (for `varConstPower`) and Johannes Ranke (adaptation to `varConstProp()`).

AIC(f_const, f_varPower, f_varConstPower, f_varConstPower_sf, f_varConstProp, f_varConstProp_sf)

# The error model parameters 3 and 0.07 are approximately recovered intervals(f_varConstProp_sf)
This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class "lme", or a nonlinear mixed-effects model, of class "nlme". The within-group error variance and standard deviation are also calculated.

Usage

VarCorr(x, sigma = 1, ...)  
## S3 method for class 'lme'  
VarCorr(x, sigma = x$sigma, rdig = 3, ...)  

## S3 method for class 'pdMat'  
VarCorr(x, sigma = 1, rdig = 3, ...)  
## S3 method for class 'pdBlocked'  
VarCorr(x, sigma = 1, rdig = 3, ...)  

Arguments

- **x**: a fitted model object, usually an object inheriting from class "lme".
- **sigma**: an optional numeric value used as a multiplier for the standard deviations. The default is x$sigma or 1 depending on class(x).
- **rdig**: an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3.
- **...**: further optional arguments passed to other methods (none for the methods documented here).

Value

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named Variance and StdDev, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named Corr, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

Examples

```r
fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)
```

**Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting \( v \) denote the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the exponential variance function is defined as \( \sigma^2(v) = \exp(2\theta v) \), where \( \theta \) is the variance function coefficient. When a grouping factor is present, a different \( \theta \) is used for each factor level.

**Usage**

```r
varExp(value, form, fixed)
```

**Arguments**

- `value` an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- `form` an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, like in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- `fixed` an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

**Value**

A `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

Examples
vf1 <- varExp(0.2, form = ~age|Sex)

---

**Description**
This function is a constructor for the varFixed class, representing a variance function with fixed variances. Letting $v$ denote the variance covariate defined in value, the variance function $\sigma^2(v)$ for this class is $\sigma^2(v) = |v|$. The variance covariate $v$ is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**
varFixed(value)

**Arguments**
- value a one-sided formula of the form ~ v specifying a variance covariate v. Grouping factors are ignored.

**Value**
a varFixed object representing a fixed variance function structure, also inheriting from class varFunc.

**varFunc**  

Variance Function Structure

**Description**

If `object` is a one-sided formula, it is used as the argument to `varFixed` and the resulting object is returned. Else, if `object` inherits from class `varFunc`, it is returned unchanged.

**Usage**

```r
varFunc(object)
```

**Arguments**

- `object` either an one-sided formula specifying a variance covariate, or an object inher-iting from class `varFunc`, representing a variance function structure.

**Value**

an object from class `varFunc`, representing a variance function structure.

**Examples**

```r
vf1 <- varFunc(~age)
```

---

**varIdent**  

Constant Variance Function

**Description**

This function is a constructor for the `varIdent` class, representing a constant variance function structure. If no grouping factor is present in `form`, the variance function is constant and equal to one, and no coefficients required to represent it. When `form` includes a grouping factor with $M > 1$ levels, the variance function allows $M$ different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only $M - 1$ coefficients are needed to represent the variance function. By default, if the elements in `value` are unnamed, the first group level is taken as the reference level.

**Usage**

```r
varIdent(value, form, fixed)
```
Arguments

value an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in form, this argument is ignored, as the resulting variance function contains no coefficients. If value has length one, its value is repeated for all coefficients in the variance function. If value has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

form an optional one-sided formula of the form ~ v, or ~ v | g, specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in form, a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the * operator, like in ~ v | g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ 1.

fixed an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.

Value

a varIdent object representing a constant variance function structure, also inheriting from class varFunc.

Examples

vf1 <- varIdent(c(Female = 0.5), form = ~ 1 | Sex)
Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include default, gls and lme. See the appropriate method documentation for a description of the arguments.

Usage

Variogram(object, distance, ...)

Arguments

object a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.

distance a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs (1,2), (1,3), ..., (n-1,n), with n representing the length of object, and must have length n(n-1)/2.

... some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Variogram.corExp

Calculate Semi-variogram for a corExp Object

Description
This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage
## S3 method for class 'corExp'
Variogram(object, distance, sig2, length.out, ...)

Arguments
- **object**: an object inheriting from class "corExp", representing an exponential spatial correlation structure.
- **distance**: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- **sig2**: an optional numeric value representing the process variance. Defaults to 1.
- **length.out**: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value
a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.corGaus

Calculate Semi-variogram for a corGaus Object

Description

This method function calculates the semi-variogram values corresponding to the Gaussian correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

## S3 method for class 'corGaus'
Variogram(object, distance, sig2, length.out, ...)

Arguments

- object: an object inheriting from class "corGaus", representing an Gaussian spatial correlation structure.
- distance: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- sig2: an optional numeric value representing the process variance. Defaults to 1.
- length.out: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- ...: some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.corLin

Describe Semi-variogram for a corLin Object

This method function calculates the semi-variogram values corresponding to the Linear corre-
lation model, using the estimated coefficients corresponding to object, at the distances defined by
distance.

Usage

## S3 method for class 'corLin'
Variogram(object, distance, sig2, length.out, ...)

Arguments

object an object inheriting from class "corLin", representing an Linear spatial corre-
lation structure.

distance an optional numeric vector with the distances at which the semi-variogram is to
be calculated. Defaults to NULL, in which case a sequence of length length.out
between the minimum and maximum values of getCovariate(object) is used.

sig2 an optional numeric value representing the process variance. Defaults to 1.

length.out an optional integer specifying the length of the sequence of distances to be used
for calculating the semi-variogram, when distance = NULL. Defaults to 50.

... some methods for this generic require additional arguments. None are used in
this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values
and the corresponding distances. The returned value inherits from class Variogram.

Variogram.corRatio  

Calculate Semi-variogram for a corRatio Object

Description
This method function calculates the semi-variogram values corresponding to the Rational Quadratic correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage
## S3 method for class 'corRatio'
Variogram(object, distance, sig2, length.out, ...)

Arguments
- **object**: an object inheriting from class "corRatio", representing an Rational Quadratic spatial correlation structure.
- **distance**: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- **sig2**: an optional numeric value representing the process variance. Defaults to 1.
- **length.out**: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

Variogram.corSpatial  Calculate Semi-variogram for a corSpatial Object

Description

This method function calculates the semi-variogram values corresponding to the model defined in FUN, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

## S3 method for class 'corSpatial'
Variogram(object, distance, sig2, length.out, FUN, ...)

Arguments

- **object**: an object inheriting from class "corSpatial", representing spatial correlation structure.
- **distance**: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- **sig2**: an optional numeric value representing the process variance. Defaults to 1.
- **length.out**: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- **FUN**: a function of two arguments, the distance and the range corresponding to object, specifying the semi-variogram model.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.corSpher

Calculate Semi-variogram for a corSpher Object

Description

This method function calculates the semi-variogram values corresponding to the Spherical correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

```r
## S3 method for class 'corSpher'
Variogram(object, distance, sig2, length.out, ...)
```

Arguments

- `object`: an object inheriting from class "corSpher", representing an Spherical spatial correlation structure.
- `distance`: an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
- `sig2`: an optional numeric value representing the process variance. Defaults to 1.
- `length.out`: an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Calculate Semi-variogram

Description

This method function calculates the semi-variogram for an arbitrary vector object, according to the distances in distance. For each pair of elements \( x, y \) in object, the corresponding semi-variogram is \( (x - y)^2 / 2 \). The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

Usage

```r
## Default S3 method:
Variogram(object, distance, ...)
```

Arguments

- **object**: a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
- **distance**: a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs \((1,2), (1,3), \ldots, (n-1,n)\), with \( n \) representing the length of object, and must have length \( n(n-1)/2 \).
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

```
Variogram.gls

Variogram.gls

Calculate Semi-variogram for Residuals from a gls Object

Description

This method function calculates the semi-variogram for the residuals from a gls fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

### S3 method for class 'gls'

Variogram(object, distance, form, resType, data, 
na.action, maxDist, length.out, collapse, nint, breaks, 
robust, metric, ...)

Arguments

object an object inheriting from class "gls", representing a generalized least squares fitted model.
distance an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.
form an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a | operator in form). Default is ~1, implying that the observation order within the groups is used to obtain the distances.
resType an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
data an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.
na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
maxDist an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.
length.out  an optional integer value. When object includes a \texttt{corSpatial} element, its semi-variogram values are calculated and this argument is used as the \texttt{length.out} argument to the corresponding \texttt{Variogram} method. Defaults to 50.

collapse  an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if “fixed”, the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint  an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust  an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If \texttt{TRUE} the robust estimator is used. Defaults to \texttt{FALSE}.

breaks  an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in \texttt{collapse} is ignored.

metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

\texttt{...}  some methods for this generic require additional arguments. None are used in this method.

\textbf{Value}

a data frame with columns \texttt{variog} and \texttt{dist} representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, \texttt{n.pairs}, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a \texttt{corSpatial} element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class \texttt{Variogram}.

Variogram.lme

Calculate Semi-variogram for Residuals from an lme Object

Description

This method function calculates the semi-variogram for the within-group residuals from an `lme` fit. The semi-variogram values are calculated for pairs of residuals within the same group. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

```r
## S3 method for class 'lme'
Variogram(object, distance, form, resType, data, na.action, maxDist, length.out, collapse, nint, breaks, robust, metric, ...)
```

Arguments

- `object`: an object inheriting from class "lme", representing a fitted linear mixed-effects model.
- `distance`: an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments `form`, `data`, and `metric`, unless `object` includes a `corSpatial` element, in which case the associated covariate (obtained with the `getCovariate` method) is used.
- `form`: an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a `|` operator in `form`). Default is ~1, implying that the observation order within the groups is used to obtain the distances.
- `resType`: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- `data`: an optional data frame in which to interpret the variables in `form`. By default, the same data used to fit `object` is used.
- `na.action`: a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
maxDist: an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

length.out: an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse: an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint: an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust: an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks: an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

Value

A data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

lme, Variogram, Variogram.default, Variogram.gls, plot.Variogram
**Examples**

```r
fm1 <- lme(weight ~ Time * Diet, data=BodyWeight, ~ Time | Rat)
Variogram(fm1, form = ~ Time | Rat, nint = 10, robust = TRUE)
```

**Description**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the power variance function is defined as $\sigma^2(v) = |v|^\theta$, where $\theta$ is the variance function coefficient. When a grouping factor is present, a different $\theta$ is used for each factor level.

**Usage**

```r
varPower(value, form, fixed)
```

**Arguments**

- **value**: an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and value has length greater than one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

- **form**: an optional one-sided formula of the form ~ v, or ~ v | g, specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ".", representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, like in ~ v | g1 * g2 * g3. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to ~ fitted(.) representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- **fixed**: an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, fixed must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.

**Value**

A `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

---

**Examples**

```r
fm1 <- lme(weight ~ Time * Diet, data=BodyWeight, ~ Time | Rat)
Variogram(fm1, form = ~ Time | Rat, nint = 10, robust = TRUE)
```

varWeights

Extract Variance Function Weights

Description
The inverse of the standard deviations corresponding to the variance function structure represented by object are returned.

Usage
varWeights(object)

Arguments

object
an object inheriting from class varFunc, representing a variance function structure.

Value
if object has a weights attribute, its value is returned; else NULL is returned.

Author(s)
José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

References

logLik.varFunc, varWeights

Examples
vf1 <- varPower(form=~age)
vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.3
varWeights(vf1)[1:10]
Description

If object includes a varStruct component, the inverse of the standard deviations of the variance function structure represented by the corresponding varFunc object are returned; else, a vector of ones of length equal to the number of observations in the data frame used to fit the associated linear model is returned.

Usage

```r
## S3 method for class 'glsStruct'
varWeights(object)
```

Arguments

- `object` an object inheriting from class "glsStruct", representing a list of linear model components, such as corStruct and "varFunc" objects.

Value

- if object includes a varStruct component, a vector with the corresponding variance weights; else, or a vector of ones.

### Wafer

*Modeling of Analog MOS Circuits*

Description

The Wafer data frame has 400 rows and 4 columns.

Format

This data frame contains the following columns:

- **Wafer**  a factor with levels 1 2 3 4 5 6 7 8 9 10
- **Site** a factor with levels 1 2 3 4 5 6 7 8
- **voltage** a numeric vector
- **current** a numeric vector

Source

The *Wheat* data frame has 48 rows and 4 columns.

This data frame contains the following columns:

- **Tray** an ordered factor with levels 3 < 1 < 2 < 4 < 5 < 6 < 8 < 9 < 7 < 12 < 11 < 10
- **Moisture** a numeric vector
- **fertilizer** a numeric vector
- **DryMatter** a numeric vector

### Source

The *Wheat2* data frame has 224 rows and 5 columns.

This data frame contains the following columns:

- **Block** an ordered factor with levels 4 < 2 < 3 < 1
- **variety** a factor with levels ARAPAHOE BRULE BUCKSKIN CENTURA CENTURK78 CHEYENNE CODY COLT GAGE HOMESTEAD KS831374 LANCER LANCOTA NE83404 NE83406 NE83407 NE83432 NE83498 NE83T12 NE84557 NE85556 NE85623 NE86482 NE86501 NE86503 NE86507 NE86509 NE86527 NE86582 NE86606 NE86607 NE86T666 NE87403 NE87408 NE87409 NE87446 NE87451 NE87457 NE87463 NE87499 NE87512 NE87513 NE87522 NE87562 NE87612 NE87613 NE87615 NE87619 NE87627 NORKAN REDLAND ROUGHRIDER SIOUXLAND TAM107 TAM200 VONA
- **yield** a numeric vector

### Source

Description

This method function extracts sub-matrices from the positive-definite matrix represented by x.

Usage

## S3 method for class 'pdMat'
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat'
x[i, j] <- value

Arguments

x
an object inheriting from class "pdMat" representing a positive-definite matrix.
i, j
optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by object. When i (j) is omitted, all rows (columns) are extracted.
drop
a logical value. If TRUE, single rows or columns are converted to vectors. If FALSE the returned value retains its matrix representation.
value
a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by x.

Value

if i and j are identical, the returned value will be pdMat object with the same class as x. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

The nnet package

class.ind  Generates Class Indicator Matrix from a Factor

Description

Generates a class indicator function from a given factor.

Usage

class.ind(cl)

Arguments

cl  factor or vector of classes for cases.

Value

a matrix which is zero except for the column corresponding to the class.

References

Examples

# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
cl <- as.factor(cl)
x <- matrix(0, n, length(levels(cl)))
x[(1:n) + n*(unclass(cl)-1)] <- 1
dimnames(x) <- list(names(cl), levels(cl))
x
}

3409
multinom

Fit Multinomial Log-linear Models

Description

Fits multinomial log-linear models via neural networks.

Usage

\[
\text{multinom(formula, data, weights, subset, na.action,}
\]
\[
\text{contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,}
\]
\[
\text{model = FALSE, ...)}
\]

Arguments

- **formula**: a formula expression as for regression models, of the form \( \text{response} \sim \text{predictors} \). The response should be a factor or a matrix with \( K \) columns, which will be interpreted as counts for each of \( K \) classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with \( K \) columns if the response is either a matrix with \( K \) columns or a factor with \( K \geq 2 \) classes, or a numeric vector for a response factor with 2 levels. See the documentation of \text{formula()}{\text{ for other details.}

- **data**: an optional data frame in which to interpret the variables occurring in \text{formula.}

- **weights**: optional case weights in fitting.

- **subset**: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

- **na.action**: a function to filter missing data.

- **contrasts**: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

- **Hess**: logical for whether the Hessian (the observed/expected information matrix) should be returned.

- **summ**: integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same \( X \) and different \( Y \), which changes the baseline for the deviance.

- **censored**: If \( Y \) is a matrix with \( K \) columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.

- **model**: logical. If true, the model frame is saved as component model of the returned object.

- **...**: additional arguments for \text{nnet}

Details

multinom calls \text{nnet}. The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.
Value

A `nnet` object with additional components:

- `deviance`: the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood.
- `edf`: the (effective) number of degrees of freedom used by the model
- `AIC`: the AIC for this fit.
- `Hessian`: (if `Hess` is true).
- `model`: (if `model` is true).

References

See Also

- `nnet`

Examples

```r
oc <- options(contrasts = c("contr.treatment", "contr.poly"))
library(MASS)
example(birthwt)
(bwt.mu <- multinom(low ~ ., bwt))
options(oc)
```

Description

Fit single-hidden-layer neural network, possibly with skip-layer connections.

Usage

```r
nnet(x, ...)
```

## S3 method for class 'formula'
```r
nnet(formula, data, weights, ..., 
  subset, na.action, contrasts = NULL)
```

## Default S3 method:
```r
nnet(x, y, weights, size, Wts, mask,  
  linout = FALSE, entropy = FALSE, softmax = FALSE, 
  censored = FALSE, skip = FALSE, rang = 0.7, decay = 0, 
  maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000, 
  abstol = 1.0e-4, reltol = 1.0e-8, ...)
```
Arguments

- **formula**: A formula of the form `class ~ x1 + x2 + ...`.
- **x**: matrix or data frame of x values for examples.
- **y**: matrix or data frame of target values for examples.
- **weights**: (case) weights for each example – if missing defaults to 1.
- **size**: number of units in the hidden layer. Can be zero if there are skip-layer units.
- **data**: Data frame from which variables specified in `formula` are preferentially to be taken.
- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- **contrasts**: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
- **Wts**: initial parameter vector. If missing chosen at random.
- **mask**: logical vector indicating which parameters should be optimized (default all).
- **linout**: switch for linear output units. Default logistic output units.
- **entropy**: switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.
- **softmax**: switch for softmax (log-linear model) and maximum conditional likelihood fitting. `linout`, `entropy`, `softmax` and `censored` are mutually exclusive.
- **censored**: A variant on `softmax`, in which non-zero targets mean possible classes. Thus for `softmax` a row of `(0, 1, 1)` means one example each of classes 2 and 3, but for `censored` it means one example whose class is only known to be 2 or 3.
- **skip**: switch to add skip-layer connections from input to output.
- **rang**: Initial random weights on `[-rang, rang]`. Value about 0.5 unless the inputs are large, in which case it should be chosen so that `rang * max(|x|)` is about 1.
- **decay**: parameter for weight decay. Default 0.
- **maxit**: maximum number of iterations. Default 100.
- **Hess**: If true, the Hessian of the measure of fit at the best set of weights found is returned as component `Hessian`.
- **trace**: switch for tracing optimization. Default `TRUE`.
- **MaxNWts**: The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing `MaxNWts` will probably allow fits that are very slow and time-consuming.
- **abstol**: Stop if the fit criterion falls below `abstol`, indicating an essentially perfect fit.
- **reltol**: Stop if the optimizer is unable to reduce the fit criterion by a factor of at least `1 - reltol`.
- **...**: arguments passed to or from other methods.
Details

If the response in formula is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to nnet.default.

Optimization is done via the BFGS method of optim.

Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

- **wts**: the best set of weights found
- **value**: value of fitting criterion plus weight decay term.
- **fitted.values**: the fitted values for the training data.
- **residuals**: the residuals for the training data.
- **convergence**: 1 if the maximum number of iterations was reached, otherwise 0.

  cres <- max.col(pred)
  table(true, cres)
}
test.cl(targets[-samp,], predict(ir1, ir[-samp,]))
```

# or
```
ird <- data.frame(rbind(iris3[,1], iris3[,2], iris3[,3]),
  species = factor(c(rep("s", 50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
              decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
```
nnetHess

Evaluates Hessian for a Neural Network

Description

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument Hess=TRUE to nnet or via vcov.multinom.

Usage

nnetHess(net, x, y, weights)

Arguments

net  
object of class nnet as returned by nnet.

x
training data.

y
classes for training data.

weights  
the (case) weights used in the nnet fit.

Value

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

References

See Also

nnet, predict.nnet

Examples

# use half the iris data
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
targets <- matrix(c(rep(c(1,0,0),50), rep(c(0,1,0),50), rep(c(0,0,1),50)),
150, 3, byrow=TRUE)
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size=2, rang=0.1, decay=5e-4, maxit=200)
eigen(nnetHess(ir1, ir[samp,], targets[samp,], TRUE)$values
predict.nnet

Describes

Predict new examples by a trained neural net.

Usage

```r
# S3 method for class 'nnet'
predict(object, newdata, type = c("raw", "class"), ...)
```

Arguments

- `object`: an object of class `nnet` as returned by `nnet`.
- `newdata`: matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case.
- `type`: Type of output
- `...`: arguments passed to or from other methods.

Details

This function is a method for the generic function `predict()` for class "nnet". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.nnet(x)` regardless of the class of the object.

Value

If `type = "raw"`, the matrix of values returned by the trained network; if `type = "class"`, the corresponding class (which is probably only useful if the net was generated by `nnet.formula`).

samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size = 2, rang = 0.1,
        decay = 5e-4, maxit = 200)
test.cl <- function(true, pred){
    true <- max.col(true)
    cres <- max.col(pred)
    table(true, cres)
}
which.is.max

Find Maximum Position in Vector

Description

Find the maximum position in a vector, breaking ties at random.

Usage

which.is.max(x)

Arguments

x  a vector

Details

Ties are broken at random.

Value

index of a maximal value.

References

car.test.frame   Automobile Data from 'Consumer Reports' 1990

Description

The car.test.frame data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of Consumer Reports. This is part of a larger dataset, some columns of which are given in cu.summary.

Usage

car.test.frame

Format

This data frame contains the following columns:

- Price  a numeric vector giving the list price in US dollars of a standard model
- Reliability  a numeric vector coded 1 to 5.
- Mileage  fuel consumption miles per US gallon, as tested.
- Type  a factor with levels Compact Large Medium Small Sporty Van
- Weight  kerb weight in pounds.
- Disp.  the engine capacity (displacement) in litres.
- HP  the net horsepower of the vehicle.

Source

Consumer Reports, April, 1990, pp. 235–288 quoted in

`car90, cu.summary`

Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

```
car90
Automobile Data from 'Consumer Reports' 1990
```

Description

Usage

data(car90)

Format

The data frame contains the following columns

- **Country**: a factor giving the country in which the car was manufactured
- **Disp**: engine displacement in cubic inches
- **Disp2**: engine displacement in liters
- **Eng.Rev**: engine revolutions per mile, or engine speed at 60 mph
- **Front.Hd**: distance between the car’s head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU
- **Frt.Leg.Room**: maximum front leg room, in inches, as measured by CU
- **Frt.Shld**: front shoulder room, in inches, as measured by CU
- **Gear.Ratio**: the overall gear ratio, high gear, for manual transmission
- **Gear2**: the overall gear ratio, high gear, for automatic transmission
- **HP**: net horsepower
- **HP.revs**: the red line—the maximum safe engine speed in rpm
- **Height**: height of car, in inches, as supplied by manufacturer
- **Length**: overall length, in inches, as supplied by manufacturer
- **Luggage**: luggage space
- **Mileage**: a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.
- **Model2**: alternate name, if the car was sold under two labels
- **Price**: list price with standard equipment, in dollars
- **Rear.Hd**: distance between the car’s head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU
- **Rear.Seating**: rear fore-and-aft seating room, in inches, as measured by CU
RearShld  rear shoulder room, in inches, as measured by CU

Reliability  an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better': contains NAs.

Rim  factor giving the rim size

Sratio.m  Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

Sratio.p  Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

Steering  steering type offered: manual, power, or both

Tank  fuel refill capacity in gallons

Tires  factor giving tire size

Trans1  manual transmission, a factor with levels '', 'man.4', 'man.5' and 'man.6'

Trans2  automatic transmission, a factor with levels '', 'auto.3', 'auto.4', and 'auto.CVT'. No car is missing both the manual and automatic transmission variables, but several had both as options

Turning  the radius of the turning circle in feet

Type  a factor giving the general type of car. The levels are: ‘Small’, ‘Sporty’, ‘Compact’, ‘Medium’, ‘Large’, ‘Van’

Weight  an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

Wheel.base  length of wheelbase, in inches, as supplied by manufacturer

Width  width of car, in inches, as supplied by manufacturer

Source

This is derived (with permission) from the data set car.all in S-PLUS, but with some further clean up of variable names and definitions.

Data on Children who have had Corrective Spinal Surgery

Description

The kyphosis data frame has 81 rows and 4 columns, representing data on children who have had corrective spinal surgery.

Usage

kypthos

Format

This data frame contains the following columns:

- **Kyphosis** a factor with levels absent present indicating if a kyphosis (a type of deformation) was present after the operation.
- **Age** in months
- **Number** the number of vertebrae involved
- **Start** the number of the first (topmost) vertebra operated on.

Source

Examples

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphos)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphos,
            parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphos,
            control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

Create Split Labels For an Rpart Object

Description

This function provides labels for the branches of an rpart tree.

Usage

```r
## S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```
Arguments

object: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

digits: the number of digits to be used for numeric values. All of the rpart functions that call labels explicitly set this value, with options("digits") as the default.

minlength: the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than 1, the abbreviate function is used, passed the minlength argument.

pretty: an argument included for compatibility with the tree package: pretty = 0 implies minlength = 0L, pretty = NULL implies minlength = 1L, and pretty = TRUE implies minlength = 4L.

collapse: logical. The returned set of labels is always of the same length as the number of nodes in the tree.

If collapse = TRUE (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node.

If FALSE, the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes.

...: optional arguments to abbreviate.

Value

Vector of split labels (collapse = TRUE) or matrix of left and right splits (collapse = FALSE) for the supplied rpart object. This function is called by printing methods for rpart and is not intended to be called directly by the users.

See Also

abbreviate

meanvar.rpart

Mean-Variance Plot for an Rpart Object

Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

Usage

meanvar(tree, ...)
Arguments

- `tree`: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `xlab`: x-axis label for the plot.
- `ylab`: y-axis label for the plot.
- `...`: additional graphical parameters may be supplied as arguments to this function.

Value

An invisible list containing the following vectors is returned.

- `x`: fitted value at terminal nodes (yval).
- `y`: deviance of node divided by number of observations at node.
- `label`: node number.

Side Effects

A plot is put on the current graphics device.

See Also

`plot.rpart`.

Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')
```

---

### na.rpart

#### Handles Missing Values in an Rpart Object

Description

Handles missing values in an "rpart" object.

Usage

```r
na.rpart(x)
```

Arguments

- `x`: a model frame.

Details

Default function that handles missing values when calling the function `rpart`. It omits cases where part of the response is missing or all the explanatory variables are missing.
Follow Paths to Selected Nodes of an Rpart Object

Description
Returns a names list where each element contains the splits on the path from the root to the selected nodes.

Usage
path.rpart(tree, nodes, pretty = 0, print.it = TRUE)

Arguments
- tree: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
- nodes: an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.
- pretty: an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A NULL, the default, signifies using elements of letters to represent the different factor levels.
- print.it: Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if nodes argument is supplied.

Details
The function has a required argument as an rpart object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

Value
A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

Graphical Interaction
A dendrogram of the rpart object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

References
This function was modified from path.tree in S.

See Also
rpart
Examples

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, nodes = c(11, 22))
```

---

**Description**

Plots an rpart object on the current graphics device.

**Usage**

```r
## S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace,
     margin = 0, minbranch = 0.3, branch.col = 1, branch.lty = 1,
     branch.lwd = 1, ...)
```

**Arguments**

- `x`: a fitted object of class "rpart", containing a classification, regression, or rate tree.
- `uniform`: if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
- `branch`: controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
- `compress`: if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes uniform=TRUE; surprisingly, the result is usually an improvement even when that is not the case.
- `nspace`: the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of branch.
- `margin`: an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
- `minbranch`: set the minimum length for a branch to minbranch times the average branch length. This parameter is ignored if uniform=TRUE. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
- `branch.col`: set the color of the branches.
- `branch.lty`: set the line type of the branches.
- `branch.lwd`: set the line width of the branches.
- `...`: arguments to be passed to or from other methods.
Details

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.

Value

The coordinates of the nodes are returned as a list, with components `x` and `y`.

Side Effects

An unlabeled plot is produced on the current graphics device: one being opened if needed.

In order to build up a plot in the usual S style, e.g., a separate `text` command for adding labels, some extra information about the plot needs be retained. This is kept in an environment in the package.

See Also

`rpart`, `text.rpart`

Examples

```r
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```

---

**plotcp** | *Plot a Complexity Parameter Table for an Rpart Fit*

Description

Gives a visual representation of the cross-validation results in an `rpart` object.

Usage

```r
plotcp(x, minline = TRUE, lty = 3, col = 1,
       upper = c("size", "splits", "none"), ...)
```

Arguments

- `x` | an object of class "rpart"
- `minline` | whether a horizontal line is drawn 1SE above the minimum of the curve.
- `lty` | line type for this line
- `col` | colour for this line
- `upper` | what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing.
- `...` | additional plotting parameters
Details

The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of \( cp \) for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by \texttt{rpart}. The \texttt{cptable} in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of \( cp \) for pruning is often the leftmost value for which the mean lies below the horizontal line.

Value

None.

Side Effects

A plot is produced on the current graphical device.

See Also

\texttt{rpart}, \texttt{printcp}, \texttt{rpart.object}

---

\texttt{post.rpart} \hspace{1cm} PostScript Presentation Plot of an \texttt{rpart} Object

Description

Generates a PostScript presentation plot of an \texttt{rpart} object.

Usage

\begin{verbatim}
post(tree, ...)  
## S3 method for class 'rpart'
post(tree, title.,  
    filename = paste(deparse(substitute(tree)), ",".ps", sep = ""),  
    digits =getOption("digits") - 2, pretty = TRUE,  
    use.n = TRUE, horizontal = TRUE, ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{tree} \hspace{1cm} fitted model object of class "\texttt{rpart}". This is assumed to be the result of some function that produces an object with the same named components as that returned by the \texttt{rpart} function.
  \item \texttt{title.} \hspace{1cm} a title which appears at the top of the plot. By default, the name of the \texttt{rpart} endpoint is printed out.
  \item \texttt{filename} \hspace{1cm} ASCII file to contain the output. By default, the name of the file is the name of the object given by \texttt{rpart} (with the suffix .ps added). If \texttt{filename = ""}, the plot appears on the current graphical device.
  \item \texttt{digits} \hspace{1cm} number of significant digits to include in numerical data.
\end{itemize}
predict.rpart

Pretty	an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation.

use.n	Logical. If TRUE (default), adds to the label #events level1/ #events level2/ etc. for method class, n for method anova, and #events/n for methods poisson and exp.

horizontal	Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape.

... other arguments to the postscript function.

Details

The plot created uses the functions plot.rpart and text.rpart (with the fancy option). The settings were chosen because they looked good to us, but other options may be better, depending on the rpart object. Users are encouraged to write their own function containing favorite options.

Side Effects

A plot of rpart is created using the postscript driver, or the current device if filename = "".

See Also

plot.rpart, rpart, text.rpart, abbreviate

Examples

## Not run:
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "") # display tree on active device
  # now construct postscript version on file "pretty.ps"
  # with no title
post(z.auto, file = "pretty.ps", title = "")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
## End(Not run)

predict.rpart

Predictions from a Fitted Rpart Object

Description

Returns a vector of predicted responses from a fitted rpart object.

Usage

## S3 method for class 'rpart'

predict(object, newdata,
        type = c("vector", "prob", "class", "matrix"),
        na.action = na.pass, ...)
Arguments

object fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

ewdata data frame containing the values at which predictions are required. The predictors referred to in the right side of formula(object) must be present by name in newdata. If missing, the fitted values are returned.

type character string denoting the type of predicted value returned. If the rpart object is a classification tree, then the default is to return prob predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of tree). Otherwise, a vector result is returned.

na.action a function to determine what should be done with missing values in newdata. The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are na.omit and na.fail.

... further arguments passed to or from other methods.

Details

This function is a method for the generic function predict for class "rpart". It can be invoked by calling predict for an object of the appropriate class, or directly by calling predict.rpart regardless of the class of the object.

Value

A new object is obtained by dropping newdata down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and frame$yval at the node is the prediction.

If type = "vector":
vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If type = "prob":
(for a classification tree) a matrix of class probabilities.

If type = "matrix":
a matrix of the full responses (frame$yval2 if this exists, otherwise frame$yval). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of at least the predicted class, the class counts at that node in the fitted tree, and the class probabilities (some versions of rpart may contain further columns).

If type = "class":
(for a classification tree) a factor of classifications based on the responses.

predict.rpart.object

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)
```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
predict(fit, type = "prob")  # class probabilities (default)
predict(fit, type = "vector")  # level numbers
predict(fit, type = "class")  # factor
predict(fit, type = "matrix")  # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data = iris, subset = sub)
fit
table(predict(fit, iris[-sub,], type = "class"), iris[-sub, "Species"])
```

---

**print.rpart**

*Print an Rpart Object*

**Description**

This function prints an `rpart` object. It is a method for the generic function `print` of class "rpart".

**Usage**

```r
## S3 method for class 'rpart'
print(x, minlength = 0, spaces = 2, cp, digits = getOption("digits"),
      nsmall = min(20, digits), ...)
```

**Arguments**

- `x` fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `minlength` Controls the abbreviation of labels: see `labels.rpart`.
- `spaces` the number of spaces to indent nodes of increasing depth.
- `digits` the number of digits of numbers to print.
- `nsmall` the number of digits to the right of the decimal. See `format`.
- `cp` prune all nodes with a complexity less than `cp` from the printout. Ignored if unspecified.
- `...` arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `print` for class "rpart". It can be invoked by calling `print` for an object of the appropriate class, or directly by calling `print.rpart` regardless of the class of the object.

**Side Effects**

A semi-graphical layout of the contents of `$frame` is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the "class" method, the class probabilities are also printed.

3) Weight<2567.5 15 186.93330 30.93333 *

## End(Not run)

printcp

Displays CP table for Fitted Rpart Object

Description

Displays the cp table for fitted rpart object.

Usage

printcp(x, digits = getOption("digits") - 2)

Arguments

x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits the number of digits of numbers to print.

Details

Prints a table of optimal prunings based on a complexity parameter.

**prune.rpart**

*Cost-complexity Pruning of an Rpart Object*

**Description**

Determines a nested sequence of subtrees of the supplied `rpart` object by recursively snipping off the least important splits, based on the complexity parameter (`cp`).

**Usage**

```r
prune(tree, ...)  
## S3 method for class 'rpart'
prune(tree, cp, ...)
```

**Arguments**

- `tree`: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- `cp`: Complexity parameter to which the `rpart` object will be trimmed.
- `...`: further arguments passed to or from other methods.

**Value**

A new `rpart` object that is trimmed to the value `cp`.

**See Also**

`rpart`
residuals.rpart

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) #plot smaller rpart object

residuals.rpart  Residuals From a Fitted Rpart Object

Description

Method for residuals for an rpart object.

Usage

## S3 method for class 'rpart'
residuals(object, type = c("usual", "pearson", "deviance"), ...)

Arguments

object fitted model object of class "rpart".

type Indicates the type of residual desired.
For regression or anova trees all three residual definitions reduce to \( y - \text{fitted} \). This is the residual returned for user method trees as well.
For classification trees the usual residuals are the misclassification losses \( L(\text{actual}, \text{predicted}) \) where \( L \) is the loss matrix. With default losses this residual is \( 0/1 \) for correct/incorrect classification. The pearson residual is \( (1-\text{fitted})/\sqrt{\text{fitted}(1-\text{fitted})} \) and the deviance residual is \( \sqrt{-2\log(\text{fitted})} \).
For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The pearson and deviance residuals are as defined in McCullagh and Nelder.

... further arguments passed to or from other methods.

Value

Vector of residuals of type type from a fitted rpart object.

References

Examples

fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
data = solder.balance, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
rpart

Recursive Partitioning and Regression Trees

Description

Fit a rpart model

Usage

rpart(formula, data, weights, subset, na.action = na.rpart, method,
model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)

Arguments

formula a formula, with a response but no interaction terms. If this is a data frame, it is
taken as the model frame (see model.frame).
data an optional data frame in which to interpret the variables named in the formula.
weights optional case weights.
subset optional expression saying that only a subset of the rows of the data should be
used in the fit.
na.action the default action deletes all observations for which y is missing, but keeps those
in which one or more predictors are missing.
method one of "anova", "poisson", "class" or "exp". If method is missing then the
routine tries to make an intelligent guess. If y is a survival object, then method = 
"exp" is assumed, if y has 2 columns then method = "poisson" is assumed, if
y is a factor then method = "class" is assumed, otherwise method = "anova" is
assumed. It is wisest to specify the method directly, especially as more criteria
may added to the function in future.
Alternatively, method can be a list of functions named init, split and eval.
Examples are given in the file ‘tests/usersplits.R’ in the sources, and in the
vignettes ‘User Written Split Functions’.
model if logical: keep a copy of the model frame in the result? If the input value for
model is a model frame (likely from an earlier call to the rpart function), then
this frame is used rather than constructing new data.
x keep a copy of the x matrix in the result.
y keep a copy of the dependent variable in the result. If missing and model is
supplied this defaults to FALSE.
parms optional parameters for the splitting function.
Anova splitting has no parameters.
Poisson splitting has a single parameter, the coefficient of variation of the prior
distribution on the rates. The default value is 1.
Exponential splitting has the same parameter as Poisson.
For classification splitting, the list can contain any of: the vector of prior prob-
babilities (component prior), the loss matrix (component loss) or the splitting
index (component split). The priors must be positive and sum to 1. The loss
matrix must have zeros on the diagonal and positive off-diagonal elements. The
splitting index can be gini or information. The default priors are proportional
to the data counts, the losses default to 1, and the split defaults to gini.
control: a list of options that control details of the rpart algorithm. See rpart.control.

cost: a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.

... arguments to rpart.control may also be specified in the call to rpart. They are checked against the list of valid arguments.

Details

This differs from the tree function in S mainly in its handling of surrogate variables. In most details it follows Breiman et al. (1984) quite closely. R package tree provides a re-implementation of tree.

Value

An object of class rpart. See rpart.object.

References

See Also

rpart.control, rpart.object, summary.rpart, print.rpart

Examples

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)

fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis, 
           control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)

rpart.control

Control for Rpart Fits

Description

Various parameters that control aspects of the rpart fit.

Usage

rpart.control(minsplit = 20, minbucket = round(minsplit/3), cp = 0.01, 
         maxcompete = 4, maxsurrogate = 5, usesurrogate = 2, xval = 10, 
         surrogatestyle = 0, maxdepth = 30, ...)
Arguments

**minsplit**
the minimum number of observations that must exist in a node in order for a split to be attempted.

**minbucket**
the minimum number of observations in any terminal `<leaf>` node. If only one of **minbucket** or **minsplit** is specified, the code either sets **minsplit** to **minbucket**×3 or **minbucket** to **minsplit**/3, as appropriate.

**cp**
complexity parameter. Any split that does not decrease the overall lack of fit by a factor of **cp** is not attempted. For instance, with anova splitting, this means that the overall R-squared must increase by **cp** at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by **cp** will likely be pruned off by cross-validation, and that hence the program need not pursue it.

**maxcompete**
the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.

**maxsurrogate**
the number of surrogate splits retained in the output. If this is set to zero the compute time will be reduced, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.

**usesurrogate**
how to use surrogates in the splitting process. **0** means display only; an observation with a missing value for the primary split rule is not sent further down the tree. **1** means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value **2**, if all surrogates are missing, then send the observation in the majority direction. A value of **0** corresponds to the action of `tree`, and **2** to the recommendations of Breiman *et al.* (1984).

**xval**
number of cross-validations.

**surrogatetyle**
controls the selection of a best surrogate. If set to **0** (default) the program uses the total number of correct classification for a potential surrogate variable, if set to **1** it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.

**maxdepth**
Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 `rpart` will give nonsense results on 32-bit machines.

... mop up other arguments.

Value

A list containing the options.

See Also

`rpart`
Description

This function does the initialization step for rpart, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

Usage

\[
\text{rpart.exp}(y, \text{offset}, \text{parms}, \text{wt})
\]

Arguments

- **y**: the response, which will be of class \texttt{Surv}
- **offset**: optional offset
- **parms**: parameters controlling the fit. This is a list with components \texttt{shrink} and \texttt{method}. The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root.
- **wt**: case weights, if present

Value

a list with the necessary initialization components

Author(s)

Terry Therneau

- \texttt{rpart}

Description

These are objects representing fitted \texttt{rpart} trees.
rpart.object

Value

frame  

A data frame with one row for each node in the tree. The row names of `frame` contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of `frame` include:
- `var`, a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level "<leaf>").
- `n`, the number of observations reaching the node.
- `wt`, the sum of case weights for observations reaching the node.
- `dev`, the deviance of the node.
- `yval`, the fitted value of the response at the node.
- `splits`, a two-column matrix of left and right split labels for each node. Also included in the frame are:
  - `complexity`, the complexity parameter at which this split will collapse.
  - `ncompete`, the number of competitor splits recorded.
  - `nsurrogate`, the number of surrogate splits recorded.

Extra response information which may be present is in `yval2`, which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node, the class probabilities and the 'node probability' (classification trees).

where  

An integer vector of the same length as the number of observations in the root node, containing the row number of `frame` corresponding to the leaf node that each observation falls into.

call  

An image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say `update(tree)`.

terms  

An object of class c("terms", "formula") (see `terms.object`) summarizing the formula. Used by various methods, but typically not of direct relevance to users.

splits  

A numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are:
- `count`, the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate).
- `ncat`, the number of categories or levels for the variable (+/-1 for a continuous variable).
- `improve`, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary.
- `index`, the numeric split point.
- The last column `adj` gives the adjusted concordance for surrogate splits.

For a factor, the `index` column contains the row number of the csplit matrix. For a continuous variable, the sign of `ncat` determines whether the subset `x < cutpoint` or `x > cutpoint` is sent to the left.

csplit  

An integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the `index` column of the `splits` matrix. The columns record:
- 1 if that level of the factor goes to the left.
- 3 if it goes to the right.
- 2 if that level is not present at this node of the tree (or not defined for the factor).

method  

Character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).

cptable  

A matrix of information on the optimal prunings based on a complexity parameter.
variable.importance
a named numeric vector giving the importance of each variable. (Only present
if there are any splits.) When printed by summary.rpart these are rescaled to
add to 100.

numresp integer number of responses; the number of levels for a factor response.

parms, control a record of the arguments supplied, which defaults filled in.

functions the summary, print and text functions for method used.

ordered a named logical vector recording for each variable if it was an ordered factor.

na.action (where relevant) information returned by model.frame on the special handling
of NAs derived from the na.action argument.

There may be attributes "xlevels" and "levels" recording the levels of any factor splitting vari-
ables and of a factor response respectively.

Optional components include the model frame (model), the matrix of predictors (x) and the response
variable variable (y) used to construct the rpart object.

Structure
The following components must be included in a legitimate rpart object.

See Also
rpart.

rsq.rpart
Plots the Approximate R-Square for the Different Splits

Description
Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus
the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-
validation versus the number of splits.

Usage
rsq.rpart(x)

Arguments
x fitted model object of class "rpart". This is assumed to be the result of some
function that produces an object with the same named components as that re-
turned by the rpart function.

Side Effects
Two plots are produced.

Note
The labels are only appropriate for the "anova" method.
Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

### Description

Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the toss argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

### Usage

```r
snip.rpart(x, toss)
```

### Arguments

- **x**: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- **toss**: an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

### Details

A dendrogram of `rpart` is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting `rpart` object.

See the documentation for the specific graphics device for details on graphical input techniques.

### Value

A `rpart` object containing the nodes that remain after specified or selected subtrees have been snipped off.

### Warning

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

### See Also

- `plot.rpart`
solder.balance

Examples

```r
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree

# can also interactively select the node using the mouse in the
# graphics window

## End(Not run)
```

solder.balance  

Soldering of Components on Printed-Circuit Boards

Description

The solder.balance data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards. The solder data frame is the full version of the data with 900 rows. It is located in both the rpart and the survival packages.

Usage

solder

Format

This data frame contains the following columns:

- **Opening**: a factor with levels ‘L’, ‘M’ and ‘S’ indicating the amount of clearance around the mounting pad.
- **Solder**: a factor with levels ‘Thick’ and ‘Thin’ giving the thickness of the solder used.
- **Mask**: a factor with levels ‘A1.5’, ‘A3’, ‘B3’ and ‘B6’ indicating the type and thickness of mask used.
- **Panel 1:3**: indicating the panel on a board being tested.
- **skips**: a numeric vector giving the number of visible solder skips.

Source

Examples

```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel, 
              data = solder.balance, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```
stagec  

**Stage C Prostate Cancer**

**Description**

A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

**Usage**

data(stagec)

**Format**

A data frame with 146 observations on the following 8 variables.

- `pgtime` Time to progression or last follow-up (years)
- `pgstat` 1 = progression observed, 0 = censored
- `age` age in years
- `eet` early endocrine therapy, 1 = no, 2 = yes
- `g2` percent of cells in G2 phase, as found by flow cytometry
- `grade` grade of the tumor, Farrow system
- `gleason` grade of the tumor, Gleason system
- `ploidy` the ploidy status of the tumor, from flow cytometry. Values are ‘diploid’, ‘tetraploid’, and ‘aneuploid’

**Details**

A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

**Examples**

```
require(survival)
rpart(Surv(pgtime, pgstat) ~ ., stagec)
```

---

**summary.rpart**  

**Summarize a Fitted Rpart Object**

**Description**

Returns a detailed listing of a fitted `rpart` object.

**Usage**

```
## S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```
Arguments

object fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits Number of significant digits to be used in the result.
cp trim nodes with a complexity of less than \( cp \) from the listing.
file write the output to a given file name. (Full listings of a tree are often quite long).
... arguments to be passed to or from other methods.

Details

This function is a method for the generic function summary for class "rpart". It can be invoked by calling summary for an object of the appropriate class, or directly by calling summary.rpart regardless of the class of the object.

It prints the call, the table shown by printcp, the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

See Also

summary, rpart.object, printcp.

Examples

## a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

## a classification tree with multiple variables and surrogate splits.
summary(rpart(Kyphosis ~ Age + Number + Start, data = kyphosis))

---

**text.rpart**

*Place Text on a Dendrogram Plot*

Description

Labels the current plot of the tree dendrogram with text.

Usage

```r
## S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
      pretty = NULL, digits = getOption("digits") - 3, use.n = FALSE,
      fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
      minlength = 1L, ...)
```
Arguments

- **x**: fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.

- **splits**: logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split.

- **label**: For compatibility with `rpart2`, ignored in this version (with a warning).

- **FUN**: the name of a labeling function, e.g. `text`.

- **all**: Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes.

- **minlength**: the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', ... Larger values use abbreviations of the label names. See the `labels.rpart` function for details.

- **pretty**: an alternative to the `minlength` argument, see `labels.rpart`.

- **digits**: number of significant digits to include in numerical labels.

- **use.n**: Logical. If TRUE, adds to label (#events level1/ #events level2/ etc. for class, n for anova, and #events/n for poisson and exp).

- **fancy**: Logical. If TRUE, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by `yval`. The edges connecting the nodes are labeled by left and right splits.

- **fwidth**: Relates to option `fancy` and the width of the ellipses and rectangles. If `fwidth < 1` then it is a scaling factor (default = 0.8). If `fwidth > 1` then it represents the number of character widths (for current graphical device) to use.

- **fheight**: Relates to option `fancy` and the height of the ellipses and rectangles. If `fheight <1` then it is a scaling factor (default = 0.8). If `fheight > 1` then it represents the number of character heights (for current graphical device) to use.

- **bg**: The color used to paint the background to annotations if `fancy = TRUE`.

- **...**: Graphical parameters may also be supplied as arguments to this function (see `par`). As labels often extend outside the plot region it can be helpful to specify `xpd = TRUE`.

Side Effects

- the current plot of a tree dendrogram is labeled.

See Also

- `text`, `plot.rpart`, `rpart`, `labels.rpart`, `abbreviate`

Examples

```r
freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)
```
Description

Gives the predicted values for an \texttt{rpart} fit, under cross validation, for a set of complexity parameter values.

Usage

\texttt{xpred.rpart(fit, xval = 10, cp, return.all = FALSE)}

Arguments

- \texttt{fit} a object of class \texttt{"rpart"}.
- \texttt{xval} number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups.
- \texttt{cp} the desired list of complexity values. By default it is taken from the \texttt{cptable} component of the fit.
- \texttt{return.all} if FALSE return only the first element of the prediction

Details

Complexity penalties are actually ranges, not values. If the \texttt{cp} values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for \texttt{cp} in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.

Value

A matrix with one row for each observation and one column for each complexity value. If \texttt{return.all} is TRUE and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; \texttt{result[1,,]} will be the matrix of predicted classes, \texttt{result[2,,]} the matrix of class 1 probabilities, etc.

\texttt{xmat <- xpred.rpart(fit)}
\texttt{xerr <- (xmat - car.test.frame$Mileage)^2}
\texttt{apply(xerr, 2, sum)}  # cross-validated error estimate

# approx same result as rel. error from printcp(fit)
\texttt{apply(xerr, 2, sum)/var(car.test.frame$Mileage)}
\texttt{printcp(fit)}
Chapter 28

The spatial package

---

anova.trls  
Anova tables for fitted trend surface objects

Description
Compute analysis of variance tables for one or more fitted trend surface model objects; where anova.trls is called with multiple objects, it passes on the arguments to anovalist.trls.

Usage
```r
## S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

Arguments

- `object`: A fitted trend surface model object from surf.ls
- `...`: Further objects of the same kind

Value
anova.trls and anovalist.trls return objects corresponding to their printed tabular output.

References

See Also
surf.ls
### correlogram

**Compute Spatial Correlograms**

#### Description

Compute spatial correlograms of spatial data or residuals.

#### Usage

```r
correlogram(krig, nint, plotit = TRUE, ...)```

#### Arguments

- `krig`: trend-surface or kriging object with columns `x`, `y`, and `z`
- `nint`: number of bins used
- `plotit`: logical for plotting
- `...`: parameters for the plot

#### Details

Divides range of data into `nint` bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

#### Value

- `x` and `y` coordinates of the correlogram, and `cnt`, the number of pairs averaged per bin.

#### Side Effects

Plots the correlogram if `plotit = TRUE`.

#### References

#### See Also

`variogram`
Expcov

Examples

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
correlogram(topo.kr, 25)
d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```

\textit{Spatial Covariance Functions}

Description

Spatial covariance functions for use with \texttt{surf.gls}.

Usage

```
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

Arguments

- \texttt{r} vector of distances at which to evaluate the covariance
- \texttt{d} range parameter
- \texttt{alpha} proportion of nugget effect
- \texttt{se} standard deviation at distance zero
- \texttt{D} dimension of spheres.

Value

vector of covariance values.

References

d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```
**Kaver**

**Average K-functions from Simulations**

**Description**

Forms the average of a series of (usually simulated) K-functions.

**Usage**

\[ \text{Kaver}(fs, nsim, \ldots) \]

**Arguments**

- `fs`: full scale for K-fn
- `nsim`: number of simulations
- `\ldots`: arguments to simulate one point process object

**Value**

list with components `x` and `y` of the average K-fn on L-scale.

**References**

**See Also**

`Kfn`, `Kenvl`

**Examples**

```r
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
for(i in 1:10) lines(Kfn(Psim(69), 10))
lims <- Kenvl(10,100,Psim(69))
lines(lims$x,lims$lower, lty=2, col="green")
lines(lims$x,lims$upper, lty=2, col="green")
lines(Kaver(10,25,Strauss(69,0.5,3.5)), col="red")
```
Kenvl

**Description**

Computes envelope (upper and lower limits) and average of simulations of K-fns

**Usage**

Kenvl(fs, nsim, ...)

**Arguments**

- **fs**
  - full scale for K-fn
- **nsim**
  - number of simulations
- **...**
  - arguments to produce one simulation

**Value**

list with components

- **x**
  - distances
- **lower**
  - min of K-fns
- **upper**
  - max of K-fns
- **aver**
  - average of K-fns

**References**

**Examples**

towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 40), type="b")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
for(i in 1:10) lines(Kfn(Psim(69), 10))
lims <- Kenvl(10, 100, Psim(69))
lines(lims$x, lims$lower, lty=2, col="green")
lines(lims$x, lims$upper, lty=2, col="green")
lines(Kaver(10, 25, Strauss(69, 0.5, 3.5)), col="red")
Kfn

Compute K-fn of a Point Pattern

Description

Actually computes \( L = \sqrt{K/\pi} \).

Usage

Kfn(pp, fs, k=100)

Arguments

pp a list such as a pp object, including components \( x \) and \( y \)
fs full scale of the plot
k number of regularly spaced distances in (0, fs)

details

relies on the domain D having been set by ppinit or ppregion.

Value

A list with components

x vector of distances
y vector of L-fn values
k number of distances returned – may be less than k if fs is too large
dmin minimum distance between pair of points
lmax maximum deviation from \( L(t) = t \)

References

Examples

towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="s", xlab="distance", ylab="L(t)")
ppgetregion

Get Domain for Spatial Point Pattern Analyses

Description
Retrieves the rectangular domain \((x_l, x_u) \times (y_l, y_u)\) from the underlying C code.

Usage
ppgetregion()

Value
A vector of length four with names \(c("x_l", "x_u", "y_l", "y_u")\).

References

See Also
ppregion

ppinit
Read a Point Process Object from a File

Description
Read a file in standard format and create a point process object.

Usage
ppinit(file)

Arguments
file string giving file name

Details
The file should contain
the number of points
a header (ignored)
x_l x_u y_l y_u scale
x y (repeated n times)

Value
class "pp" object with components x, y, x_l, x_u, y_l, y_u
Side Effects

Calls pprregion to set the domain.

References

See Also

ppregion

Examples

towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")

---

**pplik**

*Pseudo-likelihood Estimation of a Strauss Spatial Point Process*

Description

Pseudo-likelihood estimation of a Strauss spatial point process.

Usage

`pplik(pp, R, ng=50, trace=FALSE)`

Arguments

- `pp` a pp object
- `R` the fixed parameter R
- `ng` use a `ng x ng` grid with border `R` in the domain for numerical integration.
- `trace` logical? Should function evaluations be printed?

Value

estimate for `c` in the interval `[0, 1]`.

References

See Also

*Strauss*

Examples

`pines <- ppinit("pines.dat")`
`pplik(pines, 0.7)`
**ppregion**  
*Set Domain for Spatial Point Pattern Analyses*

**Description**
Sets the rectangular domain \((x_l, x_u) \times (y_l, y_u)\).

**Usage**

\[
\text{ppregion}(x_l = 0, x_u = 1, y_l = 0, y_u = 1)
\]

**Arguments**
- \(x_l\)
  - Either \(x_l\) or a list containing components \(x_l, x_u, y_l, y_u\) (such as a point-process object)
- \(x_u\)
- \(y_l\)
- \(y_u\)

**Value**
none

**Side Effects**
initializes variables in the C subroutines.

**References**

**See Also**
- ppinit, ppgetregion

**predict.trls**  
*Predict method for trend surface fits*

**Description**
Predicted values based on trend surface model object

**Usage**

\[
\text{## S3 method for class 'trls'}
\text{predict(object, x, y, ...)}
\]
**Arguments**

- **object**: Fitted trend surface model object returned by `surf.ls`
- **x**: Vector of prediction location eastings (x coordinates)
- **y**: Vector of prediction location northings (y coordinates)
- **...**: further arguments passed to or from other methods.

**Value**

`predict.trls` produces a vector of predictions corresponding to the prediction locations. To display the output with `image` or `contour`, use `trmat` or convert the returned vector to matrix form.

**References**

**See Also**

- `surf.ls`, `trmat`

** Examples**

```r
data(topo, package="MASS")
topo2 <- surf.ls(2, topo)
topo4 <- surf.ls(4, topo)
x <- c(1.78, 2.21)
y <- c(6.15, 6.15)
z2 <- predict(topo2, x, y)
z4 <- predict(topo4, x, y)
cat("2nd order predictions: ", z2, "4th order predictions: ", z4, "\n")```

---

**prmat**  
*Evaluate Kriging Surface over a Grid*

**Description**

Evaluate Kriging surface over a grid.

**Usage**

`prmat(obj, xl, xu, yl, yu, n)`

**Arguments**

- **obj**: object returned by `surf.gls`
- **xl**: limits of the rectangle for grid
- **xu**: limits of the rectangle for grid
- **yl**: limits of the rectangle for grid
- **yu**: limits of the rectangle for grid
- **n**: use n x n grid within the rectangle
**Value**

list with components x, y and z suitable for contour and image.

**References**

**See Also**

`surf.gls`, `trmat`, `semat`

**Examples**

data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))

---

**Psim**

*Simulate Binomial Spatial Point Process*

**Description**

Simulate Binomial spatial point process.

**Usage**

`Psim(n)`

**Arguments**

- `n` number of points

**Details**

relies on the region being set by `ppinit` or `ppregion`.

**Value**

list of vectors of x and y coordinates.

**Side Effects**

uses the random number generator.

**References**

Evaluate Kriging Standard Error of Prediction over a Grid

Description

Evaluate Kriging standard error of prediction over a grid.

Usage

semat(obj, xl, xu, yl, yu, n, se)

Arguments

obj object returned by surf.gls
xl limits of the rectangle for grid
xu
yl
yu
n use \( n \times n \) grid within the rectangle
se standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied.

Value

list with components \( x \), \( y \) and \( z \) suitable for contour and image.

References

surf.gls, trmat, prmat
SSI

Simulates Sequential Spatial Inhibition Point Process

Examples

```r
data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))

sesurf <- semat(topo.kr, 0, 6.5, 0, 6.5, 30)
contour(sesurf, levels=c(22,25))
```

Description

Simulates SSI (sequential spatial inhibition) point process.

Usage

```r
SSI(n, r)
```

Arguments

- `n` number of points
- `r` inhibition distance

Details

uses the region set by `ppinit` or `ppregion`.

Value

list of vectors of x and y coordinates

Side Effects

uses the random number generator.

Warnings

will never return if `r` is too large and it cannot place `n` points.

References

See Also

`Psim`, `Strauss`
Examples

towns <- ppinit("towns.dat")
par(pty = "s")
plot(Kfn(towns, 10), type = "b", xlab = "distance", ylab = "L(t)"
lines(Kaver(10, 25, SSI(69, 1.2)))

Strauss

Simulates Strauss Spatial Point Process

Description

Simulates Strauss spatial point process.

Usage

`Strauss(n, c=0, r)`

Arguments

- `n` number of points
- `c` parameter c in [0, 1]. c = 0 corresponds to complete inhibition at distances up to r.
- `r` inhibition distance

Details

Uses spatial birth-and-death process for 4n steps, or for 40n steps starting from a binomial pattern on the first call from another function. Uses the region set by `ppinit` or `ppregion`.

Value

list of vectors of x and y coordinates

Side Effects

uses the random number generator

### trls.influence

#### Regression diagnostics for trend surfaces

#### Description

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

#### Usage

```r
trls.influence(object)
```

#### Arguments

- `object`: Fitted trend surface model from `surf.ls`.
- `div`: scaling factor for influence circle radii in `plot.trls`.
- `add`: add influence plot to existing graphics if `TRUE`.
- `border`, `col`, `pch`, `cex`, `...`: additional graphical parameters.

#### Value

- `trls.influence` returns a list with components:
  - `r`: raw residuals as given by `residuals.trls`.
  - `hii`: diagonal elements of the Hat matrix.
  - `stresid`: standardised residuals.
  - `Di`: Cook's statistic.

#### References

trmat

Evaluate Trend Surface over a Grid

Description

Evaluate trend surface over a grid.

Usage

trmat(obj, xl, xu, yl, yu, n)

Arguments

obj object returned by surf.ls or surf.gls
xl limits of the rectangle for grid
xu
yl
yu
n use n x n grid within the rectangle

Value

list with components x, y and z suitable for contour and image.

**variogram**

*Examples*

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
trsurf <- trmat(topo.kr, 0, 6.5, 0, 6.5, 50)
```

---

**Description**

Compute spatial (semi-)variogram of spatial data or residuals.

**Usage**

```r
variogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

- `krig`: trend-surface or kriging object with columns `x`, `y`, and `z`.
- `nint`: number of bins used.
- `plotit`: logical for plotting.
- `...`: parameters for the plot.

**Details**

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

**Value**

- `x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

**Side Effects**

Plots the variogram if `plotit = TRUE`.

**References**

**See Also**

- `correlogram`

**Examples**

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
variogram(topo.kr, 25)
```
Chapter 29

The survival package

aareg

Aalen’s additive regression model for censored data

Description

Returns an object of class "aareg" that represents an Aalen model.

Usage

aareg(formula, data, weights, subset, na.action,
  qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
  test = c('aalen', 'variance', 'nrisk'), cluster,
  model=FALSE, x=FALSE, y=FALSE)

Arguments

formula a formula object, with the response on the left of a ‘~’ operator and the terms,
  separated by + operators, on the right. The response must be a Surv object. Due
  to a particular computational approach that is used, the model MUST include an
  intercept term. If "-1" is used in the model formula the program will ignore it.

data data frame in which to interpret the variables named in the formula,
  subset, and weights arguments. This may also be a single number to handle some
  special cases – see below for details. If data is missing, the variables in the
  model formula should be in the search path.

weights vector of observation weights. If supplied, the fitting algorithm minimizes the
  sum of the weights multiplied by the squared residuals (see below for additional
  technical details). The length of weights must be the same as the number of
  observations. The weights must be nonnegative and it is recommended that
  they be strictly positive, since zero weights are ambiguous. To exclude particular
  observations from the model, use the subset argument instead of zero weights.

subset expression specifying which subset of observations should be used in the fit. Th
  is can be a logical vector (which is replicated to have length equal to the numb
  er of observations), a numeric vector indicating the observation numbers to be
  included, or a character vector of the observation names that should be included.
  All observations are included by default.
na.action

a function to filter missing data. This is applied to the model.frame after any subset argument has been applied. The default is na.fail, which returns an error if any missing values are found. An alternative is na.exclude, which deletes observations that contain one or more missing values.

qrtol
tolerance for detection of singularity in the QR decomposition

nmin
minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when n is small and the calculations can become numerically unstable.

dfbeta
should the array of dfbeta residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a cluster term in the model formula.

taper
allows for a smoothed variance estimate. Var(x), where x is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point t, it is computed over all subjects who are still at risk at time t. The taper argument allows smoothing these estimates, for example taper=(1:4)/4 would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model.

test
selects the weighting to be used, for computing an overall “average” coefficient vector over time and the subsequent test for equality to zero.

cluster
the clustering group, optional. The variable will be searched for in the data argument.

model, x, y
should copies of the model frame, the x matrix of predictors, or the response vector y be included in the saved result.

Details

The Aalen model assumes that the cumulative hazard $H(t)$ for a subject can be expressed as $a(t) + X \cdot B(t)$, where $a(t)$ is a time-dependent intercept term, $X$ is the vector of covariates for the subject (possibly time-dependent), and $B(t)$ is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to $B$ at time $t$ is based on the subjects still at risk at time $t$. The tolerance and/or nmin parameters may act to truncate the estimate before the last death. The taper argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when n is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

Value

an object of class "aareg" representing the fit, with the following components:

n
vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation

times
vector of sorted event times, which may contain duplicates

nrisk
vector containing the number of subjects at risk, of the same length as times

coefficient
matrix of coefficients, with one row per event and one column per covariate

test.statistic
the value of the test statistic, a vector with one element per covariate
test.var         variance-covariance matrix for the test
test             the type of test; a copy of the test argument above
tweight          matrix of weights used in the computation, one row per event
call             a copy of the call that produced this result

# End(Not run)
aeqSurv

Adjudicate near ties in a Surv object

Description
The check for tied survival times can fail due to floating point imprecision, which can make actual ties appear to be distinct values. Routines that depend on correct identification of ties pairs will then give incorrect results, e.g., a Cox model. This function rectifies these.

Usage
aeqSurv(x, tolerance = sqrt(.Machine$double.eps))

Arguments
x a Surv object
tolerance the tolerance used to detect values that will be considered equal

Details
This routine is called by both survfit and coxph to deal with the issue of ties that get incorrectly broken due to floating point imprecision. See the short vignette on tied times for a simple example. Use the timefix argument of survfit or coxph.control to control the option if desired.

The rule for ‘equality’ is identical to that used by the all.equal routine. Pairs of values that are within round off error of each other are replaced by the smaller value. An error message is generated if this process causes a 0 length time interval to be created.

Value
a Surv object identical to the original, but with ties restored.

Author(s)
Terry Therneau

See Also
survfit, coxph.control
aggregate.survfit

Average survival curves

Description
For a survfit object containing multiple curves, create average curves over a grouping.

Usage
```r
## S3 method for class 'survfit'
aggregate(x, by = NULL, FUN = mean, ...)
```

Arguments
- `x`: a `survfit` object which has a data dimension.
- `by`: an optional list or vector of grouping elements, each as long as `dim(x)['data']`.
- `FUN`: a function to compute the summary statistic of interest.
- `...`: optional further arguments to `FUN`.

Details
The primary use of this is to take an average over multiple survival curves that were created from a modeling function. That is, a marginal estimate of the survival. It is primarily used to average over multiple predicted curves from a Cox model.

Value
A `survfit` object of lower dimension.

See Also
- `survfit`

Examples
```r
cfit <- coxph(Surv(futime, death) ~ sex + age*hgb, data=mgus2)
# marginal effect of sex, after adjusting for the others
dummy <- rbind(mgus2, mgus2)
dummy$sex <- rep(c("F", "M"), each=nrow(mgus2)) # population data set
dummy <- na.omit(dummy) # don't count missing hgb in our "population"
csurv <- survfit(cfit, newdata=dummy) # don't count missing hgb in our "population"
csurv2 <- aggregate(csurv, dummy$sex)
```
agreg.fit

Cox model fitting functions

Description

These are the functions called by coxph that do the actual computation. In certain situations, e.g. a simulation, it may be advantageous to call these directly rather than the usual coxph call using a model formula.

Usage

agreg.fit(x, y, strata, offset, init, control, weights, method, rownames, resid=TRUE, nocenter=NULL)
coxph.fit(x, y, strata, offset, init, control, weights, method, rownames, resid=TRUE, nocenter=NULL)

Arguments

x Matix of predictors. This should not include an intercept.
y a Surv object containing either 2 columns (coxph.fit) or 3 columns (agreg.fit).
strata a vector containing the stratification, or NULL
offset optional offset vector
init initial values for the coefficients
control the result of a call to coxph.control
weights optional vector of weights
method method for handling ties, one of "breslow" or "efron"
rownames this is only needed for a NULL model, in which case it contains the rownames (if any) of the original data.
resid compute and return residuals.
nocenter an optional list of values. Any column of the X matrix whose values lie strictly within that set will not be recentered. Note that the coxph function has (-1, 0, 1) as the default.

Details

This routine does no checking that arguments are the proper length or type. Only use it if you know what you are doing!

The resid and concordance arguments will save some compute time for calling routines that only need the likelihood, the generation of a permutation distribution for instance.

Value

a list containing results of the fit

Author(s)

Terry Therneau
Survival in patients with Acute Myelogenous Leukemia. The question at the time was whether the standard course of chemotherapy should be extended ('maintainance') for additional cycles.

Usage

```r
aml
leukemia
data(cancer, package="survival")
```

Format

- **time**: survival or censoring time
- **status**: censoring status
- **x**: maintenance chemotherapy given? (factor)

Source

---

**anova.coxph**

*Analysis of Deviance for a Cox model.*

Description

Compute an analysis of deviance table for one or more Cox model fits, based on the log partial likelihood.

Usage

```
## S3 method for class 'coxph'
anova(object, ..., test = 'Chisq')
```

Arguments

- **object**: An object of class coxph
- **...**: Further coxph objects
- **test**: a character string. The appropriate test is a chisquare, all other choices result in no test being done.
Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model Cox log-partial-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of likelihood values does not make sense (differences no longer have a chi-square distribution), and anova will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models by anova will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

See Also

coxph, anova.

Examples

```r
fit <- coxph(Surv(futime, fustat) ~ resid.ds * rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds + rx + ecog.ps, data=ovarian)
anova(fit2,fit)
```

attrassign

Create new-style "assign" attribute

Description

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

Usage

```r
## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm'
attrassign(object,...)
```
Arguments

- **object**: model matrix or linear model object
- **tt**: terms object
- **...**: ignored

Details

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact for for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as “the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3”.

The alternate (S-Plus default) form is a list

```
$\text{Intercept} \quad 1
$age \quad 2
$sex \quad 3
$\text{factor(ph.ecog)} \quad 4 \quad 5 \quad 6
```

Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

See Also

`terms`, `model.matrix`

Examples

```
formula <- Surv(time, status) - factor(ph.ecog)
 tt <- terms(formula)
 mf <- model.frame(tt, data = lung)
 mm <- model.matrix(tt, mf)
 ## a few rows of data
 mm[1:3,]
 ## old-style assign attribute
 attr(mm, "assign")
 ## alternate style assign attribute
 attrassign(mm, tt)
```
basehaz  

Alias for the survfit function

Description

Compute the predicted survival curve for a Cox model.

Usage

basehaz(fit, centered=TRUE)

Arguments

fit  
a coxph fit

centered  
if TRUE return data from a predicted survival curve at the mean values of the covariates fit$mean, if FALSE return a prediction for all covariates equal to zero.

Details

This function is simply an alias for survfit, which does the actual work and has a richer set of options. The alias exists only because some users look for predicted survival estimates under this name.

The function returns a data frame containing the time, cumhaz and optionally the strata (if the fitted Cox model used a strata statement), which are copied the survfit result. Results for all covariates =0 are a standard form found in textbooks, however, due to possible overflow in the exp() function this is, in practice, a very bad idea in practice.

Value

a data frame with variable names of hazard, time and optionally strata. The first is actually the cumulative hazard.

See Also

survfit.coxph

---

bladder

Bladder Cancer Recurrences

Description

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo, and only the first four recurrences for any patient. The status variable is 1 for recurrence and 0 for everything else (including
death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects: all those with follow-up beyond their 4th recurrence. This “follow-up” is a side effect of throwing away all events after the fourth while retaining the last follow-up time variable from the original data. The bladder2 data set found here does not make this mistake, but some analyses in the literature have done so; it results in the addition of a small amount of immortal time bias and shrinks the fitted coefficients towards zero.

Usage

```r
bladder1
bladder
bladder2
data(cancer, package="survival")
```

Format

**bladder1**

blogit

Bounded link functions

Description

Alternate link functions that impose bounds on the input of their link function

Usage

```
blogit(edge = 0.05)
bprobit(edge= 0.05)
bclloglog(edge=.05)
blog(edge=.05)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge</td>
<td>input values less than the cutpoint are replaced with the cutpoint. For all be blog input values greater than (1-edge) are replaced with (1-edge)</td>
</tr>
</tbody>
</table>

Details

When using survival pseudovalues for binomial regression, the raw data can be outside the range (0,1), yet we want to restrict the predicted values to lie within that range. A natural way to deal with this is to use `glm` with `family = gaussian(link= "logit")`. But this will fail. The reason is that the `family` object has a component `linkfun` that does not accept values outside of (0,1).

This function is only used to create initial values for the iteration step, however. Mapping the offending input argument into the range of (edge, 1-edge) before computing the link results in starting estimates that are good enough. The final result of the fit will be no different than if explicit starting estimates were given using the `etastart` or `mustart` arguments. These functions create copies of the logit, probit, and complimentary log-log families that differ from the standard ones only in this use of a bounded input argument, and are called a "bounded logit" = `blogit`, etc.

The same argument hold when using RMST (area under the curve) pseudovalues along with a log link to ensure positive predictions, though in this case only the lower boundary needs to be mapped.

Value

a family object of the same form as `make.family`.

Source

See Also

stats\{make.family\}

Examples

```r
py <- pseudo(survfit(Surv(time, status) ~ 1, lung), time=730) # 2 year survival
range(py)
pfit <- glm(py ~ ph.ecog, data=lung, family=gaussian(link=bilogit()))
# For each +1 change in performance score, the odds of 2 year survival
# are multiplied by 1/2 = exp of the coefficient.
```

Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

Usage

```r
cch(formula, data, subcoh, id, stratum=NULL, cohort.size, 
    method=c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"), 
    robust=FALSE)
```

Arguments

- **formula**: A formula object that must have a `Surv` object as the response. The `Surv` object must be of type "right", or of type "counting".
- **subcoh**: Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If `data` is a data frame then `subcoh` may be a one-sided formula.
- **id**: Vector of unique identifiers, or formula specifying such a vector.
- **stratum**: A vector of stratum indicators or a formula specifying such a vector.
- **cohort.size**: Vector with size of each stratum original cohort from which subcohort was sampled.
- **data**: An optional data frame in which to interpret the variables occurring in the formula.
- **method**: Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".
- **robust**: For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I.
Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The data argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

coef
regression coefficients.

naive.var
Self-Prentice model based variance-covariance matrix.

var
Lin-Ying empirical variance-covariance matrix.

cgd

**Chronic Granulotamous Disease data**

**Description**

Data are from a placebo controlled trial of gamma interferon in chronic granulotomous disease (CGD). Contains the data on time to serious infections observed through end of study for each patient.

**Usage**

cgd
data(cgd)

**Format**

- **id** subject identification number
- **center** enrolling center
random date of randomization
treatment placebo or gamma interferon
sex sex
age age in years, at study entry
height height in cm at study entry
weight weight in kg at study entry
inherit pattern of inheritance
steroids use of steroids at study entry, 1=yes
propylac use of prophylactic antibiotics at study entry
hos.cat a categorization of the centers into 4 groups
tstart, tstop start and end of each time interval
status 1=the interval ends with an infection
enum observation number within subject

Details
The cgd0 data set is in the form found in the references, with one line per patient and no recoding of the variables. The cgd data set (this one) has been cast into [start, stop] format with one line per event, and covariates such as center recoded as factors to include meaningful labels.

cipoisson

Confidence limits for the Poisson

Description

Confidence interval calculation for Poisson rates.

Usage

cipoisson(k, time = 1, p = 0.95, method = c("exact", "anscombe"))

Arguments

- **k**: Number of successes
- **time**: Total time on trial
- **p**: Probability level for the (two-sided) interval
- **method**: The method for computing the interval.
Details

The likelihood method is based on equation 10.10 of Feller, which relates poisson probabilities to tail area of the gamma distribution. The Anscombe approximation is based on the fact that \(\sqrt{k + 3/8}\) has a nearly constant variance of \(1/4\), along with a continuity correction.

There are many other proposed intervals: Patil and Kulkarni list and evaluate 19 different suggestions from the literature. The exact intervals can be overly broad for very small values of \(k\), many of the other approaches try to shrink the lengths, with varying success.

Value

a vector, matrix, or array. If both \(k\) and \(time\) are single values the result is a vector of length 2 containing the lower an upper limits. If either or both are vectors the result is a matrix with two columns. If \(k\) is a matrix or array, the result will be an array with one more dimension; in this case the dimensions and dimnames (if any) of \(k\) are preserved.

Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form \(\text{case.status~exposure+strata(matched.set)}\). The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.
clogit

Usage

clogit(formula, data, weights, subset, na.action,
method=c("exact", "approximate", "efron", "breslow"),
...
)

Arguments

formula Model formula
data data frame
weights optional, names the variable containing case weights
subset optional, subset the data
na.action optional na.action argument. By default the global option na.action is used.
method use the correct (exact) calculation in the conditional likelihood or one of the approximations
... optional arguments, which will be passed to coxph.control

Details

It turns out that the loglikelihood for a conditional logistic regression model = loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this 'trick' rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is 20!/10! 10! = 184756 terms. Gail et al describe a fast recursion method which partly ameliorates this; it was incorporated into version 2.36-11 of the survival package. The computation remains infeasible for very large groups of ties, say 100 ties out of 500 subjects, and may even lead to integer overflow for the subscripts – in this latter case the routine will refuse to undertake the task. The Efron approximation is normally a sufficiently accurate substitute.

Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, in which case all of the approximations for ties lead to exactly the same result. The 'approximate' option maps to the Breslow approximation for the Cox model, for historical reasons.

Case weights are not allowed when the exact option is used, as the likelihood is not defined for fractional weights. Even with integer case weights it is not clear how they should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine in this case.

Value

An object of class "clogit", which is a wrapper for a "coxph" object.

strata, coxph, glm

Examples

```r
## Not run: clogit(case ~ spontaneous + induced + strata(stratum), data=infert)
# A multinomial response recoded to use clogit
# The revised data set has one copy per possible outcome level, with new variable tocc = target occupation for this copy, and case = whether
# that is the actual outcome for each subject.
# See the reference below for the data.
resp <- levels(logan$occupation)
n <- nrow(logan)
indx <- rep(1:n, length(resp))
logan2 <- data.frame(logan[indx,]
                   , id = indx,
                   , tocc = factor(rep(resp, each=n)))
logan2$case <- (logan2$occupation == logan2$tocc)
clogit(case ~ tocc + tocc:education + strata(id), logan2)
```

Description

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. This style is now discouraged, use the `cluster` option instead.

Usage

```r
cluster(x)
```

Arguments

- `x`: A character, factor, or numeric variable.

Details

The function’s only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the “working independence” variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don’t mix.
Colon chemotherapy for stage B/C colon cancer

Value

x

See Also

coxph, survreg

Examples

marginal.model <- coxph(Surv(time, status) ~ rx, data= rats, cluster=litter, subset=(sex=='f'))
frailty.model <- coxph(Surv(time, status) ~ rx + frailty(litter), rats, subset=(sex=='f'))

Description

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death.

Usage

colon
data(cancer, package="survival")

Format

id: id
study: 1 for all patients
rx: Treatment - Observation, Lev(amisole), Lev(amisole)+5-FU
sex: 1= male
age: in years
obstruct: obstruction of colon by tumour
perfor: perforation of colon
adhere: adherence to nearby organs
nodes: number of lymph nodes with detectable cancer
time: days until event or censoring
status: censoring status
differ: differentiation of tumour (1=well, 2=moderate, 3=poor)
extent: Extent of local spread (1=submucosa, 2= muscle, 3=serosa, 4=contiguous structures)
surg: time from surgery to registration (0=short, 1=long)
node4: more than 4 positive lymph nodes
etype: event type: 1=recurrence, 2=death
The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).

Peter Higgins has pointed out a data inconsistency, revealed by `table(colon$nodes, colon$node4)`. We don’t know which of the two variables is actually correct so have elected not to ‘fix’ it. (Real data has warts, why not have some in the example data too?)

**References**

**concordance**

*Compute the concordance statistic for data or a model*

**Description**

The concordance statistic compute the agreement between an observed response and a predictor. It is closely related to Kendall’s tau-a and tau-b, Goodman’s gamma, and Somers’ d, all of which can also be calculated from the results of this function.

**Usage**

```r
concordance(object, ...)  
## S3 method for class 'formula'
concordance(object, data, weights, subset, na.action,  
cluster, ymin, ymax, timewt= c("n", "S", "S/G", "n/G", "n/G2", "I"),  
influence=0, ranks = FALSE, reverse=FALSE, timefix=TRUE, keepstrata=10, ...)
## S3 method for class 'lm'
concordance(object, ..., newdata, cluster, ymin, ymax,  
influence=0, ranks=FALSE, timefix=TRUE, keepstrata=10)
## S3 method for class 'coxph'
concordance(object, ..., newdata, cluster, ymin, ymax,  
timewt= c("n", "S", "S/G", "n/G", "n/G2", "I"), influence=0,  
ranks=FALSE, timefix=TRUE, keepstrata=10)
## S3 method for class 'survreg'
concordance(object, ..., newdata, cluster, ymin, ymax,  
timewt= c("n", "S", "S/G", "n/G", "n/G2", "I"), influence=0,  
ranks=FALSE, timefix=TRUE, keepstrata=10)
```
Arguments

object  a fitted model or a formula. The formula should be of the form \( y \sim x \) or \( y \sim x + \text{strata}(z) \) with a single numeric or survival response and a single predictor. Counts of concordant, discordant and tied pairs are computed separately per stratum, and then added.

data  a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument. Only applicable if object is a formula.

weights  optional vector of case weights. Only applicable if object is a formula.

subset  expression indicating which subset of the rows of data should be used in the fit. Only applicable if object is a formula.

na.action  a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is \( \text{options}()\$na.action \). Only applicable if object is a formula.

...  multiple fitted models are allowed. Only applicable if object is a model object.

newdata  optional, a new data frame in which to evaluate (but not refit) the models

cluster  optional grouping vector for calculating the robust variance

ymin, ymax  compute the concordance over the restricted range \( y_{\text{min}} \leq y \leq y_{\text{max}} \). (For survival data this is a time range.)

timewt  the weighting to be applied. The overall statistic is a weighted mean over event times.

influence  1 = return the dfbeta vector, 2 = return the full influence matrix, 3 = return both

ranks  if TRUE, return a data frame containing the individual ranks that make up the overall score.

reverse  if TRUE then assume that larger \( x \) values predict smaller response values \( y \); a proportional hazards model is the common example of this.

timefix  correct for possible rounding error. See the vignette on tied times for more explanation. Essentially, exact ties are an important part of the concordance computation, but "exact" can be a subtle issue with floating point numbers.

keepstrata  either TRUE, FALSE, or an integer value. Computations are always done within stratum, then added. If the total number of strata greater than keepstrata, or keepstrata=FALSE, those subtotals are not kept in the output.

Details

At each event time, compute the rank of the subject who had the event as compared to all others with a longer survival, where the rank is value between 0 and 1. The concordance is a weighted mean of these values, determined by the timewt option. For uncensored data each unique response value is compared to all those which are larger.

Using the default value for timewt gives the area under the receiver operating curve (AUC) for a binary response, and \((d+1)/2\) when \( y \) is continuous, where \( d \) is Somers’ \( d \). For a survival time, timewt of \( n \) gives Harrell’s \( c \)-statistic, which is closely related to the Gehan-Wilcoxon test, \( S \) corresponds to the Peto-Wilcoxon, \( n/G2 \) is the weighted advocated by Umo, and \( S/G \) the weighting proposed by Schemper.

When the number of strata is very large, such as in a conditional logistic regression for instance (\texttt{clogit} function), a much faster computation is available when the individual strata results are not retained; use keepstrata=FALSE or keepstrata=0 to do so. In the general case the keepstrata = 10 default simply keeps the printout managable: it retains and prints per-strata information if the number of strata is \( \leq 10 \).
Value

An object of class `concordance` containing the following components:

- **concordance**: the estimated concordance value or values
- **count**: a vector containing the number of concordant pairs, discordant, tied on x but not y, tied on y but not x, and tied on both x and y
- **n**: the number of observations
- **var**: a vector containing the estimated variance of the concordance based on the infinitesimal jackknife (IJ) method. If there are multiple models it contains the estimated variance/covariance matrix.
- **cvar**: a vector containing the estimated variance(s) of the concordance values, based on the variance formula for the associated score test from a proportional hazards model. (This was the primary variance used in the `survConcordance` function.)
- **dfbeta**: optional, the vector of leverage estimates for the concordance
- **influence**: optional, the matrix of leverage values for each of the counts, one row per observation
- **ranks**: optional, a data frame containing the Somers’ d rank at each event time, along with the time weight, case weight of the observation with an event, and variance (contribution to the proportional hazards model information matrix). A weighted mean of the ranks equals Somer’s d.

Note

A coxph model that has a numeric failure may have undefined predicted values, in which case the concordance will be NULL.

Computation for an existing coxph model along with newdata has some subtleties with respect to extra arguments in the original call. These include

- `tt()` terms in the model. This is not supported with newdata.
- `subset`. Any subset clause in the original call is ignored, i.e., not applied to the new data.
- `strata()` terms in the model. The new data is expected to have the strata variable(s) found in the original data set, with concordance computed within strata. The levels of the strata variable need not be the same as in the original data.
- `id` or `cluster` directives. This has not yet been sorted out.

fit1 <- coxph(Surv(ptime, pstat) ~ age + sex + mspike, mgus2)
concordance(fit1, timewt="n")

# logistic regression
fit2 <- glm(pstat ~ age + sex + mspike, binomial, data= mgus2)
concordance(fit2)  # equal to the AUC
```
concordancefit (Compute the concordance)

Description

This is the working routine behind the concordance function. It is not meant to be called by users, but is available for other packages to use. Input arguments, for instance, are assumed to all be the correct length and type, and missing values are not allowed: the calling routine is responsible for these things.

Usage

concordancefit(y, x, strata, weights, ymin = NULL, ymax = NULL, timewt = c("n", "S", "S/G", "n/G", "n/G2", "I"), cluster, influence = 0, ranks = FALSE, reverse = FALSE, timefix = TRUE, keepstrata=10, robustse = TRUE)

Arguments

y the response. It can be numeric, factor, or a Surv object
x the predictor, a numeric vector
strata optional numeric vector that stratifies the data
weights options vector of case weights
ymin, ymax restrict the comparison to response values in this range
timewt the time weighting to be used
cluster, influence, ranks, reverse, timefix see the help for the concordance function
keepstrata either TRUE, FALSE, or an integer value. Computations are always done within stratum, then added. If the total number of strata greater than keepstrata, or keepstrata=FALSE, those subtotals are not kept in the output.
robustse compute the robust standard error

Value

a list containing the results

Author(s)

Terry Therneau

See Also

concordance
Description

Test the proportional hazards assumption for a Cox regression model fit (coxph).

Usage

```r
cox.zph(fit, transform="km", terms=TRUE, singledf=FALSE, global=TRUE)
```

Arguments

- `fit`: the result of fitting a Cox regression model, using the `coxph` or `coxme` functions.
- `transform`: a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument.
- `terms`: if TRUE, do a test for each term in the model rather than for each separate covariate. For a factor variable with k levels, for instance, this would lead to a k-1 degree of freedom test. The plot for such variables will be a single curve evaluating the linear predictor over time.
- `squareddf`: use a single degree of freedom test for terms that have multiple coefficients, i.e., the test that corresponds most closely to the plot. If `terms=FALSE` this argument has no effect.
- `global`: should a global chi-square test be done, in addition to the per-variable or per-term tests tests.

Details

The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in `coxph`. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient $\beta(t)$. If the proportional hazards assumption holds then the true $\beta(t)$ function would be a horizontal line. The table component provides the results of a formal score test for $slope=0$, a linear fit to the plot would approximate the test.

Random effects terms such a frailty or random effects in a `coxme` model are not checked for proportional hazards, rather they are treated as a fixed offset in model.

If the model contains strata by covariate interactions, then the y matrix may contain structural zeros, i.e., deaths (rows) that had no role in estimation of a given coefficient (column). These are marked as NA. If an entire row is NA, for instance after subscripting a `cox.zph` object, that row is removed.

Value

an object of class "cox.zph", with components:

- `table`: a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain a score test of for addition of the time-dependent term, the degrees of freedom, and the two-sided p-value.
- `x`: the transformed time axis.
The **coxph** function fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

**Usage**

```r
coxph(formula, data=, weights, subset, 
na.action, init, control, 
ties=c("efron","breslow","exact"), 
singular.ok=TRUE, robust, 
model=FALSE, x=FALSE, y=TRUE, tt, method=ties, 
  id, cluster, istate, statedata, nocenter=c(-1, 0, 1), ...)
```

**Examples**

```r
fit <- coxph(Surv(futime, fustat) ~ age + ecog.ps, 
data=ovarian) 
temp <- cox.zph(fit) 
print(temp) # display the results 
plot(temp) # plot curves
```

**Note**

In versions of the package before survival3.0 the function computed a fast approximation to the score test. Later versions compute the actual score test.

**References**

**See Also**

`coxph`, `Surv`.
**Arguments**

- **formula**: a formula object, with the response on the left of a ~ operator, and the terms on the right. The response must be a survival object as returned by the `Surv` function.

- **data**: a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument.

- **weights**: vector of case weights, see the note below. For a thorough discussion of these see the book by Therneau and Grambsch.

- **subset**: expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.

- **na.action**: a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is `options()$na.action`.

- **init**: vector of initial values of the iteration. Default initial value is zero for all variables.

- **control**: Object of class `coxph.control` specifying iteration limit and other control options. Default is `coxph.control(...)`. 

- **ties**: a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, it is more accurate when dealing with tied death times, and is as efficient computationally. The “exact partial likelihood” is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values. See further below.

- **singular.ok**: logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.

- **robust**: should a robust variance be computed. The default is TRUE if: there is a cluster argument, there are case weights that are not 0 or 1, or there are id values with more than one event.

- **id**: optional variable name that identifies subjects. Only necessary when a subject can have multiple rows in the data, and there is more than one event type. This variable will normally be found in data.

- **cluster**: optional variable which clusters the observations, for the purposes of a robust variance. If present, it implies robust. This variable will normally be found in data.

- **istate**: optional variable giving the current state at the start each interval. This variable will normally be found in data.

- **statedata**: optional data set used to describe multistate models.

- **model**: logical value: if TRUE, the model frame is returned in component `model`.

- **x**: logical value: if TRUE, the x matrix is returned in component `x`.

- **y**: logical value: if TRUE, the response vector is returned in component `y`.

- **tt**: optional list of time-transform functions.

- **method**: alternate name for the `ties` argument.

- **nocenter**: columns of the X matrix whose values lie strictly within this set are not recentered. Remember that a factor variable becomes a set of 0/1 columns.

- **...**: Other arguments will be passed to `coxph.control`
The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation [start, stop].

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. Any column of the X matrix whose values lie within the center list are not recentered. The practical consequence of the default is to not recenter dummy variables corresponding to factors. However, arguments to offset are not scaled since there are situations where a large offset value is a purposefully used. In general, however, users should not avoid very large numeric values for an offset due to possible loss of precision in the estimates.

an object of class coxph representing the fit. See coxph.object and coxphms.object for details.

Depending on the call, the predict, residuals, and survfit routines may need to reconstruct the x matrix created by coxph. It is possible for this to fail, as in the example below in which the predict function is unable to find tform.

```r
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the model=TRUE option to the coxph call to obviate the need for reconstruction, at the expense of a larger fit object.

Case weights

Case weights are treated as replication weights, i.e., a case weight of 2 is equivalent to having 2 copies of that subject's observation. When computers were much smaller grouping like subjects together was a common trick to used to conserve memory. Setting all weights to 2 for instance will give the same coefficient estimate but halve the variance. When the Efron approximation for ties (default) is employed replication of the data will not give exactly the same coefficients as the weights option, and in this case the weighted fit is arguably the correct one.

When the model includes a cluster term or the robust=TRUE option the computed variance treats any weights as sampling weights; setting all weights to 2 will in this case give the same variance as weights of 1.

Special terms

There are three special terms that may be used in the model equation. A strata term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The cluster term is used to compute a robust variance for the model. The term + cluster(id) where each value of id is unique is equivalent to specifying the robust=TRUE argument. If the id variable is not unique, it is assumed that it identifies clusters of correlated observations. The robust estimate arises from many different arguments and thus has had many labels. It is variously known as the Huber sandwich estimator, White’s estimate (linear models/econometrics), the Horvitz-Thompson estimate (survey
sampling), the working independence variance (generalized estimating equations), the infinitesimal jackknife, and the Wei, Lin, Weissfeld (WLW) estimate.

A time-transform term allows variables to vary dynamically in time. In this case the \( tt \) argument will be a function or a list of functions (if there are more than one \( tt() \) term in the model) giving the appropriate transform. See the examples below.

One user mistake that has recently arisen is to slavishly follow the advice of some coding guides and prepend survival:: onto everthing, including the special terms, e.g.,

```r
survival::coxph(survival:Surv(time, status) ~ age + survival::cluster(inst),
data=lung)
```

First, this is unnecessary: arguments within the \( \text{coxph} \) call will be evaluated within the \( \text{survival} \) namespace, so another package’s \( \text{Surv} \) or \( \text{cluster} \) function would not be noticed. (Full qualification of the coxph call itself may be protective, however.) Second, and more importantly, the call just above will not give the correct answer. The specials are recognized by their name, and survival::cluster is not the same as \( \text{cluster} \); the above model would treat \( \text{inst} \) as an ordinary variable. A similar issue arises from using \( \text{stats::offset} \) as a term, in either survival or glm models.

**Convergence**

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to \( \exp \) becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Most often number 1 is the first to occur.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic \( = \) coefficient/\( \text{se(coefficient)} \) is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

**Ties**

There are three possible choices for handling tied event times. The Breslow approximation is the easiest to program and hence became the first option coded for almost all computer routines. It then ended up as the default option when other options were added in order to "maintain backwards compatibility". The Efron option is more accurate if there are a large number of ties, and it is the default option here. In practice the number of ties is usually small, in which case all the methods are statistically indistinguishable.

Using the "exact partial likelihood" approach the Cox partial likelihood is equivalent to that for matched logistic regression. (The \( \text{clogit} \) function uses the coxph code to do the fit.) It is technically appropriate when the time scale is discrete and has only a few unique values, and some packages refer to this as the "discrete" option. There is also an "exact marginal likelihood" due to Prentice which is not implemented here.

The calculation of the exact partial likelihood is numerically intense. Say for instance 180 subjects are at risk on day 7 of which 15 had an event; then the code needs to compute sums over all \( 180 - \text{choose-15} > 10^{43} \) different possible subsets of size 15. There is an efficient recursive algorithm for this task, but even with this the computation can be insufferably long. With (start, stop) data it is much worse since the recursion needs to start anew for each unique start time.

A separate issue is that of artificial ties due to floating-point imprecision. See the vignette on this topic for a full explanation or the \( \text{timefix} \) option in \( \text{coxph.control} \). Users may need to add \( \text{timefix} = \text{FALSE} \) for simulated data sets.

**Penalized regression**

coxph can maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied
penalty functions include ridge regression (ridge), smoothing splines (pspline), and frailty models (frailty).

```
coxph.control

Ancillary arguments for controlling coxph fits

Description
This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to coxph.

Usage
coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75, iter.max = 20, toler.inf = sqrt(eps), outer.max = 10, timefix=TRUE)

Arguments
eps Iteration continues until the relative change in the log partial likelihood is less than eps, or the absolute change is less than sqrt(eps). Must be positive.
toler.chol Tolerance for detection of singularity during a Cholesky decomposition of the variance matrix, i.e., for detecting a redundant predictor variable.
iter.max Maximum number of iterations to attempt for convergence.
toler.inf Tolerance criteria for the warning message about a possible infinite coefficient value.
outer.max For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop.
timefix Resolve any near ties in the time variables.

Details
The convergence tolerances are a balance. Users think they want THE maximum point of the likelihood surface, and for well behaved data sets where this is quadratic near the max a high accuracy is fairly inexpensive: the number of correct digits approximately doubles with each iteration. Conversely, a drop of .0001 from the maximum in any given direction will be correspond to only about 1/20 of a standard error change in the coefficient. Statistically, more precision than this is straining at a gnat. Based on this the author originally had set the tolerance to 1e-5, but relented in the face of multiple "why is the answer different than package X" queries.

Asking for results that are too close to machine precision (double.eps) is a fool’s errand; a reasonable criteria is often the square root of that precision. The Cholesky decomposition needs to be held to a higher standard than the overall convergence criterion, however. The tolerance.inf value controls a warning message; if it is too small incorrect warnings can appear, if too large some actual cases of an infinite coefficient will not be detected.

The most difficult cases are data sets where the MLE coefficient is infinite; an example is a data set where at each death time, it was the subject with the largest covariate value who perished. In that situation the coefficient increases at each iteration while the log-likelihood asymptotes to a maximum. As iteration proceeds there is a race condition condition for three endpoint: exp(coef) overflows, the Hessian matrix become singular, or the change in loglik is small enough to satisfy the convergence criterion. The first two are difficult to anticipate and lead to numeric difficulties, which is another argument for moderation in the choice of eps.
See the vignette "Roundoff error and tied times" for a more detailed explanation of the \texttt{timefix} option. In short, when time intervals are created via subtraction then two time intervals that are actually identical can appear to be different due to floating point round off error, which in turn can make \texttt{coxph} and \texttt{survfit} results dependent on things such as the order in which operations were done or the particular computer that they were run on. Such cases are unfortunately not rare in practice. The \texttt{timefix=TRUE} option adds logic similar to \texttt{all.equal} to ensure reliable results. In analysis of simulated data sets, however, where often by definition there can be no duplicates, the option will often need to be set to \texttt{FALSE} to avoid spurious merging of close numeric values.

**Value**

a list containing the values of each of the above constants

**See Also**

\texttt{coxph}

---

coxph.detail \hspace{1cm} \textit{Details of a Cox Model Fit}

**Description**

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

**Usage**

\texttt{coxph.detail(object, riskmat=FALSE, rorder=c("data", "time"))}

**Arguments**

- \texttt{object}: a Cox model object, i.e., the result of \texttt{coxph}.
- \texttt{riskmat}: include the at-risk indicator matrix in the output?
- \texttt{rorder}: only applicable if \texttt{riskmat=TRUE}. Should the rows of \texttt{riskmat} be in the original data order, or sorted by time within strata.

**Details**

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

**Value**

a list with components

- \texttt{time}: the vector of unique event times
- \texttt{nevent}: the number of events at each of these time points.
- \texttt{means}: a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights \(\exp(x \%\% fit$coef)\).
nrisk  number of subjects at risk.
score  the contribution to the score vector (first derivative of the log partial likelihood) at each time point.
imat  the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.
hazard the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses \texttt{object$mean} as the future subject.
varhaz the variance of the hazard increment.
x,y copies of the input data.
strata only present for a stratified Cox model, this is a table giving the number of time points of component time that were contributed by each of the strata.
riskmat a matrix with one row for each observation and one column for each unique event time, containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point. Rows are in the order of the original data (after removal of any missings by \texttt{coxph}), or in time order.

See Also
coxph, residuals.coxph

Examples

```r
fit <- coxph(Surv(futime, fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
# There is one Schoenfeld residual for each unique death. It is a # vector (covariates for the subject who died) - (weighted mean covariate # vector at that time). The weighted mean is defined over the subjects # still at risk, with exp(X beta) as the weight.

events <- fit$y[,2]==1
etime <- fit$y[events,1] # the event times --- may have duplicates
indx <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

Proportional Hazards Regression Object

**Description**

This class of objects is returned by the \texttt{coxph} class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions \texttt{print}, \texttt{summary}, \texttt{residuals}, \texttt{predict} and \texttt{survfit}.

**Arguments**

- **coefficients** the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.
- **var** the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.
Components

The following components must be included in a legitimate coxph object.

See Also

coxph, coxph.detail, cox.zph, residuals.coxph, survfit, survreg.
**coxph.wtest**  
*Compute a quadratic form*

**Description**

This function is used internally by several survival routines. It computes a simple quadratic form, while properly dealing with missings.

**Usage**

```r
coxph.wtest(var, b, toler.chol = 1e-09)
```

**Arguments**

- `var`: variance matrix
- `b`: vector
- `toler.chol`: tolerance for the internal cholesky decomposition

**Details**

Compute $b' V^{-1} b$. Equivalent to `sum(b * solve(V,b))`, except for the case of redundant covariates in the original model, which lead to NA values in V and b.

**Value**

a real number

**Author(s)**

Terry Therneau

---

**coxphms.object**  
*Multi-state Proportional Hazards Regression Object*

**Description**

This class of objects is returned by the `coxph` class of functions to represent a fitted hazards model, when the model has multiple states. The object inherits from the `coxph` class.

**Arguments**

- `states`: a character vector listing the states in the model
- `cmap`: the coefficient map. A matrix containing a column for each transition and a row for each coefficient, the value maps that transition/coefficient pair to a position in the coefficient vector. If a particular covariate is not used by a transition the matrix will contain a zero in that position, if two transitions share a coefficient the matrix will contain repeats.
smap the stratum map. The row labeled ‘(Baseline)’ identifies transitions that do or
do not share a baseline hazard. Further rows correspond to strata() terms in the
model, each of which may apply to some transitions and not others.

rmap mapping for the residuals and linear predictors. A two column matrix with one
row for each element of the vectors and two columns, the first contains the data
row and the second the transition.

Details

In a multi-state model a set of intermediate observations is created during the computation, with a
separate set of data rows for each transition. An observation (id and time interval) that is at risk
for more than one transition will for instance have a linear predictor and residual for each of the
potential transitions. As a result the vector of linear predictors will be longer than the number of
observations. The rmap matrix shows the mapping.

Components

The object has all the components of a coxph object, with the following additions and variations.

coxph, coxph.object

coxsurv.fit A direct interface to the ‘computational engine’ of survfit.coxph

Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a
‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can
lead to unexpected errors if that data is wrong.

Usage

coxsurv.fit(ctype, stype, se.fit, varmat, cluster,
y, x, wt, risk, position, strata, oldid,
y2, x2, risk2, strata2, id2, unlist=TRUE)

Arguments

stype survival curve computation: 1=direct, 2=exp(-cumulative hazard)
ctype cumulative hazard computation: 1=Breslow, 2=Efron
se.fit if TRUE, compute standard errors
vvarmat the variance matrix of the coefficients
cluster vector to control robust variance
y the response variable used in the Cox model. (Missing values removed of
course.)
x covariate matrix used in the Cox model
wt weight vector for the Cox model. If the model was unweighted use a vector of
1s.
**diabetic**

**Description**

Partial results from a trial of laser coagulation for the treatment of diabetic retinopathy.

**Usage**

```r
diabetic
data(diabetic, package="survival")
```
Format

A data frame with 394 observations on the following 8 variables.

- id: subject id
- laser: laser type: xenon or argon
- age: age at diagnosis
- eye: a factor with levels of left right
- trt: treatment: 0 = no treatment, 1 = laser
- risk: risk group of 6-12
- time: time to event or last follow-up
- status: status of 0 = censored or 1 = visual loss

Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are therefore the actual time to blindness in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

References

Huster, Brookmeyer and Self, Biometrics, 1989.

Examples

```r
# juvenile diabetes is defined as an age less than 20
juvenile <- 1*(diabetic$age < 20)
coxph(Surv(time, status) ~ trt + juvenile, cluster= id, data= diabetic)
```

---

dsurvreg

Distributions available in survreg.

Description

Density, cumulative distribution function, quantile function and random generation for the set of distributions supported by the survreg function.

Usage

```r
dsurvreg(x, mean, scale=1, distribution='weibull', pars)
psurvreg(q, mean, scale=1, distribution='weibull', pars)
qsurvreg(p, mean, scale=1, distribution='weibull', pars)
rsurvreg(n, mean, scale=1, distribution='weibull', pars)
```
Arguments

- **x**: vector of quantiles. Missing values (NAs) are allowed.
- **q**: vector of quantiles. Missing values (NAs) are allowed.
- **p**: vector of probabilities. Missing values (NAs) are allowed.
- **n**: number of random deviates to produce
- **mean**: vector of linear predictors for the model. This is replicated to be the same length as `p`, `q` or `n`.
- **scale**: vector of (positive) scale factors. This is replicated to be the same length as `p`, `q` or `n`.
- **distribution**: character string giving the name of the distribution. This must be one of the elements of `survreg.distributions`.
- **params**: optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.

Details

Elements of `q` or `p` that are missing will cause the corresponding elements of the result to be missing.

The location and scale values are as they would be for `survreg`. The label "mean" was an unfortunate choice (made in mimicry of `qnorm`); since almost none of these distributions are symmetric it will not actually be a mean, but corresponds instead to the linear predictor of a fitted model.

Translation to the usual parameterization found in a textbook is not always obvious. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting \( F(t) = 1 - \exp[-(at)^p] \) be the cumulative distribution of the Weibull using a standard parameterization in terms of \( a \) and \( p \), the `survreg` location corresponds to \(-\log(a)\) and the scale to \(1/p\) (Kalbfleisch and Prentice, section 2.2.2).

Value

density (`dsurvreg`), probability (`psurvreg`), quantile (`qsurvreg`), or for the requested distribution with mean and scale parameters `mean` and `sd`.

haz <- dsurvreg(x, 2, 3) / (1 - psurvreg(x, 2, 3))
```

```r
## Not run:
plot(x, haz, log='xy', ylab="Hazard") # line with slope (1/scale -1)
## End(Not run)
```

---

**finegray**

Create data for a Fine-Gray model

**Description**

The Fine-Gray model can be fit by first creating a special data set, and then fitting a weighted Cox model to the result. This routine creates the data set.

**Usage**

```r
finegray(formula, data, weights, subset, na.action = na.pass, etype,
         prefix="fg", count, id, timefix=TRUE)
```

**Arguments**

- **formula**: a standard model formula, with survival on the left and covariates on the right.
- **data**: an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model.
- **weights**: optional vector of observation weights
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options.
- **etype**: the event type for which a data set will be generated. The default is to use whichever is listed first in the multi-state survival object.
- **prefix**: the routine will add 4 variables to the data set: a start and end time for each interval, status, and a weight for the interval. The default names of these are "fgstart", "fgstop", "fgstatus", and "fgwt"; the prefix argument determines the initial portion of the new names.
- **count**: a variable name in the output data set for an optional variable that will contain the the replication count for each row of the input data. If a row is expanded into multiple lines it will contain 1, 2, etc.
- **id**: optional, the variable name in the data set which identifies subjects.
- **timefix**: process times through the aeqSurv function to eliminate potential roundoff issues.
Details

The function expects a multi-state survival expression or variable as the left hand side of the formula, e.g. `Surv(atime, astat)` where `astat` is a factor whose first level represents censoring and remaining levels are states. The output data set will contain simple survival data (status = 0 or 1) for a single endpoint of interest. In the output data set subjects who did not experience the event of interest become censored subjects whose times are artificially extended over multiple intervals, with a decreasing case weight from interval to interval. The output data set will normally contain many more rows than the input.

Time dependent covariates are allowed, but not (currently) delayed entry. If there are time dependent covariates, e.g., the input data set had `Surv(entry, exit, stat)` as the left hand side, then an `id` statement is required. The program does data checks in this case, and needs to know which rows belong to each subject.

The output data set will often have gaps. Say that there were events at time 50 and 100 (and none between) and censoring at 60, 70, and 80. Formally, a non event subjects at risk from 50 to 100 will have different weights in each of the 3 intervals 50-60, 60-70, and 80-100, but because the middle interval does not span any event times the subsequent Cox model will never use that row. The `finegray` output omits such rows.

See the competing risks vignette for more details.

Value

a data frame

Author(s)

Terry Therneau

                 data=mgus2, na.action=na.pass)
```
flchain

Assay of serum free light chain for 7874 subjects.

Description

This is a stratified random sample containing 1/2 of the subjects from a study of the relationship between serum free light chain (FLC) and mortality. The original sample contains samples on approximately 2/3 of the residents of Olmsted County aged 50 or greater.

Usage

flchain
data(flchain, package="survival")

Format

A data frame with 7874 persons containing the following variables.

- age: age in years
- sex: F=female, M=male
- sample.yr: the calendar year in which a blood sample was obtained
- kappa: serum free light chain, kappa portion
- lambda: serum free light chain, lambda portion
- flc.grp: the FLC group for the subject, as used in the original analysis
- creatinine: serum creatinine
- mgus: 1 if the subject had been diagnosed with monoclonal gammapathy (MGUS)
- futime: days from enrollment until death. Note that there are 3 subjects whose sample was obtained on their death date.
- death: 0=alive at last contact date, 1=dead
- chapter: for those who died, a grouping of their primary cause of death by chapter headings of the International Code of Diseases ICD-9

Details

In 1995 Dr. Robert Kyle embarked on a study to determine the prevalence of monoclonal gammopathy of undetermined significance (MGUS) in Olmsted County, Minnesota, a condition which is normally only found by chance from a test (serum electrophoresis) which is ordered for other causes. Later work suggested that one component of immunoglobulin production, the serum free light chain, might be a possible marker for immune disregulation. In 2010 Dr. Angela Dispenzieri and colleagues assayed FLC levels on those samples from the original study for which they had patient permission and from which sufficient material remained for further testing. They found that elevated FLC levels were indeed associated with higher death rates.

Patients were recruited when they came to the clinic for other appointments, with a final random sample of those who had not yet had a visit since the study began. An interesting side question is whether there are differences between early, mid, and late recruits.

This data set contains an age and sex stratified random sample that includes 7874 of the original 15759 subjects. The original subject identifiers and dates have been removed to protect patient identity. Subsampling was done to further protect this information.
Source

The primary investigator (A Dispenzieri) and statistician (T Therneau) for the study.

table(flchain$sex, age.grp)

frailty

Random effects terms

Description

The frailty function allows one to add a simple random effects term to a Cox model.

Usage

frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05,
  method = c("em","aic", "df", "fixed"), ...)
frailty.gaussian(x, sparse = (nclass > 5), theta, df,
  method =c("reml","aic", "df", "fixed"), ...)
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,
  method =c("aic", "df", "fixed"), ...)

Arguments

x
  the variable to be entered as a random effect. It is always treated as a factor.
distribution
  either the gamma, gaussian or t distribution may be specified. The routines
  frailty.gamma, frailty.gaussian and frailty.t do the actual work.
  ...
  Arguments for specific distribution, including (but not limited to)
sparse
  cutoff for using a sparse coding of the data matrix. If the total number of levels
  of x is larger than this value, then a sparse matrix approximation is used. The
  correct cutoff is still a matter of exploration: if the number of levels is very large
  (thousands) then the non-sparse calculation may not be feasible in terms of both
  memory and compute time. Likewise, the accuracy of the sparse approximation
  appears to be related to the maximum proportion of subjects in any one class,
  being best when no one class has a large membership.
frailty

theta

if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies method='fixed'.

df

if specified, this fixes the degrees of freedom for the random effect. Specifying this implies method='df'. Only one of theta or df should be specified.

method

the method used to select a solution for theta, the variance of the random effect. The fixed corresponds to a user-specified value, and no iteration is done. The df selects the variance such that the degrees of freedom for the random effect matches a user specified value. The aic method seeks to maximize Akaike’s information criteria 2*(partial likelihood - df). The em and reml methods are specific to Cox models with gamma and gaussian random effects, respectively. Please see further discussion below.

tdf

the degrees of freedom for the t-distribution.

eps

convergence criteria for the iteration on theta.

Details

The frailty plugs into the general penalized modeling framework provided by the coxph and survreg routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a gamma frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a gaussian frailty. Both of these are specific to the Cox model. Use of gamma/ml or gaussian/reml with survreg does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as frailty or pspine, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a frailty term implies a mixed effects model and use of a cluster term implies a GEE approach; these cannot be mixed.

The coxme package has superseded this method. It is faster, more stable, and more flexible.

Value

this function is used in the model statement of either coxph or survreg. It’s results are used internally.

Examples

```r
# Random institutional effect
coxph(Surv(time, status) ~ age + frailty(inst, df=4), lung)

# Litter effects for the rats data
rfit2a <- coxph(Surv(time, status) ~ rx +
    frailty.gaussian(litter, df=13, sparse=FALSE), rats,
    subset= (sex=='f'))

rfit2b <- coxph(Surv(time, status) ~ rx +
    frailty.gaussian(litter, df=13, sparse=TRUE), rats,
    subset= (sex=='f'))
```

**gbsg**

Breast cancer data sets used in Royston and Altman (2013)

Description

The gbsg data set contains patient records from a 1984-1989 trial conducted by the German Breast Cancer Study Group (GBSG) of 720 patients with node positive breast cancer; it retains the 686 patients with complete data for the prognostic variables.

Usage

```r
gbsg
data(cancer, package="survival")
```

Format

A data set with 686 observations and 11 variables.

- **pid**: patient identifier
- **age**: age, years
- **meno**: menopausal status (0= premenopausal, 1= postmenopausal)
- **size**: tumor size, mm
- **grade**: tumor grade
- **nodes**: number of positive lymph nodes
- **pgr**: progesterone receptors (fmol/l)
- **er**: estrogen receptors (fmol/l)
- **hormon**: hormonal therapy, 0= no, 1= yes
- **rfstime**: recurrence free survival time; days to first of recurrence, death or last follow-up
- **status**: 0= alive without recurrence, 1= recurrence or death

Details

These data sets are used in the paper by Royston and Altman. The Rotterdam data is used to create a fitted model, and the GBSG data for validation of the model. The paper gives references for the data source.

heart

Stanford Heart Transplant data

Description
Survival of patients on the waiting list for the Stanford heart transplant program.

Usage
heart
data(heart, package="survival")

Format

jasa: original data

  birth.dt:  birth date
  accept.dt: acceptance into program
  tx.date:  transplant date
  fu.date:  end of followup
  fustat:  dead or alive
  surgery:  prior bypass surgery
  age:  age (in years)
  futime:  followup time
  wait.time:  time before transplant
  transplant:  transplant indicator
  mismatch:  mismatch score
  hla.a2:  particular type of mismatch
  mscore:  another mismatch score
  reject:  rejection occurred

jasa1, heart: processed data

  start, stop, event:  Entry and exit time and status for this interval of time
  age:  age-48 years
  year:  year of acceptance (in years after 1 Nov 1967)
  surgery:  prior bypass surgery 1=yes
  transplant:  received transplant 1=yes
  id:  patient id
is.ratetable

Verify that an object is of class ratetable.

Description

The function verifies not only the class attribute, but the structure of the object.

Usage

is.ratetable(x, verbose=FALSE)

Arguments

x the object to be verified.
verbose if TRUE and the object is not a ratetable, then return a character string describing
the way(s) in which x fails to be a proper ratetable object.

Details

Rate tables are used by the pyears and survexp functions, and normally contain death rates for
some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and
the verbose option can help in creating a new rate table.

Value

returns TRUE if x is a ratetable, and FALSE or a description if it is not.

See Also

pyears, survexp.

Examples

is.ratetable(survexp.us)  # True
is.ratetable(lung)        # False
Kidney catheter data

Description

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

Usage

kidney
data(cancer, package="survival")

Format

patient: id
time: time
status: event status
age: in years
sex: 1=male, 2=female
disease: disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail: frailty estimate from original paper

Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

Source

Examples

kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time,status) ~ age + sex + disease + frailty(id, dist='gauss'), kidney)
levels.Surv  Return the states of a multi-state Surv object

Description

For a multi-state Surv object, this will return the names of the states.

Usage

## S3 method for class 'Surv'
levels(x)

Arguments

x            a Surv object

Value

for a multi-state Surv object, the vector of state names (excluding censoring); or NULL for an ordinary Surv object

Examples

y1 <- Surv(c(1, 5, 9, 17, 21, 30),
factor(c(0, 1, 2, 1, 0, 2), 0:2, c("censored", "progression", "death")))
levels(y1)

y2 <- Surv(1:6, rep(0:1, 3))
y2
levels(y2)

lines.survfit  Add Lines or Points to a Survival Plot

Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with plot.survfit.

Usage

## S3 method for class 'survfit'
lines(x, type="s", pch=3, col=1, lty=1,
lwd=1, cex=1, mark.time=FALSE, xmax,
fun, conf.int=FALSE,
conf.times, conf.cap=.005, conf.offset=.012,
conf.type = c("log", "log-log", "plain", "logit", "arcsin"),
mark, noplot="(s0)", cumhaz= FALSE, ...)
## S3 method for class 'survexp'
lines(x, type="l", ...)
## S3 method for class 'survfit'
points(x, fun, censor=FALSE, col=1, pch,
noplot="(s0)", cumhaz=FALSE, ...)
Arguments

x
a survival object, generated from the `survfit` or `survexp` functions.

`type`
the line type, as described in `lines`. The default is a step function for `survfit` objects, and a connected line for `survexp` objects. All other arguments for `lines.survexp` are identical to those for `lines.survfit`.

`col`, `lty`, `lwd`, `cex`
 vectors giving the mark symbol, color, line type, line width and character size for the added curves. Of this set only color is applicable to points.

`pch`
plotting characters for points, in the style of `matplot`, i.e., either a single string of characters of which the first will be used for the first curve, etc; or a vector of characters or integers, one element per curve.

`mark`
a historical alias for `pch`

`censor`
should censoring times be displayed for the `points` function?

`mark.time`
controls the labeling of the curves. If `FALSE`, no labeling is done. If `TRUE`, then curves are marked at each censoring time. If `mark.time` is a numeric vector, then curves are marked at the specified time points.

`xmax`
optinal cutoff for the right hand of the curves.

`fun`
an arbitrary function defining a transformation of the survival curve. For example, `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the `log=T` option, "event" plots cumulative events (f(y) = 1-y), "cumhaz" plots the cumulative hazard function (f(y) = -log(y)) and "cloglog" creates a complimentary log-log survival plot (f(y) = log(-log(y))) along with log scale for the x-axis.

`conf.int`
if `TRUE`, confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot. A numeric value, e.g. `conf.int = .90`, can be used to

`conf.times`
optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.

`conf.cap`
width of the horizontal cap on top of the confidence bars; only used if `conf.times` is used. A value of 1 is the width of the plot region.

`conf.offset`
the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve's bars are offset by this amount from the prior curve's bars, if it is a vector the values are used directly.

`conf.type`
One of "plain", "log" (the default), "log-log", "logit", or "none". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve +- k *se(curve), where k is determined from `conf.int`. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option bases the intervals on the log hazard or log(-log(survival)), and the logit option on log(survival/(1-survival)).

`noplot`
for multi-state models, curves with this label will not be plotted. The default corresponds to an unspecified state.

`cumhaz`
plot the cumulative hazard, rather than the survival or probability in state.

... other graphical parameters
Details

When the `survfit` function creates a multi-state survival curve the resulting object has class `survfitms`. The only difference in the plots is that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

If the user set an explicit range in an earlier `plot.survfit` call, e.g. via `xlim` or `xmax`, subsequent calls to this function remember the right hand cutoff. This memory can be erased by `options(plot.survfit) <- NULL`.

Value

A list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

Side Effects

One or more curves are added to the current plot.

See Also

`lines`, `par`, `plot.survfit`, `survfit`, `survexp`.

Examples

```r
fit <- survfit(Surv(time, status==2) ~ sex, pbc, subset=1:312)
plot(fit, mark.time=FALSE, xscale=365.25,
     xlab='Years', ylab='Survival')
lines(fit[1], lwd=2)  # darken the first curve and add marks

# Add expected survival curves for the two groups,  
# based on the US census data
# The data set does not have entry date, use the midpoint of the study
efit <- survexp(~sex, data=pbc, times= (0:24)*182, ratetable=survexp.us,
    rmap=list(sex=sex, age=age*365.35, year=as.Date('1979/01/01'))) 
temp <- lines(efit, lty=2, lwd=2:1)
text(temp, c("Male", "Female"), adj=-.1)  # labels just past the ends
title(main="Primary Biliary Cirrhosis, Observed and Expected")
```

logan

Data from the 1972-78 GSS data used by Logan

Description

Intergenerational occupational mobility data with covariates.

Usage

```r
logan
data(logan, package="survival")
```
logLik.coxph

Format
A data frame with 838 observations on the following 4 variables.

- **occupation**: subject's occupation, a factor with levels farm, operatives, craftsmen, sales, and professional
- **focc**: father's occupation
- **education**: total years of schooling, 0 to 20
- **race**: levels of non-black and black

Source
General Social Survey data, see the web site for detailed information on the variables. [https://gss.norc.org/](https://gss.norc.org/).

logLik.coxph  

*logLik method for a Cox model*

Description
The logLik function for survival models

Usage
```r
## S3 method for class 'coxph'
logLik(object, ...)
## S3 method for class 'survreg'
logLik(object, ...)
```

Arguments
- **object**: the result of a coxph or survreg fit
- **...**: optional arguments for other instances of the method

Details
The logLik function is used by summary functions in R such as AIC. For a Cox model, this method returns the partial likelihood. The number of degrees of freedom (df) used by the fit and the effective number of observations (nobs) are added as attributes. Per Raftery and others, the effective number of observations is the taken to be the number of events in the data set.

For a survreg model the proper value for the effective number of observations is still an open question (at least to this author). For right censored data the approach of logLik.coxph is the possible the most sensible, but for interval censored observations the result is unclear. The code currently does not add a nobs attribute.
Value
an object of class `logLik`

Author(s)
Terry Therneau

`logLik`

---

**lung**

*NCCTG Lung Cancer Data*

**Description**
Survival in patients with advanced lung cancer from the North Central Cancer Treatment Group. Performance scores rate how well the patient can perform usual daily activities.

**Usage**

```r
lung
data(cancer, package="survival")
```

**Format**

<table>
<thead>
<tr>
<th>inst: Institution code</th>
</tr>
</thead>
<tbody>
<tr>
<td>time: Survival time in days</td>
</tr>
<tr>
<td>status: censoring status 1=censored, 2=dead</td>
</tr>
<tr>
<td>age: Age in years</td>
</tr>
<tr>
<td>sex: Male=1 Female=2</td>
</tr>
<tr>
<td>ph.ecog: ECOG performance score as rated by the physician. 0=asymptomatic, 1= symptomatic but completely ambul</td>
</tr>
<tr>
<td>ph.karno: Karnofsky performance score (bad=0-good=100) rated by physician</td>
</tr>
<tr>
<td>pat.karno: Karnofsky performance score as rated by patient</td>
</tr>
<tr>
<td>meal.cal: Calories consumed at meals</td>
</tr>
<tr>
<td>wt.loss: Weight loss in last six months (pounds)</td>
</tr>
</tbody>
</table>
**Note**

The use of 1/2 for alive/dead instead of the usual 0/1 is a historical footnote. For data contained on punch cards, IBM 360 Fortran treated blank as a zero, which led to a policy within the section of Biostatistics to never use "0" as a data value since one could not distinguish it from a missing value. The policy became a habit, as is often the case; and the 1/2 coding endured long beyond the demise of punch cards and Fortran.

<tr>
<td>hgb</td>
<td>hemoglobin at MGUS diagnosis</td>
</tr>
<tr>
<td>mspike</td>
<td>size of the monoclonal protein spike at diagnosis</td>
</tr>
</tbody>
</table>
mgus1: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

- **start, stop:** sequential intervals of time for each subject
- **status:** =1 if the interval ends in an event
- **event:** a factor containing the event type: censor, death, or plasma cell malignancy
- **enum:** event number for each subject: 1 or 2

**Details**

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about $10^6$ different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undetermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural history of such subjects. Due to the diligence of the principle investigator 0 subjects have been lost to follow-up.

Three subjects had MGUS detected on the day of death. In data set mgus1 these subjects have the time to MGUS coded as .5 day before the death in order to avoid tied times.

These data sets were updated in Jan 2015 to correct some small errors.

**Source**

Mayo Clinic data courtesy of Dr. Robert Kyle.

**References**

**Examples**

```r
# Create the competing risk curves for time to first of death or PCM
sfit <- survfit(Surv(start, stop, event) ~ sex, mgus1, id=id, subset=(enum==1))
print(sfit)  # the order of printout is the order in which they plot
plot(sfit, xscale=365.25, lty=c(2,2,1,1), col=c(1,2,1,2),
     xlab="Years after MGUS detection", ylab="Proportion")
legend(0, .8, c("Death/male", "Death/female", "PCM/male", "PCM/female"),
       lty=c(1,1,2,2), col=c(2,1,2,1), bty='n')

title("Curves for the first of plasma cell malignancy or death")
```

# The plot shows that males have a higher death rate than females (no # surprise) but their rates of conversion to PCM are essentially the same.
Description

Natural history of 1341 sequential patients with monoclonal gammopathy of undetermined significance (MGUS). This is a superset of the mgus data, at a later point in the accrual process.

Usage

mgus2
data(cancer, package="survival")

Format

A data frame with 1384 observations on the following 10 variables.

- id: subject identifier
- age: age at diagnosis, in years
- sex: a factor with levels F M
- dxyr: year of diagnosis
- hgb: hemoglobin
- creat: creatinine
- mspike: size of the monoclonal serum spike
- ptime: time until progression to a plasma cell malignancy (PCM) or last contact, in months
- pstat: occurrence of PCM: 0=no, 1=yes
- futime: time until death or last contact, in months
- death: occurrence of death: 0=no, 1=yes

Details

This is an extension of the study found in the mgus data set, containing enrollment through 1994 and follow-up through 1999.

Source

Mayo Clinic data courtesy of Dr. Robert Kyle. All patient identifiers have been removed, age rounded to the nearest year, and follow-up times rounded to the nearest month.

References

model.frame.coxph  
Model.frame method for coxph objects

Description
Recreate the model frame of a coxph fit.

Usage
## S3 method for class 'coxph'
model.frame(formula, ...)

Arguments
formula  
the result of a coxph fit
...
other arguments to model.frame

Details
For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like residual that need to recreate the data set from a model in order to do further calculations.

Value
the model frame used in the original fit, or a parallel one for new data.

Author(s)
Terry Therneau

See Also
model.frame

model.matrix.coxph  
Model.matrix method for coxph models

Description
Reconstruct the model matrix for a cox model.

Usage
## S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg = object$contrasts, ...)

Arguments

- **object**: the result of a coxph model
- **data**: optional, a data frame from which to obtain the data
- **contrast.arg**: optional, a contrasts object describing how factors should be coded
- **...**: other possible argument to `model.frame`

Details

When there is a data argument this function differs from most of the other `model.matrix` methods in that the response variable for the original formula is *not* required to be in the data.

If the data frame contains a `terms` attribute then it is assumed to be the result of a call to `model.frame`, otherwise a call to `model.frame` is applied with the data as an argument.

Value

The model matrix for the fit

Author(s)

Terry Therneau

See Also

`model.matrix`

Examples

```r
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung,
              x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

myeloid

| Acute myeloid leukemia |

Description

This simulated data set is based on a trial in acute myeloid leukemia.

Usage

```r
myeloid
data(cancer, package="survival")
```
Format

A data frame with 646 observations on the following 9 variables.

- **id**: subject identifier, 1-646
- **trt**: treatment arm A or B
- **sex**: f=female, m=male
- **futime**: time to death or last follow-up
- **death**: 1 if futime is a death, 0 for censoring
- **txtime**: time to hematopoietic stem cell transplant
- **crtme**: time to complete response
- **rltime**: time to relapse of disease

Details

This data set is used to illustrate multi-state survival curves. The correlation between within-subject event times strongly resembles that from an actual trial, but none of the actual data values are from that source.

References

Examples

```r
coxph(Surv(futime, death) ~ trt, data=myeloid)
# See the mstate vignette for a more complete analysis
```

myeloma

Survival times of patients with multiple myeloma

Description

Survival times of 3882 subjects with multiple myeloma, seen at Mayo Clinic from 1947–1996.

Usage

```r
myeloma
data("cancer", package="survival")
```

Format

A data frame with 3882 observations on the following 5 variables.

- **id**: subject identifier
- **year**: year of entry into the study
- **entry**: time from diagnosis of MM until entry (days)
- **futime**: follow up time (days)
- **death**: status at last follow-up: 0 = alive, 1 = death
Details

Subjects who were diagnosed at Mayo will have entry =0, those who were diagnosed elsewhere and later referred will have positive values.

References

Examples

# Incorrect survival curve, which ignores left truncation
fit1 <- survfit(Surv(futime, death) ~ 1, myeloma)
# Correct curve
fit2 <- survfit(Surv(entry, futime, death) ~1, myeloma)

non-alcohol fatty liver disease

Description

Data sets containing the data from a population study of non-alcoholic fatty liver disease (NAFLD). Subjects with the condition and a set of matched control subjects were followed forward for metabolic conditions, cardiac endpoints, and death.

Usage

nafld1
nafld2
nafld3
data(nafld, package="survival")

Format

nafld1 is a data frame with 17549 observations on the following 10 variables.
id subject identifier
age age at entry to the study
male 0=female, 1=male
weight weight in kg
height height in cm
bmi body mass index
case.id the id of the NAFLD case to whom this subject is matched
futime time to death or last follow-up
status 0= alive at last follow-up, 1=dead

nafld2 is a data frame with 400123 observations and 4 variables containing laboratory data
id subject identifier
days days since index date
test the type of value recorded
value the numeric value

nafld3 is a data frame with 34340 observations and 3 variables containing outcomes
id subject identifier
days days since index date
event the endpoint that occurred

Details

The primary reference for the NAFLD study is Allen (2018). The incidence of non-alcoholic fatty liver disease (NAFLD) has been rising rapidly in the last decade and it is now one of the main drivers of hepatology practice Tapper2018. It is essentially the presence of excess fat in the liver, and parallels the ongoing obesity epidemic. Approximately 20-25% of NAFLD patients will develop the inflammatory state of non-alcoholic steatohepatitis (NASH), leading to fibrosis and eventual end-stage liver disease. NAFLD can be accurately diagnosed by MRI methods, but NASH diagnosis currently requires a biopsy.

The current study constructed a population cohort of all adult NAFLD subjects from 1997 to 2014 along with 4 potential controls for each case. To protect patient confidentiality all time intervals are in days since the index date; none of the dates from the original data were retained. Subject age is their integer age at the index date, and the subject identifier is an arbitrary integer. As a final protection, we include only a 90% random sample of the data. As a consequence analyses results will not exactly match the original paper.

There are 3 data sets: nafld1 contains baseline data and has one observation per subject, nafld2 has one observation for each (time dependent) continuous measurement, and nafld3 has one observation for each yes/no outcome that occurred.

Source

Data obtained from the author.

References

Description

A common task in medical work is to find the closest lab value to some index date, for each subject.

Usage

neardate(id1, id2, y1, y2, best = c("after", "prior"), nomatch = NA_integer_)

Find the index of the closest value in data set 2, for each entry in data set one.
Arguments

- **id1**: vector of subject identifiers for the index group
- **id2**: vector of identifiers for the reference group
- **y1**: normally a vector of dates for the index group, but any orderable data type is allowed
- **y2**: reference set of dates
- **best**: if `best='prior'` find the index of the first y2 value less than or equal to the target y1 value, for each subject. If `best='after'` find the first y2 value which is greater than or equal to the target y1 value, for each subject.
- **nomatch**: the value to return for items without a match

Details

This routine is closely related to `match` and to `findInterval`, the first of which finds exact matches and the second closest matches. This finds the closest matching date within sets of exactly matching identifiers. Closest date matching is often needed in clinical studies. For example data set 1 might contain the subject identifier and the date of some procedure and data set 2 has the dates and values for laboratory tests, and the query is to find the first test value after the intervention but no closer than 7 days.

The `id1` and `id2` arguments are similar to `match` in that we are searching for instances of `id1` that will be found in `id2`, and the result is the same length as `id1`. However, instead of returning the first match with `id2` this routine returns the one that best matches with respect to `y1`.

The `y1` and `y2` arguments need not be dates, the function works for any data type such that the expression `c(y1, y2)` gives a sensible, sortable result. Be careful about matching Date and DateTime values and the impact of time zones, however, see `as.POSIXct`. If `y1` and `y2` are not of the same class the user is on their own. Since there exist pairs of unmatched data types where the result could be sensible, the routine will in this case proceed under the assumption that "the user knows what they are doing". Caveat emptor.

Value

the index of the matching observations in the second data set, or the nomatch value for no successful match

data2[indx1, "chol"]

# Closest one, either before or after.
#
indx2 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt,
                   best="prior")
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
               ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
                       abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1))))

# closest date before or after, but no more than 21 days prior to index
indx2 <- ifelse((data1$entry.dt - data2$lab.dt[indx2]) >21, NA, indx2)
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
               ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
                       abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1))))

---

**nsk**

*Natural splines with knot heights as the basis.*

**Description**

Create the design matrix for a natural spline, such that the coefficient of the resulting fit are the values of the function at the knots.

**Usage**

```r
nsk(x, df = NULL, knots = NULL, intercept = FALSE, b = 0.05,
    Boundary.knots = quantile(x, c(b, 1 - b), na.rm = TRUE))
```

**Arguments**

- **x**
  - the predictor variable. Missing values are allowed.

- **df**
  - degrees of freedom. One can supply df rather than knots; ns() then chooses df - 1 - intercept knots at suitably chosen quantiles of x (which will ignore missing values). The default, df = NULL, sets the number of inner knots as length(knots).

- **knots**
  - breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on x. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.

- **intercept**
  - if TRUE, an intercept is included in the basis; default is FALSE

- **b**
  - default placement of the boundary knots. A value of bs=0 will replicate the default behavior of ns.

- **Boundary.knots**
  - boundary points at which to impose the natural boundary conditions and anchor the B-spline basis. Beyond these points the function is assumed to be linear. If both knots and Boundary.knots are supplied, the basis parameters do not depend on x. Data can extend beyond Boundary.knots.
**Details**

The `nsk` function behaves identically to the `ns` function, with two exceptions. The primary one is that the returned basis is such that coefficients correspond to the value of the fitted function at the knot points. If `intercept = FALSE`, there will be k-1 coefficients corresponding to the k knots, and they will be the difference in predicted value between knots 2-k and knot 1. The primary advantage to the basis is that the coefficients are directly interpretable. A second is that tests for the linear and non-linear components are simple contrasts.

The second difference with `ns` is one of opinion with respect to the default position for the boundary knots. The default here is closer to that found in the `rms::rcs` function.

This function is a trial if a new idea, it’s future inclusion in the package is not yet guaranteed.

**Value**

A matrix of dimension length(x) * df where either df was supplied or, if knots were supplied, df = length(knots) + 1 + intercept. Attributes are returned that correspond to the arguments to `kns`, and explicitly give the knots, Boundary.knots etc for use by `predict.kns()`.

**Note**

A thin flexible metal or wooden strip is called a spline, and is the traditional method for laying out a smooth curve, e.g., for a ship’s hull or an airplane wing. Pins are put into a board and the strip is passed through them, each pin is a ‘knot’.

A mathematical spline is a piecewise function between each knot. A linear spline will be a set of connected line segments, a quadratic spline is a set of connected local quadratic functions, constrained to have a continuous first derivative, a cubic spline is cubic between each knot, constrained to have continuous first and second derivatives, and etc. Mathematical splines are not an exact representation of natural splines: being a physical object the wood or metal strip will have continuous derivatives of all orders. Cubic splines are commonly used because they are sufficiently smooth to look natural to the human eye.

If the mathematical spline is further constrained to be linear beyond the end knots, this is often called a ‘natural spline’, due to the fact that a wooden or metal spline will also be linear beyond the last knots. Another name for the same object is a ‘restricted cubic spline’, since it is achieved in code by adding further constraints. Given a vector of data points and a set of knots, it is possible to create a basis matrix X with one column per knot, such that ordinary regression of X on y will fit the cubic spline function, hence these are also called ‘regression splines’. (One of these three labels is no better or worse than another, in our opinion).

Given a basis matrix X with k columns, the matrix Z= XT for any k by k nonsingular matrix T is is also a basis matrix, and will result in identical predicted values, but a new set of coefficients gamma = (T-inverse) beta in place of beta. One can choose the basis functions so that X is easy to construct, to make the regression numerically stable, to make tests easier, or based on other considerations. It seems as though every spline library returns a different basis set, which unfortunately makes fits difficult to compare between packages. This is yet one more basis set, chosen to make the coefficients more interpretable.

**Examples**

```r
# make some dummy data
```
nwtco <- data.frame(x= lung$age, y = 10*log(lung$age-35) + rnorm(228, 0, 2))
fit1 <- lm(y ~ -1 + nsk(x, df=4, intercept=TRUE), data=tdata)
fit2 <- lm(y ~ nsk(x, df=3), data=tdata)

# the knots (same for both fits)
knots <- unlist(attributes(fit1$model[[2]])[c('Boundary.knots', 'knots')])
sort(unname(knots))
unname(coef(fit1)) # predictions at the knot points
unname(coef(fit1)[-1] - coef(fit1)[1]) # differences: yhat[2:4] - yhat[1]
unname(coef(fit2))[-1] # ditto

## Not run:
plot(y ~ x, data=tdata)
points(sort(knots), coef(fit1), col=2, pch=19)
coef(fit)[1] + c(0, coef(fit)[-1])

## End(Not run)

nwtco  
Data from the National Wilm’s Tumor Study

Description
Measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

Usage
nwtco
data(nwtco, package="survival")

Format
A data frame with 4028 observations on the following 9 variables.

seqno  id number
instit Histology from local institution
histol Histology from central lab
stage Disease stage
study study
rel indicator for relapse
edrel time to relapse
age age in months
in. subcohort Included in the subcohort for the example in the paper

References
Examples

```r
with(nwtco, table(instit,histol))
anova(coxph(Surv(edrel,rel)-histol+instit,data=nwtco))
anova(coxph(Surv(edrel,rel)-instit+histol,data=nwtco))
```

**ovarian**

*Ovarian Cancer Survival Data*

**Description**

Survival in a randomised trial comparing two treatments for ovarian cancer

**Usage**

```r
ovarian
data(cancer, package="survival")
```

**Format**

- `futime`: survival or censoring time
- `fustat`: censoring status
- `age`: in years
- `resid.ds`: residual disease present (1=no, 2=yes)
- `rx`: treatment group
- `ecog.ps`: ECOG performance status (1 is better, see reference)

**Source**

**References**

**Description**

Primary sclerosing cholangitis is an autoimmune disease leading to destruction of the small bile ducts in the liver. Progression is slow but inexorable, eventually leading to cirrhosis and liver decompensation. The condition has been recognised since at least 1851 and was named "primary biliary cirrhosis" in 1949. Because cirrhosis is a feature only of advanced disease, a change of its name to "primary biliary cholangitis" was proposed by patient advocacy groups in 2014.

This data is from the Mayo Clinic trial in PBC conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

**Usage**

```r
data(pbc, package="survival")
```

**Format**

- **age**: in years
- **albumin**: serum albumin (g/dl)
- **alk.phos**: alkaline phosphotase (U/liter)
- **ascites**: presence of ascites
- **ast**: aspartate aminotransferase, once called SGOT (U/ml)
- **bili**: serum bilirubin (mg/dl)
- **chol**: serum cholesterol (mg/dl)
- **copper**: urine copper (ug/day)
- **edema**: 0 no edema, 0.5 untreated or successfully treated 1 edema despite diuretic therapy
- **hepato**: presence of hepatomegaly or enlarged liver
- **id**: case number
- **platelet**: platelet count
- **protime**: standardised blood clotting time
- **sex**: m/f
- **spiders**: blood vessel malformations in the skin
- **stage**: histologic stage of disease (needs biopsy)
- **status**: status at endpoint, 0/1/2 for censored, transplant, dead
- **time**: number of days between registration and the earlier of death, transplantation, or study analysis in July, 1986
- **trt**: 1/2/NA for D-penicillmain, placebo, not randomised
- **trig**: triglycerides (mg/dl)

**pbcseq**  
*Mayo Clinic Primary Biliary Cirrhosis, sequential data*

**Description**

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory parameters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

**Usage**

```r
pbcseq
data(pbc, package="survival")
```

plot.cox.zph

Usage

## S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', 

Arguments

x the result of a call to the aareg function
se if TRUE, standard error bands are included on the plot
maxtime upper limit for the x-axis.
type graphical parameter for the type of line, default is "steps".
... other graphical parameters such as line type, color, or axis labels.

Side Effects

A plot is produced on the current graphical device.

plot.cox.zph

Graphical Test of Proportional Hazards

Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

Usage

## S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var, 
   xlab="Time", ylab, lty=1:2, col=1, lwd=1, hr=FALSE, 

Arguments

x result of the cox.zph function.
resid a logical value, if TRUE the residuals are included on the plot, as well as the smooth fit.
se a logical value, if TRUE, confidence bands at two standard errors will be added.
df the degrees of freedom for the fitted natural spline, df=2 leads to a linear fit.
nsmo number of points to use for the lines
The `plot.survfit` function is used to plot survival curves from a `survfit` object. It allows for customization of the plot through various arguments such as `var` for the set of variables for which plots are desired, `hr` for whether to label the y-axis using the estimated hazard ratio, `xlab` for the x-axis label, `ylab` for the y-axis label, `lty`, `col`, `lwd` for line type, color, and line width, respectively, and `...` for additional graphical arguments.

### Side Effects
A plot is produced on the current graphics device.

### See Also
- `coxph`
- `cox.zph`

### Examples
```r
vfit <- coxph(Surv(time, status) ~ trt + factor(celltype) + karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=3)  # Look at Karnofsy score, old way of doing plot
plot(temp[3])     # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,3] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

### Description
A plot of survival curves is produced, one curve for each strata. The `log=T` option does extra work to avoid `log(0)`, and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

Curves are plotted in the same order as they are listed by `print` (which gives a 1 line summary of each). This will be the order in which `col, lty, etc` are used.
Usage

```r
## S3 method for class 'survfit'
plot(x, conf.int=, mark.time=FALSE, pch=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1, xlim, ylim, xmax, fun, xlab="", ylab="", xaxs="r", conf.times, conf.cap=.005, conf.offset=.012, conf.type = c("log", "log-log", "plain", "logit", "arcsin"), mark, noplot="(s0)", cumhaz=FALSE, firstx, ymim, ...)
```

Arguments

- **x**: an object of class `survfit`, usually returned by the `survfit` function.
- **conf.int**: determines whether pointwise confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata, using 95% confidence intervals. Alternatively, this can be a numeric value giving the desired confidence level.
- **mark.time**: controls the labeling of the curves. If set to `FALSE`, no labeling is done. If `TRUE`, then curves are marked at each censoring time. If `mark` is a numeric vector then curves are marked at the specified time points.
- **pch**: vector of characters which will be used to label the curves. The points help file contains examples of the possible marks. A single string such as "abcd" is treated as a vector `c("a", "b", "c", "d")`. The vector is reused cyclically if it is shorter than the number of curves. If it is present this implies `mark.time = TRUE`.
- **col**: a vector of integers specifying colors for each curve. The default value is 1.
- **lty**: a vector of integers specifying line types for each curve. The default value is 1.
- **lwd**: a vector of numeric values for line widths. The default value is 1.
- **cex**: a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.
- **log**: a logical value, if `TRUE` the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specify logarithmic horizontal and/or vertical axes.
- **xscale**: a numeric value used like `yscale` for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.
- **yscale**: a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with "$\text{lines(surv.exp(...))}$", say, will perform as it did without the `yscale` argument.
- **xlim, ylim**: optional limits for the plotting region.
- **xmax**: the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the `xlim` graphical parameter, warning messages about out of bounds points are not generated.
- **fun**: an arbitrary function defining a transformation of the survival (or probability in state, or cumulative hazard) curves. For example `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values),
and \texttt{fun=sqrt} would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: ",S" gives the usual survival curve, \"log\" is the same as using the \texttt{log=T} option, \"event\" or \"F\" plots the empirical CDF $F(t) = 1 - S(t)$ (\texttt{f(y) = 1-y}), and \texttt{cloglog} creates a complimentary log-log survival plot (\texttt{f(y) = log(-log(y))} along with log scale for the x-axis). The terms \"identity\" and \"surv\" are allowed as synonyms for \texttt{type=\"S\"}. The argument \texttt{cumhaz} causes the cumulative hazard function to be plotted.

\texttt{xlab} label given to the x-axis.

\texttt{ylab} label given to the y-axis.

\texttt{xaxs} either \"S\" for a survival curve or a standard x axis style as listed in \texttt{par}; \"r\" (regular) is the R default. Survival curves have historically been displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type \"S\" accomplishes this by manipulating the plot range and then using the \"1\" style internally. The \"S\" style is becoming increasingly less common, however.

\texttt{conf.times} optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.

\texttt{conf.cap} width of the horizontal cap on top of the confidence bars; only used if \texttt{conf.times} is used. A value of 1 is the width of the plot region.

\texttt{conf.offset} the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve’s bars are offset by this amount from the prior curve’s bars, if it is a vector the values are used directly.

\texttt{conf.type} One of \"plain\", \"log\" (the default), \"log-log\" or \"logit\". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve $\pm k \times se(curve)$, where $k$ is determined from \texttt{conf.int}. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option bases the intervals on the log hazard or log(-log(survival)), and the logit option on log(survival/(1-survival)).

\texttt{mark} a historical alias for \texttt{pch}

\texttt{noplot} for multi-state models, curves with this label will not be plotted. (Also see the \texttt{istate0} argument in \texttt{survcheck}.)

\texttt{cumhaz} plot the cumulative hazard rather than the probability in state or survival. Optionally, this can be a numeric vector specifying which columns of the \texttt{cumhaz} component to plot.

\texttt{ymin} this will normally be given as part of the \texttt{ylim} argument

\texttt{firstx} this will normally be given as part of the \texttt{xlim} argument.

... other arguments that will be passed forward to the underlying plot method, such as \texttt{xlab} or \texttt{ylab}.

\textbf{Details}

If the object contains a cumulative hazard curve, then \texttt{fun='cumhaz'} will plot that curve, otherwise it will plot -log(S) as an approximation. Theoretically, $S = \exp(-\Lambda)$ where $S$ is the survival and $\Lambda$ is the cumulative hazard. The same relationship holds for estimates of $S$ and $\Lambda$ only in special cases, but the approximation is often close.
When the `survfit` function creates a multi-state survival curve the resulting object also has class 'survfitms'. Competing risk curves are a common case. In this situation the `fun` argument is ignored.

When the `conf.times` argument is used, the confidence bars are offset by `conf.offset` units to avoid overlap. The bar on each curve are the confidence interval for the time point at which the bar is drawn, i.e., different time points for each curve. If curves are steep at that point, the visual impact can sometimes substantially differ for positive and negative values of `conf.offset`.

**Value**

A list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

**Note**

In prior versions the behavior of `xscale` and `yscale` differed: the first changed the scale both for the plot and for all subsequent actions such as adding a legend, whereas `yscale` affected only the axis label. This was normalized in version 2-36.4, and both parameters now only affect the labeling. In versions prior to approximately 2.36 a `survfit` object did not contain the cumulative hazard as a separate result, and the use of `fun="cumhaz"` would plot the approximation `-log(surv)` to the cumulative hazard. When cumulative hazards were added to the object, the `cumhaz=TRUE` argument to the plotting function was added. In version 2.3-8 the use of `fun="cumhaz"` became a synonym for `cumhaz=TRUE`.

**Examples**

```r
leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves for AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
xlab="Months", ylab="Cumulative Hazard")
```

**Description**

Predictions for a Cox model

**Usage**

```r
# S3 method for class 'coxph'
predict(object, newdata,
type=c("lp", "risk", "expected", "terms", "survival"),
se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
reference=c("strata", "sample", "zero"), ...)
```
Arguments

object the results of a coxph fit.
newdata Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit. When coxph has been called with a formula argument created in another context, i.e., coxph has been called within another function and the formula was passed as an argument to that function, there can be problems finding the data set. See the note below.
type the type of predicted value. Choices are the linear predictor ("lp"), the risk score exp(lp) ("risk"), the expected number of events given the covariates and follow-up time ("expected"), and the terms of the linear predictor ("terms"). The survival probability for a subject is equal to exp(-expected).
se.fit if TRUE, pointwise standard errors are produced for the predictions.
na.action applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations. When there is no newdata, then the behavior of missing is dictated by the na.action option of the original fit.
terms if type="terms", this argument can be used to specify which terms should be included; the default is all.
collapse optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation.
reference reference for centering predictions, see details below
...
For future methods

Details

The Cox model is a relative risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The underlying reason is both statistical and practical. First, a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Second, downstream calculations depend on the risk score exp(linear predictor), which will fall prey to numeric overflow for a linear predictor greater than .Machine\$double.max.exp. The coxph routines try to approximately center the predictors out of self protection. Using the reference="strata" option is the safest centering, since strata occasionally have different means. When the results of predict are used in further calculations it may be desirable to use a single reference level for all observations. Use of reference="sample" will use the overall means, and agrees with the linear.predictors component of the coxph object (which uses the overall mean for backwards compatibility with older code). Predictions of type="terms" are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference. A reference of "zero" causes no centering to be done.

Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the reference option has no effect on these. These values depend on the follow-up time for the future subjects as well as covariates so the newdata argument needs to include both the right and left hand side variables from the formula. (The status variable will not be used, but is required since the underlying code needs to reconstruct the entire formula.)

Models that contain a frailty term are a special case: due to the technical difficulty, when there is a newdata argument the predictions will always be for a random effect of zero.
Value

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the se.fit option is TRUE.

Note

Some predictions can be obtained directly from the coxph object, and for others it is necessary for the routine to have the entirety of the original data set, e.g., for type = terms or if standard errors are requested. This extra information is saved in the coxph object if model=TRUE, if not the original data is reconstructed. If it is known that such residuals will be required overall execution will be slightly faster if the model information is saved.

In some cases the reconstruction can fail. The most common is when coxph has been called inside another function and the formula was passed as one of the arguments to that enclosing function. Another is when the data set has changed between the original call and the time of the prediction call. In each of these the simple solution is to add model=TRUE to the original coxph call.

Examples

options(na.action=na.exclude) # retain NA in predictions
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
#lung data set has status coded as 1/2
mresid <- (lung$status-1) - predict(fit, type='expected') #Martingale resid
predict(fit,type="lp")
predict(fit,type="expected")
predict(fit,type="risk",se.fit=TRUE)
predict(fit,type="terms",se.fit=TRUE)

# For someone who demands reference='zero'
pzero <- function(fit)
  predict(fit, reference="sample") + sum(coef(fit) * fit$means, na.rm=TRUE)

predict.survreg

Predicted Values for a 'survreg' Object

Description

Predicted values for a survreg object

Usage

## S3 method for class 'survreg'
predict(object, newdata, type=c("response", "link", "lp", "linear", "terms", "quantile", "uquantile"),
  se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)
Arguments

- **object**: result of a model fit using the `survreg` function.
- **newdata**: data for prediction. If absent predictions are for the subjects used in the original fit.
- **type**: the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical.
- **se.fit**: if TRUE, include the standard errors of the prediction in the result.
- **terms**: subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.
- **p**: vector of percentiles. This is used only for quantile predictions.
- **na.action**: applies only when the `newdata` argument is present, and defines the missing value action for the new data. The default is to include all observations.
- **...**: for future methods

Value

- a vector or matrix of predicted values.

- `survreg`, `residuals.survreg`

Examples

```r
# Draw figure 1 from Escobar and Meeker, 1992.
fit <- survreg(Surv(time,status) ~ age + I(age^2), data=stanford2,
dist='lognormal')
with(stanford2, plot(age, time, xlab='Age', ylab='Days',
xlim=c(0,65), ylim=c(.1, 10^5), log='y', type='n'))
with(stanford2, points(age, time, pch=c(2,4)[status+1], cex=.7))
pred <- predict(fit, newdata=list(age=1:65), type='quantile',
p=c(.1, .5, .9))
matlines(1:65, pred, lty=c(2,1,2), col=1)

# Predicted Weibull survival curve for a lung cancer subject with
# ECOG score of 2
lfit <- survreg(Surv(time, status) ~ ph.ecog, data=lung)
pct <- 1:98/100 # The 100th percentile of predicted survival is at +infinity
ptime <- predict(lfit, newdata=data.frame(ph.ecog=2), type='quantile',
p=pct, se=TRUE)
mplot(cbind(ptime$fit, ptime$fit + 2*ptime$se.fit,
ptime$fit - 2*ptime$se.fit)/30.5, 1-pct,
xlab="Months", ylab="Survival", type='l', lty=c(1,2,2), col=1)
```
Description

Print out a fit of Aalen’s additive regression model

Usage

```r
## S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"), scale=1, ...)
```

Arguments

- `x`: the result of a call to the `aareg` function
- `maxtime`: the upper time point to be used in the test for non-zero slope
- `test`: the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point.
- `scale`: scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10^-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
- `...`: for future methods

Details

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last ‘tail’ is excluded.

Value

the calling argument is returned.

Side Effects

the results of the fit are displayed.

`aareg`
print.summary.coxph  Print method for summary.coxph objects

Description

Produces a printed summary of a fitted coxph model

Usage

```r
## S3 method for class 'summary.coxph'
print(x, digits=max(getOption("digits") - 3, 3),
     signif.stars = getOption("show.signif.stars"), expand=FALSE, ...)
```

Arguments

- `x`: the result of a call to `summary.coxph`
- `digits`: significant digits to print
- `signif.stars`: Show stars to highlight small p-values
- `expand`: if the summary is for a multi-state coxph fit, print the results in an expanded format.
- `...`: For future methods

print.summary.survexp  Print Survexp Summary

Description

Prints the results of `summary.survexp`

Usage

```r
## S3 method for class 'summary.survexp'
print(x, digits = max(options()$digits - 4, 3), ...)```

Arguments

- `x`: an object of class `summary.survexp`
- `digits`: the number of digits to use in printing the result.
- `...`: for future methods

Value

`x`, with the invisible flag set to prevent further printing.

Author(s)

Terry Therneau

`link{summary.survexp}, survexp`
print.summary.survfit  Print Survfit Summary

Description

Prints the result of summary.survfit.

Usage

## S3 method for class 'summary.survfit'
print(x, digits = max(options()$digits-4, 3), ...)

Arguments

x an object of class "summary.survfit", which is the result of the 
summary.survfit function.
digits the number of digits to use in printing the numbers.
... for future methods

Value

x, with the invisible flag set to prevent printing.

Side Effects

prints the summary created by summary.survfit.

options, print, summary.survfit.

print.survfit  Print a Short Summary of a Survival Curve

Description

Print number of observations, number of events, the restricted mean survival and its standard error, 
and the median survival with confidence limits for the median.

Usage

## S3 method for class 'survfit'
print(x, scale=1, digits = max(options()$digits - 4, 3), 
print.rmean=getOption("survfit.print.rmean"), 
rmean = getOption('survfit.rmean'),...)

print.survfit

Arguments

- **x**: the result of a call to the `survfit` function.
- **scale**: a numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, `scale=365` would scale the printout to years.
- **digits**: Number of digits to print
- **print.rmean**: Options for computation and display of the restricted mean.
- **...**: for future results

Details

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches to resolve this, which are selected by the `rmean` option. The first is to set the upper limit to a constant, e.g., `rmean=365`. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are "none" (no estimate), "common" and "individual". The "common" option uses the maximum time for all curves in the object as a common upper limit for the auc calculation. For the "individual" options the mean is computed as the area under each curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatibility, as this estimate was the default (only) one in earlier releases of the code. Note that SAS (as of version 9.3) uses the integral up to the last event time of each individual curve; we consider this the worst of the choices and do not provide an option for that calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. If that line does not intersect the curve, then the median is undefined. The intersection of the line with the lower CI band defines the lower limit for the median’s interval, and similarly for the upper band. If any of the intersections is not a point then we use the center of the intersection interval, e.g., if the survival curve were exactly equal to 0.5 over an interval. When data is uncensored this agrees with the usual definition of a median.

Value

x, with the invisible flag set to prevent printing. (The default for all print functions in R is to return the object passed to them; `print.survfit` complies with this pattern. If you want to capture these printed results for further processing, see the table component of `summary.survfit`.)

Side Effects

The number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (rmean) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

`summary.survfit`, `quantile.survfit`
**pseudo**

*Pseudo values for survival.*

**Description**

Produce pseudo values from a survival curve.

**Usage**

\[
\text{pseudo}(\text{fit}, \text{times}, \text{type}, \text{addNA}=\text{TRUE}, \text{data.frame}=\text{FALSE}, \text{minus1}=\text{FALSE}, \ldots)
\]

**Arguments**

- **fit**
  a `survfit` object, or one that inherits that class.

- **times**
  a vector of time points, at which to evaluate the pseudo values.

- **type**
  the type of value, either the probability in state `pstate`, the cumulative hazard `cumhaz` or the expected sojourn time in the state `sojourn`.

- **addNA**
  If any observations were removed due to missing values in the `fit` object, add those rows (as NA) into the return. This causes the result of pseudo to match the original dataframe.

- **data.frame**
  if TRUE, return the data in "long" form as a data.frame with id, time, and pseudo as variables.

- **minus1**
  use n-1 as the multiplier rather than n.

- **...**
  other arguments to the `residuals.survfit` function, which does the majority of the work, e.g., `collapse` and `weighted`.

**Details**

This function computes pseudo values based on a first order Taylor series, also known as the "infinitesimal jackknife" (IJ) or "dfbeta" residuals. To be completely correct these results could perhaps be called ‘IJ pseudo values’ or even pseudo psuedo-values. For moderate to large data, however, the resulting values will be almost identical, numerically, to the ordinary jackknife.

A primary advantage of this approach is computational speed. Other features, neither good nor bad, are that they will agree with robust standard errors of other survival package estimates, which are based on the IJ, and that the mean of the estimates, over subjects, is exactly the underlying survival estimate.

For the `type` variable, `surv` is an acceptable synonym for `pstate`, and `rmst` and `rmts` are equivalent to `sojourn`. All of these are case insensitive.

The result from this routine is simply n times the IJ value, where n is the number of subjects. (If the the `survfit` call included and `id` option, n is the number of unique id values, otherwise the number of rows in the data set.) IJ values are well defined for all variants of the Aalen-Johansen estimate, as computed by the `survfit` function; indeed, they are the basis for standard errors of the result. Understanding of the properties of the pseudo-values, however, is still evolving. Validity has been shown for the simplest case (Kaplan-Meier), for competing risks, and for the corresponding sojourn times. On the other hand, one must be careful when the data includes left-truncation (P. K. Andersen, personal communication), and also with pseudo-values for the cumulative hazard. As understanding evolves, treat this routine’s results as a reseach tool, not production, for the more complex models.
Value

A vector, matrix, or array. The first dimension is always the number of observations in `fit` object, in the same order as the original data set (less any missing values that were removed when creating the `survfit` object); the second, if applicable, corresponds to `fit$states`, e.g., multi-state survival, and the last dimension to the selected time points. (If there are multiple rows for a given id, there is only one pseudo-value per unique id.)

For the `data.frame` option, a data frame containing values for `id`, `time`, and `pseudo`. If the original `survfit` call contained an `id` statement, then the values in the `id` column will be taken from that variable. If the `id` statement has a simple form, e.g., `id = patno`, then the name of the `id` column will be ‘patno’, otherwise it will be named ‘`(id)`’.

residuals.survfit

Examples

```r
fit1 <- survfit(Surv(time, status) ~ 1, data=lung)
yhat <- pseudo(fit1, times=c(365, 730))
dim(yhat)
lfit <- lm(yhat[,1] ~ ph.ecog + age + sex, data=lung)

# Restricted Mean Time in State (RMST)
rms <- pseudo(fit1, times= 730, type='RMST') # 2 years
rfit <- lm(rms ~ ph.ecog + sex, data=lung)
rhat <- predict(rfit, newdata=expand.grid(ph.ecog=0:3, sex=1:2), se.fit=TRUE)
# print it out nicely
temp1 <- cbind(matrix(rhat$fitted, 4,2))
temp2 <- cbind(matrix(rhat$se.fit, 4, 2))
temp3 <- cbind(temp1[,1], temp2[,1], temp1[,2], temp2[,2])
dimnames(temp3) <- list(paste("ph.ecog", 0:3),
c("Male RMST", "(se)", "Female RMST", "(se)"))
round(temp3, 1)
# compare this to the fully non-parametric estimate
fit2 <- survfit(Surv(time, status) ~ ph.ecog, data=lung)
print(fit2, rmean=730)
# the estimate for ph.ecog=3 is very unstable (n=1), pseudovalues smooth it.
# # In all the above we should be using the robust variance, e.g., svyglm, but
# # a recommended package can't depend on external libraries.
# See the vignette for a more complete exposition.
```

pspline

Smoothing splines using a pspline basis
Description

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplification, they refer to the result as a p-spline.

Usage

```r
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, combine, ...)
```

psplineinverse(x)

Arguments

- **x**
  - for `psline`: a covariate vector. The function does not apply to factor variables. For `psplineinverse` x will be the result of a `psline` call.
- **df**
  - the desired degrees of freedom. One of the arguments `df` or `theta` must be given, but not both. If `df=0`, then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument `'caic=T'` can be used to specify the corrected AIC of Hurvich et. al.
- **theta**
  - roughness penalty for the fit. It is a monotone function of the degrees of freedom, with `theta=1` corresponding to a linear fit and `theta=0` to an unconstrained fit of `nterm` degrees of freedom.
- **nterm**
  - number of splines in the basis.
- **degree**
  - degree of splines.
- **eps**
  - accuracy for `df`
- **method**
  - the method for choosing the tuning parameter `theta`. If `theta` is given, then 'fixed' is assumed. If the degrees of freedom is given, then 'df' is assumed. If `method='aic'` then the degrees of freedom is chosen automatically using Akaike's information criterion.
- **...**
  - optional arguments to the control function
- **Boundary.knots**
  - the spline is linear beyond the boundary knots. These default to the range of the data.
- **intercept**
  - if TRUE, the basis functions include the intercept.
- **penalty**
  - if FALSE a large number of attributes having to do with penalized fits are excluded. This is useful to create a `pspline` basis matrix for other uses.
- **combine**
  - an optional vector of increasing integers. If two adjacent values of `combine` are equal, then the corresponding coefficients of the fit are forced to be equal. This is useful for monotone fits, see the vignette for more details.

Value

Object of class `pspline`, `coxph.penalty` containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the `coxph` or `survreg` functions.

For `psplineinverse` the original `x` vector is reconstructed.

fit0 <- coxph(Surv(time, status) ~ ph.ecog + age, lung)
fit1 <- coxph(Surv(time, status) ~ ph.ecog + pspline(age,3), lung)
fit3 <- coxph(Surv(time, status) ~ ph.ecog + pspline(age,8), lung)
fit0
fit1
fit3
```

pyears  

**Person Years**

Description

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/ or expected number of events in each cell.

Usage

```r
pyears(formula, data, weights, subset, na.action, rmap, ratetable, scale=365.25, expect=c('event', 'pyears'), model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

Arguments

- `formula`: a formula object. The response variable will be a vector of follow-up times for each subject, or a Surv object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by + operators (exactly as in survfit), time-dependent grouping variables such as age (specified with tcut), and optionally a ratetable term. This latter matches each subject to his/her expected cohort.
- `data`: a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.
- `weights`: case weights.
- `subset`: expression saying that only a subset of the rows of the data should be used in the fit.
a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is options()$na.action.

rmap
an optional list that maps data set names to the ratetable names. See the details section below.

ratetable
a table of event rates, such as survexp.uswhite.

scale
a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.

expect
should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.

data.frame
return a data frame rather than a set of arrays.

model, x, y
If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.

Details
Because pyears may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```r
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt),
             ratetable=survexp.us)
```

the natural unit of the ratetable is hazard per day, it is important that futime, age and entry.dt all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The ratetable being used may have different variable names than the user’s data set, this is dealt with by the rmap argument. The rate table for the above calculation was survexp.us, a call to summary(survexp.us) reveals that it expects to have variables age = age in days, sex, and year = the date of study entry, we create them in the rmap line. The sex variable is not mapped, therefore the code assumes that it exists in mydata in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

A special function tcut is needed to specify time-dependent cutpoints. For instance, assume that age is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If cut(age, c(0,2,10,25,100)) were used in the formula, the subject would be classified according to his starting age only. The tcut function has the same arguments as cut, but produces a different output object which allows the pyears function to correctly track the subject.

The results of pyears are normally used as input to further calculations. The print routine, therefore, is designed to give only a summary of the table.

Value
a list with components:

- pyears
  an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation.

- n
  an array containing the number of subjects who contribute time to each cell of the pyears array.
event an array containing the observed number of events. This will be present only if
the response variable is a Surv object.
expected an array containing the expected number of events (or person years if expect
="pyears"). This will be present only if there was a ratetable term.
data if the data.frame option was set, a data frame containing the variables n, event,
pyears and event that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in
the arrays.
offtable the number of person-years of exposure in the cohort that was not part of any
cell in the pyears array. This is often useful as an error check; if there is a
mismatch of units between two variables, nearly all the person years may be off
table.
tcut whether the call included any time-dependent cutpoints.
summary a summary of the rate-table matching. This is also useful as an error check.
call an image of the call to the function.
observations the number of observations in the input data set, after any missings were re-
moved.
na.action the na.action attribute contributed by an na.action routine, if any.

# Example #2 Create the hearta data frame:
hearta <- by(heart, heart$id,
function(x)x[x$stop == max(x$stop),])
hearta <- do.call("rbind", hearta)
# Produce pyears table of death rates on the surgical arm
# The first is by age at randomization, the second by current age
fit1 <- pyears(Surv(stop/365.25, event) ~ cut(age + 48, c(0,50,60,70,100)) +
quantile.survfit

surgery, data = hearta, scale = 1)
fit2 <- pyeas(Surv(stop/365.25, event) ~ tcut(age + 48, c(0,50,60,70,100)) +
surgery, data = hearta, scale = 1)
fit1$event/fit1$pyears #death rates on the surgery and non-surg arm
fit2$event/fit2$pyears #death rates on the surgery and non-surg arm

quantile.survfit

Quantiles from a survfit object

Description

Retrieve quantiles and confidence intervals for them from a survfit or Surv object.

Usage

## S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
    scale, tolerance= sqrt(.Machine$double.eps), ...)

## S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
    scale, tolerance= sqrt(.Machine$double.eps), ...)

## S3 method for class 'survfit'
median(x, ...)

Arguments

x a result of the survfit function
probs numeric vector of probabilities with values in [0,1]
conf.int should lower and upper confidence limits be returned?
scale optional scale factor, e.g., scale=365.25 would return results in years if the fit
object were in days.
tolerance tolerance for checking that the survival curve exactly equals one of the quantiles
... optional arguments for other methods

Details

The kth quantile for a survival curve S(t) is the location at which a horizontal line at height p= 1-k intersects the plot of S(t). Since S(t) is a step function, it is possible for the curve to have a horizontal segment at exactly 1-k, in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to 1-k, then that quantile is undefined.

In order to be consistent with other quantile functions, the argument prob of this function applies to the cumulative distribution function F(t) = 1-S(t).

Confidence limits for the values are based on the intersection of the horizontal line at 1-k with the upper and lower limits for the survival curve. Hence confidence limits use the same p-value as was in effect when the curve was created, and will differ depending on the conf.type option of survfit. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.
When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is \((19/20)(18/19)(17/18) \ldots (10/11) = 10/20\), but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than \(\text{tolerance}\) is considered to be an exact match.

\section*{Value}

The quantiles will be a vector if the \texttt{survfit} object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components \texttt{quantile}, \texttt{lower}, and \texttt{upper}, otherwise it is the vector or matrix of quantiles.

fit <- survfit(Surv(time, status) ~ ph.ecog, data=lung)
quantile(fit)

cfit <- coxph(Surv(time, status) ~ age + strata(ph.ecog), data=lung)
csurv<- survfit(cfit, newdata=data.frame(age=c(40, 60, 80)),
                conf.type ="none")
temp <- quantile(csurv, 1:5/10)
temp[2,3,] # quantiles for second level of ph.ecog, age=80
quantile(csurv[2,3], 1:5/10) # quantiles of a single curve, same result
```

\section*{ratetable \hspace{1cm} Rate table structure}

\section*{Description}

Description of the rate tables used by expected survival routines.

\section*{Details}

A rate table contains event rates per unit time for some particular endpoint. Death rates are the most common use, the \texttt{survexp.us} table, for instance, contains death rates for the United States by year of age, sex, and calendar year.

A rate table is structured as a multi-way array with the following attributes:

\begin{itemize}
  \item \texttt{dim} the dimensions of the array
\end{itemize}
**dimnames** a named list of dimnames. The names are used to match user data to the dimensions, e.g., see the rmap argument in the pyears example. If a dimension is categorical, such as sex in survexp.us, then the dimname itself is matched against user’s data values. The matching ignores case and allows abbreviations, e.g., “M”, “Male”, and “m” all successfully match the survexp.us dimname of sex=c(“male”, “female”).

**type** a vector giving the type of each dimension, which will be 1= categorical, 2= continuous, 3= date, 4= calendar year of a US rate table. If type is 3 or 4, then the corresponding cutpoints must be one of the calendar date types: Date, POSIXt, date, or chron. This allows the code to properly match user data to the ratetable. (The published US decennial rate tables’ definition is that a subject does not begin to experience a new years’ death rate on Jan 1, but rather on their next birthday. The actual impact of this delay on any given subjects’ calculation is negligible, but the code has always tried to be correct.)

**cutpoints** a list with one element per dimension. If type=1 then the corresponding list element should be NULL, otherwise it should be a vector of length dim[i] containing the starting point of the interval to which the corresponding row/col of the array applies. Cutpoints must be in the same units as the underlying table, e.g., the survexp.us table contains death rates per day, so the age cutpoint vector contains age in days while year contains a vector of Dates. Cutpoints do not need to be evenly spaced: the survexp.us table, for instance, originally had age divided up as 0-1 days, 1-7 days, 7-28 days, 28 days - 1 year, 2, 3, . . . 119 years. (Changes in the source of the tables made it difficult to continue splitting out the first year.)

**summary** an optional summarization function. If present, it will be called with a numeric matrix that has one column per dimension and one row per observation. The function returns a character string giving a summary of the data. This is used by some routines to print an informative message, and provides one way to inform users of a data mistake, e.g., if the printout states that all subjects are between 0.14 and 0.23 years old it is likely that the user’s age variable was in years when it should have been in days.

**dimid** optional attribute containing the names of the dimnames. If the dimnames list itself has names, this attribute will be ignored.

---

**ratetableDate** Convert date objects to ratetable form

**Description**

This method converts dates from various forms into the internal form used in ratetable objects.

**Usage**

ratetableDate(x)

**Arguments**

x a date. The function currently has methods for Date, date, POSIXt, timeDate, and chron objects.
Details

This function is useful for those who create new ratetables, but is normally invisible to users. It is used internally by the `survexp` and `pyears` functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

Value

a numeric vector, the number of days since 1/1/1960.

Census Data Sets for the Expected Survival and Person Years Functions

Description

Census data sets for the expected survival and person years functions.

Usage

data(survexp, package="survival")

Details

`survexp.us` total United States population, by age and sex, 1940 to 2012.

`survexp.usr` United States population, by age, sex and race, 1940 to 2014. Race is white or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used. (Over the years, the reported tables have differed wrt reporting non-white and/or black.)

`survexp.mm` total Minnesota population, by age and sex, 1970 to 2013.

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as \(- \log(1 - q)/365.25\) where \(q\) is the 1 year probability of death as reported in the original tables from the US Census. For age 25 in 1970, for instance, \(p = 1 - q\) is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day for computational convenience.

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard R arrays. See the help page for `ratetable` for details.

All numeric dimensions of a rate table must be in the same units. The `survexp.us` rate table contains daily hazard rates, the age cutpoints are in days, and the calendar year cutpoints are a Date.

**rats2**  
*Rat data from Gail et al.*

**Description**

48 rats were injected with a carcinogen, and then randomized to either drug or placebo. The number of tumors ranges from 0 to 13; all rats were censored at 6 months after randomization.

**Usage**

```r
rats2
data(cancer, package="survival")
```

**Format**

- **rat**: id
- **trt**: treatment, (1=drug, 0=control)
- **observation**: within rat
- **start**: entry time
- **stop**: exit time
- **status**: event status, 1=tumor, 0=censored

**Source**

---

**reliability**  
*Reliability data sets*

**Description**

A set of data for simple reliability analyses, taken from the book by Meeker and Escobar.

**Usage**

```r
data(reliability, package="survival")
```
Details

- **capacitor**: Data from a factorial experiment on the life of glass capacitors as a function of voltage and operating temperature. There were 8 capacitors at each combination of temperature and voltage. Testing at each combination was terminated after the fourth failure.
  - **temperature**: temperature in degrees Celsius
  - **voltage**: applied voltage
  - **time**: time to failure
  - **status**: 1=failed, 0=censored

- **cracks**: Data on the time until the development of cracks in a set of 167 identical turbine parts. The parts were inspected at 8 selected times.
  - **day**: time of inspection
  - **fail**: number of fans found to have cracks, at this inspection

- **Data set genfan**: Time to failure of 70 diesel engine fans.
  - **hours**: hours of service
  - **status**: 1=failure, 0=censored

- **Data set ifluid**: A data frame with two variables describing the time to electrical breakdown of an insulating fluid.
  - **time**: hours to breakdown
  - **voltage**: test voltage in kV

- **Data set imotor**: Breakdown of motor insulation as a function of temperature.
  - **temp**: temperature of the test
  - **time**: time to failure or censoring
  - **status**: 0=censored, 1=failed

- **Data set turbine**: Each of 432 turbine wheels was inspected once to determine whether a crack had developed in the wheel or not.
  - **hours**: time of inspection (100s of hours)
  - **inspected**: number that were inspected
  - **failed**: number that failed

- **Data set valveSeat**: Time to replacement of valve seats for 41 diesel engines. More than one seat may be replaced at a particular service, leading to duplicate times in the data set. The final inspection time for each engine will have status=0.
  - **id**: engine identifier
  - **time**: time of the inspection, in days
  - **status**: 1=replacement occurred, 0= not

Examples

```
survreg(Surv(time, status) ~ temperature + voltage, capacitor)
```
Description

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

Usage

```r
## S3 method for class 'coxph'
residuals(object, type=c("martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", "scaledsch", "partial"), collapse=FALSE, weighted= (type %in% c("dfbeta", "dfbetas")), ...)
## S3 method for class 'coxphms'
residuals(object, type=c("martingale", "score", "schoenfeld", "dfbeta", "dfbetas", "scaledsch"), collapse=FALSE, weighted= FALSE, ...)  
## S3 method for class 'coxph.null'
residuals(object, type=c("martingale", "deviance", "score", "schoenfeld"), collapse=FALSE, weighted= FALSE, ...)
```

Arguments

- `object`: an object inheriting from class coxph, representing a fitted Cox regression model. Typically this is the output from the coxph function.
- `type`: character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", "scaledsch" and "partial". Only enough of the string to determine a unique match is required.
- `collapse`: vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then collapse=c(1,1,1,2,3,3,4,4,4,4) could be used to obtain per subject rather than per observation residuals.
- `weighted`: if TRUE and the model was fit with case weights, then the weighted residuals are returned.
- `...`: other unused arguments

Value

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute strata is attached that contains the
number of observations in each strata. The scaled Schoenfeld residuals are used in the `cox.zph` function.

The score residuals are each individual’s contribution to the score vector. Two transformations of this are often more useful: `dfbeta` is the approximate change in the coefficient vector if that observation were dropped, and `dfbetas` is the approximate change in the coefficients, scaled by the standard error for the coefficients.

NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

mresid <- resid(fit, collapse=heart$id)
```

residuals.survfit

**residuals.survfit**

### I1 residuals from a survfit object.

Description

Return infinitesimal jackknife residuals from a survfit object, for the survival, cumulative hazard, or restricted mean time in state (RMTS).

Usage

```r
## S3 method for class 'survfit'
residuals(object, times, type="pstate", collapse, weighted=FALSE, method=1, ...)
```

Arguments

- **object**
  - a survfit object
- **times**
  - a vector of times at which the residuals are desired
- **type**
  - the type of residual, see below
- **collapse**
  - add the residuals for all subjects in a cluster
- **weighted**
  - weight the residuals by each observation’s weight
- **method**
  - controls a choice of algorithm. Current an internal debugging option.
- **...**
  - arguments for other methods
Details

This function is designed to efficiently compute the leverage residuals at a small number of time points; a primary use is the creation of pseudo-values. If the residuals at all time points are needed, e.g. to compute a robust pointwise confidence interval for the survival curve, then this can be done more efficiently using the influence argument of the underlying \texttt{survfit} function. But be aware that such matrices can get very large.

The residuals are the impact of each observation or cluster on the resulting probability in state curves at the given time points, the cumulative hazard curve at those time points, or the expected sojourn time in each state up to the given time points. For a simple Kaplan-Meier the \texttt{survfit} object contains only the probability in the “initial” state, i.e., the survival fraction. For the KM case the sojourn time, the expected amount of time spent in the initial state, up to the specified endpoint, is more commonly known as the restricted mean survival time (RMST). For a multistate model this same quantity is also referred to as the restricted mean time in state (RMTS). It can be computed as the area under the respective probability in state curve. The program allows any of \texttt{pstate}, \texttt{surv}, \texttt{cumhaz}, \texttt{chaz}, \texttt{sojourn}, \texttt{rmst}, \texttt{rmts} or \texttt{auc} for the type argument, ignoring upper/lowercase, so users can choose whichever abbreviation they like best.

When \texttt{collapse=TRUE} the result has the cluster identifier (which defaults to the \texttt{id} variable) as the dimname for the first dimension. If the \texttt{fit} object contains more than one curve, and the same identifier is reused in two different curves this approach does not work and the routine will stop with an error. In principle this is not necessary, e.g., the result could contain two rows with the same label, showing the separate effect on each curve, but this was deemed too confusing.

Value

A matrix or array with one row per observation or cluster, and one column for each value in \texttt{times}. For a multi-state model the three dimensions are observation, time and state. For cumulative hazard, the last dimension is the set of transitions. (A competing risks model for instance has 3 states and 2 transitions.)

\texttt{survfit}, \texttt{survfit.formula}

Examples

```
fit <- survfit(Surv(time, status) ~ x, aml)
resid(fit, times=c(24, 48), type="RMTS")
```

Description

This is a method for the function \texttt{residuals} for objects inheriting from class \texttt{survreg}.

Usage

```
## S3 method for class 'survreg'
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE, collapse=FALSE, weighted=FALSE, ...)
```
residuals.survreg

Arguments

object an object inheriting from class survreg.
type type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "1sresp", "ldshape", and "matrix".
rsigma include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).
collapse optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.
weighted give weighted residuals? Normally residuals are unweighted.
...
other unused arguments

Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the ith row gives the approximate change in the coefficients due to the addition of subject i. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let \( L \) be the log-likelihood, \( p \) be the linear predictor \( X\beta \), and \( s = \log(\sigma) \). Then the 6 columns of the matrix are \( L, \frac{dL}{dp}, \frac{\partial^2 L}{\partial p^2}, \frac{dL}{ds}, \frac{\partial^2 L}{\partial s^2} \) and \( \frac{\partial^2 L}{\partial p \partial s} \). Diagnostics based on these quantities are discussed in the book and article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (ldcase), the response value (ldresp), and the shape.

For a transformed distribution such as the log-normal or Weibull, matrix residuals are based on the log-likelihood of the transformed data \( \log(y) \). For a monotone function \( f \) the density of \( f(X) \) is the density of \( X \) divided by the derivative of \( f \) (the Jacobian), so subtract \( \log(\text{derivative}) \) from each uncensored observation's loglik value in order to match the loglik component of the result. The other columns of the matrix residual are unchanged by the transformation.

<tr>
<td>status</td>
<td>0 = censored, 1 = loss of vision in this eye</td>
</tr>
<tr>
<td>risk</td>
<td>a risk score for the eye. This high risk subset is defined as a score of 6 or greater in at least one eye.</td>
</tr>
</tbody>
</table>

Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment, and has two observations in the data set. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are the actual time to vision loss in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

rhDNase

rhDNASE data set

Description

Results of a randomized trial of rhDNase for the treatment of cystic fibrosis.

Usage

```r
rhDNase
data(rhDNase, package="survival")
```

Format

A data frame with 767 observations on the following 8 variables.

- **id**: subject id
- **inst**: enrolling institution
- **trt**: treatment arm: 0=placebo, 1= rhDNase
- **entry.dt**: date of entry into the study
- **end.dt**: date of last follow-up
- **fev**: forced expiratory volume at enrollment, a measure of lung capacity
- **ivstart**: days from enrollment to the start of IV antibiotics
- **ivstop**: days from enrollment to the cessation of IV antibiotics

Details

In patients with cystic fibrosis, extracellular DNA is released by leukocytes that accumulate in the airways in response to chronic bacterial infection. This excess DNA thickens the mucus, which then cannot be cleared from the lung by the cilia. The accumulation leads to exacerbations of respiratory symptoms and progressive deterioration of lung function. At the time of this study more than 90% of cystic fibrosis patients eventually died of lung disease.

Deoxyribonuclease I (DNase I) is a human enzyme normally present in the mucus of human lungs that digests extracellular DNA. Genentech, Inc. cloned a highly purified recombinant DNase I (rhDNase or Pulmozyme) which when delivered to the lungs in an aerosolized form cuts extracellular DNA, reducing the viscoelasticity of airway secretions and improving clearance. In 1992 the company conducted a randomized double-blind trial comparing rhDNase to placebo. Patients were then monitored for pulmonary exacerbations, along with measures of lung volume and flow. The primary endpoint was the time until first pulmonary exacerbation; however, data on all exacerbations were collected for 169 days.

The definition of an exacerbation was an infection that required the use of intravenous (IV) antibiotics. Subjects had 0–5 such episodes during the trial, those with more than one have multiple rows in the data set, those with none have NA for the IV start and end times. A few subjects were infected at the time of enrollment, subject 173 for instance has a first infection interval of -21 to 7. We do not count this first infection as an "event", and the subject first enters the risk set at day 7. Subjects who have an event are not considered to be at risk for another event during the course of antibiotics, nor for an additional 6 days after they end. (If the symptoms reappear immediately after cessation then from a medical standpoint this would not be a new infection.)

This data set reproduces the data in Therneau and Grambsch, is does not exactly reproduce those in Therneau and Hamilton due to data set updates.

# Subjects whose fu ended during the 6 day window are the reason for
# this next line
temp.end <- with(rhDNase, pmin(ivstop+6, end.dt-entry.dt))
dnase <- tmerge(dnase, rhDNase, id=id,
              infect=event(ivstart),
              end= event(temp.end))
# toss out the non-at-risk intervals, and extra variables
# 3 subjects had an event on their last day of fu, infect=1 and end=1
dnase <- subset(dnase, (infect==1 | end==0), c(id:trt, fev:infect))
agfit <- coxph(Surv(tstart, tstop, infect) ~ trt + fev, cluster=id,
data=dnase)

ridge

Ridge regression

Description

When used in a coxph or survreg model formula, specifies a ridge regression term. The likelihood is penalised by \(\theta/2\) time the sum of squared coefficients. If scale=T the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If df is specified then \(\theta\) is chosen based on an approximate degrees of freedom.

Usage

ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)

Arguments

... predictors to be ridged
theta penalty is \(\theta/2\) time sum of squared coefficients
df Approximate degrees of freedom
eps Accuracy required for df
scale Scale variables before applying penalty?

Value

An object of class coxph.penalty containing the data and control functions.
Note

If the expression \texttt{ridge(x1, x2, x3, \ldots)} is too many characters long then the internal terms() function will add newlines to the variable name and then the coxph routine simply gets lost. (Some labels will have the newline and some won’t.) One solution is to bundle all of the variables into a single matrix and use that matrix as the argument to \texttt{ridge} so as to shorten the call, e.g. \texttt{mdata$many <- as.matrix(mydata[,5:53])}.

\textbf{rotterdam} 

\textit{Breast cancer data set used in Royston and Altman (2013)}

Description

The \texttt{rotterdam} data set includes 2982 primary breast cancers patients whose records were included in the Rotterdam tumor bank.

Usage

\texttt{rotterdam}
\texttt{data(cancer, package="survival")}

Format

A data frame with 2982 observations on the following 15 variables.

- \texttt{pid} patient identifier
- \texttt{year} year of surgery
- \texttt{age} age at surgery
- \texttt{meno} menopausal status (0= premenopausal, 1= postmenopausal)
- \texttt{size} tumor size, a factor with levels \texttt{<=20} \texttt{20-50} >\texttt{50}
- \texttt{grade} differentiation grade
nodes    number of positive lymph nodes
pgr      progesterone receptors (fmol/l)
er      estrogen receptors (fmol/l)
hormon   hormonal treatment (0=no, 1=yes)
chemo    chemotherapy
rtime    days to relapse or last follow-up
recur    0= no relapse, 1= relapse
dtime    days to death or last follow-up
dead     0= alive, 1= dead

Details

These data sets are used in the paper by Royston and Altman that is referenced below. The Rotterdam data is used to create a fitted model, and the GBSG data for validation of the model. The paper gives references for the data source.

There are 43 subjects who have died without recurrence, but whose death time is greater than the censoring time for recurrence. A common way that this happens is that a death date is updated in the health record sometime after the research study ended, and said value is then picked up when a study data set is created. But it raises serious questions about censoring. For instance subject 40 is censored for recurrence at 4.2 years and died at 6.6 years; when creating the endpoint of recurrence free survival (earlier of recurrence or death), treating them as a death at 6.6 years implicitly assumes that they were recurrence free just before death. For this to be true we would have to assume that if they had progressed in the 2.4 year interval before death (while off study), that this information would also have been noted in their general medical record, and would also be captured in the study data set. However, that may be unlikely. Death information is often in a centralized location in electronic health records, easily accessed by a programmer and merged with the study data, while recurrence may require manual review. How best to address this is an open issue.

# Royston and Altman used fractional polynomials for the nonlinear terms
**royston**  
Compute Royston’s D for a Cox model

**Description**

Compute the D statistic proposed by Royston and Sauerbrei along with several pseudo-R square values.

**Usage**

`royston(fit, newdata, ties = TRUE, adjust = FALSE)`

**Arguments**

- `fit` a coxph fit
- `newdata` optional validation data set
- `ties` make a correction for ties in the risk score
- `adjust` adjust for possible overfitting

**Details**

These values are called pseudo R-squared since they involve only the linear predictor, and not the outcome.  `R.D` is the value that corresponds to the Royston and Sauerbrei `D` statistic.  `R.KO` is the value proposed by Kent and O’Quigley, `R.N` is the value proposed by Nagelkerke, and `C.GH` corresponds to Goen and Heller’s concordance measure.

An adjustment for D is based on the ratio `r = (number of events)/(number of coefficients)`. For models which have sufficient sample size (`r>20`) the adjustment will be small.

The Nagelkerke value is the Cox-Snell R-squared divided by a scaling constant. The two separate values are present in the result of `summary.coxph` as a 2 element vector `rsq`, and were listed as "Rsquare" and "max possible" in older versions of the print routine. (Since superseded in the default printout by the concordance.) The Nagelkerke estimate is not returned when `newdata` is present.

**Value**

A vector containing the value of D, the estimated standard error of D, and three or four pseudo-R squared values.

**References**

# An example used in Royston and Sauerbrei
pbc2 <- na.omit(pbc)  # no missing values
cfit <- coxph(Surv(time, status==2) ~ age + log(bili) + edema + albumin +
              stage + copper, data=pbc2, ties="breslow")
royston(cfit)

rttright

Description

For many survival estimands, one approach is to redistribute each censored observation’s weight to those other observations with a longer survival time (think of distributing an estate to the heirs). Then compute on the remaining, uncensored data.

Usage

rttright(formula, data, weights, subset, na.action, times, id, timefix = TRUE)

Arguments

formula a formula object, which must have a Surv object as the response on the left of the ~ operator and, if desired, terms separated by + operators on the right. Each unique combination of predictors will define a separate strata.
data a data frame in which to interpret the variables named in the formula, subset and weights arguments.
weights The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the subset argument.
subset expression saying that only a subset of the rows of the data should be used in the fit.
na.action a missing-data filter function, applied to the model frame, after any subset argument has been used. Default is options()$na.action.
times a vector of time points, for which to return updated weights. If missing, a time after the largest time in the data is assumed.
id optional: if the data set has multiple rows per subject, a a variable containing the subject identifier of each row.
timefix correct for possible round-off error

Details

The formula argument is treated exactly the same as in the survfit function.
Redistribution is recursive: redistribute the weight of the first censored observation to all those with longer time, which may include other censored observations. Then redistribute the next smallest and etc. up to the specified time value. After re-distributing the weight for a censored observation to other observations that are not censored, ordinary non-censored methods can often be applied. For example, redistribution of the weights, followed by computation of the weighted cumulative distribution function, reprises the Kaplan-Meier estimator.
A primary use of this routine is illustration of methods or exploration of new methods. Methods that use RTTR directly, such as the Brier score, will often do these computations internally. A covariate on the right hand side of the formula causes redistribution to occur within group: a censoring in group 1 redistributes weights to others in group 1, etc. This is appropriate when the censoring pattern depends upon group.

Value

a vector or matrix of weights, with one column for each requested time

See Also

survfit

Examples

afit <- survfit(Surv(time, status) ~ 1, data=aml)
rwt <- rttright(Surv(time, status) ~ 1, data=aml)

# Reproduce a Kaplan-Meier
index <- order(aml$time)
cdf <- cumsum(rwt[index])  # weighted CDF
cdf <- cdf[!duplicated(aml$time[index], fromLast=TRUE)]  # remove duplicate times
cbind(time=afit$time, KM= afit$surv, RTTR= 1-cdf)

# Hormonal patients have a different censoring pattern
wt2 <- rttright(Surv(dtime, death) ~ hormon, rotterdam, times= 365*c(3, 5))
dim(wt2)

solder

Data from a soldering experiment

Description

In 1988 an experiment was designed and implemented at one of AT&T’s factories to investigate alternatives in the “wave soldering” procedure for mounting electronic componentes to printed circuit boards. The experiment varied a number of factors relevant to the process. The response, measured by eye, is the number of visible solder skips.

Usage

solder
data(solder, package="survival")

Format

A data frame with 900 observations on the following 6 variables.
Opening the amount of clearance around the mounting pad (3 levels)
Solder the amount of solder (Thick or Thin)
Mask type and thickness of the material used for the solder mask (A1.5, A3, A6, B3, B6)
PadType the geometry and size of the mounting pad (10 levels)
Panel each board was divided into 3 panels
skips the number of skips
Details

This data set is used as a detailed example in chapter 1 of Chambers and Hastie. Observations 1-360 and 541-900 form a balanced design of $3 \times 2 \times 10 \times 3 = 180$ observations for four of the pad types (A1.5, A3, B3, B6), while rows 361-540 match 3 of the 6 Solder*Opening combinations with pad type A6 and the other 3 with pad type A3.

References

Examples

```r
# The balanced subset used by Chambers and Hastie
# contains the first 180 of each mask and deletes mask A6.
index <- 1 + (1:nrow(solder)) - match(solder$Mask, solder$Mask)
solder.balance <- droplevels(subset(solder, Mask != "A6" & index <= 180))
```

Description

This contains the Stanford Heart Transplant data in a different format. The main data set is in `heart`.

Usage

`stanford2`

Format

- **id**: ID number
- **time**: survival or censoring time
- **status**: censoring status
- **age**: in years
- **t5**: T5 mismatch score

Source

`predict.survreg`, `heart`
Draw a state space figure.

Description

For multi-state survival models it is useful to have a figure that shows the states and the possible transitions between them. This function creates a simple "box and arrows" figure. It's goal was simplicity.

Usage

`statefig(layout, connect, margin = 0.03, box = TRUE, cex = 1, col = 1, lwd = 1, lty = 1, bcol = col, acol = col, alwd = lwd, alty = lty, offset = 0)`

Arguments

- `layout`: describes the layout of the boxes on the page. See the detailed description below.
- `connect`: a square matrix with one row for each state. If `connect[i,j] != 0` then an arrow is drawn from state i to state j. The row names of the matrix are used as the labels for the states.
- `margin`: the fraction of white space between the label and the surrounding box, and between the box and the arrows, as a function of the plot region size.
- `box`: should boxes be drawn? TRUE or FALSE.
- `cex, col, lty, lwd`: default graphical parameters used for the text and boxes. The last 3 can be a vector of values.
- `bcol`: color for the box, if it differs from that used for the text.
- `acol, alwd, alty`: color, line type and line width for the arrows.
- `offset`: used to slight offset the arrows between two boxes x and y if there is a transition in both directions. The default of 0 leads to a double headed arrow in this case – to arrows are drawn but they coincide. A positive value causes each arrow to shift to the left, from the view of someone standing at the foot of a arrow and looking towards the arrowhead, a negative offset shifts to the right. A value of 1 corresponds to the size of the plotting region.

Details

The arguments for color, line type and line width can all be vectors, in which case they are recycled as needed. Boxes and text are drawn in the order of the rownames of `connect`, and arrows are drawn in the usual R matrix order.

The `layout` argument is normally a vector of integers, e.g., the vector (1, 3, 2) describes a layout with 3 columns. The first has a single state, the second column has 3 states and the third has 2. The coordinates of the plotting region are 0 to 1 for both x and y. Within a column the centers of the boxes are evenly spaced, with 1/2 a space between the boxes and the margin, e.g., 4 boxes would be at 1/8, 3/8, 5/8 and 7/8. If `layout` were a 1 column matrix with values of (1, 3, 2) then the layout will have three rows with 1, 3, and 2 boxes per row, respectively. Alternatively, the user can supply a 2 column matrix that directly gives the centers.
The values of the connect matrix should be 0 for pairs of states that do not have a transition and values between 0 and 2 for those that do. States are connected by an arc that passes through the centers of the two boxes and a third point that is between them. Specifically, consider a line segment joining the two centers and erect a second segment at right angles to the midpoint of length \( d \) times the distance from center to midpoint. The arc passes through this point. A value of \( d=0 \) gives a straight line, \( d=1 \) a right hand half circle centered on the midpoint and \( d=-1 \) a left hand half circle. The connect matrix contains values of \( d+1 \) with \(-1 < d < 1\).

The connecting arrow are drawn from (center of box 1 + offset) to (center of box 2 + offset), where the the amount of offset (white space) is determined by the box and margin parameters. If a pair of states are too close together this can result in an arrow that points the wrong way.

**Value**

a matrix containing the centers of the boxes, with the invisible attribute set.

**Note**

The goal of this function is to make “good enough” figures as simply as possible, and thereby to encourage users to draw them. The layout argument was inspired by the diagram package, which can draw more complex and well decorated figures, e.g., many different shapes, shading, multiple types of connecting lines, etc., but at the price of greater complexity.

Because curved lines are drawn as a set of short line segments, line types have almost no effect for that case.

**Author(s)**

Terry Therneau

**Examples**

```r
# Draw a simple competing risks figure
states <- c("Entry", "Complete response", "Relapse", "Death")
connect <- matrix(0, 4, 4, dimnames=list(states, states))
connect[1, -1] <- c(1.1, 1, 0.9)
statefig(c(1, 3), connect)
```

**strata**

Identify Stratification Variables

**Description**

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

**Usage**

```r
strata(..., na.group=FALSE, shortlabel, sep=', ', )
```
Arguments

... any number of variables. All must be the same length.
na.group a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.
shortlabel if TRUE omit variable names from resulting factor labels. The default action is to omit the names if all of the arguments are factors, and none of them was named.
sep the character used to separate groups, in the created label

Details

When used outside of a coxph formula the result of the function is essentially identical to the interaction function, though the labels from strata are often more verbose.

Value

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

See Also

coxph, interaction

Examples

a <- factor(rep(1:3,4), labels=c("low", "medium", "high"))
b <- factor(rep(1:4,3))
levels(strata(b))
levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)

summary.aareg  Summarize an aareg fit

Description

Creates the overall test statistics for an Aalen additive regression model

Usage

## S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)

Arguments

object the result of a call to the aareg function
maxtime truncate the input to the model at time "maxtime"
test the relative time weights that will be used to compute the test
scale scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10^-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
... for future methods
Details

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The `maxtime` parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in lieu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.

Value

A list is returned with the following components:

- `table`: a matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, its standard error, the z-score and a p-value.
- `test.statistic`: the time weighting used for computing the test statistics.
- `test.var`: the model based variance matrix for the test statistic.
- `test.var2`: optionally, a robust variance matrix for the test statistic.
- `chisq`: the overall test (ignoring the intercept term) for significance of any variable.
- `n`: a vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times.

## End(Not run)
### summary.coxph

**Summary method for Cox models**

**Description**

Produces a summary of a fitted coxph model

**Usage**

```r
### S3 method for class 'coxph'
summary(object, conf.int=0.95, scale=1, ...)
```

**Arguments**

- `object` the result of a coxph fit
- `conf.int` level for computation of the confidence intervals. If set to FALSE no confidence intervals are printed
- `scale` vector of scale factors for the coefficients, defaults to 1. The printed coefficients, se, and confidence intervals will be associated with one scale unit.
- `...` for future methods

**Value**

An object of class `summary.coxph`, with components:

- `n`, `n.event` number of observations and number of events, respectively, in the fit
- `loglik` the log partial likelihood at the initial and final values
- `coefficients` a matrix with one row for each coefficient, and columns containing the coefficient, the hazard ratio exp(coef), standard error, Wald statistic, and P value.
- `conf.int` a matrix with one row for each coefficient, containing the confidence limits for exp(coef)
- `logtest, sctest, waldtest` the overall likelihood ratio, score, and Wald test statistics for the model
- `concordance` the concordance statistic and its standard error
- `used.robust` whether an asymptotic or robust variance was used
- `rsq` an approximate R^2 based on Nagelkerke (Biometrika 1991).
- `fail` a message, if the underlying coxph call failed
- `call` a copy of the call
- `na.action` information on missing values
Note

The pseudo r-squared of Nagelkerke is attractive because it is simple, but further work has shown that it has poor properties and it is now deprecated. The value is no longer printed by default, and will eventually be removed from the object.

See Also

coxph, print.coxph

Examples

```r
fit <- coxph(Surv(time, status) ~ age + sex, lung)
summary(fit)
```

summary.pyyears  Summary function for pyyears objects

Description

Create a printable table of a person-years result.

Usage

```r
## S3 method for class 'pyyears'
summary(object, header = TRUE, call = header, n = TRUE,
event = TRUE, pyears = TRUE, expected = TRUE, rate = FALSE, rr =expected,
ci.r = FALSE, ci.rr = FALSE, totals=FALSE, legend = TRUE, vline = FALSE,
vertical= TRUE, nastring=".", conf.level = 0.95,
scale = 1, ...)
```

Arguments

- `object`: a pyyears object
- `header`: print out a header giving the total number of observations, events, person-years, and total time (if any) omitted from the table
- `call`: print out a copy of the call
- `n, event, pyears, expected`: logical arguments: should these elements be printed in the table?
- `rate, ci.r`: logical arguments: should the incidence rate and/or its confidence interval be given in the table?
- `rr, ci.rr`: logical arguments: should the hazard ratio and/or its confidence interval be given in the table?
- `totals`: should row and column totals be added?
- `legend`: should a legend be included in the printout?
- `vline`: should vertical lines be included in the printed tables?
- `vertical`: when there is only a single predictor, should the table be printed with the predictor on the left (vertical=TRUE) or across the top (vertical=FALSE)?
**Summary Function for a survexp Object**

Returns a list containing the values of the survival at specified times.

**Usage**

```r
## S3 method for class 'survexp'
summary(object, times, scale = 1, ...)
```
Arguments

object the result of a call to the survexp function
times vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed.
scale numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale = 365.25 would scale the output to years.
...

For future methods

Details

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

Value

a list with the following components:
surv the estimate of survival at time t.
time the timepoints on the curve.
n.risk In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation.

Author(s)

Terry Therneau

See Also

survexp

Summary of a Survival Curve

Returns a list containing the survival curve, confidence limits for the curve, and other information.

Usage

## S3 method for class 'survfit'
summary(object, times, censored=FALSE, scale=1,
extend=FALSE, rmean=getOption('survfit.rmean'), ...)
summary.survfit

Arguments

object
the result of a call to the `survfit` function.
times
vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If `censored=T`, the default times vector contains all the unique times in fit, otherwise the default times vector uses only the event (death) times.
censored
logical value: should the censoring times be included in the output? This is ignored if the times argument is present.
scale
numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, scale = 365.25 would scale the output to years.
extend
logical value: if TRUE, prints information for all specified times, even if there are no subjects left at the end of the specified times. This is only used if the times argument is present.
rmean
Show restricted mean: see `print.survfit` for details
...
for future methods

Value

a list with the following components:
surv
the estimate of survival at time t+0.
time
the timepoints on the curve.
n.risk
the number of subjects at risk at time t-0 (but see the comments on weights in the `survfit` help file).
n.event
if the times argument is missing, then this column is the number of events that occurred at time t. Otherwise, it is the cumulative number of events that have occurred since the last time listed until time t+0.
n.entered
This is present only for counting process survival data. If the times argument is missing, this column is the number of subjects that entered at time t. Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time t.
n.exit.censored
if the times argument is missing, this column is the number of subjects that left without an event at time t. Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time t+0. This is only present for counting process survival data.
std.err
the standard error of the survival value.
conf.int
level of confidence for the confidence intervals of survival.
lower
lower confidence limits for the curve.
upper
upper confidence limits for the curve.
strata
indicates stratification of curve estimation. If `strata` is not NULL, there are multiple curves in the result and the surv, time, n.risk, etc. vectors will contain multiple curves, pasted end to end. The levels of strata (a factor) are the labels for the curves.
call
the statement used to create the fit object.
na.action
same as for fit, if present.
table
table of information that is returned from `print.survfit` function.
type
type of data censoring. Passed through from the fit object.
Details
This routine has two uses: printing out a survival curve at specified time points (often yearly), or extracting the values at specified time points for further processing. In the first case we normally want extend=FALSE, i.e., don’t print out data past the end of the curve. If the times option only contains values beyond the last point in the curve then there is nothing to print and an error message will result. For the second usage we almost always want extend=TRUE, so that the results will have a predictable length.

The survfit object itself will have a row of information at each censoring or event time, it does not save information on each unique entry time. For printout at two time points t1, t2, this function will give the the number at risk at the smallest event times that are >= t1 and >= t2, respectively, the survival curve at the largest recorded times <= t1 and <= t2, and the number of events and censorings in the interval t1 < t <= t2.

When the routine is called with counting process data many users are confused by counts that are too large. For example, Surv(c(0,0, 5, 5), c(2, 3, 8, 10), c(1, 0, 1, 0)) followed by a request for the values at time 4. The survfit object has entries only at times 2, 3, 8, and 10; there are 2 subjects at risk at time 8, so that is what will be printed.

See Also
survfit, print.summary.survfit

Examples
summary( survfit( Surv(futime, fustat)-1, data=ovarian))
summary( survfit( Surv(futime, fustat)-rx, data=ovarian))

Description
Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

Usage
Surv(time, time2, event,
    type=c('right', 'left', 'interval', 'counting', 'interval2', 'mstate'),
    origin=0)
is.Surv(x)

Arguments

time for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.

event The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. For multiple endpoint data the event variable will be a factor, whose first level is treated as censoring. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event.
time2 ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, (start, end]. For counting process data, event indicates whether an event occurred at the end of the interval.

type character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", "interval2" or "mstate".

origin for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful.

x any R object.

Details

When the type argument is missing the code assumes a type based on the following rules:

• If there are two unnamed arguments, they will match time and event in that order. If there are three unnamed arguments they match time, time2 and event.

• If the event variable is a factor then type mstate is assumed. Otherwise type right if there is no time2 argument, and type counting if there is.

As a consequence the type argument will normally be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level of the factor is taken to represent censoring and remaining ones a transition to the given state. (If the status variable is a factor then mstate is assumed.)

Interval censored data can be represented in two ways. For the first use type = "interval" and the codes shown above. In that usage the value of the time2 argument is ignored unless event=3. The second approach is to think of each observation as a time interval with (-infinity, t2) for left censored, (t1, infinity) for right censored, (t,t) for exact and (t1, t2) for an interval. This is the approach used for type = interval2. Infinite values can be represented either by actual infinity (Inf) or NA. The second form has proven to be the more useful one.

Presently, the only methods allowing interval censored data are the parametric models computed by survreg and survival curves computed by survfit; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for censored data via the condition if (max(status)==2). If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., Surv(time, status==3) would indicate that ’3’ is the code for an event. For multi-state survival the status variable will be a factor, whose first level is assumed to correspond to censoring.

Surv objects can be subscripted either as a vector, e.g. x[1:3] using a single subscript, in which case the drop argument is ignored and the result will be a survival object; or as a matrix by using two subscripts. If the second subscript is missing and drop=F (the default), the result of the subcripting will be a Surv object, e.g., x[1:3,,drop=F], otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

Value

An object of class Surv. There are methods for print, is.na, and subscripting survival objects. Surv objects are implemented as a matrix of 2 or 3 columns that has further attributes. These include the type (left censored, right censored, counting process, etc.) and labels for the states for
multi-state objects. Any attributes of the input arguments are also preserved in inputAttributes. This may be useful for other packages that have attached further information to data items such as labels; none of the routines in the survival package make use of these values, however.

In the case of is.Surv, a logical value TRUE if x inherits from class "Surv", otherwise an FALSE.

Note

The use of 1/2 coding for status is an interesting historical artifact. For data contained on punch cards, IBM 360 Fortran treated blank as a zero, which led to a policy within the Mayo Clinic section of Biostatistics to never use "0" as a data value since one could not distinguish it from a missing value. Policy became habit, as is often the case, and the use of 1/2 coding for alive/dead endured long after the demise of the punch cards that had sired the practice. At the time Surv was written many Mayo data sets still used this obsolete convention, e.g., the lung data set found in the package.

rev(x)
## S3 method for class 'Surv'
t(x)
## S3 method for class 'Surv'
tail(x, ...)
## S3 method for class 'Surv'
unique(x, ...)

Arguments

- **x**
  - a `Surv` object
- **probs**
  - a vector of probabilities
- **na.rm**
  - remove missing values from the calculation
- **value**
  - a character vector of up to the same length as x, or NULL
- **...**
  - other arguments to the method

Details

These functions extend the standard methods to `Surv` objects. The arguments and results from these are mostly as expected, with the following further details:

- The as.character function uses "5+" for right censored at time 5, "5-" for left censored at time 5, "[2,7]" for an observation that was interval censored between 2 and 7, "(1,6]" for a counting process data denoting an observation which was at risk from time 1 to 6, with an event at time 6, and "(1,6+]" for an observation over the same interval but not ending with and event. For a multi-state survival object the type of event is appended to the event time using ":type".
• The print and format methods make use of as.character.
• The as.numeric and as.integer methods perform these actions on the survival times, but do not affect the censoring indicator.
• The as.matrix and t methods return a matrix
• The length of a Surv object is the number of survival times it contains, not the number of items required to encode it, e.g., x <- Surv(1:4, 5:9, c(1,0,1,0)); length(x) has a value of 4. Likewise names(x) will be NULL or a vector of length 4. (For technical reasons, any names are actually stored in the rownames attribute of the object.)
• For a multi-state survival object levels returns the names of the endpoints, otherwise it is NULL.
• The median, quantile and plot methods first construct a survival curve using survfit, then apply the appropriate method to that curve.
• The concatenation method c() is asymmetric, its first argument determines the execution path. For instance c(Surv(1:4), Surv(5:6)) will concatenate the two objects, c(Surv(1:4), 5:6) will give an error, and c(5:6, Surv(1:4)) is equivalent to c(5:6, as.vector(Surv(1:4))).

See Also

Surv

Surv2

Create a survival object

Description

Create a survival object from a timeline style data set. This will almost always be the response variable in a formula.

Usage

Surv2(time, event, repeated=FALSE)

Arguments

time
  a timeline variable, such as age, time from enrollment, date, etc.

event
  the outcome at that time. This can be a 0/1 variable, TRUE/FALSE, or a factor. If the latter, the first level of the factor corresponds to ‘no event was observed at this time’.

repeated
  if the same level of the outcome repeats, without an intervening event of another type, should this be treated as a new event?

Details

This function is still experimental.

When used in a coxph or survfit model, Surv2 acts as a trigger to internally convert a timeline style data set into counting process style data, which is then acted on by the routine.

The repeated argument controls how repeated instances of the same event code are treated. If TRUE, they are treated as new events, an example where this might be desired is repeated infections in a subject. If FALSE, then repeats are not a new event. An example would be a data set where we wanted to use diabetes, say, as an endpoint, but this is repeated at each medical visit.
Surv2data

Description
The multi-state survival functions coxph and survfit allow for two forms of input data. This routine converts between them. The function is normally called behind the scenes when Surv2 is as the response.

Usage
Surv2data(formula, data, subset, id)

Arguments
formula a model formula
data a data frame
subset optional, selects rows of the data to be retained
id a variable that identified multiple rows for the same subject, normally found in the referenced data set

Details
For timeline style data, each row is uniquely identified by an (identifier, time) pair. The time could be a date, time from entry to a study, age, etc, (there may often be more than one time variable). The identifier and time cannot be missing. The remaining covariates represent values that were observed at that time point. Often, a given covariate is observed at only a subset of times and is missing at others. At the time of death, in particular, often only the identifier, time, and status indicator are known.

In the resulting data set missing covariates are replaced by their last known value, and the response y will be a Surv(time1, time2, endpoint) object.

Value
a list with elements
mf an updated model frame (fewer rows, unchanged columns)
S2.y the constructed response variable
S2.state the current state for each of the rows

See Also
Surv2data, coxph, survfit
survcheck

Checks of a survival data set

Description

Perform a set of consistency checks on survival data

Usage

survcheck(formula, data, subset, na.action, id, istate, istate0="(s0)",
timefix=TRUE,...)

Arguments

formula a model formula with a Surv object as the response
data data frame in which to find the id, istate and formula variables
subset expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
na.action a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()$na.action.
id an identifier that labels unique subjects
istate an optional vector giving the current state at the start of each interval
istate0 default label for the initial state of each subject (at their first interval) when istate is missing
timefix process times through the aeqSurv function to eliminate potential roundoff issues.
... other arguments, which are ignored (but won’t give an error if someone added weights for instance)

Details

This routine will examine a multi-state data set for consistency of the data. The basic rules are that if a subject is at risk they have to be somewhere, can not be two states at once, and should make sensible transitions from state to state. It reports the number of instances of the following conditions:

overlap two observations for the same subject that overlap in time, e.g. intervals of (0, 100) and (90, 120). If y is simple (time, status) survival observation intervals implicitly start at 0, so in that case any duplicate identifiers will generate an overlap.

jump a hole in a subject’s timeline, where they are in one state at the end of the prior interval, but a new state in the at the start subsequent interval.

gap one or more gaps in a subject’s timeline; they are presumably in the same state at their return as when they left.

teleport two adjacent intervals for a subject, with the first interval ending in one state and the subsequent interval starting in another. They have instantaneously changed states with experiencing a transition.

The total number of occurrences of each is present in the flags vector. Optional components give the location and identifiers of the flagged observations.
survdiff 3591

Value

a list with components

states the vector of possible states
transitions a matrix giving the count of transitions from one state to another
statecount table of the number of visits per state, e.g., 18 subjects had 2 visits to the "infection" state
flags a vector giving the counts of each check
istate a copy of the istate vector, if it was supplied; otherwise a constructed istate that satisfies all the checks
overlap a list with the row number and id of overlaps (not present if there are no overlaps)
gaps a list with the row number and id of gaps (not present if there are no gaps)
teleport a list with the row number and id of inconsistent rows (not present if there are none)
jumps a list with the row number and id of jumps (not present if there are no jumps)

Note

For data sets with time-dependent covariates, a given subject will often have intermediate rows with a status of ‘no event at this time’. (numeric value of 0). For instance a subject who started in state 1 at time 0, transitioned to state 2 at time 10, had a covariate x change from 135 to 156 at time 20, and a final transition to state 3 at time 30. The response would be Surv(c(0, 10, 20), c(10, 20, 30), c(2,0,3)): the status variable records changes in state, and there was no change at time 20. The istate variable would be (1, 2, 2); it contains the current state, and so the value is unchanged when status = censored.

Thus, when there are intermediate observations istate is not simply a lagged version of the status, and may be more challenging to create. One approach is to let survcheck do the work: call it with an istate argument that is correct for the first row of each subject, or no istate argument at all, and then insert the returned value into ones data frame.

survdiff Test Survival Curve Differences

Description

Tests if there is a difference between two or more survival curves using the $G^p$ family of tests, or for a single curve against a known alternative.

Usage

survdiff(formula, data, subset, na.action, rho=0, timefix=TRUE)
**Arguments**

*formula*  
a formula expression as for other survival models, of the form `Surv(time, status) ~ predictors`. For a one-sample test, the predictors must consist of a single `offset(sp)` term, where `sp` is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A `strata` term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `strata` function with its `na.group=T` argument.

*data*  
an optional data frame in which to interpret the variables occurring in the formula.

*subset*  
expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.

*na.action*  
a missing-data filter function. This is applied to the `model.frame` after any subset argument has been used. Default is `options()$na.action`.

*rho*  
a scalar parameter that controls the type of test.

*timefix*  
process times through the `aeqSurv` function to eliminate potential roundoff issues.

**Value**

a list with components:

*n*  
the number of subjects in each group.

*obs*  
the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum.

*exp*  
the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum.

*chisq*  
the chisquare statistic for a test of equality.

*var*  
the variance matrix of the test.

*strata*  
optionally, the number of subjects contained in each stratum.

*pvalue*  
the p-value corresponding to the Chisquare statistic

**Description**

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of $S(t)^\rho$, where $S(t)$ is the Kaplan-Meier estimate of survival. With $\rho = 0$ this is the log-rank or Mantel-Haenszel test, and with $\rho = 1$ it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

Peto and Peto show that the Gehan-Wilcoxon test can be badly biased if the two groups have different censoring patterns, and proposed an alternative. Prentice and Marek later showed an actual example where this issue occurs. For most data sets the Gehan-Wilcoxon and Peto-Peto-Prentice variant will hardly differ, however.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument to recode the righthand-side covariate.

## Stratified 7-sample test
survdiff(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on
## US mortality tables
expect <- survexp(futime ~ 1, data=jasa, cohort=FALSE,
                  rmap=list(age=accept.dt-birth.dt), sex=1, year=accept.dt),
                  ratetable=survexp.us)

## actual survival is much worse (no surprise)
survdiff(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

### survexp

**Compute Expected Survival**

**Description**

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

**Usage**

```r
survexp(formula, data, weights, subset, na.action, rmap, times,
         method=c("ederer", "hakulinen", "conditional", "individual.h",
                   "individual.s"),
         cohort=TRUE, conditional=FALSE,
         ratetable=survexp.us, scale=1,
         se.fit, model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

- `formula`: formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the `+` operator (as in `survfit`), and is often `~1`, i.e., expected survival for the entire group.
- `data`: data frame in which to interpret the variables named in the formula, subset and weights arguments.
weights  case weights. This is most useful when conditional survival for a known population is desired, e.g., the data set would contain all unique age/sex combinations and the weights would be the proportion of each.

subset  expression indicating a subset of the rows of data to be used in the fit.

na.action  function to filter missing data. This is applied to the model frame after subset has been applied. Default is options()$na.action.

rmap  an optional list that maps data set names to the ratetable names. See the details section below.

times  vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of times supplied in the response value of the formula.

method  computational method for the creating the survival curves. The individual option does not create a curve, rather it retrieves the predicted survival individual.s or cumulative hazard individual.h for each subject. The default is to use method='ederer' if the formula has no response, and method='hakulinen' otherwise.

cohort  logical value. This argument has been superseded by the method argument. To maintain backwards compatibility, if is present and FALSE, it implies method='individual.s'.

conditional  logical value. This argument has been superseded by the method argument. To maintain backwards compatibility, if it is present and TRUE it implies method='conditional'.

ratetable  a table of event rates, such as survexp.mn, or a fitted Cox model. Note the survival:: prefix in the default argument is present to avoid the (rare) case of a user who expects the default table but just happens to have an object named "survexp.us" in their own directory.

scale  numeric value to scale the results. If ratetable is in units/day, scale = 365.25 causes the output to be reported in years.

se.fit  compute the standard error of the predicted survival. This argument is currently ignored. Standard errors are not a defined concept for population rate tables (they are treated as coming from a complete census), and for Cox models the calculation is hard. Despite good intentions standard errors for this latter case have not been coded and validated.

model,x,y  flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.

Details

Individual expected survival is usually used in models or testing, to 'correct' for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study, sex and actual survival time are all known for a group of subjects. The survexp.us population tables contain expected death rates based on calendar year, sex and age. Then

```r
haz <- survexp(fu.time ~ 1, data=mydata,
               rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),
               method='individual.h'))
```

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable fu.time) This probability can be used as a rescaled time value in models:
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)

In the first model, a test for intercept=0 is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable x after adjustment for age and sex.

The ratetable being used may have different variable names than the user’s data set, this is dealt with by the rmap argument. The rate table for the above calculation was survexp.us, a call to summary(survexp.us) reveals that it expects to have variables age = age in days, sex, and year = the date of study entry, we create them in the rmap line. The sex variable was not mapped, therefore the function assumes that it exists in mydata in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored, for this case no response variable is required in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

Value

if cohort=TRUE an object of class survexp, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time. The cohort survival is the hypothetical survival for a cohort of subjects enrolled from the population at large, but matching the data set on the factors found in the rate table.

survexp.fit

Compute Expected Survival

Description
Compute expected survival times.

Usage
survexp.fit(group, x, y, times, death, ratetable)

Arguments
- group: if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer.
- x: A matrix whose columns match the dimensions of the ratetable, in the correct order.
- y: the follow up time for each subject.
- times: the vector of times at which a result will be computed.
- death: a logical value, if TRUE the conditional survival is computed, if FALSE the cohort survival is computed. See survexp for more details.
- ratetable: a rate table, such as survexp.uswhite.

Details
For conditional survival y must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate times should be a superset of y, so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the times spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are > .99.

For a subgroup of size 1 and times > y, the conditional method reduces to exp(-h) where h is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.
Value

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

Warning

Most users will call the higher level routine `survexp`. Consequently, this function has very few error checks on its input arguments.

`survexp, survexp.us`.

---

survexp.object  

*Expected Survival Curve Object*

Description

This class of objects is returned by the `survexp` class of functions to represent a fitted survival curve.

Objects of this class have methods for `summary`, and inherit the `print`, `plot`, `points` and `lines` methods from `survfit`.

Arguments

- `surv` the estimate of survival at time $t+0$. This may be a vector or a matrix.
- `n.risk` the number of subjects who contribute at this time.
- `time` the time points at which the curve has a step.
- `std.err` the standard error of the cumulative hazard or $-\log(survival)$.
- `strata` if there are multiple curves, this component gives the number of elements of the `time` etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
- `method` the estimation method used. One of "Ederer", "Hakulinen", or "conditional".
- `na.action` the returned value from the `na.action` function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.
- `call` an image of the call that produced the object.

Structure

The following components must be included in a legitimate `survfit` object.

Subscripts

Survexp objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves.
Details

In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk printed here is the number of those hypothetical subject who are still part of the calculation. In particular, for the Ederer method all hypotheticals are retained for all time, so \( n.risk \) will be a constant.

See Also

plot.survfit, summary.survexp, print.survfit, survexp.

survfit

Description

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously fitted Cox model, or a previously fitted accelerated failure time model.

Usage

survfit(formula, ...)

Arguments

formula either a formula or a previously fitted model
...
other arguments to the specific method

Details

A survival curve is based on a tabulation of the number at risk and number of events at each unique death time. When time is a floating point number the definition of "unique" is subject to interpretation. The code uses factor() to define the set. For further details see the documentation for the appropriate method, i.e., ?survfit.formula or ?survfit.coxph.

A survfit object may contain a single curve, a set of curves (vector), a matrix of curves, or even a 3 way array: \( \text{dim}(\text{fit}) \) will reveal the dimensions. Predicted curves from a coxph model have one row for each stratum in the Cox model fit and one column for each specified covariate set. Curves from a multi-state model have one row for each stratum and a column for each state, the strata correspond to predictors on the right hand side of the equation. The default printing and plotting order for curves is by column, as with other matrices.

Value

An object of class survfit containing one or more survival curves.

Note

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., survfit(Surv(time, status)), in which case the formula argument is not actually a formula. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.
survfit.coxph

survfit.coxph  Compute a Survival Curve from a Cox model

Description
Computes the predicted survivor function for a Cox proportional hazards model.

Usage
## S3 method for class 'coxph'
survfit(formula, newdata, 
    se.fit=TRUE, conf.int=.95, individual=FALSE, stype=2, ctype, 
    conf.type=c("log","log-log","plain","none", "logit", "arcsin"), 
    censor=TRUE, start.time, id, influence=FALSE, 
    na.action=na.pass, type, ...)

## S3 method for class 'coxphms'
survfit(formula, newdata, 
    se.fit=FALSE, conf.int=.95, individual=FALSE, stype=2, ctype, 
    conf.type=c("log","log-log","plain","none", "logit", "arcsin"), 
    censor=TRUE, start.time, id, influence=FALSE, 
    na.action=na.pass, type, p0=NULL, ...)

Arguments

formula  A coxph object.

newdata  a data frame with the same variable names as those that appear in the coxph formula. It is also valid to use a vector, if the data frame would consist of a single row.

The curve(s) produced will be representative of a cohort whose covariates correspond to the values in newdata. Default is the mean of the covariates used in the coxph fit.

se.fit  a logical value indicating whether standard errors should be computed. Default is TRUE for standard models, FALSE for multi-state (code not yet present for that case.)

conf.int  the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

individual  deprecated argument, replaced by the general id

stype  computation of the survival curve, 1=direct, 2=exponential of the cumulative hazard.

ctype  whether the cumulative hazard computation should have a correction for ties, 1=no, 2=yes.
conf.type  One of "none", "plain", "log" (the default), "log-log" or "logit". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals $curve + k \cdot se(curve)$, where $k$ is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The log-log option uses the log hazard or log(-log(survival)), and the logit log(survival/(1-survival)).

censor  if FALSE time points at which there are no events (only censoring) are not included in the result.

id  optional variable name of subject identifiers. If this is present, it will be search for in the newdata data frame. Each group of rows in newdata with the same subject id represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the coxph fit had strata then that must also be specified in newdata. If newid is not present, then each individual row of newdata is presumed to represent a distinct subject.

start.time  optional starting time, a single numeric value. If present the returned curve contains survival after start.time conditional on surviving to start.time.

influence  option to return the influence values

na.action  the na.action to be used on the newdata argument

type  older argument that encompassed stype and ctype, now deprecated

p0  optional, a vector of probabilities. The returned curve will be for a cohort with this mixture of starting states. Most often a single state is chosen

...  for future methods

Details

This routine produces Pr(state) curves based on a coxph model fit. For single state models it produces the single curve for $S(t) = Pr(\text{remain in initial state at time } t)$, known as the survival curve; for multi-state models a matrix giving probabilities for all states. The stype argument states the type of estimate, and defaults to the exponential of the cumulative hazard, better known as the Breslow estimate. For a multi-state Cox model this involves the exponential of a matrix. The argument stype=1 uses a non-exponential or "direct" estimate. For a single endpoint coxph model the code evaluates the Kalbfleich-Prentice estimate, and for a multi-state model it uses an analog of the Aalen-Johansen estimator. The latter approach is the default in the mstate package.

The ctype option affects the estimated cumulative hazard, and if stype=2 the estimated Pr(state) curves as well. If not present it is chosen so as to be concordant with the ties option in the coxph call. (For multistate coxphms objects only ctype=1 is currently implemented.) Likewise the choice between a model based and robust variance estimate for the curve will mirror the choice made in the coxph call, any clustering is also inherited from the parent model.

If the newdata argument is missing, then a curve is produced for a single "pseudo" subject with covariate values equal to the means of the data set. The resulting curve(s) almost never make sense, but The default remains due to an unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about equal numbers of observations for each. The "mean" covariate level will be 0.5 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with age*sex. The "mean" value for the age:sex interaction term will be about 30, a value that does not occur in the data. Users are strongly advised to use the newdata argument. For these reasons predictions from a multistate coxph model require the newdata argument.
When the original model contains time-dependent covariates, then the path of that covariate through
time needs to be specified in order to obtain a predicted curve. This requires newdata to contain
multiple lines for each hypothetical subject which gives the covariate values, time interval, and
strata for each line (a subject can change strata), along with an id variable which demarks which
rows belong to each subject. The time interval must have the same (start, stop, status) variables as
the original model: although the status variable is not used and thus can be set to a dummy value of
0 or 1, it is necessary for the response to be recognized as a Surv object. Last, although predictions
with a time-dependent covariate path can be useful, it is very easy to create a prediction that is
senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When a model contains strata but no time-dependent covariates the user of this routine has a choice.
If newdata argument does not contain strata variables then the returned object will be a matrix of
survival curves with one row for each strata in the model and one column for each row in newdata.
(This is the historical behavior of the routine.) If newdata does contain strata variables, then the
result will contain one curve per row of newdata, based on the indicated stratum of the original
model. In the rare case of a model with strata by covariate interactions the strata variable must be
included in newdata, the routine does not allow it to be omitted (predictions become too confusing).
(Note that the model Surv(time, status) ~ age*strata(sex) expands internally to strata(sex) + age:sex;
the sex variable is needed for the second term of the model.)

See **survfit** for more details about the counts (number of events, number at risk, etc.)

### Value

An object of class "survfit". See **survfit.object** for details. Methods defined for survfit objects
are print, plot, lines, and points.

### Notes

*If the following pair of lines is used inside of another function then the model=TRUE argument must
be added to the coxph call: fit <- coxph(...); survfit(fit). This is a consequence of the
non-standard evaluation process used by the model.frame function when a formula is involved.*

survfit.formula  
Compute a Survival Curve for Censored Data

Description

Computes an estimate of a survival curve for censored data using the Aalen-Johansen estimator. For ordinary (single event) survival this reduces to the Kaplan-Meier estimate.

Usage

```r
## S3 method for class 'formula'
survfit(formula, data, weights, subset, na.action,
    stype=1, ctype=1, id, cluster, robust, istate, timefix=TRUE,
    etype, error, ...)
```

Arguments

- `formula`: a formula object, which must have a `Surv` object as the response on the left of the `~` operator and, if desired, terms separated by `+` operators on the right. One of the terms may be a `strata` object. For a single survival curve the right hand side should be `~ 1`.
- `data`: a data frame in which to interpret the variables named in the formula, `subset` and `weights` arguments.
- `weights`: The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the `subset` argument.
- `subset`: expression saying that only a subset of the rows of the data should be used in the fit.
- `na.action`: a missing-data filter function, applied to the model frame, after any `subset` argument has been used. Default is `options()$na.action`.
- `stype`: the method to be used estimation of the survival curve: 1 = direct, 2 = \( \exp(\text{cumulative hazard}) \).
- `ctype`: the method to be used for estimation of the cumulative hazard: 1 = Nelson-Aalen formula, 2 = Fleming-Harrington correction for tied events.
- `id`: identifies individual subjects, when a given person can have multiple lines of data.
- `cluster`: used to group observations for the infinitesimal jackknife variance estimate, defaults to the value of `id`.
- `robust`: logical, should the function compute a robust variance. For multi-state survival curves this is true by default. For single state data see details, below.
- `istate`: for multi-state models, identifies the initial state of each subject or observation.
- `timefix`: process times through the `aeqSurv` function to eliminate potential roundoff issues.
- `etype`: a variable giving the type of event. This has been superseded by multi-state `Surv` objects and is deprecated; see example below.
- `error`: this argument is no longer used.
The following additional arguments are passed to internal functions called by `survfit`.

`se.fit` logical value, default is TRUE. If FALSE then standard error computations are omitted.

`conf.type` One of "none", "plain", "log" (the default), "log-log", "logit" or "arcsin". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals \( \text{curve} \pm k \times \text{se(curve)} \), where \( k \) is determined from `conf.int`. The log option calculates intervals based on the cumulative hazard or \( \log(\text{survival}) \). The log-log option bases the intervals on the log hazard or \( \log(-\log(\text{survival})) \), the logit option on \( \log(\text{survival}/(1-\text{survival})) \) and arcsin on \( \text{arcsin}(\text{survival}) \).

`conf.lower` a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are "usual" (unmodified), "peto", and "modified". The modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor \( m/n \), where \( n \) is the number currently at risk and \( m \) is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.

The Peto lower limit is based on the same "effective n" argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

`start.time` numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to `start.time`.

`conf.int` the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

`se.fit` a logical value indicating whether standard errors should be computed. Default is TRUE.

`influence` a logical value indicating whether to return the infinitesimal jackknife (influence) values for each subject. These contain the values of the derivative of each value with respect to the case weights of each subject: \( \frac{\partial p}{\partial w_i} \), evaluated at the vector of weights. The resulting object will contain `influence.surv` and `influence.chaz` components. Alternatively, options of `influence=1` or `influence=2` will return values for only the survival or hazard curves, respectively.

`p0` this applies only to multi-state curves. An optional vector giving the initial probability across the states. If this is missing, then \( p0 \) is estimated using the frequency of the starting states of all observations at risk at `start.time`, or if that is not specified, at the time of the first event.

`type` an older argument that combined `stype` and `ctype`, now deprecated. Legal values were "kaplan-meier" which is equivalent to `stype=1`, `ctype=1", "fleming-harrington" which is equivalent to `stype=2`, `ctype=1`, and "fh2" which is equivalent to `stype=2`, `ctype=2`.

Details

If there is a data argument, then variables in the `formula`, `codeweights`, `subset`, `id`, `cluster` and `istate` arguments will be searched for in that data set.
The routine returns both an estimated probability in state and an estimated cumulative hazard estimate. The cumulative hazard estimate is the Nelson-Aalen (NA) estimate or the Fleming-Harrington (FH) estimate, the latter includes a correction for tied event times. The estimated probability in state can estimated either using the exponential of the cumulative hazard, or as a direct estimate using the Aalen-Johansen approach. For single state data the AJ estimate reduces to the Kaplan-Meier and the probability in state to the survival curve; for competing risks data the AJ reduces to the cumulative incidence (CI) estimator. For backward compatibility the type argument can be used instead.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. Currently this algorithm is very slow, only a survival curve is produced, and it does not support a robust variance.

Robust variance: If a robust is TRUE, or for multi-state curves, then the standard errors of the results will be based on an infinitesimal jackknife (IJ) estimate, otherwise the standard model based estimate will be used. For single state curves, the default for robust will be TRUE if one of: there is a cluster argument, there are non-integer weights, or there is a id statement and at least one of the id values has multiple events, and FALSE otherwise. The default represents our best guess about when one would most often desire a robust variance. When there are non-integer case weights and (time1, time2) survival data the routine is at an impasse: a robust variance likely is called for, but requires either id or cluster information to be done correctly; it will default to robust=FALSE.

One unanticipated side effect of defaulting to a robust variance when there are non integer case weights is that a fit using interval censored data, which iterates an underlying KM using an updated weight vector, now returns a robust variance by default. Based on Sun (2001) this may be preferred, as the naive estimate ignores the estimation of the weights. The prior behavior can be obtained with robust=FALSE.

With the IJ estimate, the leverage values themselves can be returned as arrays with dimensions: number of subjects, number of unique times, and for a multi-state model, the number of unique states. Be forwarned that these arrays can be huge. If there is a cluster argument this first dimension will be the number of clusters and the variance will be a grouped IJ estimate; this can be an important tool for reducing the size. A numeric value for the influence argument allows finer control: 0= return neither (same as FALSE), 1= return the influence array for probability in state, 2= return the influence array for the cumulative hazard, 3= return both (same as TRUE).

Value

an object of class "survfit". See survfit.object for details. Methods defined for survfit objects are print, plot, lines, and points.

plot(fitCR, xscale=365.25, xmax=7300, mark.time=FALSE,
    col=2:3, xlab="Years post diagnosis of MGUS",
    ylab="P(state)"
```

survfit.matrix

Create Aalen-Johansen estimates of multi-state survival from a matrix of hazards.

Description

This allows one to create the Aalen-Johansen estimate of P, a matrix with one column per state and
one row per time, starting with the individual hazard estimates. Each row of P will sum to 1. Note
that this routine has been superseded by the use of multi-state Cox models, and will eventually be
removed.

Usage

## S3 method for class 'matrix'
survfit(formula, p0, method = c("discrete", "matexp"),
       start.time, ...)

Arguments

- **formula**: a matrix of lists, each element of which is either NULL or a survival curve
  object.
- **p0**: the initial state vector. The names of this vector are used as the names of the
  states in the output object. If there are multiple curves then p0 can be a matrix
  with one row per curve.
- **method**: use a product of discrete hazards, or a product of matrix exponentials. See details
  below.
- **start.time**: optional; start the calculations at a given starting point
- **...**: further arguments used by other survfit methods

Details

On input the matrix should contain a set of predicted curves for each possible transition, and NULL
in other positions. Each of the predictions will have been obtained from the relevant Cox model.
This approach for multistate curves is easy to use but has some caveats. First, the input curves must
be consistent. The routine checks as best it can, but can easy be fooled. For instance, if one were
to fit two Cox models, obtain predictions for males and females from one, and for treatment A and
B from the other, this routine will create two curves but they are not meaningful. A second issue is
that standard errors are not produced.

The names of the resulting states are taken from the names of the vector of initial state probabilities.
If they are missing, then the dimnames of the input matrix are used, and lacking that the labels ’1’,
’2’, etc. are used.
For the usual Aalen-Johansen estimator the multiplier at each event time is the matrix of hazards $H$ (also written as $I + dA$). When using predicted survival curves from a Cox model, however, it is possible to get predicted hazards that are greater than 1, which leads to probabilities less than 0. If the method argument is not supplied and the input curves are derived from a Cox model this routine instead uses the approximation $\expm(H-I)$ as the multiplier, which always gives valid probabilities. (This is also the standard approach for ordinary survival curves from a Cox model.)

**Value**

a `survfitms` object

**Note**

The R syntax for creating a matrix of lists is very fussy.

**Author(s)**

Terry Therneau

**See Also**

`survfit`

**Examples**

```r
etime <- with(mgus2, ifelse(pstat==0, futime, ptime))
event <- with(mgus2, ifelse(pstat==0, 2*death, 1))
event <- factor(event, 0:2, labels=c("censor", "pcm", "death"))
cfit1 <- coxph(Surv(etime, event="pcm") ~ age + sex, mgus2)
cfit2 <- coxph(Surv(etime, event="death") ~ age + sex, mgus2)

# predicted competing risk curves for a 72 year old with mspike of 1.2
# (median values), male and female.
# The survfit call is a bit faster without standard errors.
newdata <- expand.grid(sex=c("F", "M"), age=72, mspike=1.2)
AJmat <- matrix(list(), 3,3)
AJmat[1,2] <- list(survfit(cfit1, newdata, std.err=FALSE))
AJmat[1,3] <- list(survfit(cfit2, newdata, std.err=FALSE))
ccurv <- survfit(AJmat, p0 =c(entry=1, PCM=0, death=0))
```

```r
```
Arguments

n  total number of subjects in each curve.
time  the time points at which the curve has a step.
n.risk  the number of subjects at risk at t.
n.event  the number of events that occur at time t.
n.enter  for counting process data only, the number of subjects that enter at time t.
n.censor  for counting process data only, the number of subjects who exit the risk set, without an event, at time t. (For right censored data, this number can be computed from the successive values of the number at risk).
surv  the estimate of survival at time t+0. This may be a vector or a matrix. The latter occurs when a set of survival curves is created from a single Cox model, in which case there is one column for each covariate set.
pstate  a multi-state survival will have the pstate component instead of surv. It will be a matrix containing the estimated probability of each state at each time, one column per state.
std.err  for a survival curve this contains standard error of the cumulative hazard or -log(survival), for a multi-state curve it contains the standard error of prev. This difference is a reflection of the fact that each is the natural calculation for that case.
cumhaz hazard  optional. Contains the cumulative hazard for each possible transition.
strata  if there are multiple curves, this component gives the number of elements of the time vector corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
upper  optional upper confidence limit for the survival curve or pstate
lower  options lower confidence limit for the survival curve or pstate
start.time  optional, the starting time for the curve if other than 0
p0, sp0  for a multistate object, the distribution of starting states. If the curve has a strata dimension, this will be a matrix one row per stratum. The sp0 element has the standard error of p0, if p0 was estimated.
newdata  for survival curves from a fitted model, this contains the covariate values for the curves
n.all  the total number of observations that were available. For counting process data, and any time that the start.time argument was used, not all may have been used in creating the curve, in which case this value will be larger than n above. The print and plot routines in the package do not use this value, it is for information only.
conf.type  the approximation used to compute the confidence limits.
conf.int  the level of the confidence limits, e.g. 90 or 95%.
transitions  for multi-state data, the total number of transitions of each type.
aa.action  the returned value from the na.action function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.
call  an image of the call that produced the object.
type  type of survival censoring.
optional influence matrices for the pstate (or surv) and for the cumhaz estimates. A list with one element per stratum, each element of the list is an array indexed by subject, time, state.

version the version of the object. Will be missing, 2, or 3

Structure

The following components must be included in a legitimate survfit or survfitms object.

Subscripts

Survfit objects can be subscripted. This is often used to plot a subset of the curves, for instance. From the user’s point of view the survfit object appears to be a vector, matrix, or array of curves. The first dimension is always the underlying number of curves or “strata”; for multi-state models the state is always the last dimension. Predicted curves from a Cox model can have a second dimension which is the number of different covariate prediction vectors.

Details

The survfit object has evolved over time: when first created there was no thought of multi-state models for instance. This evolution has almost entirely been accomplished by the addition of new elements. One change in survival version 3 is the addition of a survfitconf routine which will compute confidence intervals for a survfit object. This allows the computation of CI intervals to be deferred until later, if desired, rather than making them a permanent part of the object. Later iterations of the base routines may omit the confidence intervals.

The survfit object starts at the first observation time, but survival curves are normally plotted from time 0. A helper routine survfit0 can be used to add this first time point and align the data.

See Also

plot.survfit, summary.survfit, print.survfit, survfit, survfit0

Description

Add the point for a starting time (time 0) to a survfit object’s elements. This is useful for plotting.

Usage

survfit0(x, start.time=0)

Arguments

x a survfit object

start.time the desired starting time; see details below.
Details

Survival curves are traditionally plotted forward from time 0, but since the true starting time is not
known as a part of the data, the `survfit` routine does not include a time 0 value in the resulting
object. Someone might look at cumulative mortgage defaults versus calendar year, for instance,
with the ‘time’ value a Date object. The plotted curve probably should not start at 0 = 1970/01/01.
Due to this uncertainty, it was decided not to include a "time 0" as part of a survfit object. If the
original survfit call included a `start.time` argument, that value is of course retained.

Whether that (1989) decision was wise or foolish, it is now far too late to change it. (We tried it
once as a trial, resulting in over 20 errors in the survival test suite. We extrapolate that it might break
1/2 - 2/3 of the other CRAN packages that depend on survival, if made a default.) If the original
survfit call included a `start.time` argument, that value is of course retained.

One problem with this choice is that some functions must choose a starting point, plots for example.
This utility function is used by `plot.survfit` and `summary.survfit` to do so, adding a new time
point at the front of each curve in a consistent way: the optional argument to the `survfit0` function
as the first choice (if supplied), then the user's `start.time` if present, otherwise `min(0, x$time)`.
The resulting object is not guaranteed to work with functions that further manipulate a survfit
object such as subscripting, aggregation, pseudovalues, etc. (remember the 20 errors). Rather it is
intended as a penultimate step, most often when creating a plot.

Value

a reformulated version of the object with an initial data point at `start.time` added. The time,
`surv`, `pstate`, `cumhaz`, `std.err`, `std.cumhaz` and other components will all be aligned, so as to
make plots and summaries easier to produce.

survfitcoxph.fit

A direct interface to the 'computational engine' of survfit.coxph

Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a
‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can
lead to unexpected errors if that data is wrong.

Usage

`survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype,
vartype, varmat, id, y2, strata2, unlist=TRUE)`

Arguments

y
the response variable used in the Cox model. (Missing values removed of
course.)

x
covariate matrix used in the Cox model

wt
weight vector for the Cox model. If the model was unweighted use a vector of
1s.

x2
matrix describing the hypothetical subjects for which a curve is desired. Must
have the same number of columns as x.
risk the risk score exp(X beta) from the fitted Cox model. If the model had an offset, include it in the argument to exp.

newrisk risk scores for the hypothetical subjects

strata strata variable used in the Cox model. This will be a factor.

se.fit if TRUE the standard errors of the curve(s) are returned

survtype 1=Kalbfleisch-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for ‘exact’, N-A for ‘breslow’ and Efron for ‘efron’.

date type 1=Greenwood, 2=Aalen, 3=Efron

varmat the variance matrix of the coefficients

id optional; if present and not NULL this should be a vector of identifiers of length nrow(x2). A non-null value signifies that x2 contains time dependent covariates, in which case this identifies which rows of x2 go with each subject.

y2 survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of x2. Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however.

strata2 vector of strata indicators for x2. This must be a factor.

unlist if FALSE the result will be a list with one element for each strata. Otherwise the strata are “unpacked” into the form found in a survfit object.

Value

a list containing nearly all the components of a survfit object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a coxph object), and the class.

Note

The source code for both this function and survfit.coxph is written using noweb. For complete documentation see the inst/sourcecode.pdf file.

survfit.coxph

survConcordance(formula, data, weights, subset, na.action) # use concordance
survConcordance.fit(y, x, strata, weight) # use concordancefit
Arguments

**formula**
- A formula object, with the response on the left of a `~` operator, and the terms on the right. The response must be a survival object as returned by the `Surv` function.

**data**
- A data frame

**weights**, **subset**, **na.action**
- As for `coxph`

**x**, **y**, **strata**, **weight**
- Predictor, response, strata, and weight vectors for the direct call

See Also

* Deprecated

```r
survobrien
```

### Description

Peter O’Brien’s test for association of a single variable with survival. This test is proposed in Biometrics, June 1978.

### Usage

```r
survobrien(formula, data, subset, na.action, transform)
```

### Arguments

**formula**
- A valid formula for a cox model.

**data**
- A data frame in which to interpret the variables named in the `formula`, or in the `subset` and the `weights` argument.

**subset**
- Expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.

**na.action**
- A missing-data filter function. This is applied to the model frame after any subset argument has been used. Default is `options()$na.action`.

**transform**
- The transformation function to be applied at each time point. The default is O’Brien’s suggestion `logit(tr)` where `tr = (rank(x) - 1/2)/length(x)` is the rank shifted to the range 0-1 and `logit(x) = log(x/(1-x))` is the logit transform.

### Value

A new data frame. The response variables will be column names returned by the `Surv` function, i.e., "time" and "status" for simple survival data, or "start", "stop", "status" for counting process data. Each individual event time is identified by the value of the variable `.strata`. Other variables retain their original names. If a predictor variable is a factor or is protected with `I()`, it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows that the original data, approximately the original number of rows * number of deaths/2.
Method

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O’Brien’s method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

Note

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that strategy does not work if the original formula has a strata statement. This new data set will be the same size, but the coxph routine will process it slightly faster.

Examples

xx <- survobrien(Surv(futime, fustat) ~ age + factor(rx) + I(ecog.ps), data=ovarian)
coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
Arguments

formula: a formula expression as for other regression models. The response is usually a survival object as returned by the `Surv` function. See the documentation for `Surv`, `lm` and `formula` for details.
data: a data frame in which to interpret the variables named in the formula, weights or the subset arguments.
weights: optional vector of case weights
subset: subset of the observations to be used in the fit
na.action: a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is `options()$na.action`.
dist: assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from `survreg.distributions`. These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in `survreg.distributions`.
parms: a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.
init: optional vector of initial values for the parameters.
scale: optional fixed value for the scale. If set to <=0 then the scale is estimated.
control: a list of control values, in the format produced by `survreg.control`. The default value is `survreg.control()`
model,x,y: flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.
score: return the score vector. (This is expected to be zero upon successful convergence.)
robust: Use robust sandwich error instead of the asymptotic formula. Defaults to TRUE if there is a `cluster` argument.
cluster: Optional variable that identifies groups of subjects, used in computing the robust variance. Like `model` variables, this is searched for in the dataset pointed to by the data argument.
...
other arguments which will be passed to `survreg.control`.

Details

All the distributions are cast into a location-scale framework, based on chapter 2.2 of Kalbfleisch and Prentice. The resulting parameterization of the distributions is sometimes (e.g. gaussian) identical to the usual form found in statistics textbooks, but other times (e.g. Weibull) it is not. See the book for detailed formulas.

When using weights be aware of the difference between replication weights and sampling weights. In the former, a weight of ‘2’ means that there are two identical observations, which have been combined into a single row of data. With sampling weights there is a single observed value, with a weight used to achieve balance with respect to some population. To get proper variance with replication weights use the default variance, for sampling weights use the robust variance. Replication weights were once common (when computer memory was much smaller) but are now rare.

Value

an object of class `survreg` is returned.
survreg.control

survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist="exponential")

# A model with different baseline survival shapes for two groups, i.e.,
# two different scale parameters
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

# There are multiple ways to parameterize a Weibull distribution. The survreg
# function embeds it in a general location-scale family, which is a
# different parameterization than the rweibull function, and often leads
# to confusion.
# survreg's scale = 1/rweibull shape
# survreg's intercept = log(rweibull scale)
# For the log-likelihood all parameterizations lead to the same value.
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")

# Economists fit a model called 'tobit regression', which is a standard
# linear regression with Gaussian errors, and left censored data.
tobinfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant, data=tobin, dist='gaussian')

survreg.control

Package options for survreg and coxph

Description
This functions checks and packages the fitting options for survreg

Usage
survreg.control(maxiter=30, rel.tolerance=1e-09, toler.chol=1e-10, iter.max, debug=0, outer.max=10)

Arguments
maxiter maximum number of iterations
rel.tolerance relative tolerance to declare convergence
toler.chol Tolerance to declare Cholesky decomposition singular
Value

A list with the same elements as the input

See Also

survreg

survreg.distributions  Parametric Survival Distributions

Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf $F$ and density $f$ of a canonical member of the family.

Usage

survreg.distributions

Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

name: name of distribution

variance: function(parms) returning the variance (currently unused)

init(x, weights, ...): Function returning an initial estimate of the mean and variance (used for initial values in the iteration)

density(x, parms): Function returning a matrix with columns $F$, $1 - F$, $f$, $f'/f$, and $f''/f$

quantile(p, parms): Quantile function

scale: Optional fixed value for the scale parameter

parms: Vector of default values and names for any additional parameters

deviance(y, scale, parms): Function returning the deviance for a saturated model; used only for deviance residuals.

and to define one distribution in terms of another

name: name of distribution

dist: name of parent distribution

trans: transformation (eg log)

dtrans: derivative of transformation

itrans: inverse of transformation

scale: Optional fixed value for scale parameter
Details

There are four basic distributions: extreme, gaussian, logistic and t. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

\[ F = 1 - e^{-e^t}. \]

When the logarithm of survival time has one of the first three distributions we obtain respectively weibull, lognormal, and loglogistic. The location-scale parameterization of a Weibull distribution found in survreg is not the same as the parameterization of rweibull.

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of survreg.distributions with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying survreg.distributions a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)
```
survreg.object  

Parametric Survival Model Object

**Description**

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

**COMPONENTS**

The following components must be included in a legitimate `survreg` object.

- **coefficients** the coefficients of the `linear.predictors`, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

- **icoef** coefficients of the baseline model, which will contain the intercept and log(scale), or multiple scale factors for a stratified model.

- **var** the variance-covariance matrix for the parameters, including the log(scale) parameter(s).

- **loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.

- **iter** the number of iterations required

- **linear.predictors** the linear predictor for each subject.

- **df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

- **scale** the scale factor(s), with length equal to the number of strata.

- **idf** degrees of freedom for the initial model.

- **means** a vector of the column means of the coefficient matrix.

- **dist** the distribution used in the fit.

- **weights** included for a weighted fit.

The object will also have the following components found in other model results (some are optional): `linear.predictors`, `weights`, `x`, `y`, `model`, `call`, `terms` and `formula`. See `lm`.

**See Also**

- `survreg`, `lm`
survregDtest

Verify a survreg distribution

Description
This routine is called by survreg to verify that a distribution object is valid.

Usage
survregDtest(dlist, verbose = F)

Arguments
dlist  the list describing a survival distribution
verbose return a simple TRUE/FALSE from the test for validity (the default), or a ver-
bose description of any flaws.

details
If the survreg function rejects your user-supplied distribution as invalid, this routine will tell you
why it did so.

Value
TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if
not.

Examples
# An invalid distribution (it should have "init =" on line 2)
# survreg would give an error message
mycauchy <- list(name='Cauchy',
  init<- function(x, weights, ...)
    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
         temp/pi, -2*x*temp, 2*temp^2*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)

survregDtest(mycauchy, TRUE)
survSplit  

Split a survival data set at specified times

Description

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

Usage

survSplit(formula, data, subset, na.action = na.pass, cut, start = "tstart", id, zero = 0, episode, end = "tstop", event = "event")

Arguments

- formula: a model formula
- data: a data frame
- subset, na.action: rows of the data to be retained
- cut: the vector of timepoints to cut at
- start: character string with the name of a start time variable (will be created if needed)
- id: character string with the name of new id variable to create (optional). This can be useful if the data set does not already contain an identifier.
- zero: If start doesn’t already exist, this is the time that the original records start.
- episode: character string with the name of new episode variable (optional)
- end: character string with the name of event time variable
- event: character string with the name of censoring indicator

Details

Each interval in the original data is cut at the given points; if an original row were (15, 60] with a cut vector of (10, 30, 40) the resulting data set would have intervals of (15, 30], (30, 40] and (40, 60]. Each row in the final data set will lie completely within one of the cut intervals. Which interval for each row of the output is shown by the episode variable, where 1= less than the first cutpoint, 2= between the first and the second, etc. For the example above the values would be 2, 3, and 4.

The routine is called with a formula as the first argument. The right hand side of the formula can be used to delimit variables that should be retained; normally one will use ~ , as a shorthand to retain them all. The routine will try to retain variable names, e.g. Surv(adam, joe, fred)~. will result in a data set with those same variable names for tstart, end, and event options rather than the defaults. Any user specified values for these options will be used if they are present, of course. However, the routine is not sophisticated; it only does this substitution for simple names. A call of Surv(time, stat==2) for instance will not retain “stat” as the name of the event variable.

Rows of data with a missing time or status are copied across unchanged, unless the na.action argument is changed from its default value of na.pass. But in the latter case any row that is missing for any variable will be removed, which is rarely what is desired.
Value

New, longer, data frame.

tcut

**Factors for person-year calculations**

Description

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

Usage

`tcut(x, breaks, labels, scale=1)`

## S3 method for class 'tcut'

levels(x)

Arguments

- `x` numeric/date variable
- `breaks` breaks between categories, which are right-continuous
- `labels` labels for categories
- `scale` Multiply `x` and `breaks` by this.

Value

An object of class `tcut`

See Also

`cut, pyears`
Examples

# For pyears, all time variable need to be on the same scale; but
# futime is in months and age is in years
test <- mgus2
test$years <- test$futime/30.5  # follow-up in years

# first grouping based on years from starting age (= current age)
# second based on years since enrollment (all start at 0)
test$agegrp <- tcut(test$age, c(0,60, 70, 80, 100),
                   c("<=60", "60-70", "70-80", ">80")

test$fgrp <- tcut(rep(0, nrow(test)), c(0, 1, 5, 10, 100),
                   c("0-1yr", "1-5yr", "5-10yr", ">10yr")

# death rates per 1000, by age group
pfit1 <- pyears(Surv(years, death) ~ agegrp, scale =1000, data=test)
round(pfit1$event/ pfit1$pyears)

#death rates per 100, by follow-up year and age
# there are excess deaths in the first year, within each age stratum
pfit2 <- pyears(Surv(years, death) ~ fgrp + agegrp, scale =1000, data=test)
round(pfit2$event/ pfit2$pyears)

---

tmerge

Time based merge for survival data

Description

A common task in survival analysis is the creation of start,stop data sets which have multiple intervals for each subject, along with the covariate values that apply over that interval. This function aids in the creation of such data sets.

Usage

tmerge(data1, data2, id,..., tstart, tstop, options)

Arguments

data1 the primary data set, to which new variables and/or observation will be added
data2 second data set in which all the other arguments will be found
id subject identifier
... operations that add new variables or intervals, see below
tstart optional variable to define the valid time range for each subject, only used on an initial call
tstop optional variable to define the valid time range for each subject, only used on an initial call
options a list of options. Valid ones are idname, tstartname, tstopname, delay, na.rm, and tdcstart. See the explanation below.
Details

The program is often run in multiple passes, the first of which defines the basic structure, and subsequent ones that add new variables to that structure. For a more complete explanation of how this routine works refer to the vignette on time-dependent variables.

There are 4 types of operational arguments: a time dependent covariate (tdc), cumulative count (cumtdc), event (event) or cumulative event (cumevent). Time dependent covariates change their values before an event, events are outcomes.

• newname = tdc(y, x, init) A new time dependent covariate variable will created. The argument y is assumed to be on the scale of the start and end time, and each instance describes the occurrence of a "condition" at that time. The second argument x is optional. In the case where x is missing the count variable starts at 0 for each subject and becomes 1 at the time of the event. If x is present the value of the time dependent covariate is initialized to value of init, if present, or the tdcstart option otherwise, and is updated to the value of x at each observation. If the option na.rm=TRUE missing values of x are first removed, i.e., the update will not create missing values.

newname = cumtdc(y,x, init) Similar to tdc, except that the event count is accumulated over time for each subject. The variable x must be numeric.

newname = event(y,x) Mark an event at time y. In the usual case that x is missing the new 0/1 variable will be similar to the 0/1 status variable of a survival time.

newname = cumevent(y,x) Cumulative events.

The function adds three new variables to the output data set: tstart, tstop, and id. The options argument can be used to change these names. If, in the first call, the id argument is a simple name, that variable name will be used as the default for the idname option. If data1 contains the tstart variable then that is used as the starting point for the created time intervals, otherwise the initial interval for each id will begin at 0 by default. This will lead to an invalid interval and subsequent error if say a death time were <= 0.

The na.rm option affects creation of time-dependent covariates. Should a data row in data2 that has a missing value for the variable be ignored or should it generate an observation with a value of NA? The default of TRUE causes the last non-missing value to be carried forward. The delay option causes a time-dependent covariate’s new value to be delayed, see the vignette for an example.

Value

a data frame with two extra attributes tm.retain and tcount. The first contains the names of the key variables, and which names correspond to tdc or event variables. The tcount variable contains counts of the match types. New time values that occur before the first interval for a subject are "early", those after the last interval for a subject are "late", and those that fall into a gap are of type "gap". All these are are considered to be outside the specified time frame for the given subject. An event of this type will be discarded. An observation in data2 whose identifier matches no rows in data1 is of type "missid" and is also discarded. A time-dependent covariate value will be applied to later intervals but will not generate a new time point in the output.

The most common type will usually be "within", corresponding to those new times that fall inside an existing interval and cause it to be split into two. Observations that fall exactly on the edge of an interval but within the (min, max] time for a subject are counted as being on a "leading" edge, "trailing" edge or "boundary". The first corresponds for instance to an occurrence at 17 for someone with an intervals of (0,15] and (17, 35]. A tdc at time 17 will affect this interval but an event at 17 would be ignored. An event occurrence at 15 would count in the (0,15] interval. The last case is where the main data set has touching intervals for a subject, e.g. (17, 28] and (28,35] and a new occurrence lands at the join. Events will go to the earlier interval and counts to the latter one. A
last column shows the number of additions where the id and time point were identical. When this occurs, the tdc and event operators will use the final value in the data (last edit wins), but ignoring missing, while cumtdc and cumevent operators add up the values.

These extra attributes are ephemeral and will be discarded if the dataframe is modified. This is intentional, since they will become invalid if for instance a subset were selected.

# The first data set contains data on 312 subjects in a clinical trial plus
# 106 that agreed to be followed off protocol, the second data set has data
# only on the trial subjects.
temp <- subset(pbc, id <= 312, select=c(id:sex, stage)) # baseline data
pbc2 <- tmerge(temp, temp, id=id, endpt = event(time, status))
pbc2 <- tmerge(pbc2, pbcseq, id=id, ascites = tdc(day, ascites),
               bili = tdc(day, bili), albumin = tdc(day, albumin),
               protime = tdc(day, protime), alk.phos = tdc(day, alk.phos))

fit <- coxph(Surv(tstart, tstop, endpt==2) ~ protime + log(bili), data=pbc2)

tobin Tobin’s Tobit data

Description

Economists fit a parametric censored data model called the ‘tobit’. These data are from Tobin’s original paper.

Usage

tobin
data(tobin, package="survival")

Format

A data frame with 20 observations on the following 3 variables.

durable  Durable goods purchase
age  Age in years
quant  Liquidity ratio (x 1000)
transplant

Source

Examples

tfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
data=tobin, dist='gaussian')
predict(tfit,type="response")

transplant  Liver transplant waiting list

Description

Subjects on a liver transplant waiting list from 1990-1999, and their disposition: received a transplant, died while waiting, withdrew from the list, or censored.

Usage

transplant
data(transplant, package="survival")

Format

A data frame with 815 (transplant) observations on the following 6 variables.

age  age at addition to the waiting list
sex  m or f
abo  blood type: A, B, AB or O
year  year in which they entered the waiting list
futime time from entry to final disposition
event final disposition: censored, death, ltx or withdraw

Details

This represents the transplant experience in a particular region, over a time period in which liver transplant became much more widely recognized as a viable treatment modality. The number of liver transplants rises over the period, but the number of subjects added to the liver transplant waiting list grew much faster. Important questions addressed by the data are the change in waiting time, who waits, and whether there was an consequent increase in deaths while on the list.

Blood type is an important consideration. Donor livers from subjects with blood type O can be used by patients with A, B, AB or O blood types, whereas an AB liver can only be used by an AB recipient. Thus type O subjects on the waiting list are at a disadvantage, since the pool of competitors is larger for type O donor livers.

This data is of historical interest and provides a useful example of competing risks, but it has little relevance to current practice. Liver allocation policies have evolved and now depend directly on
each individual patient’s risk and need, assessments of which are regularly updated while a patient is on the waiting list. The overall organ shortage remains acute, however.

The transplant data set was a version used early in the analysis, transplant2 has several additions and corrections, and was the final data set and matches the paper.

udca

Data from a trial of usrodeoxycholic acid

Description

Data from a trial of ursodeoxycholic acid (UDCA) in patients with primary biliary cirrhosis (PBC).

Usage

udca
udca2
data(udca, package="survival")

Format

A data frame with 170 observations on the following 15 variables.

id subject identifier
trt treatment of 0=placebo, 1=UDCA
entry.dt date of entry into the study
last.dt date of last on-study visit
stage stage of disease
bili bilirubin value at entry
riskscore the Mayo PBC risk score at entry
death.dt date of death
untangle.specials

This data set is used in the Therneau and Grambsh. The udca1 data set contains the baseline variables along with the time until the first endpoint (any of death, transplant, ..., worsening). The udca2 data set treats all of the endpoints as parallel events and has a stratum for each.

References

Examples

# values found in table 8.3 of the book
fit1 <- coxph(Surv(futime, status) ~ trt + log(bili) + stage,
  cluster =id , data=udca1)
fit2 <- coxph(Surv(futime, status) ~ trt + log(bili) + stage +
  strata(endpoint), cluster=id, data=udca2)

untangle.specials Help Process the ‘specials’ Argument of the ‘terms’ Function.

Description

Given a terms structure and a desired special name, this returns an index appropriate for subscripting the terms structure and another appropriate for the data frame.

Usage

untangle.specials(tt, special, order=1)

Arguments

  tt a terms object.
  special the name of a special function, presumably used in the terms object.
  order the order of the desired terms. If set to 2, interactions with the special function will be included.
Value

a list with two components:
vars a vector of variable names, as would be found in the data frame, of the specials.
terms a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special.

Examples

```
formula <- Surv(tt, ss) ~ x + z*strata(id)
tms <- terms(formula, specials="strata")
## the specials attribute
attr(tms, "specials")
## main effects
untangle.specials(tms, "strata")
## and interactions
untangle.specials(tms, "strata", order=1:2)
```

Description

US population by age and sex, for 2000 through 2020

Format

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

Details

This data is often used as a "standardized" population for epidemiology studies.

age <- as.integer(dimnames(us50)[[1]])
smat <- model.matrix(~ factor(floor(age/5)) -1)
ustot <- t(smat) %*% us50 # totals by 5 year age groups
temp <- c(50, 55, 60, 65, 70, 75, 80, 85, 90, 95)
dimnames(ustot) <- list(c(paste(temp, temp+4, sep="-"), "100+"), c("male", "female"))
```
**vcov.coxph**

**Variance-covariance matrix**

**Description**

Extract and return the variance-covariance matrix.

**Usage**

```r
## S3 method for class 'coxph'
vcov(object, complete=TRUE, ...)
## S3 method for class 'survreg'
vcov(object, complete=TRUE, ...)
```

**Arguments**

- `object`: a fitted model object
- `complete`: logical indicating if the full variance-covariance matrix should be returned. This has an effect only for an over-determined fit where some of the coefficients are undefined, and `coef(object)` contains corresponding NA values. If `complete=TRUE` the returned matrix will have row/column for each coefficient, if FALSE it will contain rows/columns corresponding to the non-missing coefficients. The `coef()` function has a similar `complete` argument.
- `...`: additional arguments for method functions

**Details**

For the `coxph` and `survreg` functions the returned matrix is a particular generalized inverse: the row and column corresponding to any NA coefficients will be zero. This is a side effect of the generalized cholesky decomposition used in the underlying computation.

**Value**

- a matrix

---

**veteran**

**Veterans’ Administration Lung Cancer study**

**Description**

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

**Usage**

```r
veteran
data(cancer, package="survival")
```
xtfrm.Surv

Sorting order for Surv objects

Description
Sort survival objects into a partial order, which is the same one used internally for many of the calculations.

Usage

```r
## S3 method for class 'Surv'
xtfrm(x)
```

Arguments

- `x`: a `Surv` object

Details
This creates a partial ordering of survival objects. The result is sorted in time order, for tied pairs of times right censored events come after observed events (censor after death), and left censored events are sorted before observed events. For counting process data (`tstart, tstop, status`) the ordering is by stop time, status, and start time, again with censoring last. Interval censored data is sorted using the midpoint of each interval.

The `xtfrm` routine is used internally by `order` and `sort`, so these results carry over to those routines.

Value

A vector of integers which will have the same sort order as `x`.

Author(s)
Terry Therneau
See Also
sort, order

Examples

test <- c(Surv(c(10, 9, 9, 8, 8, 7, 5, 5, 4), rep(1:0, 5)), Surv(6.2, NA))
test
sort(test)

Description

Compute population marginal means (PMM) from a model fit, for a chosen population and statistic.

Usage

yates(fit, term, population = c("data", "factorial", "sas"),
levels, test = c("global", "trend", "pairwise"), predict = "linear",
options, nsim = 200, method = c("direct", "sgtt"))

Arguments

fit a model fit. Examples using lm, glm, and coxph objects are given in the vignette.
term the term from the model which is to be evaluated. This can be written as a character string or as a formula.
population the population to be used for the adjusting variables. User can supply their own data frame or select one of the built in choices. The argument also allows "empirical" and "yates" as aliases for data and factorial, respectively, and ignores case.
levels optional, what values for term should be used.
test the test for comparing the population predictions.
predict what to predict. For a glm model this might be the 'link' or 'response'. For a coxph model it can be linear, risk, or survival. User written functions are allowed.
options optional arguments for the prediction method.
nsim number of simulations used to compute a variance for the predictions. This is not needed for the linear predictor.
method the computational approach for testing equality of the population predictions. Either the direct approach or the algorithm used by the SAS glim procedure for "type 3" tests.

Details

The many options and details of this function are best described in a vignette on population prediction.
Value

an object of class yates with components of

- **estimate**: a data frame with one row for each level of the term, and columns containing the level, the mean population predicted value (mppv) and its standard deviation.
- **tests**: a matrix giving the test statistics
- **mvar**: the full variance-covariance matrix of the mppv values
- **summary**: optional: any further summary if the values provided by the prediction method.

Author(s)

Terry Therneau

Examples

```r
fit1 <- lm(skips ~ Solder*Opening + Mask, data = solder)
yates(fit1, ~Opening, population = "factorial")

fit2 <- coxph(Surv(time, status) ~ factor(ph.ecog)*sex + age, lung)
yates(fit2, ~ ph.ecog, predict="risk") # hazard ratio
```

---

Value

an object of class yates with components of

- **estimate**: a data frame with one row for each level of the term, and columns containing the level, the mean population predicted value (mppv) and its standard deviation.
- **tests**: a matrix giving the test statistics
- **mvar**: the full variance-covariance matrix of the mppv values
- **summary**: optional: any further summary if the values provided by the prediction method.

Author(s)

Terry Therneau

Examples

```r
fit1 <- lm(skips ~ Solder*Opening + Mask, data = solder)
yates(fit1, ~Opening, population = "factorial")

fit2 <- coxph(Surv(time, status) ~ factor(ph.ecog)*sex + age, lung)
yates(fit2, ~ ph.ecog, predict="risk") # hazard ratio
```

Description

This is a method which is called by the yates function, in order to setup the code to handle a particular model type. Methods for glm, coxph, and default are part of the survival package.

Usage

```r
yates_setup(fit, ...)
```

Arguments

- **fit**: a fitted model object
- **...**: optional arguments for some methods

Details

If the predicted value should be the linear predictor, the function should return NULL. The yates routine has particularly efficient code for this case. Otherwise it should return a prediction function or a list of two elements containing the prediction function and a summary function. The prediction function will be passed the linear predictor as a single argument and should return a vector of predicted values.

Note

See the vignette on population prediction for more details.
