

Package ‘cNORM’

January 6, 2021

Type Package

Title Continuous Norming

Version 2.0.1

Maintainer Wolfgang Lenhard <wolfgang.lenhard@uni-wuerzburg.de>

Date 2021-01-05

Description Conventional methods for producing standard scores in psychometrics or biometrics are often plagued with “jumps” or “gaps” (i.e., discontinuities) in norm tables and low confidence for assessing extreme scores. The continuous norming method introduced by A. Lenhard et al. (2016, <doi:10.1177/1073191116656437>; 2019, <doi:10.1371/journal.pone.0222279>) and generates continuous test norm scores on the basis of the raw data from standardization samples, without requiring assumptions about the distribution of the raw data: Norm scores are directly established from raw data by modeling the latter ones as a function of both percentile scores and an explanatory variable (e.g., age). The method minimizes bias arising from sampling and measurement error, while handling marked deviations from normality, addressing bottom or ceiling effects and capturing almost all of the variance in the original norm data sample. An online demonstration is available via <<https://cnorm.shinyapps.io/cNORM/>>.

|------------------------|--|
| <code>bestModel</code> | <i>Retrieve the best fitting regression model based on powers of A, L and interactions</i> |
|------------------------|--|

Description

The function computes a series of regressions with an increasing number of predictors and takes the best fitting model per step. The aim is to find a model with as few predictors as possible, which at the same time manages to explain as much variance as possible from the original data. In psychometric test construction, this approach can be used to smooth the data and eliminate noise from norm sample stratification, while preserving the overall diagnostic information. Values around $R^2 = .99$ usually show excellent results. The selection of the model can either be based on the number of terms in the regression functions or the share of explained variance of the model (R^2). If both are specified, first the method tries to select the model based on the number of terms and in case, this does not work, use R^2 instead. Pushing R^2 by setting the number of terms, the R^2 cut off and k to high values might lead to an over-fit, so be careful! These parameters depend on the distribution of the norm data. As a rule of thumb, terms = 5 or $R^2 = .99$ and $k = 4$ is a good starting point for the analyses. `plotSubset(model)` can be used to weigh up R^2 and information criteria (C_p , an AIC like measure) and fitted versus manifest scores can be plotted with `'plotRaw'`, `'plotNorm'` and `'plotPercentiles'`. Use `checkConsistency(model)` to check the model for violations. `cnorm.cv` can help in identifying the ideal number of predictors.

Usage

```
bestModel(  
  data,  
  raw = NULL,  
  R2 = NULL,  
  k = NULL,  
  predictors = NULL,  
  terms = 0,  
  weights = NULL,  
  force.in = NULL,  
  plot = TRUE  
)
```

Arguments

| | |
|-------------------------|---|
| <code>data</code> | The preprocessed dataset, which should include the variables 'raw' and the powers and interactions of the norm score (L = Location; usually T scores) and an explanatory variable (usually age = A) |
| <code>raw</code> | the name of the raw score variable (default raw) |
| <code>R2</code> | Adjusted R square as a stopping criterion for the model building (default R2 = 0.99) |
| <code>k</code> | The power constant. Higher values result in more detailed approximations but have the danger of over-fit (default = 4, max = 6) |
| <code>predictors</code> | List of the names of predictor to use for the model selection. The parameter overrides the 'k' parameter and it can be used to preselect the variables entering the regression, or even to add variables like sex, that are not part of the original model building. Please note, that adding other variables than those based on L and A, plotting, prediction and normTable function will most likely not work, but at least the regression formula can be obtained that way. The parameter as well accepts a formula object, f. e. when applying a pre computed model to a new dataset. In this case, k is as well overridden. In order to include all predictors in the regression, you might want to adjust the terms parameter to the number of predictors as well. |
| <code>terms</code> | Selection criterion for model building. The best fitting model with this number of terms is used |
| <code>weights</code> | Optional vector with weights for the single cases. By default, if data has been weighting in ranking, these weights are reused here as well. Please set to FALSE to deactivate this behavior. All weights have to be positive. This is currently an EXPERIMENTAL feature and will probably be deprecated in a future release. |
| <code>force.in</code> | List of variable names forced into the regression function. This option can be used to force the regression to include covariates like sex or other background variables. This can be used to model separate norm scales for different groups in order the sample. Variables specified here, that are not part of the initial regression function resp. list of predictors, are ignored without further notice and thus do not show up in the final result. Additionally, all other functions like norm table generation and plotting are so far not yet prepared to handle covariates. |
| <code>plot</code> | If set to TRUE (default), the percentile plot of the model is shown |

Value

The model meeting the R2 criteria with coefficients and variable selection in `model$coefficients`. Use `plotSubset(model)` and `plotPercentiles(data,model)` to inspect model

See Also

`plotSubset`, `plotPercentiles`, `plotPercentileSeries`, `checkConsistency`

Other model: `checkConsistency()`, `cnorm.cv()`, `derive()`, `modelSummary()`, `print.cnorm()`, `printSubset()`, `rangeCheck()`, `regressionFunction()`, `summary.cnorm()`

Examples

```
## Not run:
# Standard example with sample data
normData <- prepareData(elfe)
model <- bestModel(normData)
plotSubset(model)
plotPercentiles(normData, model)

# It is possible to specify the variables explicitly - useful to smuggle
# in variables like sex
preselectedModel <- bestModel(normData, predictors = c("L1", "L3", "L1A3", "A2", "A3"))
print(regressionFunction(preselectedModel))

# Example for modeling based on continuous age variable and raw variable,
# based on the CDC data. We use the default k=4 parameter; raw variable has
# to be set to "bmi".
bmi.data <- prepareData(CDC, raw = "bmi", group = "group", age = "age")
bmi.model <- bestModel(bmi.data, raw = "bmi")
printSubset(bmi.model)

# Use the formula of the pre calculated bmi data to compute models for girls and
# boys seperately
bmi.model.boys <- bestModel(bmi.data[bmi.data$sex == 1, ], predictors = bmi.model$terms)
bmi.model.girls <- bestModel(bmi.data[bmi.data$sex == 2, ], predictors = bmi.model$terms)

# Custom list of predictors (based on k = 3) and forcing in the sex variable
# While calculating the regression model works well, all other functions like
# plotting and norm table generation are not yet prepared to use covariates
bmi.sex <- bestModel(bmi.data, raw = "bmi", predictors = c(
  "L1", "L2", "L3",
  "A1", "A2", "A3", "L1A1", "L1A2", "L1A3", "L2A1", "L2A2",
  "L2A3", "L3A1", "L3A2", "L3A3", "sex"
), force.in = c("sex"))

## End(Not run)
```

calcPolyInL

Internal function for retrieving regression function coefficients at specific age

Description

The function is an inline for searching zeros in the inverse regression function. It collapses the regression function at a specific age and simplifies the coefficients.

Usage

```
calcPolyInL(raw, age, model)
```

Arguments

| | |
|-------|---|
| raw | The raw value (subtracted from the intercept) |
| age | The age |
| model | The cNORM regression model |

Value

The coefficients

| | |
|-----------------|--|
| calcPolyInLBase | <i>Internal function for retrieving regression function coefficients at specific age</i> |
|-----------------|--|

Description

The function is an inline for searching zeros in the inverse regression function. It collapses the regression function at a specific age and simplifies the coefficients.

Usage

```
calcPolyInLBase(raw, age, coeff, k)
```

Arguments

| | |
|-------|---|
| raw | The raw value (subtracted from the intercept) |
| age | The age |
| coeff | The cNORM regression model coefficients |
| k | The cNORM regression model power parameter |

Value

The coefficients

CDC

BMI growth curves from age 2 to 25

Description

By the courtesy of the Center of Disease Control (CDC), cNORM includes human growth data for children and adolescents age 2 to 25 that can be used to model trajectories of the body mass index and to estimate percentiles for clinical definitions of under- and overweight. The data stems from the NHANES surveys in the US and was published in 2012 as public domain. The data was cleaned by removing missing values and it includes the following variables from or based on the original dataset.

Usage

CDC

Format

A data frame with 45053 rows and 7 variables:

age continuous age in years, based on the month variable

group age group; chronological age in years at the time of examination

month chronological age in month at the time of examination

sex sex of the participant, 1 = male, 2 = female

height height of the participants in cm

weight weight of the participants in kg

bmi the body mass index, computed by $(\text{weight in kg})/(\text{height in m})^2$

A data frame with 45035 rows and 7 columns

 checkConsistency

Check the consistency of the norm data model

Description

While abilities increase and decline over age, within one age group, the norm scores always have to show a linear increase or decrease with increasing raw scores. Violations of this assumption are a strong indication for problems in modeling the relationship between raw and norm scores. There are several reasons, why this might occur:

1. Vertical extrapolation: Choosing extreme norm scores, e. g. values $-3 \leq x$ and $x \geq 3$ In order to model these extreme values, a large sample dataset is necessary.
2. Horizontal extrapolation: Taylor polynomials converge in a certain radius. Using the model values outside the original dataset may lead to inconsistent results.
3. The data cannot be modeled with Taylor polynomials, or you need another power parameter (k) or R2 for the model.

In general, extrapolation (point 1 and 2) can carefully be done to a certain degree outside the original sample, but it should in general be handled with caution.

Usage

```
checkConsistency(
  model,
  minAge = NULL,
  maxAge = NULL,
  minNorm = NULL,
  maxNorm = NULL,
  minRaw = NULL,
  maxRaw = NULL,
  stepAge = 1,
  stepNorm = 1,
  warn = FALSE,
  silent = FALSE,
  covariate = NULL
)
```

Arguments

| | |
|---------|---|
| model | The model from the bestModel function or a cnorm object |
| minAge | Age to start with checking |
| maxAge | Upper end of the age check |
| minNorm | Lower end of the norm value range |
| maxNorm | Upper end of the norm value range |
| minRaw | clipping parameter for the lower bound of raw scores |

| | |
|-----------|--|
| maxRaw | clipping parameter for the upper bound of raw scores |
| stepAge | Stepping parameter for the age check, usually 1 or 0.1; lower values indicate higher precision / closer checks |
| stepNorm | Stepping parameter for the norm table check within age with lower scores indicating a higher precision. The choice depends of the norm scale used. With T scores a stepping parameter of 1 is suitable |
| warn | If set to TRUE, already minor violations of the model assumptions are displayed (default = FALSE) |
| silent | turn off messages |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

Value

Boolean, indicating model violations (TRUE) or no problems (FALSE)

See Also

Other model: [bestModel\(\)](#), [cnorm.cv\(\)](#), [derive\(\)](#), [modelSummary\(\)](#), [print.cnorm\(\)](#), [printSubset\(\)](#), [rangeCheck\(\)](#), [regressionFunction\(\)](#), [summary.cnorm\(\)](#)

Examples

```
result <- cnorm(raw = elfe$raw, group = elfe$group)
modelViolations <- checkConsistency(result,
  minAge = 2, maxAge = 5, stepAge = 0.1,
  minNorm = 25, maxNorm = 75, minRaw = 0, maxRaw = 28, stepNorm = 1
)
plotDerivative(result, minAge = 2, maxAge = 5, minNorm = 25, maxNorm = 75)
```

cnorm *Continuous Norming*

Description

Conducts continuous norming in one step and returns an object including ranked raw data and the continuous norming model. Please consult the function description ' of 'rankByGroup', 'rankBySlidingWindow' and 'bestModel' for specifics of the steps in the data preparation and modeling process. In addition to the raw scores, either provide

- a numeric vector for the grouping information (group)
- a numeric vector for both grouping and age (group, age)
- a numeric age vector and the width of the sliding window (age, width)

for the ranking of the raw scores. You can adjust the grade of smoothing of the regression model by setting the k and terms parameter. In general, increasing k to more than 4 and the number of terms lead to a higher fit, while lower values lead to more smoothing.

Usage

```
cnorm(
  raw = NULL,
  group = NULL,
  age = NULL,
  width = NA,
  weights = NULL,
  scale = "T",
  method = 4,
  descend = FALSE,
  k = 4,
  terms = 0,
  R2 = NULL
)
```

Arguments

| | |
|---------|---|
| raw | Numeric vector of raw scores |
| group | Numeric vector of grouping variable, e. g. grade |
| age | Numeric vector with chronological age, please additionally specify width of window |
| width | Size of the moving window in case an age vector is used |
| weights | Vector or variable name in the dataset with weights for each individual case. It can be used to compensate for moderate imbalances due to insufficient norm data stratification. Weights should be numerical and positive. Please note, that this feature is currently EXPERIMENTAL and subject to ongoing work! Precision of weighting increases with sample size. On the other hand, in large samples, it is easy to stratificate and then weighting is not needed anymore. |
| scale | type of norm scale, either T (default), IQ, z or percentile (= no transformation); a double vector with the mean and standard deviation can as well, be provided f. e. c(10, 3) for Wechsler scale index points |
| method | Ranking method in case of bindings, please provide an index, choosing from the following methods: 1 = Blom (1958), 2 = Tukey (1949), 3 = Van der Warden (1952), 4 = Rankit (default), 5 = Levenbach (1953), 6 = Filliben (1975), 7 = Yu & Huang (2001) |
| descend | ranking order (default descent = FALSE): inverses the ranking order with higher raw scores getting lower norm scores; relevant for example when norming error scores, where lower scores mean higher performance |
| k | The power constant. Higher values result in more detailed approximations but have the danger of over-fit (default = 4, max = 6) |
| terms | Selection criterion for model building. The best fitting model with this number of terms is used |
| R2 | Adjusted R square as a stopping criterion for the model building (default R2 = 0.99) |

Value

cnorm object including the ranked raw data and the regression model

rankByGroup, rankBySlidingWindow, computePowers, bestModel

Examples

```
# Using this function with the example dataset 'elfe'
cnorm.elfe <- cnorm(raw = elfe$raw, group = elfe$group)

# return norm tables including 90% confidence intervals for a
# test with a reliability of r = .85; table are set to mean of quartal
# in grade 3 (children completed 2 years of schooling)
normTable(c(2.125, 2.375, 2.625, 2.875), cnorm.elfe, CI = .90, reliability = .95)

# ... or instead of raw scores for norm scores, the other way round
rawTable(c(2.125, 2.375, 2.625, 2.875), cnorm.elfe, CI = .90, reliability = .95)

# Not really a plausible scenario, but just for demonstration purposes, we will
# use the PPVT dataset and sex as the weighting variable (1 = male, 2 = female),
# and consequently, females will get the double weight. This procedure can be used
# to correct imbalances in the dataset, but it is still experimental. Please use
# positive, non-zero numerics, preferably integers for this:
## Not run:
cnorm.ppvt <- cnorm(raw = ppvt$raw, group = ppvt$group, weight = ppvt$sex)

## End(Not run)
```

Description

This function helps in selecting the number of terms for the model by doing repeated Monte Carlo cross validation with 80 percent of the data as training data and 20 percent as the validation data. The cases are drawn randomly but stratified by norm group. Successive models are retrieved with increasing number of terms and the RMSE of raw scores (fitted by the regression model) is plotted for the training, validation and the complete dataset. Additionally to this analysis on the raw score level, it is possible (default) to estimate the mean norm score reliability and crossfit measures. For this, please set the norms parameter to TRUE. Due to the high computational load when computing norm scores, it takes time to finish when doing repeated cv or comparing models up to the maximum number of terms. When using the `cv = "full"` option, the ranking is done for the test and validation dataset separately (always based on T scores), resulting in a complete cross validation. In order to only validate the modeling, you as well can use a pre-ranked data set with `prepareData(elfe)` already applied. In this case, the training and validation data is drawn from the already ranked data and the scores for the validation set should improve. It is however no independent test, as the ranking between both samples is interlinked. In the output, you will get RMSE for the raw score models, norm score R2 and delta R2, the crossfit and the norm score SE sensu Oosterhuis, van der Ark, & Sijtsma (2016). For assessing, if a model over-fits the data and to what extent, we need cross-validation. We assumed that an overfitting occurred when a model captures more variance of the observed norm scores of the training sample compared to the captured variance of the norm scores of the validation sample. The overfit can therefore be described as:

$$CROSSFIT = R(Training; Model)^2 / R(Validation; Model)^2$$

A CROSSFIT higher than 1 is a sign of overfitting. Value lower than 1 indicate an underfit due to a suboptimal modeling procedure, i. e. the method may not have captured all the variance of the observed data it could possibly capture. Values around 1 are ideal, as long as the raw score RMSE is low and the norm score validation R2 reaches high levels. As a suggestion for real tests:

- Use visual inspection of the percentiles with `plotPercentiles` or `plotPercentileSeries`
- Combine the visual inspection of the percentiles with a repeated cross validation (e. g. 10 repetitions)
- Focus on low raw score RMSE, high norm score R2 in the validation dataset and avoid a number of terms with a high overfit (e. g. `crossfit > 1.1`).

Usage

```
cnorm.cv(
  data,
  formula = NULL,
  repetitions = 5,
  norms = TRUE,
  min = 1,
  max = 12,
```

```

cv = "full",
pCutoff = NA,
width = NA,
raw = NA,
group = NA,
age = NA
)

```

Arguments

| | |
|-------------|---|
| data | data frame of norm sample with ranking, powers and interaction of L and A or a cnorm object |
| formula | prespecified formula, e. g. from an existing regression model; min and max functions will be ignored In case a cnorm object is used, this functions automatically draws on the formula of the inbuilt regression function |
| repetitions | number of repetitions for cross validation |
| norms | determine norm score crossfit and R2 (if set to TRUE). The option is computationally intensive and duration increases with sample size, number of repetitions and maximum number of terms (max option). |
| min | Minimum number of terms to start from, default = 1 |
| max | Maximum number of terms in model up to $2*k + k^2$ |
| cv | If set to full (default), the data is split into training and validation data and ranked afterwards, otherwise, a pre ranked dataset has to be provided, which is then split into train and validation (and thus only the modeling, but not the ranking is independent) |
| pCutoff | The function checks the stratification for unbalanced data sampling. It performs a t-test per group. pCutoff specifies the p-value per group that the test result has to reach at least. To minimize beta error, the value is set to .2 per default |
| width | If provided, ranking is done via rankBySlidingWindow, otherwise by group |
| raw | Name of the raw variable |
| group | Name of the grouping variable |
| age | Name of the age variable |

Value

table with results per term number, including RMSE for raw scores in training, validation and complete sample, R2 for the norm scores and the crossfit measure (1 = ideal, <1 = underfit, >1 = overfit)

Examples

```
# plot cross validation RMSE by number of terms up to 9 with three repetitions
data <- prepareData(elfe)
cnorm.cv(data, min = 3, max = 7, norms = FALSE)

# cross validate prespecified formula
# here, we will use the formula from a model to cross validate it and to retrieve norm RMSE
# own regression functions can of course be used as well
# result <- cnorm(raw = efe$raw, group = elfe$group)
# cnorm.cv(result, repetitions = 5)
```

cNORM.GUI

Launcher for the graphical user interface of cNORM

Description

Launcher for the graphical user interface of cNORM

Usage

```
cNORM.GUI(launch.browser = TRUE)
```

Arguments

`launch.browser` Default TRUE; automatically open browser for GUI

Examples

```
## Not run:
# Launch graphical user interface
cNORM.GUI()

## End(Not run)
```

| | |
|---------------|--|
| computePowers | <i>Compute powers of the explanatory variable a as well as of the person location l (data preparation)</i> |
|---------------|--|

Description

The function computes powers of the norm variable e. g. T scores (location, L), an explanatory variable, e. g. age or grade of a data frame (age, A) and the interactions of both (L X A). The k variable indicates the degree up to which powers and interactions are build. These predictors can be used later on in the `bestModel` function to model the norm sample. Higher values of k allow for modeling the norm sample closer, but might lead to over-fit. In general k = 3 or k = 4 (default) is sufficient to model human performance data. For example, k = 2 results in the variables L1, L2, A1, A2, and their interactions L1A1, L2A1, L1A2 and L2A2 (but k = 2 is usually not sufficient for the modeling). Please note, that you do not need to use a normal rank transformed scale like T r IQ, but you can as well use the percentiles for the 'normValue' as well.

Usage

```
computePowers(
  data,
  k = 4,
  norm = NULL,
  age = NULL,
  covariate = NULL,
  silent = FALSE
)
```

Arguments

| | |
|-----------|--|
| data | data.frame with the norm data |
| k | degree |
| norm | the variable containing the norm data in the data.frame; might be T scores, IQ scores, percentiles ... |
| age | Explanatory variable like age or grade, which was as well used for the grouping. Can be either the grouping variable itself or a finer grained variable like the exact age. Other explanatory variables can be used here instead an age variable as well, as long as the variable is at least ordered metric, e. g. language or development levels ... The label 'age' is used, as this is the most common field of application. |
| covariate | Include a binary covariate into the preparation and subsequently modeling, either by specifying the variable name or including the variable itself. If this has already been done in the ranking, the function uses the according variable. BEWARE! Not all subsequent functions are already prepared for it. It is an experimental feature and may lead to unstable models subsequently. |
| silent | set to TRUE to suppress messages |

Value

data.frame with the powers and interactions of location and explanatory variable / age

See Also

bestModel

Other prepare: [prepareData\(\)](#), [rankByGroup\(\)](#), [rankBySlidingWindow\(\)](#)

Examples

```
# Dataset with grade levels as grouping
data.elfe <- rankByGroup(elfe)
data.elfe <- computePowers(data.elfe)

# Dataset with continuous age variable and k = 5
data.ppv <- rankByGroup(ppvt)
data.ppv <- computePowers(data.ppv, age = "age", k = 5)
```

| | |
|-----------------|--|
| derivationTable | <i>Create a table based on first order derivative of the regression model for specific age</i> |
|-----------------|--|

Description

In order to check model assumptions, a table of the first order derivative of the model coefficients is created.

Usage

```
derivationTable(
  A,
  model,
  minNorm = NULL,
  maxNorm = NULL,
  step = 0.1,
  covariate = NULL
)
```

Arguments

| | |
|-----------|---|
| A | the age |
| model | The regression model or a cnorm object |
| minNorm | The lower bound of the norm value range |
| maxNorm | The upper bound of the norm value range |
| step | Stepping parameter with lower values indicating higher precision |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

Value

data.frame with norm scores and the predicted scores based on the derived regression function

See Also

plotDerivative, derive

Other predict: [getNormCurve\(\)](#), [normTable\(\)](#), [predictNorm\(\)](#), [predictRaw\(\)](#), [rawTable\(\)](#)

Examples

```
# Generate cnorm object from example data
cnorm.elfe <- cnorm(raw = elfe$raw, group = elfe$group)

# retrieve function for time point 6
d <- derivationTable(6, cnorm.elfe, step = 0.5)
```

| | |
|--------|---------------------------------------|
| derive | <i>Derivative of regression model</i> |
|--------|---------------------------------------|

Description

Calculates the derivative of the location / norm value from the regression model with the first derivative as the default. This is useful for finding violations of model assumptions and problematic distribution features as f. e. bottom and ceiling effects, non-progressive norm scores within an age group or in general #' intersecting percentile curves.

Usage

```
derive(model, order = 1, covariate = NULL)
```

Arguments

| | |
|-----------|---|
| model | The regression model or a cnorm object |
| order | The degree of the derivate, default: 1 |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

Value

The derived coefficients

Examples

```
normData <- prepareData(elfe)
m <- bestModel(normData)
derivedCoefficients <- derive(m)
```

elfe

Sentence completion test from ELFE 1-6

Description

A dataset containing the raw data of 1400 students from grade 2 to 5 in the sentence comprehension test from ELFE 1-6 (Lenhard & Schneider, 2006). In this test, students are presented lists of sentences with one gap. The student has to fill in the correct solution by selecting from a list of 5 alternatives per sentence. The alternatives include verbs, adjectives, nouns, pronouns and conjunctives. Each item stems from the same word type. The text is speeded, with a time cutoff of 180 seconds. The variables are as follows:

Usage

elfe

Format

A data frame with 1400 rows and 3 variables:

personID ID of the student

group grade level, with x.5 indicating the end of the school year and x.0 indicating the middle of the school year

raw the raw score of the student, spanning values from 0 to 28

A data frame with 1400 rows and 3 columns

Source

<https://www.psychometrica.de/elfe2.html>

References

Lenhard, W. & Schneider, W.(2006). Ein Leseverstaendnistest fuer Erst- bis Sechstklaesser. Goettingen/Germany: Hogrefe.

Examples

```
# prepare data, retrieve model and plot percentiles
data.elfe <- prepareData(elfe)
model.elfe <- bestModel(data.elfe)
plotPercentiles(data.elfe, model.elfe)
```

| | |
|-----|---|
| epm | <i>Simulated dataset (Educational and Psychological Measurement, EPM)</i> |
|-----|---|

Description

A simulated dataset, based on the the simRasch function. The data were generated on the basis of a 1PL IRT model with 50 items with a normal distribution and a mean difficulty of $m = 0$ and $sd = 1$ and 1400 cases. The age trajectory features a curve linear increase wit a slight scissor effect. The sample consists of seven age groups with 200 cases each and it includes information on the latent ability, the age specific latent ability and norm scores based on conventional norming with differing granularity of the age brackets.

Usage

epm

Format

A data frame with 1400 rows and 10 variables:

raw the raw score

ageSpecificZ the age specific latent ability, z standardized

latentTrait the overall latent trait with respect to the population model

age the chronological age

halfYearGroup grouping variable based on six month age brackets

spcnT Resulting norm score of cNORM, based on the automatic model selection

T1 conventional T scores on the basis of one month age brackets

T3 conventional T scores on the basis of three month age brackets

T6 conventional T scores on the basis of six month age brackets

T12 conventional T scores on the basis of one year age brackets

A data frame with 1400 rows and 10 columns

Examples

```
## Not run:
# Example with continuous age variable
data.epm <- prepareData(epm, raw=epm$raw, group=epm$halfYearGroup, age=epm$age)
model.epm <- bestModel(data.epm)

## End(Not run)
```

getNormCurve

Computes the curve for a specific T value

Description

As with this continuous norming regression approach, raw scores are modeled as a function of age and norm score (location), getNormCurve is a straightforward approach to show the raw score development over age, while keeping the norm value constant. This way, e. g. academic performance or intelligence development of a specific ability is shown.

Usage

```
getNormCurve(
  norm,
  model,
  minAge = NULL,
  maxAge = NULL,
  step = 0.1,
  minRaw = NULL,
  maxRaw = NULL,
  covariate = NULL
)
```

Arguments

| | |
|-----------|---|
| norm | The specific norm score, e. g. T value |
| model | The model from the regression modeling or a cnorm object |
| minAge | Age to start from |
| maxAge | Age to stop at |
| step | Stepping parameter for the precision when retrieving of the values, lower values indicate higher precision (default 0.1). |
| minRaw | lower bound of the range of raw scores (default = 0) |
| maxRaw | upper bound of raw scores |
| covariate | In case, a covariate has been used, please specify the degree of the covariate or the specific value here. |

Value

data.frame of the variables raw, age and norm

See Also

Other predict: [derivationTable\(\)](#), [normTable\(\)](#), [predictNorm\(\)](#), [predictRaw\(\)](#), [rawTable\(\)](#)

Examples

```
# Generate cnorm object from example data
cnorm.elfe <- cnorm(raw = elfe$raw, group = elfe$group)
getNormCurve(35, cnorm.elfe)
```

| | |
|----------------|--|
| getNormScoreSE | <i>Calculates the standard error (SE) of the norm scores</i> |
|----------------|--|

Description

Calculates the standard error (SE) of the norm scores

Usage

```
getNormScoreSE(model)
```

Arguments

model a cnorm object

Value

The standard error (SE) of the norm scores sensu Oosterhuis et al. (2016)

References

Oosterhuis, H. E. M., van der Ark, L. A., & Sijtsma, K. (2016). Sample Size Requirements for Traditional and Regression-Based Norms. *Assessment*, 23(2), 191–202. <https://doi.org/10.1177/1073191115580638>

 life

Life expectancy at birth from 1960 to 2017

Description

The data is available by the courtesy of the World Bank under Creative Commons Attribution 4.0 (CC-BY 4.0). It includes the life expectancy at birth on nation level from 1960 to 2017. The data has been converted to long data format, aggregates for groups of nations and missings have been deleted and a grouping variable with a broader scope spanning 4 years each has been added. It shows, that it can be better to reduce predictors. The model does not converge anymore after using 8 predictors and the optimal solution is achieved with four predictors, equaling $R^2=0.9825$.

Usage

```
life
```

Format

A data frame with 11182 rows and 4 variables:

Country The name of the country

year reference year of data collection

life the life expectancy at birth

group a grouping variable based on 'year' but with a lower resolution; spans intervals of 4 years each

A data frame with 11182 rows and 4 columns

Source

<https://data.worldbank.org/indicator/sp.dyn.le00.in>

References

The World Bank (2018). Life expectancy at birth, total (years). Data Source World Development Indicators available <https://data.worldbank.org/indicator/sp.dyn.le00.in> (date of retrieval: 01/09/2018)

Examples

```
## Not run:
# data preparation
data.life <- rankByGroup(life, raw="life")
data.life <- computePowers(data.life, age="year")

#determining best suiting model by plotting series
model.life <- bestModel(data.life, raw="life")
plotPercentileSeries(data.life, model.life, end=10)
```

```
# model with four predictors seems to work best
model2.life <- bestModel(data.life, raw="life", terms=4)

## End(Not run)
```

| | |
|--------------|--|
| modelSummary | <i>Prints the results and regression function of a cnorm model</i> |
|--------------|--|

Description

Prints the results and regression function of a cnorm model

Usage

```
modelSummary(object, ...)
```

Arguments

| | |
|--------|------------------------------------|
| object | A regression model or cnorm object |
| ... | additional parameters |

Value

A report on the regression function, weights, R2 and RMSE

See Also

| | |
|-----------|---|
| mortality | <i>Mortality of infants per 1000 life birth from 1960 to 2017</i> |
|-----------|---|

Description

The data is available by the courtesy of the World Bank under Creative Commons Attribution 4.0 (CC-BY 4.0). It includes the mortality rate of life birth per country from 1960 to 2017. The data has been converted to long data format, aggregates for groups of nations and missings have been deleted and a grouping variable with a broader scope spanning 4 years each has been added. It can be used for demonstrating intersecting percentile curves at bottom effects.

Usage

```
mortality
```

Format

A data frame with 9547 rows and 4 variables:

Country The name of the country

year reference year of data collection

mortality the mortality per 1000 life born children

group grouping variable based on 'year' with a lower resolution; spans intervals of 4 years each

Source

<https://data.worldbank.org/indicator/SP.DYN.IMRT.IN>

References

Examples

```
## Not run:
# data preparation
data.mortality <- rankByGroup(mortality, raw="mortality")
data.mortality <- computePowers(data.mortality, age="year")

# modeling
model.mortality <- bestModel(data.mortality, raw="mortality")
plotSubset(model.mortality, type = 0)
plotPercentileSeries(data.mortality, model.mortality, end=9, percentiles = c(.1, .25, .5, .75, .9))

## End(Not run)
```

normTable

Create a norm table based on model for specific age

Description

This function generates a norm table for a specific age based on the regression model by assigning raw scores to norm scores. Please specify the range of norm scores, you want to cover. A T value of 25 corresponds to a percentile of .6. As a consequence, specifying a range of T = 25 to T = 75 would cover 98.4 the population. Please be careful when extrapolating vertically (at the lower and upper end of the age specific distribution). Depending on the size of your standardization sample, extreme values with T < 20 or T > 80 might lead to inconsistent results. In case a confidence coefficient (CI) and the reliability is specified, confidence intervals are computed as well, including a correction for regression to the mean.

Usage

```
normTable(
  A,
  model,
  minNorm = NULL,
  maxNorm = NULL,
  minRaw = NULL,
  maxRaw = NULL,
  step = NULL,
  covariate = NULL,
  monotonuous = TRUE,
  CI = 0.9,
  reliability = NULL
)
```

Arguments

| | |
|-------------|---|
| A | the age as single value or a vector of age values |
| model | The regression model or a cnorm object |
| minNorm | The lower bound of the norm score range |
| maxNorm | The upper bound of the norm score range |
| minRaw | clipping parameter for the lower bound of raw scores |
| maxRaw | clipping parameter for the upper bound of raw scores |
| step | Stepping parameter with lower values indicating higher precision |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |
| monotonuous | corrects for decreasing norm scores in case of model inconsistencies (default) |
| CI | confidence coefficient, ranging from 0 to 1, default .9 |
| reliability | coefficient, ranging between 0 to 1 |

Value

either data.frame with norm scores, predicted raw scores and percentiles in case of simple A value or a list #' of norm tables if vector of A values was provided

See Also

rawTable

Other predict: [derivationTable\(\)](#), [getNormCurve\(\)](#), [predictNorm\(\)](#), [predictRaw\(\)](#), [rawTable\(\)](#)

Examples

```
# Generate cnorm object from example data
cnorm.elfe <- cnorm(raw = elfe$raw, group = elfe$group)

# create single norm table
```

```

norms <- normTable(3.5, cnorm.elfe, minNorm = 25, maxNorm = 75, step = 0.5)

# create list of norm tables
norms <- normTable(c(2.5, 3.5, 4.5), cnorm.elfe,
  minNorm = 25, maxNorm = 75,
  step = 1, minRaw = 0, maxRaw = 26
)

```

plot.cnorm

S3 function for plotting cnorm objects

Description

S3 function for plotting cnorm objects

Usage

```

## S3 method for class 'cnorm'
plot(x, y, ...)

```

Arguments

| | |
|-----|---|
| x | the cnorm object |
| y | the type of plot as a string, can be one of 'raw', 'norm', 'curves', 'percentiles', 'series', 'subset', or 'derivative' |
| ... | additional parameters for the specific plotting function |

See Also

Other plot: [plotDensity\(\)](#), [plotDerivative\(\)](#), [plotNormCurves\(\)](#), [plotNorm\(\)](#), [plotPercentileSeries\(\)](#), [plotPercentiles\(\)](#), [plotRaw\(\)](#), [plotSubset\(\)](#)

plotCnorm

General convenience plotting function

Description

General convenience plotting function

Usage

```

plotCnorm(x, y, ...)

```

Arguments

| | |
|-----|---|
| x | a cnorm object |
| y | the type of plot as a string, can be one of 'raw', 'norm', 'curves', 'percentiles', 'series', 'subset', or 'derivative' |
| ... | additional parameters for the specific plotting function |

| | |
|-------------|---|
| plotDensity | <i>Plot the density function per group by raw score</i> |
|-------------|---|

Description

The function plots the density curves based on the regression model against the actual percentiles from the raw data. As in 'plotNormCurves', please check for inconsistent curves, especially curves showing implausible shapes as f. e. violations of biuniqueness.

Usage

```
plotDensity(
  model,
  minRaw = NULL,
  maxRaw = NULL,
  minNorm = NULL,
  maxNorm = NULL,
  group = NULL,
  covariate = NULL
)
```

Arguments

| | |
|-----------|---|
| model | The model from the bestModel function or a cnorm object |
| minRaw | Lower bound of the raw score |
| maxRaw | Upper bound of the raw score |
| minNorm | Lower bound of the norm score |
| maxNorm | Upper bound of the norm score |
| group | Column of groups to plot |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

See Also

plotNormCurves, plotPercentiles

Other plot: [plot.cnorm\(\)](#), [plotDerivative\(\)](#), [plotNormCurves\(\)](#), [plotNorm\(\)](#), [plotPercentileSeries\(\)](#), [plotPercentiles\(\)](#), [plotRaw\(\)](#), [plotSubset\(\)](#)

Examples

```
# Load example data set, compute model and plot results for age values 2, 4 and 6
result <- cnorm(raw = elfe$raw, group = elfe$group)
plotDensity(result, group = c(2, 4, 6))
```

plotDerivative

Plot first order derivative of regression model

Description

Plots the scores obtained via the first order derivative of the regression model in dependence of the norm score. The results indicate the progression of the norm scores within each age group. The regression based modeling approach relies on the assumption of a linear progression of the norm scores. Negative scores in the first order derivative indicate a violation of this assumption. Scores near zero are typical for bottom and ceiling effects in the raw data. The regression models usually converge within the range of the original values. In case of vertical and horizontal extrapolation, with increasing distance to the original data, the risk of assumption violation increases as well. ATTENTION: plotDerivative is currently still incompatible with reversed raw score scales ('descent' option)

Usage

```
plotDerivative(
  model,
  minAge = NULL,
  maxAge = NULL,
  minNorm = NULL,
  maxNorm = NULL,
  stepAge = 0.2,
  stepNorm = 1,
  order = 1
)
```

Arguments

| | |
|----------|--|
| model | The model from the bestModel function or a cnorm object |
| minAge | Age to start with checking |
| maxAge | Upper end of the age check |
| minNorm | Lower end of the norm score range, in case of T scores, 25 might be good |
| maxNorm | Upper end of the norm score range, in case of T scores, 25 might be good |
| stepAge | Stepping parameter for the age check, usually 1 or 0.1; lower values indicate higher precision / closer checks |
| stepNorm | Stepping parameter for norm scores |
| order | Degree of the derivative (default = 1) |

See Also

checkConsistency, bestModel, derive

Other plot: [plot.cnorm\(\)](#), [plotDensity\(\)](#), [plotNormCurves\(\)](#), [plotNorm\(\)](#), [plotPercentileSeries\(\)](#), [plotPercentiles\(\)](#), [plotRaw\(\)](#), [plotSubset\(\)](#)

Examples

```
# Load example data set, compute model and plot results
result <- cnorm(raw = elfe$raw, group = elfe$group)
plotDerivative(result, minAge=2, maxAge=5, step=.2, minNorm=25, maxNorm=75, stepNorm=1)
```

plotNorm

Plot manifest and fitted norm scores

Description

The function plots the manifest norm score against the fitted norm score from the inverse regression model per group. This helps to inspect the precision of the modeling process. The scores should not deviate too far from regression line. The computation of the standard error is based on Oosterhuis, van der Ark and Sijtsma (2016).

Usage

```
plotNorm(data, model, group = "", minNorm = NULL, maxNorm = NULL, type = 0)
```

Arguments

| | |
|---------|---|
| data | The raw data within a data.frame or a cnorm object |
| model | The regression model (optional) |
| group | The grouping variable, use empty string for no group |
| minNorm | lower bound of fitted norm scores |
| maxNorm | upper bound of fitted norm scores |
| type | Type of display: 0 = plot manifest against fitted values, 1 = plot manifest against difference values |

```
# Load example data set, compute model and plot results
## Not run:
result <- cnorm(raw = elfe$raw, group = elfe$group)
plotNorm(result, group="group", minNorm=25, maxNorm=75)

## End(Not run)
```

plotNormCurves

Plot norm curves

Description

The function plots the norm curves based on the regression model. Please check the function for inconsistent curves: The different curves should not intersect. Violations of this assumption are a strong indication for violations of model assumptions in modeling the relationship between raw and norm scores. There are several reasons, why this might occur:

1. Vertical extrapolation: Choosing extreme norm scores, e. g. scores $-3 \leq x$ and $x \geq 3$ In order to model these extreme scores, a large sample dataset is necessary.
2. Horizontal extrapolation: Taylor polynomials converge in a certain radius. Using the model scores outside the original dataset may lead to inconsistent results.
3. The data cannot be modeled with Taylor polynomials, or you need another power parameter (k) or R2 for the model.

In general, extrapolation (point 1 and 2) can carefully be done to a certain degree outside the original sample, but it should in general be handled with caution. checkConsistency and derivationPlot can be used to further inspect the model.

Usage

```
plotNormCurves(
  model,
  normList = c(30, 40, 50, 60, 70),
  minAge = NULL,
  maxAge = NULL,
  step = 0.1,
  minRaw = NULL,
  maxRaw = NULL,
  covariate = NULL
)
```

Arguments

| | |
|----------|---|
| model | The model from the bestModel function or a cnorm object |
| normList | Vector with norm scores to display |
| minAge | Age to start with checking |

| | |
|-----------|--|
| maxAge | Upper end of the age check |
| step | Stepping parameter for the age check, usually 1 or 0.1; lower scores indicate higher precision / closer checks |
| minRaw | Lower end of the raw score range, used for clipping implausible results (default = 0) |
| maxRaw | Upper end of the raw score range, used for clipping implausible results |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

See Also

checkConsistency, derivationPlot, plotPercentiles

Other plot: [plot.cnorm\(\)](#), [plotDensity\(\)](#), [plotDerivative\(\)](#), [plotNorm\(\)](#), [plotPercentileSeries\(\)](#), [plotPercentiles\(\)](#), [plotRaw\(\)](#), [plotSubset\(\)](#)

Examples

```
# Load example data set, compute model and plot results
normData <- prepareData(elfe)
m <- bestModel(data = normData)
plotNormCurves(m, minAge=2, maxAge=5)
```

plotPercentiles *Plot norm curves against actual percentiles*

Description

The function plots the norm curves based on the regression model against the actual percentiles from the raw data. As in 'plotNormCurves', please check for inconsistent curves, especially intersections. Violations of this assumption are a strong indication for problems in modeling the relationship between raw and norm scores. In general, extrapolation (point 1 and 2) can carefully be done to a certain degree outside the original sample, but it should in general be handled with caution. The original percentiles are displayed as distinct points in the according color, the model based projection of percentiles are drawn as lines. Please note, that the estimation of the percentiles of the raw data is done with the quantile function with the default settings. Please consult `help(quantile)` and change the 'type' parameter accordingly. In case, you get 'jagged' or disorganized percentile curve, try to reduce the 'k' parameter in modeling.

Usage

```
plotPercentiles(
  data,
  model,
  minRaw = NULL,
  maxRaw = NULL,
  minAge = NULL,
```

```

maxAge = NULL,
raw = NULL,
group = NULL,
percentiles = c(0.025, 0.1, 0.25, 0.5, 0.75, 0.9, 0.975),
scale = NULL,
type = 7,
title = NULL,
covariate = NULL
)

```

Arguments

| | |
|-------------|---|
| data | The raw data including the percentiles and norm scores or a cnorm object |
| model | The model from the bestModel function (optional) |
| minRaw | Lower bound of the raw score (default = 0) |
| maxRaw | Upper bound of the raw score |
| minAge | Variable to restrict the lower bound of the plot to a specific age |
| maxAge | Variable to restrict the upper bound of the plot to a specific age |
| raw | The name of the raw variable |
| group | The name of the grouping variable; the distinct groups are automatically determined |
| percentiles | Vector with percentile scores, ranging from 0 to 1 (exclusive) |
| scale | The norm scale, either 'T', 'IQ', 'z', 'percentile' or self defined with a double vector with the mean and standard deviation, f. e. c(10, 3) for Wechsler scale index points; if NULL, scale information from the data preparation is used (default) |
| type | The type parameter of the quantile function to estimate the percentiles of the raw data (default 7) |
| title | custom title for plot |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. If no covariate is specified, both degrees will be plotted. |

Examples

```

# Load example data set, compute model and plot results
result <- cnorm(raw = elfe$raw, group = elfe$group)
plotPercentiles(result)

```

plotPercentileSeries *Generates a series of plots with number curves by percentile for different models*

Description

This functions makes use of 'plotPercentiles' to generate a series of plots with different number of predictors. It draws on the information provided by the model object to determine the bounds of the modeling (age and standard score range). It can be used as an additional model check to determine the best fitting model. Please have a look at the 'plotPercentiles' function for further information.

Usage

```
plotPercentileSeries(
  data,
  model,
  start = 1,
  end = NULL,
  group = NULL,
  percentiles = c(0.025, 0.1, 0.25, 0.5, 0.75, 0.9, 0.975),
  type = 7,
  filename = NULL
)
```

Arguments

| | |
|-------------|--|
| data | The raw data including the percentiles and norm scores or a cnorm object |
| model | The model from the bestModel function (optional) |
| start | Number of predictors to start with |
| end | Number of predictors to end with |
| group | The name of the grouping variable; the distinct groups are automatically determined |
| percentiles | Vector with percentile scores, ranging from 0 to 1 (exclusive) |
| type | The type parameter of the quantile function to estimate the percentiles of the raw data (default 7) |
| filename | Prefix of the filename. If specified, the plots are saves as png files in the directory of the workspace, instead of displaying them |

Value

the complete list of plots

plotPercentileSeries(result, start=1, end=5, group="group")
```

plotRaw

Plot manifest and fitted raw scores

Description

The function plots the raw data against the fitted scores from the regression model per group. This helps to inspect the precision of the modeling process. The scores should not deviate too far from regression line.

Usage

```
plotRaw(data, model, group = NULL, raw = NULL, type = 0)
```

Arguments

| | |
|-------|---|
| data | The raw data within a data.frame or cnorm object |
| model | The regression model (optional) |
| group | The grouping variable |
| raw | The raw score variable |
| type | Type of display: 0 = plot manifest against fitted values, 1 = plot manifest against difference values |

See Also

Other plot: [plot.cnorm\(\)](#), [plotDensity\(\)](#), [plotDerivative\(\)](#), [plotNormCurves\(\)](#), [plotNorm\(\)](#), [plotPercentileSeries\(\)](#), [plotPercentiles\(\)](#), [plotSubset\(\)](#)

Examples

```
# Compute model with example dataset and plot results
result <- cnorm(raw = elfe$raw, group = elfe$group)
plotRaw(result)
```

plotSubset

Evaluate information criteria for regression model

Description

Plots the information criterion - either Cp (default) or BIC - against the adjusted R square of the feature selection in the modeling process. Both BIC and Mallows' Cp are measures to avoid overfitting. Please choose the model that has a high information criterion, while modeling the original data as close as possible. R2 adjusted values of ~ .99 might work well, depending on your scenario. In other words: Look out for the elbow in the curve and choose the model where the information criterion begins to drop. Nonetheless, inspect the according model with `plotPercentiles(data, group)` to visually inspect the course of the percentiles. In the plot, Mallows' Cp is log transformed and the BIC is always highly negative. The R2 cutoff that was specified in the `bestModel` function is displayed as a dashed line.

Usage

```
plotSubset(model, type = 0, index = FALSE)
```

Arguments

| | |
|-------|---|
| model | The regression model from the <code>bestModel</code> function or a <code>cnorm</code> object |
| type | Type of chart with 0 = adjusted R2 by number of predictors, 1 = log transformed Mallows' Cp by adjusted R2, 2 = Bayesian Information Criterion (BIC) by adjusted R2 and 3 = Root Mean Square Error (RMSE) by number of predictors |
| index | add index labels to data points |

`bestModel`, `plotPercentiles`, `printSubset`

Other plot: `plot.cnorm()`, `plotDensity()`, `plotDerivative()`, `plotNormCurves()`, `plotNorm()`, `plotPercentileSeries()`, `plotPercentiles()`, `plotRaw()`

Examples

```
# Compute model with example data and plot information function
cnorm.model <- cnorm(raw = elfe$raw, group = elfe$group)
plotSubset(cnorm.model)
```

Description

A dataset based on an unstratified sample of PPVT4 data (German adaption). The PPVT4 consists of blocks of items with 12 items each. Each item consists of 4 pictures. The test taker is given a word orally and he or she has to point out the picture matching the oral word. Bottom and ceiling blocks of items are determined according to age and performance. For instance, when a student knows less than 4 word from a block of 12 items, the testing stops. The sample is not identical with the norm sample and includes doublets of cases in order to align the sample size per age group. It is primarily intended for running the cNORM analyses. The cleaned and stratified data is available on request.

Usage

```
ppvt
```

Format

A data frame with 5600 rows and 4 variables:

age the chronological age of the child

group the according age group, e.g. age group 4 consists of children age 3.5 to 4.5

sex the sex of the test taker, 1=male, 2=female

raw the raw score of the student, spanning values from 0 to 228

A data frame with 5600 rows and 9 columns

Examples

```
## Not run:
# Example with continuous age variable
data.ppvt <- rankBySlidingWindow(ppvt, age="age", width=1.5)
data.ppvt <- computePowers(data.ppvt, age="age")
model.ppvt <- bestModel(data.ppvt, R2 = .994)

# plot information function
plotSubset(model.ppvt, type=2)
```

```
# check model consistency
checkConsistency(model.ppvt)

# plot percentiles
plotPercentiles(data.ppvt, model.ppvt)

## End(Not run)
```

| | |
|-------------|--|
| predictNorm | <i>Retrieve norm value for raw score at a specific age</i> |
|-------------|--|

Description

In real test scenarios, usually the results are available as raw values, for which norm scores have to be looked up. This function conducts this reverse transformation via a numerical solution: A precise norm table is generated and the closest fitting norm score for a raw score is returned.

Usage

```
predictNorm(
  raw,
  A,
  model,
  minNorm = NULL,
  maxNorm = NULL,
  force = FALSE,
  covariate = NULL
)
```

Arguments

| | |
|-----------|---|
| raw | The raw value, either single numeric or list of values |
| A | the age, either single numeric or list of values |
| model | The regression model or a cnorm object |
| minNorm | The lower bound of the norm score range |
| maxNorm | The upper bound of the norm score range |
| force | Try to resolve missing norm scores in case of inconsistent models |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

Value

The predicted norm score for a raw score, either single value or list of results

See Also

Other predict: [derivationTable\(\)](#), [getNormCurve\(\)](#), [normTable\(\)](#), [predictRaw\(\)](#), [rawTable\(\)](#)

Examples

```
# Generate cnorm object from example data
cnorm.elfe <- cnorm(raw = elfe$raw, group = elfe$group)

# return norm value for raw value 21 for grade 2, month 9
specificNormValue <- predictNorm(raw = 21, A = 2.75, cnorm.elfe)
```

| | |
|------------|---------------------------------|
| predictRaw | <i>Predict single raw value</i> |
|------------|---------------------------------|

Description

Most elementary function to predict raw score based on Location (L, T score), Age (grouping variable) and the coefficients from a regression model. **WARNING!** This function, and all functions depending on it, only works with regression functions including L, A and interactions. Manually adding predictors to bestModel via the predictors parameter is currently incompatible. In that case, and if you are primarily interested on fitting a complete data set, rather use the predict function of the stats:lm package on the ideal model solution. You than have to provide a prepared data frame with the according input variables.

Usage

```
predictRaw(
  norm,
  age,
  coefficients,
  minRaw = -Inf,
  maxRaw = Inf,
  covariate = NULL
)
```

Arguments

| | |
|--------------|--|
| norm | The norm score, e. g. a specific T score or a vector of scores |
| age | The age value or a vector of scores |
| coefficients | The coefficients from the regression model or a cnorm model |
| minRaw | Minimum score for the results; can be used for clipping unrealistic outcomes, usually set to the lower bound of the range of values of the test (default: 0) |
| maxRaw | Maximum score for the results; can be used for clipping unrealistic outcomes usually set to the upper bound of the range of values of the test |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |

Value

the predicted raw score or a data.frame of scores in case, lists of norm scores or age is used

See Also

Other predict: [derivationTable\(\)](#), [getNormCurve\(\)](#), [normTable\(\)](#), [predictNorm\(\)](#), [rawTable\(\)](#)

Examples

```
# Prediction of single scores
normData <- prepareData(elfe)
m <- bestModel(data = normData)
predictRaw(35, 3.5, m$coefficients)

# using a cnorm object
result <- cnorm(raw = elfe$raw, group = elfe$group)
predictRaw(35, 3.5, result)

# Fitting complete data sets
fitted.values <- predict(m)

# break up contribution of each predictor variable
fitted.partial <- predict(m, type = "terms")
```

prepareData

Prepare data for modeling in one step (convenience method)

Description

This is a convenience method to either load the inbuilt sample dataset, or to provide a data frame with the variables "raw" (for the raw scores) and "group" The function ranks the data within groups, computes norm values, powers of the norm scores and interactions. Afterwards, you can use these preprocessed data to determine the best fitting model.

Usage

```
prepareData(
  data = NULL,
  group = "group",
  raw = "raw",
  age = "group",
  k = 4,
  width = NA,
  weights = NULL,
  scale = "T",
  descend = FALSE,
  silent = FALSE
)
```

Arguments

| | |
|---------|---|
| data | data.frame with a grouping variable named 'group' and a raw score variable named 'raw'. |
| group | grouping variable in the data, e. g. age groups, grades ... Setting group = FALSE deactivates modeling in dependence of age. Use this in case you do want conventional norm tables. |
| raw | the raw scores |
| age | the continuous explanatory variable; by default set to "group" |
| k | The power parameter, default = 4 |
| width | if a width is provided, the function switches to rankBySlidingWindow to determine the observed raw scores, otherwise, ranking is done by group (default) |
| weights | Vector or variable name in the dataset with weights for each individual case. It can be used to compensate for moderate imbalances due to insufficient norm data stratification. Weights should be numerical and positive. Please note, that this feature is currently EXPERIMENTAL and subject to ongoing work! Precision of weighting increases with sample size. On the other hand, in large samples, it is easy to stratificate and then weighting is not needed anymore. |
| scale | type of norm scale, either T (default), IQ, z or percentile (= no transformation); a double vector with the mean and standard deviation can as well, be provided f. e. c(10, 3) for Wechsler scale index point |
| descend | ranking order (default descent = FALSE): inverses the ranking order with higher raw scores getting lower norm scores; relevant for example when norming error scores, where lower scores mean higher performance |
| silent | set to TRUE to suppress messages |

Value

data frame including the norm scores, powers and interactions of the norm score and grouping variable

See Also

Other prepare: [computePowers\(\)](#), [rankByGroup\(\)](#), [rankBySlidingWindow\(\)](#)

Examples

```
# conducts ranking and computation of powers and interactions with the 'elfe' dataset
data.elfe <- prepareData(elfe)

# use vectors instead of data frame
data.elfe <- prepareData(raw=elfe$raw, group=elfe$group)

# variable names can be specified as well, here with the BMI data included in the package
data.bmi <- prepareData(CDC, group = "group", raw = "bmi", age = "age")

# modeling with only one group with the 'elfe' dataset as an example
# this results in conventional norming
```

```
data.elfe2 <- prepareData(data = elfe, group = FALSE)
m <- bestModel(data.elfe2)
```

print.cnorm

S3 method for printing model selection information

Description

After conducting the model fitting procedure on the data set, the best fitting model has to be chosen. The print function shows the R2 and other information on the different best fitting models with increasing number of predictors.

Usage

```
## S3 method for class 'cnorm'
print(x, ...)
```

Arguments

x The model from the 'bestModel' function or a cnorm object
... additional parameters

Value

A table with information criteria

See Also

Other model: [bestModel\(\)](#), [checkConsistency\(\)](#), [cnorm.cv\(\)](#), [derive\(\)](#), [modelSummary\(\)](#), [printSubset\(\)](#), [rangeCheck\(\)](#), [regressionFunction\(\)](#), [summary.cnorm\(\)](#)

printSubset

Convenience method for printing model selection information

Description

After conducting the model fitting procedure on the data set, the best fitting model has to be chosen. The print function shows the R2 and other information on the different best fitting models with increasing number of predictors.

Usage

```
printSubset(x, ...)
```

Arguments

x The model from the 'bestModel' function or a cnorm object
 ... additional parameters

Value

A table with information criteria

See Also

Other model: [bestModel\(\)](#), [checkConsistency\(\)](#), [cnorm.cv\(\)](#), [derive\(\)](#), [modelSummary\(\)](#),
[print.cnorm\(\)](#), [rangeCheck\(\)](#), [regressionFunction\(\)](#), [summary.cnorm\(\)](#)

Examples

```
# Generate cnorm object from example data
result <- cnorm(raw = elfe$raw, group = elfe$group)
printSubset(result)
```

rangeCheck

Check for horizontal and vertical extrapolation

Description

Regression model only work in a specific range and extrapolation horizontally (outside the original range) or vertically (extreme norm scores) might lead to inconsistent results. The function generates a message, indicating extrapolation and the range of the original data.

Usage

```
rangeCheck(
  object,
  minAge = NULL,
  maxAge = NULL,
  minNorm = NULL,
  maxNorm = NULL,
  digits = 3,
  ...
)
```

Arguments

object The regression model or a cnorm object
 minAge The lower age bound
 maxAge The upper age bound
 minNorm The lower norm value bound

| | |
|---------|--|
| maxNorm | The upper norm value bound |
| digits | The precision for rounding the norm and age data |
| ... | additional parameters |

Value

the report

See Also

Other model: [bestModel\(\)](#), [checkConsistency\(\)](#), [cnorm.cv\(\)](#), [derive\(\)](#), [modelSummary\(\)](#), [print.cnorm\(\)](#), [printSubset\(\)](#), [regressionFunction\(\)](#), [summary.cnorm\(\)](#)

Examples

```
normData <- prepareData(elfe)
m <- bestModel(normData)
rangeCheck(m)
```

rankByGroup

Determine the norm scores of the participants in each subsample

Description

This is the initial step, usually done in all kinds of test norming projects, after the scale is constructed and the norm sample is established. First, the data is grouped according to a grouping variable and afterwards, the percentile for each raw value is retrieved. The percentile can be used for the modeling procedure, but in case, the samples to not deviate too much from normality, T, IQ or z scores can be computed via a normal rank procedure based on the inverse cumulative normal distribution. In case of bindings, we use the medium rank and there are different methods for estimating the percentiles (default RankIt).

Usage

```
rankByGroup(
  data = NULL,
  group = "group",
  raw = "raw",
  weights = NULL,
  method = 4,
  scale = "T",
  descend = FALSE,
  descriptives = TRUE,
  covariate = NULL,
  na.rm = TRUE
)
```

Arguments

| | |
|--------------|---|
| data | data.frame with norm sample data. If no data.frame is provided, the raw score and group vectors are directly used |
| group | name of the grouping variable (default 'group') or numeric vector, e. g. grade, setting group to FALSE cancels grouping (data is treated as one group) |
| raw | name of the raw value variable (default 'raw') or numeric vector |
| weights | Vector or variable name in the dataset with weights for each individual case. It can be used to compensate for moderate imbalances due to insufficient norm data stratification. Weights should be numerical and positive. Please note, that this feature is currently EXPERIMENTAL and subject to ongoing work! Precision of weighting increases with sample size. On the other hand, in large samples, it is easy to stratificate and then weighting is not needed anymore. |
| method | Ranking method in case of bindings, please provide an index, choosing from the following methods: 1 = Blom (1958), 2 = Tukey (1949), 3 = Van der Warden (1952), 4 = Rankit (default), 5 = Levenbach (1953), 6 = Filliben (1975), 7 = Yu & Huang (2001) |
| scale | type of norm scale, either T (default), IQ, z or percentile (= no transformation); a double vector with the mean and standard deviation can as well, be provided f. e. c(10, 3) for Wechsler scale index points |
| descend | ranking order (default descent = FALSE): inverses the ranking order with higher raw scores getting lower norm scores; relevant for example when norming error scores, where lower scores mean higher performance |
| descriptives | If set to TRUE (default), information in n, mean, median and standard deviation per group is added to each observation |
| covariate | Include a binary covariate into the preparation and subsequently modeling, either by specifying the variable name or including the variable itself. BEWARE! Not all subsequent functions are already prepared for it. It is an experimental feature. |
| na.rm | remove values, where the percentiles could not be estimated, most likely happens in the context of weighting |

Value

the dataset with the percentiles and norm scales per group

Remarks on using covariates

So far the inclusion of a binary covariate is experimental and far from optimized. The according variable name has to be specified in the ranking procedure and the modeling includes this in the further process. At the moment, during ranking the data are split into the according cells group x covariate, which leads to small sample sizes. Please take care to have enough cases in each combination. Additionally, covariates can lead to unstable modeling solutions. The question, if it is really reasonable to include covariates when norming a test is a decision beyond the pure data modeling. Please use with care or alternatively split the dataset into the two groups beforehand and model them separately.

See Also

rankBySlidingWindow, computePowers

Other prepare: [computePowers\(\)](#), [prepareData\(\)](#), [rankBySlidingWindow\(\)](#)

Examples

```
# Transformation with default parameters: RankIt and converting to T scores
data.elfe <- rankByGroup(elfe, group = "group") # using a data frame with vector names
data.elfe2 <- rankByGroup(raw=elfe$raw, group=elfe$group) # use vectors for raw score and group

# Transformation into Wechsler scores with Yu & Huang (2001) ranking procedure
data.elfe <- rankByGroup(raw = elfe$raw, group = elfe$group, method = 7, scale = c(10, 3))

# cNORM can as well be used for conventional norming, in case no group is given
d <- rankByGroup(raw = elfe$raw)
d <- computePowers(d)
m <- bestModel(d)
rawTable(0, model = m) # please use an arbitrary value for age when generating the tables
```

| | |
|---------------------|---|
| rankBySlidingWindow | <i>Determine the norm scores of the participants by sliding window (experimental)</i> |
|---------------------|---|

Description

The function retrieves all individuals in the predefined age range ($x \pm \text{width}/2$) around each case and ranks that individual based on this individually drawn sample. This function can be directly used with a continuous age variable in order to avoid grouping. When collecting data on the basis of a continuous age variable, cases located far from the mean age of the group receive distorted percentiles when building discrete groups and generating percentiles with the traditional approach. The distortion increases with distance from the group mean and this effect can be avoided by the sliding window. Nonetheless, please ensure, that the optional grouping variable in fact represents the correct mean age of the respective age groups, as this variable is later on used for displaying the manifest data in the percentile plots.

Usage

```
rankBySlidingWindow(
  data = NULL,
  age = "age",
  raw = "raw",
  weights = NULL,
  width,
  method = 4,
  scale = "T",
  descend = FALSE,
  descriptives = TRUE,
```

```

nGroup = 0,
group = NA,
covariate = NULL,
na.rm = TRUE
)

```

Arguments

| | |
|--------------|---|
| data | data.frame with norm sample data |
| age | the continuous age variable. Setting 'age' to FALSE inhibits computation of powers of age and the interactions |
| raw | name of the raw value variable (default 'raw') |
| weights | Vector or variable name in the dataset with weights for each individual case. It can be used to compensate for moderate imbalances due to insufficient norm data stratification. Weights should be numerical and positive. Please note, that this feature is currently EXPERIMENTAL and subject to ongoing work! Precision of weighting increases with sample size. On the other hand, in large samples, it is easy to stratificate and then weighting is not needed anymore. |
| width | the width of the sliding window |
| method | Ranking method in case of bindings, please provide an index, choosing from the following methods: 1 = Blom (1958), 2 = Tukey (1949), 3 = Van der Warden (1952), 4 = Rankit (default), 5 = Levenbach (1953), 6 = Filliben (1975), 7 = Yu & Huang (2001) |
| scale | type of norm scale, either T (default), IQ, z or percentile (= no transformation); a double vector with the mean and standard deviation can as well, be provided f. e. c(10, 3) for Wechsler scale index points |
| descend | ranking order (default descent = FALSE): inverses the ranking order with higher raw scores getting lower norm scores; relevant for example when norming error scores, where lower scores mean higher performance |
| descriptives | If set to TRUE (default), information in n, mean, median and standard deviation per group is added to each observation |
| nGroup | If set to a positive value, a grouping variable is created with the desired number of equi distant groups, named by the group mean age of each group. It creates the column 'group' in the data.frame and in case, there is already one with that name, overwrites it. |
| group | Optional parameter for providing the name of the grouping variable (if present; overwritten if ngroups is used) |
| covariate | Include a binary covariate into the preparation and subsequently modeling, either by specifying the variable name or including the variable itself. BEWARE! Not all subsequent functions are already prepared for it. It is an experimental feature. |
| na.rm | remove values, where the percentiles could not be estimated, most likely happens in the context of weighting |

Details

In case of bindings, the function uses the medium rank and applies the algorithms already described in the [rankByGroup](#) function. At the upper and lower end of the data sample, the sliding stops and the sample is drawn from the interval $\text{min} + \text{width}$ and $\text{max} - \text{width}$, respectively.

Value

the dataset with the individual percentiles and norm scores

Remarks on using covariates

So far the inclusion of a binary covariate is experimental and far from optimized. The according variable name has to be specified in the ranking procedure and the modeling includes this in the further process. At the moment, during ranking the data are split into the according degrees of the covariate and the ranking is done separately. This may lead to small sample sizes. Please take care to have enough cases in each combination. Additionally, covariates can lead to unstable modeling solutions. The question, if it is really reasonable to include covariates when norming a test is a decision beyond the pure data modeling. Please use with care or alternatively split the dataset into the two groups beforehand and model them separately.

Examples

```
## Not run:
# Transformation using a sliding window
data.elfe2 <- rankBySlidingWindow(relfe, raw = "raw", age = "group", width = 0.5)

# Comparing this to the traditional approach should give us exactly the same
# values, since the sample dataset only has a grouping variable for age
data.elfe <- rankByGroup(elfe, group = "group")
mean(data.elfe$normValue - data.elfe2$normValue)

## End(Not run)
```

rawTable

Create a table with norm scores assigned to raw scores for a specific age based on the regression model

Description

This function is comparable to 'normTable', despite it reverses the assignment: A table with raw scores and the according norm scores for a specific age based on the regression model is generated. This way, the inverse function of the regression model is solved numerically with brute force. Please specify the range of raw values, you want to cover. With higher precision and smaller stepping, this function becomes computational intensive. In case a confidence coefficient (CI) and the reliability is specified, confidence intervals are computed as well, including a correction for regression to the mean.

Usage

```
rawTable(
  A,
  model,
  minRaw = NULL,
  maxRaw = NULL,
  minNorm = NULL,
  maxNorm = NULL,
  step = 1,
  covariate = NULL,
  monotonuous = TRUE,
  CI = 0.9,
  reliability = NULL
)
```

Arguments

| | |
|-------------|---|
| A | the age, either single value or vector with age values |
| model | The regression model or a cnorm object |
| minRaw | The lower bound of the raw score range |
| maxRaw | The upper bound of the raw score range |
| minNorm | Clipping parameter for the lower bound of norm scores (default 25) |
| maxNorm | Clipping parameter for the upper bound of norm scores (default 25) |
| step | Stepping parameter for the raw scores (default 1) |
| covariate | In case, a covariate has been used, please specify the degree of the covariate / the specific value here. |
| monotonuous | corrects for decreasing norm scores in case of model inconsistencies (default) |
| CI | confidence coefficient, ranging from 0 to 1, default .9 |
| reliability | coefficient, ranging between 0 to 1 |

Value

either data.frame with raw scores and the predicted norm scores in case of simple A value or a list of norm tables if vector of A values was provided

```

| | |
|--------------------|----------------------------|
| regressionFunction | <i>Regression function</i> |
|--------------------|----------------------------|

Description

The method builds the regression function for the regression model, including the beta weights. It can be used to predict the raw scores based on age and location.

Usage

```
regressionFunction(model, raw = NULL, digits = NULL)
```

Arguments

| | |
|--------|--|
| model | The regression model from the <code>bestModel</code> function or a <code>cnorm</code> object |
| raw | The name of the raw value variable (default 'raw') |
| digits | Number of digits for formatting the coefficients |

Value

The regression formula as a string

simSD(age)
```

Arguments

age the age variable

Value

return predicted sd

Examples

```
## Not run:
x <- simSD(a)

## End(Not run)
```

simulateRasch

Simulate raw test scores based on Rasch model

Description

For testing purposes only: The function simulates raw test scores based on a virtual Rasch based test with n results per age group, an evenly distributed age variable, items.n test items with a simulated difficulty and standard deviation. The development trajectories over age group are modeled by a curve linear function of age, with at first fast progression, which slows down over age, and a slightly increasing standard deviation in order to model a scissor effects. The item difficulties can be accessed via $\$theta$ and the raw data via $\$data$ of the returned object.

Usage

```
simulateRasch(
  data = NULL,
  n = 100,
  minAge = 1,
  maxAge = 7,
  items.n = 21,
  items.m = 0,
  items.sd = 1,
  Theta = "random",
  width = 1
)
```

Arguments

| | |
|-----------------------|--|
| <code>data</code> | data.frame from previous simulations for recomputation (overrides <code>n</code> , <code>minAge</code> , <code>maxAge</code>) |
| <code>n</code> | The sample size per age group |
| <code>minAge</code> | The minimum age (default 1) |
| <code>maxAge</code> | The maximum age (default 7) |
| <code>items.n</code> | The number of items of the test |
| <code>items.m</code> | The mean difficulty of the items |
| <code>items.sd</code> | The standard deviation of the item difficulty |
| <code>Theta</code> | irt scales difficulty parameters, either "random" for drawing a random sample, "even" for evenly distributed or a set of predefined values, which then overrides the <code>items.n</code> parameters |

width The width of the window size for the continuous age per group; $\pm 1/2$ width around group center on items.m and item.sd; if set to FALSE, the distribution is not drawn randomly but normally nonetheless

Value

a list containing the simulated data and thetas

data the data.frame with only age, group and raw

sim the complete simulated data with item level results

theta the difficulty of the items

Examples

```
# simulate data for a rather easy test (m = -1.0)
sim <- simulateRasch(n=150, minAge=1,
                    maxAge=7, items.n = 30, items.m = -1.0,
                    items.sd = 1, Theta = "random", width = 1.0)

# Show item difficulties
mean(sim$theta)
sd(sim$theta)
hist(sim$theta)

# Plot raw scores
boxplot(raw~group, data=sim$data)

# Model data
data <- prepareData(sim$data, age="age")
model <- bestModel(data, k = 4)
printSubset(model)
plotSubset(model, type=0)
```

|---------------|--|
| summary.cnorm | <i>S3 method for printing the results and regression function of a cnorm model</i> |
|---------------|--|

Description

S3 method for printing the results and regression function of a cnorm model

Usage

```
## S3 method for class 'cnorm'
summary(object, ...)
```

Arguments

object A regression model or cnorm object
... additional parameters

Value

A report on the regression function, weights, R2 and RMSE

See Also

Other model: `bestModel()`, `checkConsistency()`, `cnorm.cv()`, `derive()`, `modelSummary()`, `print.cnorm()`, `printSubset()`, `rangeCheck()`, `regressionFunction()`

| | |
|-------------------|------------------------------------|
| weighted.quantile | <i>Weighted quantile estimator</i> |
|-------------------|------------------------------------|

Description

Computes weighted quantiles (code from Andrey Akinshin via <https://aakinshin.net/posts/weighted-quantiles/> Code made available via the CC BY-NC-SA 4.0 license) on the basis of either the weighted Harrell-Davis quantile estimator or an adaption of the type 7 quantile estimator of the generic quantile function in the base package. Please provide a vector with raw values, the probabilities for the quantiles and an additional vector with the weight of each observation. In case the weight vector is NULL, a normal quantile estimation is done. The vectors may not include NAs and the weights should be positive non-zero values.

Usage

```
weighted.quantile(x, probs, weights = NULL, type = "Type7")
```

Arguments

| | |
|---------|--|
| x | A numerical vector |
| probs | Numerical vector of quantiles |
| weights | A numerical vector with weights; should have the same length as x |
| type | Type of estimator, can either be "Harrell-Davis" using a beta function to approximate the weighted percentiles (Harrell & Davis, 1982) or "Type7" (default; Hyndman & Fan, 1996), an adaption of the generic quantile function in R, including weighting. All code based on the work of Akinshin (2020). |

Value

the weighted quantiles

weighted.quantile.harrell.davis

Weighted Harrell-Davis quantile estimator

Description

Computes weighted quantiles; code from Andrey Akinshin via <https://aakinshin.net/posts/weighted-quantiles/> Code made available via the CC BY-NC-SA 4.0 license

Usage

```
weighted.quantile.harrell.davis(x, probs, weights = NULL)
```

Arguments

| | |
|---------|---|
| x | A numerical vector |
| probs | Numerical vector of quantiles |
| weights | A numerical vector with weights; should have the same length as x. If no weights are provided (NULL), it falls back to the base quantile function, type 7 |

Value

the quantiles

weighted.quantile.type7

Weighted type7 quantile estimator

Description

Computes weighted quantiles; code from Andrey Akinshin via <https://aakinshin.net/posts/weighted-quantiles/> Code made available via the CC BY-NC-SA 4.0 license

Usage

```
weighted.quantile.type7(x, probs, weights = NULL)
```

Arguments

| | |
|---------|---|
| x | A numerical vector |
| probs | Numerical vector of quantiles |
| weights | A numerical vector with weights; should have the same length as x. If no weights are provided (NULL), it falls back to the base quantile function, type 7 |

Value

the quantiles

| | |
|---------------|---------------------------------|
| weighted.rank | <i>Weighted rank estimation</i> |
|---------------|---------------------------------|

Description

Conducts weighted ranking on the basis of either the weighted Harrell-Davis quantile estimator or an adaption of the type 7 quantile estimator of the generic quantile function in the base package. Please provide a vector with raw values and an additional vector with the weight of each observation. In case the weight vector is NULL, a normal ranking is done. The vectors may not include NAs and the weights should be positive non-zero values.

Usage

```
weighted.rank(x, weights = NULL, n = 1000, type = "Type7")
```

Arguments

| | |
|---------|--|
| x | A numerical vector |
| weights | A numerical vector with weights; should have the same length as x |
| n | Granularity for approximation |
| type | Type of estimator, can either be "Harrell-Davis" using a beta function to approximate the weighted percentiles (Harrell & Davis, 1982) or "Type7" (default; Hyndman & Fan, 1996), an adaption of the generic quantile function in R, including weighting. All code based on the work of Akinshin (2020). |

Value

the weighted ranks
